Abstract: Fire in buildings is nearly always man-made, i.e. resulting from negligence or error, which can cause immense damage in terms of lives and property [1]. But when we deal with nuclear constructions (like nuclear power plants NPP), the dangers of fire do not stop only at the potential damage that the concrete structure is exposed to, but rather extends to the risk of a radiation leak that may cause serious damage to the human life and all living creatures. For this reason, designers of nuclear constructions (which are mostly reinforced concrete) give special attention for making the concrete structure capable of resisting the effects of fire or thermal leakage, as well as having a high ability to resist all types of radiation (especially gamma ray radiation). On the other hand, incorporation of nano additives into concrete structures components become a promising field of research these days. The current study tries to investigate the effect of using different nano materials (Nano silica, Nanoclay, and hybrid mix of both materials) as a cement replacement into the concrete radiation resistance ability (in the term of linear attenuation coefficient µ). Results showed remarkable enhancement on the values of µ at all temperature degrees. For the conduct of reliable estimate and prediction of the values µ, this study adopts the fuzzy logic models as powerful tools of artificial intelligence to model the non-linear cause and effect relationships. Prediction results was superior when compared with traditional linear regression analysis.

Key Words: Nanoparticles, linear attenuation coefficient, Fuzzy logic models, Artificial intelligence, technologies. Nanosilica, Nanoclay, Nano carbon tubes, and many other Nanomaterials were investigated for application in concrete industry. On the other hand, there is a problem that scientists and engineers always face when dealing with concrete, which is the inability to predict its behavior due to the large number of variables that control the results of any characteristic of concrete such as compressive strength, residual strength after fire exposure, or radiation shielding ability. Hence the idea of using artificial intelligence applications to overcome these obstacles has come. Fuzzy Logic Systems FLS which considered as a strong tool of artificial intelligence techniques were used for the conduct of reliable estimate of the complex nonlinear behaviour of concrete gamma ray linear attenuation coefficient µ after fire exposure. The Fuzzy system modelling approach is simpler and more direct than traditional statistical methods, particularly when

1. Introduction
Concrete is widely used as a construction material due to its different advantages, such as the high strength, workability, and durability properties (corrosion, fire, and radiation resistance ability). As a result of these advantages, concrete is the basic and most important material in the process of building nuclear power plants NPP. Usually heavy weight concrete is the most popular concrete type to use in the construction of NPP due to its high ability to resist radiation compared to the other types of concrete. However, this advantage can be achieved by using ordinary concrete supported by some additives that enable it to reach a high capacity, whether in resistance to fire or radiation. Nanotechnology opened a world of modern materials with unique characteristics that made it represents a scientific revolution in the world of building materials technology and all branches of science and manufacturing
modelling nonlinear multivariate interrelationships. Artificial Intelligent-based modelling techniques like Fuzzy system models have been utilized to approximate non-linear and complex behaviour for various properties of construction materials [2]. A general fuzzy system is presented in Figure (1). According to Figure (1), the system has basically four components: fuzzification, fuzzy rule base, fuzzy output engine, and defuzzification [3]. Fuzzification converts each piece of input data to degrees of membership by a lookup in one or more several membership functions. Fuzzy rule base contains rules that include all possible fuzzy relation between inputs and outputs. These rules are expressed in the IF–THEN The key idea in fuzzy logic, in fact, is the allowance of partial belongings of any object to different subsets of a universal set instead of belonging to a single set completely. Partial belonging to a set can be described numerically by a membership function, which assumes values between 0 and 1 inclusive. Intuition, inference, rank ordering, angular fuzzy sets, neural networks, genetic algorithms, and inductive reasoning can be, among many, ways to assign membership values or functions to fuzzy variables. Fuzzy membership functions may take many forms, but in practical applications, simple linear functions, such as triangular ones, are preferable. In the current FLS model, different conditions from temperature degree, nanoparticles type, and replacement ratios are represented major data inputs, while the predicted value of $\mu$ after fire exposure represent the model output.

