Abstract

AIM

To evaluate the hepatoprotective effect of lycopene (Ly) on non-alcoholic fatty liver disease (NAFLD) in rat.

METHODS

A rat model of NAFLD was first established by feeding a high-fat diet for 14 wk. Sixty-five rats were randomly divided into normal group, model group and Ly treatment groups. Alanine aminotransferase (ALT), aspartate aminotransferase (AST), triglycerides (TG), total cholesterol (TC) in serum and low density lipoprotein-cholesterol (LDL-C), high density lipoprotein-cholesterol (HDL-C), free fatty acid (FFA), malondialdehyde (MDA), superoxide dismutase (SOD), glutathione (GSH) in liver tissue were evaluated, respectively. While the hepatoprotective effect was also confirmed by histopathological analysis, the expression levels of TNF-α and cytochrome P450 (CYP) 2E1 in rat liver were determined by immunohistochemistry analysis.

RESULTS

A significant decrease was observed in the levels of serum AST (2.07-fold), ALT (2.95-fold), and the blood lipid TG (2.34-fold) and TC (1.66-fold) in the dose of 20 mg/kg Ly-treated rats (P < 0.01), compared to the model group. Pretreatment with 5, 10 and 20 mg/kg of Ly significantly raised the levels of antioxidant enzyme SOD in a dose-dependent manner,
to 90.95 ± 9.56, 109.52 ± 11.34 and 121.25 ± 10.68 ($P < 0.05$, $P < 0.01$), as compared with the model group. Similarly, the levels of GSH were significantly increased ($P < 0.05$, $P < 0.01$) after the Ly treatment. Meanwhile, pretreatment with 5, 10 and 20 mg/kg of Ly significantly reduced MDA amount by 30.87, 45.51 and 54.49% in the liver homogenates, respectively ($P < 0.01$). The Ly treatment group showed significantly decreased levels of lipid products LDL-C ($P < 0.05$, $P < 0.01$), improved HDL-C level and significantly decreased content of FFA, compared to the model group ($P < 0.05$, $P < 0.01$). Furthermore, the Ly-treated group also exhibited a down-regulated TNF-α and CYP2E1 expression, decreased infiltration of liver fats and reversed histopathological changes, all in a dose-dependent manner ($P < 0.05$, $P < 0.01$).

CONCLUSION
This study suggests that Ly has a protective effect on NAFLD, down-regulates expression of TNF-α, and that CYP2E1 may be one of the action mechanisms for Ly.

Key words: Lycopene; Antioxidant; Hepatoprotective; Non-alcoholic fatty liver; Cytochrome P450 2E1

Core tip: Lycopene (Ly), a phytochemical belonging to the carotenoid family, is a red-colored pigment, apolar and acyclic carotenoid. The present study was designed to evaluate the possible hepatoprotective effect of Ly on non-alcoholic fatty liver disease (NAFLD) in rat. This study represents the first examination of the effects of Ly on the therapy of NAFLD, and showed down-regulated expression of TNF-α and indicated that CYP2E1 may be one of the action mechanisms for Ly.

INTRODUCTION
Non-alcoholic fatty liver disease (NAFLD) is one of the causes of fatty liver, occurring when fat is deposited (steatosis) in the liver due to causes other than excessive alcohol use. NAFLD is considered to cover a spectrum of liver diseases, including simple steatosis, non-alcoholic steatohepatitis (NASH), liver fibrosis, liver cirrhosis and hepatocellular carcinoma (HCC)[1,2]. Ninety percent of patients with NAFLD show close relation with one or more of the following risk factors: hypertension, dyslipidemia, elevated triglyceride (TG) levels, obesity, insulin resistance, metabolic syndrome, type 2 diabetes mellitus and cardiovascular disease[3].

Currently, the percentage of people with NAFLD is approximately 20% worldwide and 25% in Western countries, making it one of the most dominant causes of chronic liver disease affecting both adults and children[4]. NAFLD is more common in patients with severe diabetes and obesity, mortality and disease evolution to liver fibrosis or liver cirrhosis is increased in old people with NAFLD[5]. Recently, the “two-hit” theory has arisen as a popular mechanism, although the cause of NAFLD remains to be clearly elucidated[6]. Furthermore, there is not any specific drug available for NAFLD, and no drug has yet to be tested in clinical phase III trials. Therefore, no specific therapy can be firmly recommended to the patients with NAFLD[7].

