Diagnostic role of secretin-enhanced MRCP in patients with unsuccessful ERCP

László Czakó, Tamás Takács, Zita Morvay, László Csernay, János Lonovics

INTRODUCTION

The most sensitive diagnostic modality in suspected biliopancreatic diseases is endoscopic retrograde cholangiopancreatography (ERCP)[1-4]. However, the success rate of the examination mainly depends on the experience of the endoscopist, and does not exceed 95-98% even in the largest specialized centers. Previous operations (Billroth II, Roux-en-Y or biliary-enteric anatomy), duodenal stenosis, or duodenal diverticulum may camouflage the ducts difficult or even impossible, and increase the risk of complications[5-7]. If ERCP fails, intravenous ( iv) or percutaneous transhepatic cholangiography (PTC) is the alternative method. Since the diagnostic accuracy of iv cholangiography is very low, it is no longer used. PTC is invasive, may be associated with severe complications, and can successfully be applied if the intrahepatic biliary tree is dilated. PTC and iv cholangiography are both unable to visualize the pancreatic duct[8-10]. There is clearly a need for a noninvasive, sensitive and specific diagnostic modality for patients with suspected biliopancreatic disease if ERCP fails[11]. Magnetic resonance cholangiopancreatography (MRCP) is a new noninvasive diagnostic modality capable of producing high-quality images of the pancreatobiliary tree. It has been emphasized that its sensitivity (81-100%), specificity (94-98%), positive (86-93%) and negative (94-98%) predictive values and diagnostic accuracy (94-97%) are as high as those of ERCP, which makes MRCP a promising alternative to diagnostic ERCP[12-16]. Moreover, MRCP has the following advantages over ERCP. It is noninvasive, there are no complications, no radiation, no need for any contrast agent. It causes less discomfort for the patients, and can provide useful information on the parenchymatous organs in this region in combination with conventional cross-sectional MR sequences.

The aim of our study was to assess the value of MRCP in the management of patients with biliopancreatic diseases in whom ERCP was failed.

MATERIALS AND METHODS

Between January 2000 and June 2003 a prospective study was conducted. Twenty-two patients were enrolled, in whom ERCP performed by experts at our endoscopic unit failed to adequately visualize the clinically relevant duct(s). Failure meant two unsuccessful ERCP attempts by precut papillotomy with a needle knife when the ducts were not cannulated with the conventional approach. There were 10 males and 12 females, with a mean age of 51.2 years, range 24-82 years. The indications for ERCP were obstructive jaundice (n = 9), abnormal liver enzymes (n = 8), suspected chronic pancreatitis (n = 2), recurrent acute pancreatitis (n = 2), or suspected pancreatic cancer (n = 1). The reasons for the ERCP failure were the postsurgical anatomy (n = 7), duodenal stenosis (n = 3), duodenal diverticulum (n = 2), and technical failure (n = 10). MRCP images were evaluated before and 5 and 10 min after i.v. administration of 0.5 IU/kg secretin.

RESULTS: The MRCP images were diagnosed in all 21 patients. Five patients gave normal MR findings and required no further intervention. MRCP revealed abnormalities (primary sclerosing cholangitis, chronic pancreatitis, cholangitis, cholecystolithiasis or common bile duct dilatation) in 10 patients, who were followed up clinically. Four patients subsequently underwent laparotomy (hepaticojejunostomy in consequence of common bile duct stenosis caused by unresectable pancreatic cancer; hepaticotomyc+Kehr drainage because of insufficient biliary-enteric anastomosis; choledochojejunostomy, gastrojejunostomy and cysto-Wirsungo gastrostomy because of chronic pancreatitis, or choledochojejunostomy because of common bile duct stenosis caused by chronic pancreatitis). Three patients participated in therapeutic percutaneous transhepatic drainage. The indications were choledocholithiasis with choledochojejunostomy, insufficient biliary-enteric anastomosis, or cholangiocarcinoma.

CONCLUSION: MRCP can assist the diagnosis and management of patients in whom ERCP is not possible.

