(Received 5 October 2005; published 30 August 2006)

Using density functional theory we perform theoretical investigations of the electronic properties of a freestanding one-dimensional organometallic vanadium-benzene wire. This system represents the limiting case of multidecker \( V_nBz \) clusters which can be synthesized with established methods. We predict that the ground state of the wire is a 100% spin-polarized ferromagnet (half-metal). Its density of states is metallic at the Fermi energy for the minority electrons and shows a semiconductor gap for the majority electrons. We find that the half-metallic behavior is conserved up to 12% longitudinal elongation of the wire. Ab initio electron transport calculations reveal that finite size vanadium-benzene clusters coupled to ferromagnetic Ni or Co electrodes will work as nearly perfect spin filters.

During the last few years, molecular magnets have been attracting enormous attention because they are considered as potential candidates for future applications in high-density information storage and quantum computing. Among such novel systems, we would like to focus on vanadium-benzene multidecker clusters (\( V_nBz_n \)). These are molecular magnets appearing in a gas phase [1,2]. The synthesis of the V-Bz clusters was realized up to \( n = 6 \) during a reaction of laser-vaporized metal atoms with benzene in a He atmosphere [2,3]. The mass spectrometric measurements [2,4] and theoretical studies [5–7] suggested that \( V_nBz_{n+1} \) clusters should have a one-dimensional structure which is settled by the metal-ligand interactions confined to a single molecular axis.

In this Letter, we present an ab initio study of the infinite one-dimensional (1D) organometallic vanadium-benzene (V-Bz) wire shown in Fig. 1 which could be considered as the limiting case of the \( V_nBz_{n+1} \) clusters with \( n \rightarrow \infty \). We have performed calculations of the electronic structure of the system and predict that the wire under consideration is a new, unusual example of a one-dimensional half-metallic ferromagnet. It has an integer magnetic moment of \( \frac{1}{2} \mu_B \) per unit cell and a spin-polarized band structure with a finite density of states at the Fermi level for one spin channel and a semiconductor gap for the other (Fig. 2).

Thus, the electronic properties of this organometallic wire are similar to that of the known Heusler compound, NiMnSb, which has been predicted to be a half-metal by de Groot et al. in 1983 [8]. Furthermore, our electron transport calculations have shown that a finite fragment of the wire would act as a nearly perfect molecular spin filter (Fig. 4) when a V-Bz cluster is placed between magnetic electrodes [9].

The calculations of the properties of the V-Bz wire are based on density functional theory and were performed within the linear combination of atomic orbitals formalism implemented in the highly accurate CRYSTAL code [10]. The Perdew-Wang [11] generalized-gradient approximation (GGA) for the exchange and correlation energy was used. The description of the electron subsystem was done with the full electron basis set 6-311G** [12] for carbon and hydrogen atoms and with a frozen core basis set SBKJC [13] for vanadium. Convergent results were achieved using the Pack-Monkhorst grid with 24 \( k \) points in the 1D Brillouin zone. The wire under consideration (Fig. 1) has a one-dimensional hexagonal lattice with

![FIG. 1 (color online). The structure of the V(C6H6) wire.](image)
P6/mmm ($D_{1h}^1$) rod symmetry. From calculations of the total energy of the system we have found that the optimal structure corresponds to the following interatomic distances: $d_{VBz} = 1.69$ Å, $r_{CC} = 1.45$ Å, and $r_{CH} = 1.09$ Å, that is in good agreement with other studies [14,15]. We have also examined another, staggered-type, geometry of the wire when the consecutive benzol rings were rotated by $30^\circ$ with respect to each other. We have found that the staggered geometry is energetically less favorable, with a total energy per unit cell being 0.06 eV higher than the lowest-energy of the wire with $D_{1h}^1$ symmetry. Moreover, our calculations showed that the rotation of the benzene ring did not change the electronic properties of the wire.

In Fig. 2 we present the spin-polarized band structure of the V-Bz wire (left) [16] together with the corresponding density of states (middle). We accompanied these data by plotting the crystalline orbitals evaluated at the $\Gamma$ point. The symmetry of the bands corresponds to the $C_{6v}$ point group relevant for the Bloch vectors. We see that for the minority spin electrons the $A_1$ band and the doubly degenerate $E_2$ band cross the Fermi level, while for the majority spin electrons the Fermi energy ($E_F$) lies in the gap. The direct gap has a width of $E_g = 1.18$ eV while the spin-flip gap is $\Delta_s = 0.12$ eV at the $\Gamma$ point. Such a system would have ballistic conductance of $3e^2/h$ in one spin channel and zero transmission for the other. To verify the validity of the obtained result with respect to a more careful treatment of the on-site correlation effects between $d$ electrons of vanadium, we have performed additional calculations within the local density approximation LDA + $U$ scheme [17] using the projector augmented wave method [18] implemented in the VASP [19], as well as within the hybrid B3LYP exchange-correlation functional [20]. It was confirmed that the half-metallic behavior is robust against details of the calculations. The size of the gap and the relative positions of bands are of course subject to the chosen method (Table I). The inclusion of a Hubbard $U$ term results in a downward shift of the majority $A_1$ and $E_2$ bands leading to an increase of the spin-flip gap $\Delta_s$, while the minority bands crossing the Fermi level are unaffected. The B3LYP functional pulls the majority spin bands even more strongly away from $E_F$. In addition, the antiferromagnetic state of the wire was found to be energetically less preferable as compared with the ferromagnetic configuration.