Lycopene (Ly), a phytochemical belonging to carotenoid family, is a red-colored pigment, acyclic and apolar carotenoid[8]. It is abundantly found in red-colored vegetables and fruits, such as tomatoes, papaya, gac fruit, pink grapefruit, pink guava, carrots and watermelon, with the concentrations ranging from 9 to 42 mg/kg depending on the variety[9]. Ly displays a range of unique and distinct biological properties owing to its acyclic structure, hydrophobicity and large array of conjugated double bonds. Recently, diverse studies have been reported that lycopene exerts powerful antioxidant activity both in vitro and in vivo against the oxidation of proteins, lipids and DNA, and also has the potential of quenching singlet oxygen 100 times more efficiently than vitamin E and 125 times more than glutathione (GSH)[10]. Furthermore, even at low oxygen tension, it can also scavenge peroxyl radicals, inhibiting the process of lipid peroxidation[11]. It is the most efficient quencher of singlet oxygen among all naturally occurring carotenoids[11] and recently it has been in great demand as a food additive and a natural antioxidant. Additionally, Ly also exhibited potent neuroprotective, anti-inflammatory, anti-proliferative, maintenance of normal cell metabolism, cognition enhancing properties, regulating blood lipid metabolism and so on[12-14]. Therefore, with this background, we aimed to investigate the possible beneficial effects and the possible action mechanism of Ly on NAFLD using a rat model system.

MATERIALS AND METHODS

Materials and reagents
Alanine aminotransferase (ALT), aspartate aminotransferase (AST), TG, total cholesterol (TC), low density lipoprotein-cholesterol (LDL-C), high density lipoprotein-cholesterol (HDL-C), free fatty acid (FFA), malondialdehyde (MDA), superoxide dismutase (SOD) and GSH kits were obtained from Nanjing Jiancheng Bioengineering Institute (Nanjing, China). Protein assay kit was from Zhongshan Institute of Biotechnology (Beijing, China).

Mouse anti-TNF-α, rabbit anti-cytochrome P450 2E1 (CYP2E1), horseradish peroxidase (HRP)-conjugated goat anti-mouse IgG and HRP-conjugated goat anti-
right liver lobe was fixed in 10% formalin to prepare
mogenizing the liver tissue in 150 mmol/L Tris-HCl
Liver homogenate (10%, w/v) was prepared by ho-
Measurement of MDA formation in lipid peroxidation
The absorbance of the SOD reaction was read at 550
and the data are expressed as U/mg protein, while
the GSH reaction was read at 420 nm and the enzyme
activity was calculated as mg/g protein.
Measurement of liver LDL-C, HDL-C and FFA activity
LDL-C, HDL-C and FFA in liver tissue were measured
by commercial kit from Jiancheng Biological Engi-
neering Institute following the protocol provided by
the manufacturer. The absorbance of LDL-C, HDL-C
and FFA reaction was read at 546 nm and the data are
expressed as mmol/L.
Histopathological observation
Liver specimens were fixed overnight in 10% formal-
dehyde buffer, then embedded in paraffin and cut
into 5 µm thickness sections according to the routine
procedure. The sections were stained with hematoxylin
and eosin (HE) for routine histopathological exami-
nation, and examined under a light microscope (BX-50;
Olympus) at 200 × magnification for the degree of
hepatic steatosis and photographed.
Immunohistochemistry analysis of hepatic TNF-α and
CYP2E1
Paraffin-embedded sections (5 µm) were mounted
on glass slides, then deparaffinized, incubated in 3% H2O2
for 10 min to quench endogenous peroxidase
dactivity. The sections were stained with mouse anti-
TNF-α antibody and rabbit anti-CYP2E1 antibody at
4 °C overnight respectively, after blocking with normal
goose serum for 20 min. Then, the sections were
incubated with HRP-conjugated goat anti-mouse and
HRP-conjugated goat anti-rabbit antibody at 37 °C
for 30 min, respectively. The immunoreactive antibodies
were visualized by incubation with DAB-H2O2 at room
temperature for 10 min. Images were taken at original
magnification of 200 × (Olympus BX-50 Microscope
and a Leica DMI; Leica Microsystems, Wetzlar,
Germany).
Statistical analysis
Data were expressed as mean ± SD and all statistical
comparisons were made by means of a one-way
ANOVA test followed by Dunnett’s t-test. P < 0.05 and
< 0.01 were considered statistically significant.