2. The aim of study
In the current study, the experimental work focused on the effects of adding Nanosilica, Nanoclay, and hybrid mix of the two materials into normal concrete composition in order to improve its ability to resist radiation and high temperature. In another words, the current investigation aims to explore the ability of normal strength concrete supported with Nanoadditives to replace the heavy concrete as a construction material in the structures exposed to radiation and high temperature effects. There are different methods to detects the ability of different materials to resist radiation. In that study, linear attenuation coefficient calculated from Beer lambert equation was adopted to determine the ability of the different concrete mixes to absorb the gamma ray radiation. Beer lambert formulate the general law to calculate the value of linear attenuation coefficient: $\mu = \frac{1}{t} \ln \left( \frac{I_0}{I} \right)$, where $\mu$ is the linear attenuation coefficient, $t$ is the thickness of the shield material, $I_0$ represent the initial intensity of gamma rays emits from the radiation source without using the shield material, and $I$ represent the final intensity of gamma rays emits from the radiation source after using the shield material. The higher the value of linear attenuation coefficient is, the higher the material's ability to resist radiation. Moreover, the current study adopted Fuzzy Logic Systems models as a strong Artificial Intelligence tool in order to develop smart prediction model of the value of gamma ray linear attenuation coefficient $\mu$ at different conditions of temperature degrees, Nano addition type, and Nano addition proportion.

To assure and verify the high prediction accuracy of the developed Fuzzy Logic model, prediction results were compared to the results of linear regression analysis. Regression analysis is a set of statistical processes for estimating the relationships among variables [4]. It includes many techniques for modeling and analysing several variables, when the focus is on the relationship between a dependent variable and one or more variables. Regression analysis is widely used for prediction and forecasting, where its use has substantial overlap with the
field of machine learning. Regression analysis is also used to understand which among the independent variables are related to the dependent variable, and to explore the forms of these relationships. The performance of regression analysis methods in practice depends on the form of the data generating process, and how it relates to the regression approach being used [5].

In addition to the verification process of the proposed FLS model, sensitivity analysis of the model variables was performed. Sensitivity analysis (SA) usually used to determine which subset of input factors accounts for most of the output variance and in what percentage. Sensitivity Analysis can be explained as how much the model response is influenced by changes in the model input parameters [6]. To assess the impact of each of the key four input parameters on gamma ray linear attenuation coefficient, a Sensitivity Analysis was performed using Statistical Package for the Social Sciences software (SPSS).

3. Experimental work
Recently, many of Pozzolanic materials with particles in nano size available in the local market were proposed to be used in enhancing the properties of cementitious mixes (cement pastes, cement mortar and concrete). Nano silica (NS) and Nano clay (NC) are the two nanomaterials widely used in concrete construction sector. Also, some previous studies proposed using the hybrid of them for the same purpose. To achieve the targets of the current research, the experimental program was designed to cover a wide range of variables changing in order to provide sufficient amount of data to build up the FLS model. At concrete curing age of 28 days, specimens of different mixes were tested to calculate the gamma ray linear attenuation coefficient values at room conditions, and with different temperatures (200°C, 400°C, 600°C, 800°C), and exposure time of two hours. The results of μ of 65 cubic specimens of 10×10×10 cm represents the input data of the Fuzzy Logic prediction model. All used materials description, mixes proportions, and tests criteria and results are provided in the following sections.

3.1 used materials
3.1.1 cement
In this study, CEM I 42.5 N. Testing of cement was carried out as the Egyptian Standard Specifications ESS 4756-1/2009 [7], with specific gravity of 3.15. The properties of the used cement are shown in Table (1).

| Property       | Value | ESS Limits  |
|----------------|-------|-------------|
| Specific gravity | 3.15  | -------     |
| IS time (min)   | 198   | > 60 min    |
| FS time         | 256   | < 600 min   |
| Fineness %      | 7%    | < 10 %      |
| Soundness (mm)  | 3     | < 10 mm     |

The chemical composition of used cement shown in Table (2).

| Oxide Composition  | CEMI By Mass % |
|--------------------|----------------|
| Silicon dioxide (SiO2) | 20.24          |
| Aluminum oxide (Al2O3) | 6.09           |
| Ferric oxide (Fe2O3)  | 3.38           |
| Calcium oxide (CaO)   | 62.65          |
| Magnesium oxide (MgO) | 2.03           |
| Sulphur trioxide (SO3) | 2.24          |
| Potassium oxide (K2O) | 0.87           |
| Titanium dioxide (TiO2) | –             |
| Sodium oxide (Na2O)   | 0.78           |
| Loss on Ignition     | 1.68           |

3.1.2 Fine Aggregate
Fine aggregate used in concrete cubes mixing are natural clean siliceous sand with specific gravity of 2.64. The physical properties of sand including specific weight, bulk density, and percentage of silt and fine impurities are shown in Table (3).

| Test          | Siliceous Sand | Limits |
|---------------|----------------|--------|
|               |                |        |
Specific Gravity | 2.65 |
---|---
Bulk Density \((t/m^3)\) | 1.70 |
Fineness Modulus | 2.92 |
Materials Finer than 200 Sieve \((\text{No.} \%)\) | 2.6 Less than 3% |

Sieve analysis of the used fine aggregate illustrated in Table 4. All values lie within the range of fine grading zone according to the classification of the Egyptian code of practice for design of concrete structures [8], and the requirement of ESS 1109/2002 [9].

