Condensed matter systems realizing Weyl fermions exhibit striking phenomenology derived from their topologically protected surface states as well as chiral anomalies induced by electromagnetic fields. More recently, inhomogeneous strain or magnetization were predicted to result in chiral electric $E_b$ and magnetic $B_b$ fields, which modify and enrich the Landau anomaly with additional terms. In this work we develop a lattice-based approach to describe the chiral anomaly, which involves Landau and pseudo-Landau levels and treats all anomalous terms on equal footing, while naturally incorporating Fermi arcs. We exemplify its potential by physically interpreting the largely overlooked role of Fermi arcs in the covariant (Fermi level) contribution to the anomaly and revisiting the factor of 1/3 difference between the covariant and consistent (complete band) contributions to the $E_b$, $B_b$ term in the anomaly. Our framework provides a versatile tool for the analysis of anomalies in realistic lattice models as well as a source of simple physical intuition for understanding strained and magnetized inhomogeneous Weyl semimetals.

Quantum anomalies describe the breaking of a classical symmetry by quantum fluctuations [1]. The chiral anomaly, the nonconservation of the chiral charge of three-dimensional Weyl fermions, is relevant to different domains in physics since Weyl fermions mediate the electromagnetic fields. To motivate this, recall that their vector ($E_5 = \nabla \times b$) and pseudoelectric ($E_5 = -\partial_t b - \nabla b_0$) fields, which couple with opposite signs to opposite chiralities [16, 17, 29–39]. Unlike $B$, which generates Landau levels dispersing in opposite directions for opposite chiralities, $B_5$ generates pseudo-Landau levels that disperse in the same direction for both chiralities [16, 17, 25, 26, 40]. Applying the Landau level picture to chiral fields leads to puzzling conclusions: for example, because of the chirality independent dispersion of the zeroth pseudo-Landau level due to $B_5$, $E$ increases (or decreases) the number of fermions for both chiralities at a rate proportional to $E \cdot B_5$, giving an apparent nonconservation of the total charge. This is expressed as the so-called covariant anomaly [1, 40]

$$\partial_{\mu} J_{5,\text{cov}}^\mu = \frac{1}{2\pi^2} (E \cdot B + E_5 \cdot B_5),$$

$$\partial_{\mu} J_{\text{cov}}^\mu = \frac{1}{2\pi^2} (E_5 \cdot B + B_5 \cdot E).$$

Neither the covariant chiral ($J_{5,\text{cov}}^\mu = J_{L,\text{cov}}^\mu - J_{R,\text{cov}}^\mu$) nor vector ($J_{\text{cov}}^\mu = J_{L,\text{cov}}^\mu + J_{R,\text{cov}}^\mu$) currents are conserved. In field theory, to explicitly restore charge conservation, the covariant currents are supplemented by Bardeen poly-
nomials $\delta j^\mu$, which act like boundary conditions for the accumulated charge at the cut-off energy [41–44]. This procedure defines the \textit{consistent} anomaly [1, 40]

$$\partial_\nu J^\mu = \frac{1}{2\pi^2} \left( E \cdot B + \frac{1}{3} E_5 \cdot B_5 \right),$$

$$\partial_\mu J^\mu = 0.$$  \hspace{1cm} (3)

The \textit{consistent} anomaly conserves charge, and thus determines observables [42, 45] by discarding unphysical responses [40–42, 46]. The Bardeen polynomials, however, sacrifice intuition of the covariant picture based on Landau levels and obfuscate the restoration of charge conservation in specific lattice implementations.

Despite the field theory of the \textit{consistent} and covariant anomalies being well understood for a long time [40], a simple physical picture of their origin on a lattice, with guaranteed charge conservation, is still missing. In this work we provide such a picture using building blocks of the Landau and pseudo-Landau levels. It leads to our two main results: first, we identify the Fermi arcs as a source for the covariant anomaly terms of Eq. (2) and relate them to the Bardeen polynomials. Second, we show that when $B_5 > B$ the Fermi surface twists into a bowtie shape, a property central to our understanding of how the term $E \cdot B_5$ redistributes charge within the sample. Our picture allows us to address as well the 1/3 disparity between the second term in Eq. (3) and Eq. (1). We argue that a necessary condition for its identification is a structure in the second term in Eq. (3) and Eq. (1). We argue that a necessary condition for its identification is a $B_5$ profile that spatially separates chiral charge creation and annihilation. Similar to how Landau levels simplified our understanding of the chiral anomaly [10], we use pseudo-Landau levels (developed in Ref. 17) to provide a unified and simple lattice picture of the consistent and covariant anomalies with specific implications for experiment.