Jiang W et al. Hepatoprotective effects of lycopene

rabbit IgG antibodies were provided by Proteintech
Group, Inc. (Chicago, IL, United States).
Ly (> 95%) was purchased from North China
Pharmaceutical Co., Ltd. (Shijiazhuang, China).
The high-fat diet (HFD: 88% basic feed + 10% lard
+ 2% cholesterol) was prepared in our lab.

Animals
Male Wistar rats (body weight 150 ± 10 g) were
obtained from the Experimental Animal Center of
Harbin Medical University (China). Six rats were kept in
each single polycrylic cage and were quarantined for
1 wk before the experiments. All animals were housed
under standard controlled conditions (temperature:
24 ± 1 °C, humidity: 50% ± 5% and 12 h light/dark
cycle), with free access to food and water, and received
humane care according to National Institutes of Health
Guidelines of the United States (National Research
Council of United States, 1996) and the related ethical
regulations of Harbin Medical University. Animals were
fasted for 12 h before sampling of material.

Experimental design
After acclimatization for 1 wk, 65 Wistar male rats were
randomized into 2 groups. Group 1 (normal group) was
raised with normal feed (n = 12), and Group 2 (model
group) was raised on HFD (n = 53) for consecutive 8
wk. From the 9th wk, all the surviving rats in the model
group were further randomly divided into 1 model group
and 3 Ly treatment groups, which were given Ly at a
dose of 5, 10 or 20 mg/kg/d (n = 12), respectively. The
model group was continued on the HFD for 6 wk as
before, and the Ly groups were administered orally and
continued on the HFD for 6 wk as before.
Rats were sacrificed by cervical dislocation at the
end of the experiment, and blood samples of all rats
were harvested for serum biochemical markers assay.
The fresh liver obtained was weighed to calculate liver
weight/body weight × 100. The other assays.

Serum biochemical markers assay
Serum was collected from blood after centrifugation
at 3000 rpm for 10 min at 4 °C. Serum ALT, AST,
TG and TC were detected using commercial kits
according to the manufacturer’s instructions and
using a multifunctional biochemistry analyzer (AU600;
Olympus, Tokyo, Japan). The absorbance of ALT and
AST was read at 505 nm and the enzyme activity
was calculated as U/L. The absorbance of TG and TC
was read at 510 nm and the content was calculated as
mmol/L.

Measurement of MDA formation in lipid peroxidation
Liver homogenate (10%, w/v) was prepared by ho-

RESULTS

Effects of Ly on body weight and liver coefficient

After 8 wk of HFD feeding, the body weights of rats in the model group were significantly increased compared to that of rats in the control group ($P < 0.01$, Figure 1A). Meanwhile, after Ly treatment for 6 wk, the gain in body weight for the rats in the 10 and 20 mg/kg Ly-treated groups was lower than that for the rats in the model group ($P < 0.01$, Figure 1A), which indicated that Ly treatment could inhibit the occurrence of obesity in HFD-administrated rats. Furthermore, consistent with these modifications, the liver coefficient was also reduced markedly in the Ly-treated rats ($P < 0.05$, $P < 0.01$, Figure 1B), compared to the control group.

Effect of Ly on serum ALT and AST levels

Serum levels of AST and ALT indirectly reflects the failure of liver function. As shown in Table 1, serum AST (2.67-fold) and ALT (3.66-fold) activities were significantly increased after the administration of HFD, as compared with the normal group ($P < 0.01$). Compared with the model group, the levels of AST and ALT were significantly decreased in a dose-dependent manner after Ly treatment (5, 10 and 20 mg/kg) ($P < 0.05$, $P < 0.01$, Table 1).

Table 1 Effect of lycopene on serum liver function markers and blood lipid levels

| Group       | ALT (IU/L) | AST (IU/L) | TG (mmol/L) | TC (mmol/L) |
|-------------|------------|------------|-------------|-------------|
| Control     | 16.72 ± 2.62 | 60.63 ± 6.28 | 0.52 ± 0.04 | 0.81 ± 0.06 |
| Model       | 61.25 ± 13.55 | 162.17 ± 35.53 | 1.38 ± 0.21 | 3.04 ± 0.72 |
| Ly 5 mg/kg  | 30.90 ± 3.84 | 95.91 ± 13.65 | 1.02 ± 0.10 | 2.31 ± 0.24 |
| Ly 10 mg/kg | 26.33 ± 2.06 | 88.53 ± 9.18  | 0.75 ± 0.06 | 2.00 ± 0.12 |
| Ly 20 mg/kg | 20.77 ± 3.52 | 78.44 ± 9.79  | 0.59 ± 0.03 | 1.83 ± 0.15 |

Data are expressed as mean ± SD ($n = 12$) for each group. $^bP < 0.01$ vs control group; $^cP < 0.05$, $^dP < 0.01$ vs model group. Ly: Lycopene; ALT: Alanine aminotransferase; AST: Aspartate aminotransferase; TG: Triglycerides; TC: Total cholesterol.