The spin-density map (Fig. 3) indicates a small negative magnetic moment ($-0.28 \mu_B$) redistributed over 6 C atoms and a quite localized positive magnetic moment at the V atom (+1.28 $\mu_B$). The integer magnetic moment (1.0 $\mu_B$) of the wire unit cell arises mainly from the minority spin $A_1$ states labeled as (b) in Fig. 2 that is in agreement with theoretical [6] and experimental [1,2,21–23] data. Since the corresponding wave function (b) is nearly a pure $d_{3z^2-r^2}$ vanadium orbital, its symmetry is reflected in the angular distribution of the spin density around the V atom. Furthermore, we note that the small negative magnetic moment on the C atoms results from the uncompensated $E_2$ band (c) whose molecular orbital contains an admixture of the carbon $p$ states (Fig. 2).

TABLE I. The spin-flip gap $\Delta_s$ (the energy difference between $E_F$ and the top of the majority spin valence band), the direct gap $E_g$, and the lattice constant of the V(C$_6$H$_6$)$_n$ wire.

| Method     | $\Delta_s$, eV | $E_g$, eV | $d_{VBz}$, Å |
|------------|----------------|-----------|--------------|
| GGA        | 0.12           | 1.18      | 1.695        |
| LDA + $U$ (2 eV) | 0.22           | 1.04      | 1.663        |
| LDA + $U$ (3 eV) | 0.57           | 1.25      | 1.676        |
| LDA + $U$ (4 eV) | 1.04           | 1.58      | 1.696        |
| B3LYP      | 1.22           | 2.52      | 1.760        |
The HOMO-LUMO gap is smaller than the gap in the majority spin channel. The vanadium hybridization effect between the states of the same symmetry, marked by (i) direct exchange, and (ii) indirect, superexchange interaction which can be established through the π-type orbitals of benzene. Pursuing the first mechanism, we have compared spin-projected local densities of states (LDOS) at the V atom for the ferromagnetic (FM) and the antiferromagnetic (AFM) state and found the LDOS not to be identical. That indicates the direct exchange, since without mutual influence of the localized moments one could expect the LDOS for both phases to be almost alike. We observed that the AFM phase was not any more half-metallic and the vanadium magnetic moment was reduced to 0.62μB. The direct exchange inter-
action between V moments favors the FM phase. However, we cannot exclude another, indirect type of spin coupling, which is governed by the Kramers-Anderson mechanism \cite{29,30} of the superexchange interaction. For the considered system, because of the overlap of the HOMO (HOMO – 1) $\pi$-type orbital of benzene with the $d_{yz}$, $d_{x^2}$ orbitals of vanadium, one of the $p$ electrons from benzene can hop over to one of the V atoms and the remaining unpaired $p$ electron on Bz can enter into a direct exchange with the other V atom. Applying the Goodenough-Kanamori rules \cite{30} regarding the sign of the effective exchange integral, we conclude that the indirect exchange interaction tends to align vanadium moments antiparallel and thus it competes with the direct coupling.

We have also studied the effect of the longitudinal stretching on the properties of the V-Bz wire. In Fig. 5 we show the binding energy between V and Bz as a function of the unit cell length. At the critical unit cell length of about 3.75 Å, the system exhibits a transition to a high-spin state. Just before the critical point the partially occupied minority spin $A_1$ band (b) nearby $E_F$ is transformed to the very narrow peak pinned to the Fermi level. Under further stretching this band is pushed above $E_F$ and a fractional charge of about 0.3e per unit cell from the minority spin band flows to the upper lying majority spin band of $E_g$ symmetry (f) which now intersects the Fermi level close to the edge of the Brillouin zone. Thus, the transition is accompanied by an abrupt jump in the magnetic moment (Fig. 5, inset), from 1$\mu_B$ up to $\sim$1.6$\mu_B$ per unit cell, and the high-spin state becomes energetically favorable because of the gain in the exchange energy.

To summarize, the most important conclusion of our research is that recently synthesized multidecker vanadium-benzene clusters, when carrying spin-polarized currents, will work as highly effective spin filters.

We would like to thank B. Yavorsky, V. Stepanyuk, M. Ruben, and F. Weigend for fruitful discussions. This work was supported by DFG, No. SPP 1165.