• CLINICAL RESEARCH •
axial plane fast spoiled gradient (FSPGR) images were acquired. These images were used to evaluate the liver and pancreas parenchyma and also to plan the MRCP data collection. The heavily T2-weighted MRCP images were taken in two sets. With a single shot technique, one 30.0-70.0-mm-thick slice was first acquired at TR 5 000 ms, TE 500 ms, with a 320×320 matrix and 40×36 FOV. In the second set, 9-13 thin (5.0 mm) slices with a 2-mm gap were taken from the same region. The breath-hold technique was used for all sequences. “Dualflex” flexible body coil was applied. MRCP images were evaluated before and 5 and 10 min after the iv administration of 0.5 IU/kg secretin (Secretolin, Hoechst, Frankfurt am Main, Germany).

RESULTS

The MRCP images were of diagnostic quality in all but 1 patient. MRCP furnished normal findings in 5 cases and revealed abnormalities in 17 patients (Table 1). Conservative medical treatment was applied in 10 cases. MRCP demonstrated mild bile duct dilation caused by chronic pancreatitis in 3 patients. Since they were mainly asymptomatic, surgical intervention was not indicated. Primary sclerosing cholangitis was indicated by MRCP in 3 patients, the cholestasis was improved after treatment with ursodeoxycholic acid. Gallbladder stones were found in an 82-year-old female patient, operation was not recommended because of her age. In a 77-year-old female patient who had previously undergone choledochocholangiostomy, the extrahepatic biliary tree exhibited caliber changes. This finding was considered to correspond to cholangitis, the abnormal liver function was normalized by antibiotic therapy. In 2 patients with previous cholecystectomy and abnormal liver enzymes, MRCP revealed mild extrahepatic bile duct dilation (postcholecystectomy syndrome?). The liver function normalized without treatment in 1 patient, and in response to ursodeoxycholic acid treatment in the other (Table 1).

Seven patients required therapeutic interventions. Four of these 7 patients underwent surgery. The indication for operation was based on the MRCP findings, which were confirmed at surgery in 3 of the 4 cases. In 1 patient (No. 10, Figure 1), MRCP revealed only the site, but not the cause of the bile duct obstruction. This patient was referred to the endoscopy unit because of obstructive jaundice. MRCP demonstrated a preapillary common bile duct obstruction. The Wirsung duct was not visible. These findings, the clinical picture and the result of duodenoscopy led to a suspicion of pancreatic head carcinoma. The patient was operated on, and the surgery confirmed the suspicion. Curative resection was not possible because of the local invasiveness of the tumor, bilio-enteric anastomosis was performed.

In 1 patient in whom ERCP was failed because of a previous Billroth II resection, MRCP demonstrated a stricture of the choledochojejunostomy anastomosis as the cause of a bile duct obstruction (No. 1, Figure 2). The intrahepatic biliary tree was markedly dilated and contained secondary stones. The patient subsequently underwent hepaticotomy and Kehr drainage.

In a patient with chronic pancreatitis, whose disease was not followed up regularly, ERCP was indicated because of obstructive jaundice, but it failed in consequence of duodenal stenosis. MRCP showed obstruction of the Wirsung duct and the common bile duct by the calcified pancreatic head, with an upstream dilation in both ducts, causing the “double duct sign”. The intrahepatic biliary tree and the cystic duct are also dilated. The patient underwent choledochojejunostomy, gastrojejunostomy and Wirsungogastrostomy.

In a patient with chronic pancreatitis in whom ERCP failed because of duodenal stenosis. The calcified pancreatic head obstructs the Wirsung duct and the common bile duct (arrow) with an upstream dilation, causing the “double duct sign”. The intrahepatic biliary tree and the cystic duct are also dilated. The patient underwent choledochojejunostomy, gastrojejunostomy and Wirsungogastrostomy. Similarly, in a patient with chronic pancreatitis in whom a previous Billroth II resection precluded ERCP, MRCP demonstrated an intrapancreatic bile duct obstruction. Choledochoenterostomy was performed (No. 19).

In 3 patients of advanced age in a moribund physical status, the bile duct obstruction was treated with percutaneous transhepatic drainage (PTD). MRCP indicated common bile duct stones in a patient who had previously undergone choledochojejunostomy.
(No. 3), another with a hepaticojejunostomy anastomotic stricture (No. 4) and one with prepapillary cholangiocarcinoma (No. 8, Figure 4). These findings were confirmed by PTC and the patients subsequently underwent biliary drainage.