Effects of Ly on blood lipid levels

HFD-induced NAFLD provoked a marked incremental change in TC and TG levels compared with those in the normal group ($P < 0.01$, Table 1), which indicates the successful establishment of the NAFLD model in rats. However, after Ly exposure, the concentrations of both TC and TG in blood were remarkably decreased in dose-dependent manners, as compared to the NAFLD model group ($P < 0.05$, $P < 0.01$, Table 1). All of these findings indicate that Ly exerts obvious lipid-lowering effects against NAFLD.

Effects of Ly on liver tissue SOD, GSH and MDA levels

The levels of liver antioxidant activities of SOD and GSH were measured due to the oxidative stress exhibited in the development of NAFLD[17]. SOD and GSH are capable of scavenging the lipid hydroperoxides, lipid peroxide radicals and other products which are toxic metabolites of NAFLD. Therefore, our study measured the contents of SOD, GSH and MDA in liver tissue of rats. From Table 2, we can clearly see the significant differences between the HFD-treated model group and the normal group for the levels of SOD and GSH, which were largely decreased ($P < 0.01$, Table 2) in the HFD-treated group compared with that of normal group. However, pretreatment with 5, 10 and 20 mg/kg of Ly significantly raised the levels of the antioxidant enzyme SOD in a dose-dependent manner, to 90.95 ± 9.56, 109.52 ± 11.34 and 121.25 ± 10.68 respectively ($P < 0.05$, $P < 0.01$, Table 2), as compared with the model.
group. Similarly, the levels of GSH were significantly increased by treatment with 10 and 20 mg/kg of Ly (P < 0.05, P < 0.01, Table 2).

MDA, an end-product of the breakdown of poly-unsaturated fatty acids and related esters, is an important index of lipid peroxidation in many organ homogenates[17]. Administration of HFD caused a significant increase in MDA concentration (2.19-fold), as compared with the normal group (P < 0.01, Table 2). However, pretreatment with 5, 10 and 20 mg/kg of Ly significantly reduced the MDA amount by 30.87, 45.51 and 54.49% in the liver homogenates respectively (P < 0.01, Table 2).

Effects of Ly on LDL-C, HDL-C and FFA levels in liver tissue
Levels of lipid products were significantly increased after 8 wk of HFD feeding in the model group compared to the control group (P < 0.01, Table 3). Results showed that LDL-C was significantly increased in the model group compared with the normal group (P < 0.01, Table 3) and dramatically decreased in the Ly-treatment group, as compared with that in the model group (P < 0.05, P < 0.01, Table 3). In contrast, HDL-C level was significantly decreased at the end of the experiment, and Ly treatment significantly improved the HDL-C level, as compared with that in the model group (P < 0.05, P < 0.01, Table 3). Similarly, the concentration of FFA was remarkably increased after HFD administration, and pretreatment with Ly significantly decreased the content of FFA in a dose-dependent manner (P < 0.05, P < 0.01, Table 3).

Histopathological changes in the liver tissue
Observed with the naked eye, the livers of the control group were deep red, moist, glossy and resilient (Figure 2A I ), while those of the model group showed yellow necrotic foci, grey-red color, loss of luster and tumescent (Figure 2A II ). However, in Ly-treated rats, the liver injury was attenuated dramatically in a dose-dependent manner (Figure 2A III - V ).

HE-stained sections are shown in Figure 2B. Under the photomicroscope, liver sections from the normal control group showed normal lobular architecture, liver cells with well-preserved cytoplasm and well-defined nucleus (Figure 2B I ). Meanwhile liver sections from the model group showed full fat vacuoles in lobule cells, infiltration of inflammatory cells, cell swelling and lipid degeneration in the central region of the lobules (Figure 2B II ). Furthermore, in the liver sections of the Ly-treated group, inflammatory response and lipid degeneration were remarkably alleviated, as compared with the model group, and the liver cell volume became smaller, the fat droplet number was reduced and the hepatic lobules were clearly delineated (Figure 2B III - V ).