Our starting point is the Weyl semimetal model [46]

$$\mathcal{H} = w \left[ \sin(k_y)\sigma_x - \sin(k_x)\sigma_y \right] \tau_z + v \sin(k_z)\tau_y + m \tau_x + t \sum_i \left[ 1 - \cos(k_i) \right] \tau_z + v \sum_{\mu} u^\mu b^\mu,$$  \hspace{1cm} (5)

with $a = 1$ the lattice constant, $\sigma_i$ ($\tau_i$) spin (orbital) Pauli matrices, and $u^\mu = (\sigma_z \tau_y, -\sigma_x \tau_x, -\sigma_y \tau_x, \sigma_z)$. For small $b^\mu = (b_0, b)$ and $m^2 < v^2 (b^2 - b_0^2)$, the model has one pair of Weyl nodes located near $\Gamma$ [46, 47]. Unless stated otherwise, we set $m = 0$ and $t = 2v/\sqrt{3}$. When $b$ is oriented along a reciprocal lattice vector, this parameter choice gives two Weyl nodes located at $b^\mu [1 + O(b^2_0)] + O(b^4_0)$ and energies $\pm v b_0 [1 + O(b^2_0)] + O(b^4_0)$. Our results also apply to generalizations of Eq. (5) that model Dirac (e.g., Cd$_3$As$_2$, Na$_3$Bi) and Weyl (e.g., TaAs family) materials [48–50].

We further define $\gamma^3 = (\tau_x, i\sigma_y \tau_y, -i\sigma_x \tau_x, i\tau_z)$ and $\gamma^5 = \tau_z \gamma^3 = \sigma_z \sigma_y$ with $u^\mu = \gamma^5 u^\mu \gamma^3$ and the space-dependent chiral charge density is

$$J_5^\mu(x) \equiv \rho_5(x) = \sum_{n \in \text{occ.}} \langle \psi_n(x) | \gamma^5 | \psi_n(x) \rangle.$$  \hspace{1cm} (6)

![FIG. 1. Anomalies due to $E \cdot B$ and $E \cdot B_5$. (a) The spectrum of Hamiltonian (5) for a slab finite along $y$, showing the coexisting Fermi arcs and Landau levels of $B = B\hat{z}$. The color scale denotes the wave function’s position along $y$. (b), (c) The Landau (pseudo-Landau) levels of $B$ ($B_5$) on the red (blue) triangle plane show the anomaly in the presence of $E = E_x \hat{z}$ ($E = E_x \hat{x}$), where the spectral flow at the Fermi surface is shown by green (orange) arrows. We implement $E$ using the gauge choice $\mathbf{k} \to \mathbf{k} - \mathbf{E} t$. The left panels show the occupation at $t = 0$, while the right panels show the dispersion for $t > 0$ with $E_x, t = 0.08$ and the same momenta occupied as in the left panels, cf. Supplemental Material. Here $L = 100$ and $\ell_B = 1/\sqrt{B} = 11.2$. The charge density, $\rho(x)$, is obtained by replacing $\gamma^5$ with the identity in Eq. (6). While our lattice model (5) includes a $\tau_x$ term that explicitly breaks conservation of $\rho_5$, we show in the Supplemental Material how this effect is controlled.

The Hamiltonian (5) (with $v = 1$) derives from an effective field theory with action

$$S = \int d^4x \bar{\psi} \left[ \gamma^\mu \left( i\partial_\mu - A_\mu - b_\mu \gamma^5 \right) - m \right] \psi,$$  \hspace{1cm} (7)

where $\bar{\psi} = \psi^\dagger \gamma^0$ and repeated indices are summed. $S$ yields two species of Weyl fermions of opposite chiralities, coupled to an external chiral field $b_\mu$ and a vector field $A_\mu$, and separated by $b_\mu$ for $m = 0$. The lattice regularized by the Wilson map $k_i \to \sin k_i$ [51], and $m \to m + t \sum_i (1 - \cos k_i)$ [52].

Spatial and temporal variations of $b$ generate the chiral fields $B_5 = \nabla \times b$ and $E_5 = -\partial_t b$. The simplest realization of $B_5$ occurs at the boundary of any Weyl semimetal with vacuum, where the Weyl node separation $b_\mu$ goes to zero [17, 26, 40]. For example, for a slab along $y$, $b_\mu(y) = b_z (\Theta(y - L/2) - \Theta(y + L/2)) \hat{z}$ gives $B_5(y) = b_z [\delta(y - L/2) - \delta(y + L/2)] \hat{x}$, localized at the surface, which generates surface pseudo-Landau levels dispersing along $\pm k_x$, with opposite signs at each surface [17]. Their Fermi surface traces an arc, establishing the correspondence between surface pseudo-Landau levels induced by $B_5$ and topological surface states. Analogously, a uniform external magnetic field $B = B\hat{z}$ parallel to the Weyl node separation leads to a spectrum hosting...
bulk Landau levels dispersing along $\pm k_z$, where the sign is set by the Weyl node chirality. When both $B$ and a surface $B_5$ are present, Landau and pseudo-Landau levels coexist and the Fermi surface at the Fermi energy $\varepsilon_F$ (set to $\varepsilon_F = 0$ hereafter) traces a rectangle \[53\], see Fig. 1(a) \[54, 55\].

The coexistence of Landau and pseudo-Landau levels provides an ideal platform to discuss the anomalies. Applying $E = E_z \hat{z}$ pumps charges of one chirality to the other, connecting Landau levels of $B$ through the band bottom and realizing the $E \cdot B$ term in Eq. (3) \[10\] [see Fig. 1(b)]. Similarly, since the pseudo-Landau levels disperse along $\pm k_z$ on each surface, applying $E = E_x \hat{x}$ depletes charges from one surface and generate charges on the other [Fig. 1(c)]. We can interpret \[10\] this as an anomaly of each surface state due to $E \cdot B_5$. In contrast to the chiral anomaly in the absence of chiral fields, where the total charge is locally conserved, the spatial separation of the two surfaces leads to an apparent violation of local charge conservation, as in Eq. (2). Our pseudo-Landau level picture demonstrates the surface origin of the covariant anomaly, $\sim E \cdot B_5$.