**Table (4) Sieve analysis of fine aggregates**

| Sieve Size (mm) | % Passing |
|-----------------|-----------|
| 4.75            | 95.2      |
| 2.8             | 91.6      |
| 1.4             | 77.3      |
| 0.71            | 57.2      |
| 0.355           | 13.8      |
| 0.177           | 1.9       |

3.1.3 Coarse Aggregate

Coarse aggregate used at this experimental study was local crushed limestone (dolomite) with a specific gravity of 2.66, bulk unit weight of 1618 Kg/m3, void percentage 39.2%, fineness modulus of 6.35, according to the requirement of ESS 1109/2002 [9].

3.1.4 Water

Tap water was used for both mixing and curing the test specimens according to the requirement of the (ECP 203-2007) [8].

3.1.5 Nano Silica

In this study amorphous Nanosilica \((\text{SiO}2)\) with particle size ranged from 15-80 nm was used in preparation of the Nanosilica blended concrete specimens. The Nanosilica used is powder type, Colorless (White), and with average density 2.2 - 2.6 g/mL at 25 °C as shown in Figure (2). Transmission Electron Microscope (TEM) micrograph of Nanosilica used in this study are shown in Figure (3).

**Table (5) Chemical Composition of Nano silica**

| Composition | % of mass |
|-------------|-----------|
| SiO2        | 99.86     |
| Al2O3       | 0.02      |
| CaO         | 0.03      |
| Fe2O3       | 0.01      |
| TiO2        | 0.01      |
| Loss on Ignition | 0.05 |

3.1.6 Nanoclay

The Nano-clay used in this work is Nano Metakaolin which produced from heat treatment
of kaolin. This heat treatment, at about 900 °C, and (5) respectively. Breaks down the structure of kaolin such that the alumina and silica layers become puckered and lose their long-term order, producing Nano Metakaolin MK. The Nano-clay used is powder with (off white) color, and with average density of 0.6 – 0.8 gm/cm³ at 25 °C. The appearance of a sample of Nanoclay used for this research study and its TEM micrograph are shown in Figures (4)

Table (6) Chemical Composition of Nano clay

| Composition | % of mass |
|-------------|-----------|
| SiO₂        | 51.52     |
| Al₂O₃       | 40.18     |
| CaO         | 2.00      |
| Fe₂O₃       | 1.23      |
| TiO₂        | 2.27      |
| Loss on Ignition | 2.01 |

3.1.7 Hybrid Nano silica - Nano clay

Hybrid Nano silica – Nano clay is a composition resulting from mixing the two Nanomaterials to obtain improved characteristics as compared to those relevant to each individual component. Previous studies have shown that Nanosilica is more amorphous than Nanoclay so, it has more contribution in increasing of the C-S-H gel during the hydration process of cement [10]. On the other hand, other previous researches have indicated that Nanoclay acts as a filler material having better effect than Nanosilica in decreasing the voids and producing denser concrete [11]. Accordingly, a hybrid mix of (NS+NC) may contribute positively in producing denser, stronger, and less voids concrete. These characteristics may have a good effect on the values of gamma ray linear attenuation coefficient μ.

3.1.8 Chemical Admixture

One type of chemical admixtures was used. A superplasticizer based on a modified polycarboxylic ether was employed to obtain a satisfactory workability for the mixes and accelerates the cement hydration. A commercial superplasticizer (GLENIUM ACE 30) produced by chemicals company (BASF) in Egypt was used at all mixes with fixed proportion by 2.77% by weight of water as recommended percentage by the manufacturer was 1-3%.