**Figure 4** Normal Wirsung duct and bilateral renal cysts in an 81-year-old female patient. The intraluminal focus with low signal intensity in the distal common bile duct (arrow) proved to be cholangiocarcinoma. The biliary tree is dilated. With regard to her age and physical status, the patient underwent biliary stent implantation to ensure bile flow.

### Table 1 Indications for ERCP, reasons for ERCP failure, MRCP findings, and management of patients

| Patient | Indication for ERCP | Reason for ERCP failure | MRCP findings | Management of patients |
|---------|---------------------|--------------------------|---------------|------------------------|
| 1       | Obstructive jaundice| Billroth II anatomy      | stricture of choledochojunostrumosis | hepaticotomy +Kehr drainage |
| 2       | Obstructive jaundice| Billroth II anatomy      | choledocholithiasis | antibiotic treatment |
| 3       | Obstructive jaundice| choledochojunostrumosis  | choledocholithiasis | PTD |
| 4       | Obstructive jaundice| Roux and Y anatomy       | stricture of choledochojunostrumosis | PTD |
| 5       | Cholestasis         | technical                | cholecystolithiasis | follow-up |
| 6       | Cholestasis         | technical                | mild CBD dilatation | follow-up |
| 7       | Suspected pancreatic cancer | duodenal stenosis | chronic pancreatitis | follow-up |
| 8       | Obstructive jaundice| technical                | cholangiocarcinoma | PTD |
| 9       | Cholestasis         | technical                | PSC            | follow-up |
| 10      | Obstructive jaundice| technical                | distal stricture of CBD | hepaticоjunostrumosis unresectable pancreas carcinoma choledochojunostrumosis gastrojunostrumosis Wirsung gastrojunostrumosis |
| 11      | Obstructive jaundice| chronic pancreatitis     | “double duct sign” | choledochojunostrumosis gastrojunostrumosis Wirsung gastrojunostrumosis |
| 12      | Obstructive jaundice| chronic pancreatitis     | intrapancreatic stricture of CBD, chronic pancreatitis | follow-up |
| 13      | Cholestasis         | technical                | normal         | follow-up |
| 14      | Cholestasis         | duodenal diverticulum    | PSC            | follow-up |
| 15      | Cholestasis         | technical                | PSC            | follow-up |
| 16      | Obstructive jaundice| duodenal diverticulum    | normal         | follow-up |
| 17      | Recurrent pancreatitis| technical                | normal         | follow-up |
| 18      | Recurrent pancreatitis| technical                | normal         | follow-up |
| 19      | Obstructive jaundice| Billroth II anatomy      | intrapancreatic stricture of CBD, chronic pancreatitis | choledochoenterostomy cholecystectomy |
| 20      | Cholestasis         | technical                | mild CBD dilatation | follow-up |
| 21      | Obstructive jaundice| duodenal stenosis        | intrapancreatic stricture of CBD, chronic pancreatitis | follow-up |
| 22      | Cholestasis         | Billroth II anatomy      | normal         | follow-up |

CBD: common bile duct; PSC: primary sclerosing cholangitis; PTD: percutan transhepatic drainage.

**DISCUSSION**

ERCP is the most sensitive and specific technique currently available for visualization of the biliary tree and pancreatic duct. Beside the establishment of a diagnosis, this examination at the same time offers therapeutic options. However, ERCP is invasive, and may be associated with complications, and patients who undergo ERCP need sedation. Another disadvantage is that it affords no information on extraductal lesions, and does not opacify the obstructed segment in the event of total duct obstruction. It was unsuccessful in 3-10% of the cases, even in the largest endoscopic centers[5-7]. Inexperience of the endoscopist and anatomic factors such as previous gastroenteroanastomosis, duodenal stenosis, or periampullary diverticulum might lead to higher rates of unsuccessful ERCP[19,20]. When the papilla of Vater is in the visual field of the duodenoscope, but conventional cannulation fail, precut papillotomy could be performed with a needle knife, and cannulation could subsequently be achieved. However, precut papillotomy could increase the frequency and severity of complications as compared with conventional ERCP (6-12% vs 1-5%)[21,22]. Iv cholangiography or PTC examinations are the alternative choices for visualization of the biliary tree. However, iv cholangiography has been no longer used, because its
diagnostic accuracy was limited\cite{9,10}. PTC is a sensitive method of detecting biliary abnormalities, but it was invasive, might be associated with severe complications, and could successfully be applied if the intrahepatic biliary tree was dilated. In addition, neither PTC nor IV cholangiography was able to visualize the pancreatic duct\cite{9,10}.