Our picture tracks how charge is explicitly conserved. The spectral flow between the pseudo-Landau levels at each surface happens via the bulk Landau levels connecting them, fixing local charge conservation. The effect of $E$ results in an adiabatic shift of $k_z$, which via position-momentum locking \[17\] generates a Hall current

$$\delta j = -\frac{1}{2\pi^2} b_z E_x \hat{y}. \quad \text{(8)}$$

We can interpret this as the net current flowing along $\hat{y}$ between surfaces through the bottom of the band. In the bulk, $b_z$ is constant leading to $\nabla \cdot \delta j = 0$ and no accumulation of charge. At the surface, the Weyl node separation varies, leading to a finite divergence of the spatial current, positive on one surface and negative on the other.

Similarly, more general profiles of $B$ and $B_5$ can be understood in terms of Landau and pseudo-Landau levels. For instance, a uniform bulk $B_5 \parallel \hat{z}$ arises from $b = B_5 \hat{y} \hat{z}$. Its spectrum [Fig. 2(a)] shows a characteristic butterfly Fermi surface, obtained from the rectangular Fermi surface Fig. 1(a) by noticing that the two bulk Landau levels have lengths $B \pm B_5$. When $B_5 > B$, the Fermi surface twists, leading to Fig. 2(a) [found to lead to peculiar quantum oscillation signals in an unrelated context \[56\]]. An $E = E \hat{z}$ parallel to $B_5$ [Figs. 2(b) and (c)] makes the bulk gain charge above the Fermi level (upward arrows), while the surface loses charge (downward arrows). This is consistent with the lattice numerics [Fig. 2(e)] where the spatial profile of the charge relative to that at $t = 0$ is shown for different times.

Our previous examples (Figs. 1 and 2) are a consequence of the covariant anomaly which only considers the depletion and growth of charges at the Fermi level. By construction, the corresponding current $J_\mu^{cov}$ misses information from states away from the Fermi level, and thus it is not conserved as dictated by Eq. (2), cf. Supplemental Material. The consistent current, $J^\mu$, is obtained from the covariant current by adding the Bardeen polynomials $\delta j^\mu$ such that $\partial_\mu (J_\mu^{cov} + \delta j^\mu) = \partial_\mu J^\mu = 0$ \[41, 42\].

\[\text{FIG. 2. Anomaly due to } E \cdot B_5 \text{ with a constant bulk } B_5 = B_5 \hat{z}. \text{ (a) Energy spectrum with the same color coding and boundary conditions as Fig. 1. FIG. 4. Anomaly due to $\mathbf{E}_5 \cdot \mathbf{B}_5$. (a) The Weyl node separation (10) and its corresponding $\mathbf{B}_5$. (b) Energy spectrum with a real space color encoding that reflects the periodic boundary conditions. (c), (d) Where $\mathbf{B}_5 > 0$ [red in (d)], a parallel $\mathbf{E}_5$ pushes left- and right-handed chiral charges above and below the Fermi level respectively, annihilating chiral charge. Where $\mathbf{B}_5 < 0$ (blue), chiral charge is created. (e) The spatial distribution of chiral charge creation and annihilation follows $\delta j \sim \mathbf{B} \cdot \mathbf{E}$, as predicted by the consistent anomaly (black dotted line). We use $L = 360$, a $\mathbf{B}_5$ broadening $\xi = 6$ and peak height $c_B = 1.25$, and a delta function broadening $\eta = 10^{-6} \text{e}$, cf. Supplemental Material.

Using Eq. (2) and the definition of the pseudo-fields,

$$
\delta j^0 \approx \frac{1}{2\pi^2} \mathbf{b} \cdot \mathbf{B}, \quad \delta j \approx \frac{1}{2\pi^2} (\mathbf{b}_0 \mathbf{B} - \mathbf{b} \times \mathbf{E}).
$$

(9)

Comparing (9) to (8) of our first example (Fig. 1), we identify the latter as a part of the Bardeen polynomials [40]. The benefit of the Landau level approach is its intuitive interpretation: in the first example, $\mathbf{E}_5 = 0$ and the finite $\mathbf{E} \cdot \mathbf{B}_5$ pumps charge from one surface to another via the anomalous Hall effect [Eq. (8)] through $\partial_t \mathcal{J}^0_{\text{cov}} = \mathbf{E} \cdot \mathbf{B}_5/(2\pi^2)$. Our second example, Fig. 2, can be interpreted similarly. In the bulk charge grows as $\partial_t \mathcal{J}^0_{\text{cov}} = \mathbf{E} \cdot \mathbf{B}_5/(2\pi^2)$ locally while at the surface charge is depleted since $\mathbf{B}_5$ has the opposite sign. The corresponding current (9) pumps charge from the surface to the bulk. Since $\mathbf{b} = B_5 y \hat{z}$, there are local currents in the bulk $\delta j \sim B_5 E_5 y \hat{z}$ and $\nabla \cdot \delta j = \mathbf{B}_5 \cdot \mathbf{E}/(2\pi^2)$ is precisely the growth rate of local charge [Fig. 2(c)], reconciling the Fermi surface (covariant) picture with the charge conserving (consistent) picture on the lattice [57].