3.2 Mixing properties

To achieve the objectives of this work, three groups with a total numbers of 12 concrete mixes in addition to control mix were prepared and investigated. The first group was designed using different ratios of Nanoclay as a cement
replacement with percentages 1, 3, 5, 7, 9 %. The second group with different ratios of Nanosilica as a cement replacement with percentages 1, 2, 3, and 4%. The third group with hybrid mix between Nano silica and Nano clay using different ratio, and to answer about the question why that hybrid mix was investigated, the answer is related about characteristics of each material. Previous studies showed that Nano silica is more amorphous than the Nano clay, which means that Nano silica is very effective and contribute in increasing of the C-S-H gel during the hydration process of cement [12]. However, Nano clay can be classified as filler material that help in making concrete dense and durable by decreasing voids ratio [13]. Thence, design combination between Nano silica and Nano clay can make a moderate area between the two materials. Fixed proportion with five liters for each one cubic meters of concrete of chemical additive of Superplasticizer was used to obtain a satisfactory workability for the mixes and accelerates the cement hydration. Constant contents of cement, water, and aggregate, in all concrete mixes, were contemplated to achieve comparable results that reflect the effect of adding different levels of Nanoparticles. The compositions of the concrete mixtures are shown in Table (7).

| Groups   | Mix       | Symbol | Cement (kg) | Aggregate (kg) | Water (lit) | Nano Silica (kg) | Nano Clay (kg) |
|----------|-----------|--------|-------------|---------------|-------------|-----------------|----------------|
| Control mix | M0  | 400    | 1170        | 656           | 180         | ----            | ----           |
| Group (1) | 1%NC | M1     | 396         | 1170          | 656         | 180             | ----           |
|          | 3%NC | M2     | 388         | 1170          | 656         | 180             | ----           |
|          | 5%NC | M3     | 380         | 1170          | 656         | 180             | ----           |
|          | 7%NC | M4     | 372         | 1170          | 656         | 180             | ----           |
|          | 9%NC | M5     | 360         | 1170          | 656         | 180             | ----           |

3.3 Measuring of linear attenuation coefficient μ
Firstly, it’s worth mentioning that the current experimental work represents an extension to previous experiments were performed with the same conditions of materials proportions, temperature degrees, and fire exposure times in order to investigate the positive effects of adding the same nano additives on the value of residual compressive strength of normal strength concrete after fire exposure [1]. At 28 days age, results showed that Nano clay gives the optimum improvement compressive strength in room conditions at 5% replacement of cement ratio with 17.1% improvement ration, followed by the hybrid mix at (1%NS + 4% NC) with 15% improvement ratio, and Nano silica at 2% with 11% improvement ratio. After fire exposure, the optimum additives ratios for the most of temperature degrees were 5% for Nano clay, (1% + 4%) for the hybrid mix., and 3% for Nano silica. The values of concrete residual compressive strength can give us general view to predict the direction of the expected μvalues.
In the previous experiments [1], six target temperatures (200°C, 400°C, 500°C, 600°C, 700°C, and 800°C) were chosen, besides ambient temperature, to capture the effect of elevated temperature on compressive strength of concrete specimens for exposure times of (60-120) minutes with total number of 156 specimens. While the total number of the cubic specimens in the current study was minimized by excluding the temperatures degrees of (500°C, 700°C), and the exposure time of (60 minutes) with total number of 65 specimens. The reason of minimizing the total specimens number is to verify the power of the Fuzzy Logic model to achieve high prediction accuracy with lower available amount of data.

The furnace used to simulate the conditions of actual fire exposure is a natural gas furnace, equipped with two net of gas burners, each network contains twenty-one of the gas burners with dimensions of (400×1300 mm) up to the target temperatures. The outer dimensions of the furnace are 150×120×80 cm while, the inner dimensions are 140×110×70 cm. The flame was intended to simulate the heating conditions in an actual fire. The concrete specimens were burnt by direct fire flame as shown in Figure (6). Control valves and thermocouples were utilized to control and measure the inside temperature during the firing process. The digital thermometer continuously recorded the temperature as shown in Figure (7).

Figure (6) Burning of Concrete specimens

Figure (7) The digital Thermometer

As previously stated, Beer Lambert equation was used to calculate µ values before and after fire exposure using gamma ray radiation source of Co-60 (1173 keV). The transmitted gamma ray intensity was measured using a gamma-ray spectrometer with Nal detector. Figure (8) illustrates the used technique to detect the concrete shield ability to absorb and resist gamma ray radiation. Firstly, the initial intensity of gamma rays I0 was measured without using the cubic 10x10x10 cm concrete shield. Then the different nano concrete shields were put to oppose the way of gamma rays and the intensity of radiation was recalculated I.