The need for a safe and noninvasive technique for examination of the biliary tree and pancreatic duct resulted in the development of MRCP. A number of studies have demonstrated that the sensitivity, specificity, positive and negative predictive values and diagnostic accuracy of MRCP in the detection of biliopancreatic diseases are as high as those of ERCP\cite{12-16}. Despite these data, the actual role of MRCP in the diagnostic work-up of patients with suspected biliopancreatic disease is not clear. Besides its advantages, MRCP has certain drawbacks. Most importantly, it does not allow simultaneous therapeutic intervention. While ERCP offers a therapeutic option in the same session after the diagnosis is made (papillotomy, removal of choledocholithiasis, stenting of a biliary stricture, etc.), MRCP yields only the diagnosis. Clips, stents, pneumobilia, hemobilia and ascites might result in artifacts and impede interpretation of the MRCP image. Despite the new technological advances in MR imaging, its resolution has remained behind that of ERCP\cite{23}.

In the present study we assessed the value of MRCP in the management of patients in whom ERCP was unsuccessful. MRCP prevented an invasive procedure in 15 of 22 cases and guided therapy in the remaining 7. Ten patients were treated conservatively. They did not require further diagnostic examinations or therapeutic interventions; they were asymptomatic or responded well to the medical therapy during the follow-up. In 7 patients, therapeutic intervention was indicated by the MRCP findings. The information provided by MRCP was sufficient for the decision-making, and a further diagnostic work-up was required in only 1 patient. This patient (No. 10) was referred to the endoscopy unit because of obstructive jaundice. Duodenoscopy revealed an enlarged papilla of Vater with an irregular surface, which was suspicious of malignancy. Cannulation of the biliary or the pancreatic duct was impossible, even after precut papillotomy. The histological examination of the biopsy specimens taken from the papilla indicated no malignancy. MRCP demonstrated a dilated biliary tree with a severe prepyloric stricture (Figure 1). The pancreas was not separated well from its surroundings in the conventional axial plane MR images, because of the lack of peripancreatic fatty tissue. The Wirsung duct was not depicted or could not be identified among the fluid-filled bowels, despite the use of secretin. The evaluation of the MR images was hampered by the technical artifacts. These findings and the clinical picture together suggested pancreatic head carcinoma. The patient was operated on. The surgery confirmed the suspicion, but a curative resection was impossible as a result of the local invasiveness of the tumor. Biliary-enteric anastomosis was performed.

The sensitivity, specificity, positive and negative predictive values and diagnostic accuracy of MR imaging in the detection of pancreatic cancer were at least as high as those of computer tomography or ERCP\cite{24,25}. The combination of conventional MR imaging with MRCP and MR angiography could increase the accuracy in the diagnosis, the staging of pancreatic malignancies and the assessment of resectability\cite{26,29}. With this combined MR imaging technique, the biliary tree and pancreatic duct with the surrounding vessels and parenchymatous organs could be depicted in one examination, which makes it cost-effective. In our case, the poor quality of the MR imaging with significant amount of artifacts might explain why it was unable to diagnose the cause of the biliary obstruction.

Four patients underwent surgery without further diagnostic examinations. In 3 cases the diagnosis made by MR was confirmed by the surgical findings. In 1 case (No. 10), the MR revealed only the site, but not the cause (i.e. pancreatic cancer) of the bile duct obstruction, which was diagnosed during the operation. In 3 patients, surgery was not recommended because of their moribund physical status. PTC was performed and in each case confirmed the results of MRCP. These patients subsequently underwent biliary drainage.

Seven out of 22 patients required intervention after MRCP. This points the major drawbacks of MRCP. It is unable to combine therapy with diagnosis. It could be argued that the 3 patients with obstructive jaundice who required PTC and PTBD after MRCP might have better served by proceeding to this modality directly. However, the fact that MRCP is noninvasive is a powerful point in its favor. It can identify those patients where therapeutic intervention is needed.

Our results suggest that MRCP is a feasible and valuable diagnostic modality in patients in whom ERCP fails. MRCP facilitates the management of these patients. It differentiates patients who require invasive therapy from those who can be treated conservatively, and provides information necessary for the planning of surgical or radiological interventions.