Effect of Ly on immunohistochemistry analysis of hepatic TNF-α and CYP2E1
The immunohistochemistry (IHC) analysis of liver tissue showed no TNF-α expression in the normal group (Figure 3A I ), but increased expression of TNF-α in the HFD-model group (Figure 3A II ). After pretreatment with Ly (5, 10 and 20 mg/kg), TNF-α expression decreased in a dose-dependent manner, but remained higher than that in the normal group (Figure 3A III - V ). Quantification of the positive expression of TNF-α is shown in Figure 3A VI. The results are presented as mean ± SD of (n = 12). P < 0.01 was significantly different from the normal group; P < 0.05 and P < 0.01 were significantly different from the model group, respectively.

In Figure 3B, the normal liver expressed the lowest amount of CYP2E1 (Figure 3B I ). The HFD-model group showed significantly higher expression of CYP2E1, as compared with the controls (P < 0.01, Figure 3B II ). Meanwhile the Ly-treated group (5, 10 and 20 mg/kg) showed markedly decreased CYP2E1 expression (Figure 3B III - V ). Quantification of the positive expression of CYP2E1 is shown in Figure 3B VI. The results are presented as mean ± SD (n = 12). P < 0.01 was significantly different from the control group; P < 0.05 and P < 0.01 were significantly different from the model group, respectively.

DISCUSSION
NAFLD is defined by hepatic fat deposition in the absence of excessive alcohol intake, which is also associated with the insulin resistance (IR) and metabolic syndrome[18-20]. Generally, NAFLD is defined as a concentration of hepatic TG exceeding 5% liver weight, and often exhibits a histological spectrum ranging from simple steatosis to NASH. NASH is characterized by hepatocellular damage, fibrogenesis and lobular necro-inflammation[21,22], which may evolve to hepatic cirrhosis and HCC[23,24]. Although HFD-induced NAFLD animal models need a lengthy feeding period, they are more close to human NAFLD in pathophysiology, including induced obesity, IR and hepatic steatosis in mice or rats[25]. Emotional
disorders or poor diet with the key points of blood stasis and phlegm is regarded as the etiology of NAFLD, and these etiologies are related to the organs of liver, spleen and kidney, according to the traditional medicine theory. Thus, promoting blood circulation to remove meridian obstruction, reducing phlegm, removing dampness and liver-kidney-tonifying are an effective approach to treatment of NAFLD. However, at present, although tremendous effort has made in prevention of NAFLD by clinicians and researchers alike, there are no approved treatment drugs for NAFLD. Hence, developing and exploring a novel agent to delay or reverse the pathogenesis progression in NAFLD are very important objectives.

Ly is a natural pigment, synthesized by plants and microorganisms. Red fruits and vegetables are the most common sources of Ly, which exhibits the highest antioxidant activity among all dietary carotenoids.
Furthermore, the Mediterranean dietary pattern, which includes proportionally high consumption of vegetables and fruits with Ly, has shown notable benefits for NAFLD patients[27,28]. Therefore, nowadays, the potential role of Ly in human health is beginning to be recognized, and the most important health benefits are hypothesized to occur through their ability to protect against oxidative damage[29,30]. In vitro studies have demonstrated that Ly is an effective antioxidant and radical scavenger[31,32]. Ly is the most potent singlet oxygen quencher among natural carotenoids, due to its high number of conjugated dienes[33], and recent studies have shown that Ly is at least two times as active as β-carotene in protecting lymphocytes for NO-· radial-induced membrane damage[34,35], which indicates that Ly is the most potent scavenger of ROS among other major dietary carotenoids[36,37]. In addition, Ly was shown to protect human LDL against photosensitized oxidative damage[38]. Thus, based on the benefits of Ly, the aim of the present study was to explore the effect of Ly in prevention of HFD-induced NAFLD in a rat model. To the best of our knowledge, this is the first time research has attempted to explore the potent effects of Ly on HFD-induced NAFLD rats.