Figure (8) Measuring of µ for different Nano-concretes

4. Result and Discussion
4.1 linear attenuation coefficient values
By substituting the measured values of I and I0 in Lambert equation, µ values were calculated as reported in table (8). Results showing obvious
improvement in $\mu$ values for the different nano-concrete specimens, (shaded cells values will be used for prediction process using Fuzzy Logic Systems model later). At the conditions of room temperature, improvement ratios of (15.8%, 14.3%, and 14.3%) were recorded comparing with the control mix for the optimum nanoreplacement ratios at 5% NC, 3%NS, and (1%+4%) for the hybrid mix. For the different temperature degrees, the improvement ratios vary according to the different mixes and temperatures as illustrated in figure (9) for the optimum replacement proportions.

| 28 days/2hr | Nano clay (NC)% | Nano silica (NS)% | Hybrid (NS + NC)% |
|-------------|-----------------|-------------------|------------------|
| Property    | Control mix     | 1 3 5 7 9         | 1 2 3 4          |
|             | 25°C            | 0.13 0.14 0.18 0.11 0.13 | 0.1 0.1 0.1 0.1 0.1 |
|             | 200°C           | 0.12 0.13 0.13 0.11 0.11 | 0.1 0.1 0.1 0.1 0.1 |
|             | 400°C           | 0.11 0.13 0.13 0.11 0.11 | 0.1 0.1 0.1 0.1 0.1 |
|             | 600°C           | 0.10 0.11 0.13 0.13 0.13 | 0.1 0.1 0.1 0.1 0.1 |
|             | 800°C           | 0.09 0.10 0.13 0.13 0.13 | 0.1 0.1 0.1 0.1 0.1 |

Figure (9) $\mu$ improvement ratios according to optimum replacement values.

It’s remarkable that Nanoclay is the most effective nano material for all temperature degrees in linear attenuation coefficient improving. This can be explained by nature of Nanoclay that acts as a filler material which contribute to make the concrete shield denser and with less voids. This property enables the concrete shield to be more effective in resisting
the radioactive waves such as gamma ray radiation. On the other hand, Nanosilica particles also have positive effect in $\mu$ improving. They act as a supplementary cementitious material and contribute in additional hydration activity and denser concrete. The hybrid mix effect lies in a moderate area between Nanosilica and Nanosilica.

4.2 Visual observations of concrete samples after burning

The following figures (10), (11), and (12) show the effect of fire exposure on concrete specimens at different temperature degrees. After two-hours exposure, for all Nanoadditives specimens there was a little visible effect on the surface of heated specimens up to 400 °C. Small cracks and partial spalling were when the temperature reached 600 °C. It was observed that the aggregates decomposed and lost their integrity as the temperature reached 800 °C.

5.Fuzzy Logic Systems model

5.1 Fuzzy model structure

In 1965, Lotfi Zadeh developed the Fuzzy set theory in order to deal with the imprecision and uncertainty that is often present in real world applications [14]. As previously mentioned, the general fuzzy Logic systems (FLS) consists of four components: fuzzification, fuzzy rule base, fuzzy output engine and defuzzification, while, input and output data can be added [15] as illustrated in Figure (13). The fuzzification process role is to convert the input data into different degrees of membership by a lookup in one or more several membership functions (simple linear functions, such as gauss or triangular ones, are preferable) [16,17]. All of the proposed membership functions in this study consist of three inputs (Nanoadditives type, Nanoadditives proportions, and Temperature degree), and one output (linear attenuation coefficient $\mu$). The membership function plots of input variables used in the training process are shown in Figure (14). Fuzzy rule base contains rules that include all possible fuzzy relation between inputs and outputs. These rules are expressed in the IF-THEN format [18]. Fuzzy output engine considers all the fuzzy rules in the fuzzy rule base and learns how to transform a set of inputs to corresponding outputs. The final step of defuzzification converts the resulting fuzzy outputs from the fuzzy output engine to a number [3].
5.2 Simulation of FLS model and regression analysis.
Parameter prediction is determination of aimed values response to evident input values of constituted model. For this aim, in the study 65 data of experiment results as reported in table (6) were used in the processes of fuzzy inference model in FLS. Five specimens results (shaded cells in table6) were omitted for use in the prediction process. Simulation and prediction results using FLS found to be very strong when compared to traditional linear regression analysis. The technique of regression depends on making the best fitting line through a big number of results, that line can represent the overall direction of results, and then the equation of the line can be concluded. Employing data of the 60 specimens, the main deliverable of SPSS was the following empirical formula:

$$\mu = 0.14501 -5.16158E-05 X_1 + 0.0011218 X_2 + 0.002068X_3$$

Where: $X_1$ represents temperature degree, $X_2$ Nano clay ratio, and $X_3$ represents Nano silica ratio. Table (9) showing all the expected $\mu$ values using FLS and linear regression analysis.