Moving on to spatio-temporally varying Weyl node separations, consider first $\mathbf{b} = -E_5 t \hat{z}$, yielding uniform $\mathbf{E}_5 \parallel \hat{z}$. A $\mathbf{B} \neq 0$ activates the second term of (2), suggesting that charge is created at the Fermi surface at a rate $\mathbf{E}_5 \cdot \mathbf{B}/(2\pi^2)$. For our lattice model (5), $\mathbf{E}_5$ shifts the band bottom, pushing charge above a fixed energy [Fig. 3(a)]. Rigid shifts of the band conserve total charge, giving the consistent picture of the anomaly. However, if one insists on only considering the low-energy gray region in Fig. 3(a), the charge appears to emerge from the vacuum, as expected from the covariant anomaly. The connection between these pictures is shown in Fig. 3(b), where charge growth near the Fermi surface equals charge loss near the band bottom, which in turn equals the Bardeen polynomial $\delta j^0$, Eq. (9).

We end by addressing the factor of $1/3$ disparity between the prefactors of the $\mathbf{E}_5 \cdot \mathbf{B}_5$ anomalies. This difference implies that the band bottom current must add $-2/3$ to the Fermi surface contribution, irrespective of the precise pseudo-field profile. One may argue that this factor arises from the topological nature of the Bardeen polynomials [44], yet we find that topology alone does not explain the conditions which give $1/3$ for a generic lattice model.

To illustrate the conditions for isolating the $1/3$, consider [36]

$$
b = \frac{c_B}{2} \left[ \text{erf} \left( \frac{y - \frac{1}{2}}{\sqrt{2\xi}} \right) - \text{erf} \left( \frac{y + \frac{1}{2}}{\sqrt{2\xi}} \right) \right] \hat{x} + b_z \hat{z},
$$

(10)

with $c_B$ a constant and $\text{erf}(x)$ the error function [Fig. 4(a)]. In a periodic system of length $L$ in the $y$ direction, this profile realizes interfaces at $\pm L/4$ between two Weyl semimetals with different node separations, connected by regions where $\mathbf{b}$ smoothly changes to give $\mathbf{B}_5 = B_5(y) \hat{z}$ with $B_5(y) = \frac{c_B}{\sqrt{2\xi}} e^{-\left(\frac{y-\frac{1}{2}}{\xi}\right)^2/(2\xi^2)} - e^{-\left(\frac{y+\frac{1}{2}}{\xi}\right)^2/(2\xi^2)}$. This profile maintains the useful property that the two chiralities (eigenstates of $\gamma^5$) are well separated in momentum space [Fig. 4(e)]. Adding $\mathbf{E}_5 \parallel \mathbf{B}_5$ to produce a chiral anomaly, chiral charge (6) is created/annihilated in spatially separated regions [Fig. 4(d)], at a rate that closely follows the spatial profile of $\mathbf{B}_5$ as expected from Eq. (3) [Fig. 4(e)]. The Fermi surface contribution to the chiral charge is calculated as

$$
\frac{dp^E_{FS}}{d\mathbf{b}} = \sum_n \langle \psi_n | \gamma^5 \Pi_y | \psi_n \rangle \langle \psi_n | \partial_\mathbf{b} \mathcal{H} | \psi_n \rangle \delta(\mu - \varepsilon_n).
$$

(11)

with $\Pi_y$ the projector to the position $y$, cf. Supplemental Material. Comparing the chiral charge pumped at the Fermi surface and that in the full spectrum to the expected value proportional to $B_5$, we see that they are close, but neither perfectly reproduces the field theory prediction.

To determine the factors behind this mismatch we note that the erf profile minimizes the spatial overlap between regions of chiral charge creation and annihilation.
Supplemental Material

Summary of consistent and covariant anomalies

For completeness, we provide a summary of the relevant facts of consistent and covariant anomalies derived from quantum field theory. As discussed in the main text electric and magnetic fields that satisfy $E \cdot B \neq 0$ generate an anomalous imbalance between left and right movers. Additionally pseudo-magnetic ($B_5$) and pseudo-electric ($E_5$) field—the fields that couple with opposite signs to opposite chiralities—will result in the same chiral imbalance, since the contributions of the two chiralities to the chiral current $J_{\text{cov}}^\nu = J_{L,\text{cov}}^\nu - J_{R,\text{cov}}^\nu$ ($\mu = 0, 1, 2, 3$) will add up. However, these considerations imply also that the vector current $J_{\text{cov}}^\nu = J_{L,\text{cov}}^\nu + J_{R,\text{cov}}^\nu$ is not conserved. Mathematically

\begin{align}
\partial_\mu J_{\text{cov}}^\mu &= \frac{1}{2\pi^2} (E \cdot B + E_5 \cdot B_5), \quad (12a) \\
\partial_\mu J_{\text{cov}}^\mu &= \frac{1}{2\pi^2} (E \cdot B_5 + E_5 \cdot B), \quad (12b)
\end{align}

a result which can be obtained either diagrammatically [1, 41] or semiclassically [16, 17, 25, 42]. Eqs. (12) define the covariant chiral anomaly [40, 41] of the covariant vector and axial currents $J_{\text{cov}}^\mu$ and $J_{\text{cov}}^5$, respectively.