In the present study, compared to a normal control group, it was demonstrated that the liver coefficient and the levels of serum ALT, AST, TG and TC were significantly increased, the levels of LDL-C and FFA in liver were markedly increased, and HDL-C was markedly reduced in HFD-induced NAFLD model rats. Pretreatment with Ly showed that Ly is able to inhibit the incremental changes in ALT and AST, to decrease the TG, TC, LDL-C and FFA levels, and to increase the HDL-C level. In addition, the histopathological changes from microscopy observation correlated with the examination of liver function. The centrilobular hepatic necrosis, ballooning degeneration, fatty change and infiltrating lymphocytes were observed in NAFLD model group. Treatment with Ly prevented these histopathological changes in rats induced with HFD. Thus, these results suggested that the inhibition of the elevation of liver function markers, obvious lipid-lowering and liver damage may related to the protective effect of Ly against HFD-induced NAFLD. Moreover, Ly enhanced the activities of SOD, increased GSH and diminished MDA against the HFD-induced NAFLD in these animals, suggesting that the activity of antioxidants may play a role in the mechanism of its hepatoprotective effects.

TNF-α is a central proinflammatory cytokine, which is associated with a variety of physiological and pathological conditions, including cytotoxicity, growth stimulation, immune-modulation and pro-inflammatory activity. In addition, TNF-α is produced predominantly by the monocyte macrophage lineage in liver, and the main population of this lineage is Kupffer cells. Thus, increased TNF-α production by activated Kupffer cells may be responsible for NAFLD. Furthermore, the most current studies have indicated that inhibition of TNF-α could decrease the content of hepatic fatty storage in the HFD-induced NAFLD model[38]. In our study, the effects of TNF-α in damaged liver was evaluated by IHC. Compared to the normal group, rats treated with HFD showed up-regulated expression of TNF-α, while pretreatment with Ly led to down-regulated expression of TNF-α compared to the HFD-model group.

The isofrm 2E1 of CYP is one of the most potent microsome cytochromes to generate ROS, and it is involved in the metabolism of isoniazid and the mediation of its hepatotoxicity[39], which has been exhibited to be invariably increased in the livers of NAFLD patients[40]. In this study, the expression of CYP2E1 in the HFD-model group was observed to be increased, while the Ly treatment group showed a significant down-regulation of its expression, especially in the high-dose Ly-treated group.

In conclusion, oral administration of Ly improved lipid profiles and remarkably decreased the levels of serum AST, ALT, TG and TC, alleviated the levels of liver LDL-C and FFA, increased the activities of antioxidant enzymes (GSH, SOD) and reduced the lipid peroxides in liver (MDA) in NAFLD model rats. Further, the Ly-treated group also showed down-regulated expression of TNF-α and CYP2E1, decreased liver fats infiltration and improved histopathological changes, all in dose-dependent manners. The increased antioxidant enzyme levels and the decreased lipid peroxides contents are suggested to be important mechanisms of Ly in preventing the development of liver damage induced by HFD.

COMMENTS

Background
Non-alcoholic fatty liver disease (NAFLD) is one of the causes of fatty liver, which encompasses a spectrum of liver diseases, including simple steatosis, non-alcoholic steatohepatitis (NASH), liver fibrosis, liver cirrhosis and hepatocellular carcinoma (HCC). Until now, there is not any specific drug available, and no drug has currently been tested in clinical phase III trials. Lycopene (Ly), a phytochemical belonging to the carotenoid family, is a red-colored pigment, apolar and acyclic carotenoid. Ly exhibits a range of distinct antioxidant and radical-induced membrane damage properties owing to its acyclic structure, hydrophobicity and large array of conjugated double bonds. A recent report showed that the Mediterranean dietary pattern, which includes proportionally high consumption of vegetables and fruits with Ly, has notable benefits for NAFLD patients. Thus, with this background, we aimed to investigate the possible beneficial effects and the possible action mechanism of Ly on NAFLD in a rat model system.

Research frontiers
No specific drug has been tested in clinical phase III trials for NAFLD to date, and there are few research studies of the hepatoprotective effects of Ly.

Innovations and breakthroughs
This study represents the first investigation of the effects of Ly as a therapy of NAFLD, and showed that down-regulated expression of TNF-α and CYP2E1 may be one of the action mechanisms for Ly.

Applications
This study suggests that Ly has a protective effect on NAFLD, which is very important for the future development of a potent NAFLD drug.
This is a meaningful study, in which the effects of "lycopene" were examined on research studies have focused on the traditional Chinese medicines.

**Terminology**

NAFLD is one of the causes of fatty liver, defined as biopsy-proven hepatic steatosis. It covers a spectrum of liver diseases, including simple steatosis, NASH, liver fibrosis, liver cirrhosis and HCC. Recently, many NAFLD drug research studies have focused on the traditional Chinese medicines.

**Peer-review**

This is a meaningful study, in which the effects of "lycopene" were examined on research studies have focused on the traditional Chinese medicines.