| Experimental | FLS            | Regression analysis |
|--------------|----------------|---------------------|
| 0.133        | 0.135775107    | 0.143721726         |
| 0.142        | 0.139001182    | 0.144843481         |

To assess the goodness -of-fit of the developed formula, the coefficient of determination ($R^2$) and the standard error of estimate are the most widely used statistics for this purpose. In this analysis, $(R^2)$ associated with the equation fitted is equal to $(0.909)$ as shown in figure (15). While $(R^2)$ value for the FLS found to be $(0.993)$ which represents an extremely accurate and superior value as shown in figure (16).

| Experimental | FLS | Regression analysis |

Figure (15) Regression Plot for the predicted values of $\mu$ using the developed empirical formula.

Figure (16) Regression Plot for the predicted values of $\mu$ using FLS
5.3 prediction process using FLS.
Data of 5 specimens randomly selected, as shaded in table (6), were reserved so that they are employed to assess and verify the proposed model. Using data (values of input variables and the corresponding experimental results of $\mu$) of the 5 reserved specimens, the proposed FLS model is assessed for its efficiency in accurately simulating the linear attenuation coefficient ($\mu$) after fire exposure. In other words, the developed FLS model is assessed by comparing experimental results and simulated (predicted) values with one another for 5 specimens reserved to this end. The results of the comparison provided in table (10) showing strong accuracy and high efficiency.

Table (10) Simulation results for the reserved five specimens for $\mu$ prediction model.

| Sample | 1  | 2  | 3  | 4  | 5  |
|--------|----|----|----|----|----|
| Temperature degree | 25 | 400 | 25 | 400 | 600 |
| NC (%) | 5  | 0  | 0  | 0  | 1  |
| NS (%) | 0  | 0  | 4  | 1  | 4  |
| $\mu$ experimental results | 0.15 | 0.11 | 0.14 | 0.12 | 0.12 |
| FLS predicted values | 0.15 | 0.11 | 0.14 | 0.12 | 0.12 |

5.4 Sensitivity Analysis
Sensitivity Analysis (SA) can be explained as how much the model response is influenced by changes in the model input parameters [19]. Generally, the accuracy of the outputs prediction is highly dependent on the number of input variables. In other words, the more the number of input parameters are, the more accurate the results of the predictor models would be [6]. Results of Sensitivity Analysis are summarized in table (11) and figure (17). Results show that temperature degree has the most impact on $\mu$. In addition, $\mu$ is influenced by levels of Nanoclay more than those of Nano silica.

Table (11) Independent Variable Importance for RCS prediction model

| Variable | Temperature | NC | NS |
|----------|-------------|----|----|
| Importance | .763 | .137 | .1 |
| Normalized Importance | 100.0% | 17.9 % | 13.1% |

Figure (17) Relative importance of input parameters
5. Conclusion
According to the results of both the experimental investigation and the developed Fuzzy Logic systems model, the following points could be concluded:
1- Nanomaterials used in this study (Nanoclay, Nanosilica, and hybrid mix of both) lead to obvious improvement in linear attenuation coefficient values for the different concrete mixes either at room temperature conditions or after elevated temperature exposure.
2- Improvement rates in linear attenuation coefficient values are influenced by type and proportion of Nanomaterials used in this study.
3- After two hours of fire exposure at 800°C, µ value of the control mix was reduced by 27.82%. The addition of 5% NC could reduce that ratio to the level of 14.28%, while improvement ratios of (15.8%, 14.3%, and 14.3%) were recorded comparing with the control mix for the optimum nano replacement ratios at 5% NC, 3%NS, and (1%+4%) for the hybrid mix.
4- Linear attenuation coefficient values are influenced by levels of Nanoclay more than those of Nanosilica according to sensitivity analysis results.
5- In general, complex nonlinear behavior of concrete can be effectively processed using Fuzzy Logic Systems model, while the current study verified the high accuracy of FLS in µ values simulation before and after fire exposure.
6- Statistical technique of regression analysis was performed in order formulate mathematical prediction equation of µ values with acceptable regression value of 0.909.
7- Prediction results provided by simulation of linear attenuation coefficient values using the developed FLS model is found superior compared with regression analysis.