This result is troublesome: a theory which does not conserve charge is unphysical, yet the fields $B_5$ and $E_5$ can be physically realized in the solid state [16, 17, 25]. At the quantum field theory level curing the nonconservation of charge amounts to acknowledging that Eqs. (12) are determined solely by the Fermi surface, but that counteracting currents are necessary at energies comparable to the cut-off energy [41]. To ensure this constraint is satisfied, two additional Chern-Simons currents, $\delta j_5^\mu$ and $\delta j_5^\mu$, known as Bardeen polynomials, are added, which transfer the necessary charge and guarantee charge conservation [43]. They relate the covariant currents ($J_{\text{cov}}^\mu$, $J_{\text{cov}}^5$) to the physical consistent currents ($J_5^\mu$, $J_5^5$) through $J_5^\mu = J_{\text{cov}}^\mu + \delta j_5^\mu$ and $J_5^5 = J_{\text{cov}}^5 + \delta j_5^5$, respectively, and take the form

\begin{align}
\delta j_5^0 &= \frac{1}{2\pi^2} A_5 \cdot B; \quad \delta j_5^i = \frac{1}{2\pi^2} (A_5^i B - A_5 \times E); \\
\delta j_5^5 &= \frac{1}{6\pi^2} A_5 \cdot B_5; \quad \delta j_5 = \frac{1}{6\pi^2} (A_5^i B_5 - A_5 \times E_5),
\end{align}

where the chiral gauge field $A_5^\mu$ defines the pseudo-fields $B_5 = \nabla \times A_5$ and $E_5 = -\nabla A_5^0 - \partial_0 A_5$. Together with Eqs. (12) results in the consistent anomaly [41, 42]

\begin{align}
\partial_\mu J_5^\mu &= \frac{1}{2\pi^2} \left( E \cdot B + \frac{1}{3} E_5 \cdot B_5 \right); \quad \partial_\mu J_5^5 = 0. \quad (15)
\end{align}

Eqs. (12) and (15) summarize the two versions of the quantum anomalies.
We note that the consistent and covariant currents have been discussed in the context of the two-dimensional quantum Hall effect [59]. In this case the edge current is the sum of the edge consistent current plus the anomalous inflow from the 2+1D bulk Chern Simons term, which combined form the covariant edge current [60]. In a similar way, consistent and covariant currents can be defined for a 3+1D Weyl fermion living at the edge of a 4+1D quantum Hall effect.

Details of the lattice calculations

We are interested in the response of a Weyl semimetal to external fields \( \mathbf{E} \) and \( \mathbf{E}_5 \). A time-dependent vector potential \( \mathbf{A} = -\mathbf{E}t \) gives an electric field, and analogously a time-dependent node separation \( \mathbf{b} = -\mathbf{E}_5 t \). We express the time-derivative of any expectation value \( f \) in terms of the response to changes in \( \mathbf{A} \) and \( \mathbf{b} \),

\[
\frac{df}{dt} = -\mathbf{E} \cdot \partial_\mathbf{A} f - \mathbf{E}_5 \cdot \partial_\mathbf{b} f ,
\]

which is especially handy when evaluating time-derivatives proportional to \( \mathbf{E} \) and \( \mathbf{E}_5 \), such as \( \partial_\mathbf{A} j_5^\mu \) and \( \partial_\mathbf{b} j_5^\mu \) where \( f \) corresponds to the densities \( \rho \) or \( \rho_5 \).

The response of the density to external fields \( \mathbf{E} \) and \( \mathbf{E}_5 \) is the response to a shift \( \mathbf{A} \to \mathbf{A} + d\mathbf{A} \) and \( \mathbf{b} \to \mathbf{b} + d\mathbf{b} \) respectively. Explicitly, the chiral density at site \( y \) reads

\[
\rho_5(y) = \sum_{n \in \text{occ.}} \langle \psi_n | \gamma^5 \Pi_y | \psi_n \rangle ,\]

where \( \Pi_y \) projects onto site \( y \). When performing an infinitesimal shift of the Weyl node separation \( \mathbf{b} \to \mathbf{b} + d\mathbf{b} \), the single-particle states change as

\[
\ket{\psi_n(\mathbf{b} + d\mathbf{b})} = \ket{\psi_n} + d\mathbf{b} \cdot \sum_{m \neq n} \frac{\bra{\psi_m} \bra{\psi_n} \partial_\mathbf{b} \mathcal{H} \ket{\psi_m}}{\varepsilon_n - \varepsilon_m} \]

resulting in a change of the chiral density

\[
\frac{d\rho_5(y)}{d\mathbf{b}} = \sum_{n \in \text{occ.}, \ m \neq n} \frac{\langle \psi_n | \gamma^5 \Pi_y | \psi_m \rangle \langle \psi_m | \partial_\mathbf{b} \mathcal{H} | \psi_n \rangle}{\varepsilon_n - \varepsilon_m} + \text{h.c.} \tag{19}
\]

Note that the sum goes over the states \( n \) that are initially occupied at a node separation \( \mathbf{b} \).

The Fermi surface contribution, on the other hand, just counts the subset of states that are lifted above the Fermi level when shifting \( \mathbf{b} \to \mathbf{b} + d\mathbf{b} \), minus the states that are pushed below the Fermi level, \( d\rho_5^{FS} = d\rho_5^+ - d\rho_5^- \) with

\[
d\rho_5^+(y) = \sum_{\varepsilon_n < \mu, \ \varepsilon_n + \Delta \varepsilon_n > \mu} \langle \psi_n | \gamma^5 \Pi_y | \psi_n \rangle \tag{20}
\]

\[
d\rho_5^-(y) = \sum_{\varepsilon_n > \mu, \ \varepsilon_n + \Delta \varepsilon_n < \mu} \langle \psi_n | \gamma^5 \Pi_y | \psi_n \rangle \tag{21}
\]

or, expressed in terms of Heaviside functions,

\[
d\rho_5^{\pm}(y) = \pm \sum_n \langle \psi_n | \gamma^5 \Pi_y | \psi_n \rangle \Theta(\pm \varepsilon_n)
\times (\Theta(\mu - \varepsilon_n) - \Theta(\mu - (\varepsilon_n + d\varepsilon_n))) . \tag{22}
\]

To first order in perturbation theory, the infinitesimal change in the energies is

\[
d\varepsilon_n = d\mathbf{b} \cdot \langle \psi_n | \partial_\mathbf{b} \mathcal{H} | \psi_n \rangle \tag{23}
\]

and the sum of Heaviside functions reduces to

\[
\Theta(\mu - \varepsilon_n) - \Theta(\mu - (\varepsilon_n + d\varepsilon_n)) = d\varepsilon_n \delta(\mu - \varepsilon_n) , \tag{24}
\]

which finally gives

\[
\frac{d\rho_5^{FS}(y)}{d\mathbf{b}} = \sum_n \langle \psi_n | \gamma^5 \Pi_y | \psi_n \rangle \langle \psi_n | \partial_\mathbf{b} \mathcal{H} | \psi_n \rangle \delta(\mu - \varepsilon_n) \tag{25}
\]

as used in the main text. Numerically, we use a Lorentz approximation to the delta function, \( \delta(x) = \lim_{\eta \to 0} \eta/(\pi(x^2 + \eta^2)) \).

The quest for 1/3

Two effects challenge the calculation of the chiral anomaly due to \( \mathbf{E}_5 \cdot \mathbf{B}_5 \) on a lattice. First, \( \mathbf{B}_5 \) always averages to zero over the whole sample [17], which implies that a length scale \( \xi \) exists that characterizes the typical size of the variations in \( \mathbf{B}_5 \). Second, a mass term \( m \) changes the response of the chiral charge \( \partial_\mu j_5^\mu \).

Effect of \( \xi \)

We demonstrate the lattice effect set by the length \( \xi \) explicitly by using the same profile of the node separation \( \mathbf{b} \) as in the main text (10). In Fig. 5 (a) and (b), we show how the responses of the total chiral charge \( \rho_5 \) and the charge around the Fermi surface \( \rho_5^{FS} \) are affected by different sizes of \( \xi \) respectively. The two conditions for \( \xi \) discussed in the main text that allow for the identification of 1/3 are both demonstrated explicitly. When \( \xi \approx a \) the variation of \( B_5 \) occurs on the scale of the lattice constant forcing the density variations Eqs. (19) and (25) to interpolate smoothly between lattice sites such that the quantum field theory predictions breaks down. When \( \xi \ll L \) is not satisfied, tails of the regions with positive and negative \( B_5(y) \) (positive and negative chiral charge creation) overlap, leading to notable finite size effect and again conflicting with the field theory predictions.
Effect of a finite mass

The response of the chiral and total charge to fields $E$ and $B$ computed on a lattice can deviate from the expectation based on the simplest quantum field theory due to corrections set by the mass term, as mentioned in the main text. In this section, we carefully investigate one example, the electromagnetic contribution to the chiral anomaly on a lattice, $\partial_\mu J_5^\mu = E_5 \cdot B / (2\pi^2)$ and argue how a mass term influences the chiral anomaly. We further show that the mass term does not play the same role for the covariant anomaly $\partial_\mu J_5^{\mu}_{\text{cov}} = E_5 \cdot B / (2\pi^2)$.