التنبؤ بمعامل التهوين الخطى لأشعة جاما لانواع مختلفة من خرسانات النانو باستخدام الذكاء الصناعي

ملخص البحث:

يعد تصميم وانشاء المبانى المقاومة للاشعاع بغرض حماية الناس والمعدات من تأثيراته الضارة واحداً من أكبر التحديات التي تواجه مجالات الهندسة المدنية والنووية. لقد أظهرت الخرسانة أنها مادة قوية وفعالة وإقتصادية لإنشاء المبانى المقاومة للإشعاع، فقد تم استخدامها للعديد من الأغراض ك셈ات دائمة مثل محطات الطاقة النووية ومعامل الإبحاث والتفاعلات المستخدمة للاعراض البحثية. هناك توقع كبير في المواد التي تستخدم في الخلطات الخرسانية المعدة لانالاخ خرسانات مقاومة للإشعاع والتي يكون الغرض الرئيسي من استخدامها هو إضعاف وتهوين إشعاع جاما.

إن استخدام مواد النانو في انتاج الخرسانة بغرض تحسين خواصها الطبيعية والميكانيكية يعد مجالاً بحثياً واعداً هذه الأيام، حيث أن المواد في جسم النانو تميز بنفس المساحة الطبيعية العالية مقارنة بالحجم وكذلك نشاطها وفاعلها الكبير ولهذا فاستخدامات مواد النانو يمكنها إنتاج خرسانات أقوى وأكثر كثافة وقليلة الفراغات، وهي خصائص لها تأثير ملحوظ في تحسين مقاومة الخرسانة للإشعاع. والذى يعبر عنه بمعامل التهويل الخطى لاشعة جاما. يهدف هذا البحث إلى استكشاف تأثير العديد من مواد النانو على مقاومة الخرسانة للإشعاع وعلى خصائصها كدرع واقى من الإشعاع وهي مواد (نانو السيليكا-نانو الطين-خلط من كلا المادتين).

ومن ناحية أخرى، يهدف هذا البحث إلى تطوير نموذج ذكي يستطيع التنبؤ بمعامل التهويل الخطى لاشعة جاما وذلك لانواع مختلفة من خرسانات وبنسبة إضافات مختلفة لمواد النانو، وهذا فإن الدراسة تعود على استخدام نماذج المنطق الضبابي كأحد أساليب الذكاء الصناعي لتحقيق هذه الغاية. إن نماذج المنطق الضبابي وكونها سريعة وقابلة صناعية لها العديد من الاستخدامات خاصة في مجالات تصنيف البيانات والتنبؤ بها تستطيع نمذجة العلاقات غير الحالية والمعقدة بين المتغيرات التي على أساسها تكون قيمة معامل التهويل الخطى لاشعة جاما. نماذج المنطق الضبابي يمكن تصنيفها كأداة تستطيع نمذجة البيانات الإحصائية غير الخطية للمدخلات المخرجات التي تتميز بالتعقيد، ولذا فالعديد من التطبيقات والبرامج المعتمدة على نماذج المنطق الضبابي أصبحت متوفرة واستخدمت في العديد من البدائل السابقة وفي مجالات هندسة متعددة. تحتجم نماذج المنطق الضبابي إلى كميات من البيانات لتحمل بكفاءة هذه البيانات توقعت من نتائج التجارب العملية التي تم إجرائها من خلال هذا البحث، وتعد إضافات مواد النانو بنسب وأنواع مختلفة بيانات إدخال رئيسية للنموذج الذكي الصناعي المستخدم.

أدت إضافات النانو المستخدمة إلى تحسن ملحوظ في مقاومة الخرسانة للإشعاع من خلال تحسن قيمة معامل التهويل الخطى لمختلف الخلطات عقب تعرضها لظروف مختلفة من التعرض للحرق تصل إلى 800 درجة بيئية. من ناحية أخرى يمكن تطوير نموذج ذكي باستخدام نماذج المنطق الضبابي لديها القدرة على المحاكاة والتنبؤ بقيمة معامل التهويل الخطى لمختلف الخلطات الخرسانية.