The main source of lattice corrections to the anomaly is that the Wilson fermion Hamiltonian [61] used for all tight-binding calculations, Eq. (5), has a momentum-dependent mass term

$$M_k = m + t \sum_i (1 - \cos k_i),$$

that ensures the absence of copies of the Weyl nodes, or doublers, on the lattice [61]. When $t > 0$, the minimum of $M_k$ is at the $\Gamma$ point and its maximum at $(\pi, \pi, \pi)$; for $m = 0$, as set in the main text, the term is zero at $k = 0$ and increases away from $\Gamma$. The term $M_k$ sets the momentum-independent mass term $m$ in the action (7) that couples both chiralities and changes the response to electric and magnetic fields [62–64]. Such a term results in an additional classical contribution to the chiral anomaly, $\partial_\mu J_5^{\mu}_{\text{class}} = 2m_\psi \gamma^5 \psi$ [1], that is zero in all equilibrium situations we consider, which we confirm numerically. Instead, another consequence of $m$ affects the chiral anomaly: when $m \neq 0$ in the field theory, the eigenfunctions of the corresponding Hamiltonian are no longer eigenfunctions of the chiral matrix $\gamma^5$. Instead, close to the Weyl node of chirality $\chi$, the overlap with $\gamma^5$ for the low-energy eigenstates with a linear dispersion can be obtained analytically to be

$$\langle \psi^\alpha | \gamma^5 | \psi^\beta \rangle = \chi \sqrt{1 - \frac{m^2}{|b|^2}},$$

FIG. 5. (a) Responses $\partial p_3 / \partial b_3$ and (b) $\partial p_F^S / \partial b_3$ for our lattice model [Eq. (5)] with periodic boundary conditions in $y$-directions of length $L = 360$ and $c_{y} = 1.25$, cf. Eq. (10). We show results for different widths $\xi$ of the regions with non-zero $B_3$. The best matching of the field theory predictions are found for $\xi = 6$, which mostly satisfies the condition $a \ll \xi \ll L$. For $\xi = 2$, the condition $a \ll \xi$ is not satisfied, making the mass term does not play the same role for the covariant anomaly on a lattice, $\partial \rho / \partial A$. The crosses denote the numerical results from tight-binding calculations, the solid line the results of a fit with $f(L) = c_0 + c_1 \exp(-L/\xi)$, and the dashed line the coefficient $c_0$, i.e., the result in the limit $L \to \infty$. The color denotes different values of $m$, as shown in panel (b), and we further choose $b = 0.4$. (b) The response $\partial p_3 / \partial A_3$ in the limit $L \to \infty$ as a function of $m^2/b^2$. The different symbols denote different combinations of $b$ and $t$ and the gray line shows the expectation from the lattice model (29). (c) Response of the chiral charge around the Fermi surface to an electric field $E$ and axial field, $\partial p_F^S / \partial A_3$, as a function of the level broadening $\eta$ for $b = 0.4$. The dashed lines denote the result from panel (a), $\lim_{L \to \infty} \partial p_3 / \partial A_3$. (d) Response of the total charge around the Fermi surface to an axial field, $\partial p_F^S / \partial A_3$, as a function of $\eta$. The dashed line denotes the field theory result $\partial p / \partial A_3 = B/(2\pi^2)$ as a guide for the eyes.

FIG. 6. (a) Convergence of the response $\partial p_3 / \partial A_3$ for a tight-binding system governed by the Hamiltonian (5) with periodic boundary conditions in $y$-directions of length $L$ and a node separation $b = b$. A magnetic field $B = B z$ that satisfies periodic boundary conditions is included, with a magnetic length $l_B = \sqrt{2\pi L}$. The crosses denote the numerical results from tight-binding calculations, the solid line the results of a fit with $f(L) = c_0 + c_1 \exp(-L/\xi)$, and the dashed line the coefficient $c_0$, i.e., the result in the limit $L \to \infty$. The color denotes different values of $m$, as shown in panel (b), and we further choose $b = 0.4$. (b) The response $\partial p_3 / \partial A_3$ in the limit $L \to \infty$ as a function of $m^2/b^2$. The different symbols denote different combinations of $b$ and $t$ and the gray line shows the expectation from the lattice model (29). (c) Response of the chiral charge around the Fermi surface to a magnetic field $B$ and axial field, $\partial p_F^S / \partial A_3$, as a function of the level broadening $\eta$. The dashed line denotes the field theory result $\partial p / \partial A_3 = B/(2\pi^2)$ as a guide for the eyes.
FIG. 7. (a) Response $\partial\rho/\partial b_z$ for a tight-binding system governed by the Hamiltonian (5) with periodic boundary conditions in $y$-directions of length $L = 360$. An axial field $B_z = B_z(y)\tilde{y}$ generated by $b(y)$, Eq. (10), with $\xi = 6$ and $\epsilon_B = 1$ that satisfies periodic boundary conditions is included. The different colors denote different values of $\tilde{m}$ (cf. panel (b)) and the bold red line shows the profile of $B_z(y)$. (b) The integral over $y$ around the peak is computed numerically for different values of $\tilde{m}$. The dashed line denotes the value of the integral that is expected from quantum field theory. In (c) and (d), we show the response of the chiral charge around the Fermi surface $\partial p^{FS}/\partial b_z$ as a function of the level broadening $\eta$ with the different colors denoting different values of $\eta$. The bold red line shows the profile of $B_z(y)$, the filled region is minimal difference between $B_z$ and $\partial p^{FS}/\partial b_z$. In (e), we show the numerically computed integral over $y$ around the peak in $B_z$ for different values of $\tilde{m}$. The dashed line denotes the value of the integral that is expected from quantum field theory.

with $b^2 = b_yb^\mu$, i.e., the chiral density around the Weyl is reduced by a nonzero mass term. We note that a similar factor appears in the effective action for this model and is related to the Weyl node separation [63, 64].

On a lattice, the eigenstates of the Hamiltonian (5) are only eigenstates of $\gamma^5$ for those momenta $k$ where $M_k = 0$. In particular, the overlap with $\gamma^5$ of states of chirality $\chi = \pm$ close to the Weyl nodes $\chi_{kW}$ is

$$
\langle \psi^\chi_{kW} | \gamma^5 | \psi^\chi_{kW} \rangle = \chi \sqrt{1 - \frac{M^2_{kW}}{b^2}},
$$

i.e., it scales with the value of $M_k$ at the Weyl nodes, $\tilde{m} \equiv M_{kW}$. In the presence of $\tilde{m} \neq 0$ the eigenstates are not strictly eigenstates of $\gamma^5$ yet in order to define the chiral anomaly using Eq. (6) we effectively assume that they are. An alternative definition of chirality that does not possess this problem is to partition the Brillouin zone into two and declare left and right chiral charges as done in Ref. 65. While it has the advantage of having a clear definition of chirality, it does not reduce to any representative matrix at the field theory level and so we retain the first definition.

With these definitions it is tempting to upgrade the chiral anomaly to

$$
\partial_\mu j_5^\mu = \frac{1}{2\pi^2} \sqrt{1 - \frac{\tilde{m}^2}{b^2}} \mathbf{E} \cdot \mathbf{B}.
$$

(29)

It is interesting to note that a similar equation would be obtained if one interprets the prefactor as an effective renormalization of the chiral electric charge $e_5 = e\sqrt{1 - \tilde{m}^2/b^2}$ that would enter the chiral anomaly throughout the coupling to an external chiral gauge field $e_5A_5$ in analogy with ordinary charge [66]. We have unsuccessfully attempted to derive Eq. (29) from the effective field theory responses for the action Eq. (7) discussed in [62–64]. However, our numerical results on the corrections presented below suggest a richer structure when the mass is non-zero, which has motivated us to leave the precise connection between the quantum field theory discussion in these works and our results for a separate study.

At the end of the section we specify the conditions where our numerics coincide with the massless field theory expectation validating our results in the main text, up to a given order in momentum.

To gain insight on the above expectation numerically, we investigate how the chiral anomaly changes with $\tilde{m}$. Differentiating between the total charge and the charge around the Fermi surface, we compute the response to external fields $\mathbf{E}$ and $\mathbf{E}_5$ via Eqs. (19) and (25) on a lattice with periodic boundary conditions and a constant $\mathbf{B}$.

We show the response of the chiral charge $j_5$ in Fig. 6(a) and (b). In panel (a), we show the convergence with system size, whereas in panel (b), we show that, in the limit of $L \to \infty$, the response of the chiral charge scales with $\sqrt{1 - \tilde{m}^2/b^2}$ as dictated by Eq. (29).

Taking into account just states around the Fermi surface via Eq. (25), the chiral charge $j_5^{FS}$ responds approximately in the same way as shown in Fig. 6(b), cf. panel (c). Thus, the consistent and covariant anomalies are the same for the term $\mathbf{E} \cdot \mathbf{B}$, even in the presence of a mass $m$. In panel (d), we show the response of the total charge around the Fermi surface to a field $\mathbf{E}_5$: due to the covariant anomaly, $\partial j_5^{FS}/\partial A_5 \neq 0$. In contrast to $\partial j_5^{FS}/\partial A_3$, the contribution $\partial j_5^{FS}/\partial A_3$ is not much affected by $\tilde{m} \neq 0$.

The chiral-symmetry breaking term $M_k$ has more intricate consequences for the anomaly in the chiral charge .
due to $\mathbf{E}_5 \cdot \mathbf{B}_5$. We find numerically that the dependence of $\partial \rho_5 / \partial b_1$ and $\partial \rho_{FS} / \partial b_2$ on $\tilde{m}$ are different. In Fig. 7(a), we show the response of the total chiral charge for different values of $\tilde{m}$ with the profile of $\mathbf{b}$ according to Eq. (10). It allows us to obtain panel (b), where the value of the integral over the curves in Fig. 7(a) as a function of $\tilde{m}$ is compared to the result expected from the massless quantum field theory, i.e. the 1/3 prefactor difference between the second term of equations (13) and (15) shown as a dashed line. $\partial \rho / \partial b$ is closest to the massless field theory prediction for a value $\tilde{m} \sim 0.1v$, close to $m = 0$. This contrasts with the $\mathbf{E} \cdot \mathbf{B}$ analyzed above where the massless field theory expectation was reached when $\tilde{m} = 0$. Finally, the effect of $\tilde{m}$ on $\partial \rho_{FS} / \partial b_2$ is shown in Fig. 7(c) and (d) for various values of the level broadening $\eta$. The integral over one peak decreases with $\tilde{m}$, as visible in Fig. 7(e), different from the total charge contribution.

In conclusion, the massless quantum field theory expectation is recovered numerically when $\tilde{m} \sim m \sim 0$. This is satisfied when quadratic corrections are negligible and we choose $m \sim 0$, a regime which is largely satisfied by our parameter choices in the main text. The small yet rich deviations that we have quantified numerically (Figs. 6 and 7) indicate that further effort beyond the scope of this work is required to precisely connect with quantum field theory expectations with a finite mass.
