Abstract

There has been some confusion concerning the number of (1,1)-forms in orbifold compactifications of the heterotic string in numerous publications. In this note we point out the relevance of the underlying torus lattice on this number. We answer the question when different lattices mimic the same physics and when this is not the case. As a byproduct we classify all symmetric $Z_N$-orbifolds with (2,2) worldsheet supersymmetry obtaining also some new ones.

1 Introduction

String compactifications on toroidal $Z_N$-orbifolds \cite{1} are among the most intensively studied ones. They provide us with the simplest string models which have semi realistic features. Because the one loop partition function and the couplings can be calculated explicitly in dependence of the untwisted moduli, many generic properties concerning the string moduli space and the effective low energy theory can be investigated here in detail\cite{1}. Including all background parameters in the framework of heterotic compactifications and allowing for the most general twists, a rich class of models, with partly phenomenological very attractive features, emerges. The question is still open, whether some standard string model, which can be related in a painless manner to the known phenomenology, is contained in this class.

Toroidal orbifolds have also attracted the attention of the mathematicians, because the partition functions of (2,2) models contain informations, which can be interpreted as topological data of a Calabi-Yau manifold. The latter can indeed be constructed by a certain

\footnote{Supported by Deutsche Forschungsgemeinschaft}

\footnote{The situation for more general compactification schemes has improved, as P. Candelas, X. De la Ossa, P. Green and L. Parkes worked out the modulus dependence explicitly \cite{2} for the quintic threefold in $\mathbb{P}^4$. Other Calabi-Yau manifolds were investigated in \cite{3}.}
resolving process of the orbifold singularities, which establishes an exciting relation between singularity theory and the theory of modular functions.

In this situation it comes as a surprise that some of the most fundamental properties from the physical as well as from the mathematical point of view, namely the individual numbers of generations and antigenerations, i.e. \((1,1)\)-forms and \((2,1)\)-forms respectively, on the orbifold have been reported incorrectly in the literature.

\(Z_N\)-orbifolds \([1]\) are unambiguously defined through a twist acting as an automorphism in some torus lattice. Clearly, a given twist matrix determines both the spectrum of twist eigenvalues and the lattices possessing the automorphism. Some properties like the number of chiral generations, the number of space time supersymmetries or the number of untwisted moduli fields only depend on these eigenvalues. On the other hand, however, the role of the underlying lattice has been underestimated in the past. For instance, it determines the modular symmetry group \([4, 5, 6, 7, 8]\), which has attracted much attention due to its importance for discussions of low energy effective actions \([3]\).

In this communication we will point out that the lattice has even impact on the number of \((1,1)\)-forms \((h_{1,1})\) and thus on the massless spectrum. Since this fact has been overlooked up to now, the true total number of \(27\)'s and \(\overline{27}\)'s depart from those stated in the literature. Especially the Lie-algebra lattices assigned to a stated \(h_{1,1}\) differ from the results of this publication. Neglecting the dependence of orbifold properties on the lattice, has also led to an incomplete classification of symmetric \(Z_N\)-orbifolds with \((2,2)\) world sheet supersymmetry and vanishing discrete background field. We have found 18 inequivalent orbifolds in this class.\(^3\)

One should stress, that the correct treatment does not lead to any changes for the two prime orbifolds \(Z_3\) and \(Z_7\), where no fixed tori occur. In the case of non prime orbifolds we have typically the situation, that there exits a lattice to which apply parts of the reasoning that appear in the literature. This lattice is, however, usually not the one the authors refer to.

There is a variety of methods to obtain informations about the spectra of \(Z_N\)-orbifolds. One is to study the possible resolutions of orbifold singularities \([11, 12, 13]\). In three (complex) dimensions these are either related to fixed points or to fixed curves. The cases of fixed points are completely understood. In the presence of fixed curves, however, more care is needed and different torus lattices give rise to different resolutions.

Another possibility is to construct the one loop partition function as done in \([14]\). This is equivalent to knowing all massless and massive states.\(^3\) We will show that those parts of the partition function which are related to sectors, where the corresponding twist matrix leaves fixed tori, have a somewhat different structure.

Finally, one can construct twist invariant vertex operators by using the mode expansions of the untwisted and twisted coordinates \([16]\). Again we will argue that in sectors with fixed directions different solutions arise whenever the underlying lattice is changed.

Since the main purpose of this note is to emphasize the importance of the compactification lattice, we will construct the complete list of symmetric \(Z_N\)-orbifolds of \((2,2)\)-type with vanishing discrete background fields \(B_{\mu\nu}\). As shown in \([7]\) non-vanishing discrete background

\(^2\)There exists a more natural and much more efficient way of constructing \((2,2)\) string compactifications using the Landau-Ginzburg approach. A classification of these string vacua was performed in \([11]\).

\(^3\)In more general constructions like \(Z_N \times Z_M\) or non-abelian orbifolds one-loop modular invariance might be insufficient for all loop modular invariance and also for defining the model completely \([13]\).
fields very much mimic asymmetric orbifolds. It was also shown there that they can sometimes be transformed to orbifolds without such backgrounds. If this is the case the defining torus lattice in the transformed model typically differs from the original one. Thus we are also led to discuss these class of models.

The organization of the paper is as follows: In section 2 we construct in a systematic way all models of the above mentioned type. This includes all Coxeter-twists but also more general ones. Using methods developed in [7], we will also recognize equivalences of models considered as different before [10]. Section 3 is devoted to the proof that \( h_{1,1} \) depends on the chosen lattice. It uses the one loop partition function as described above and discusses also some aspects of the mode expansion approach. In section 4 we confirm our results by a completely different method utilizing results of singularity theory. We give an easy prescription how to calculate \( h_{1,1} \) and \( h_{1,2} \) from the fixed sets.

2 Classification of the \( Z_N - \)Orbifolds

In this section we classify \((2, 2)\) string theories on orbifolds, which can be obtained by dividing out a \( Z_N \) group in a symmetric way from a six dimensional torus \( T^6 \) with vanishing discrete \( B \)-field.

To be more precise we will classify equivalence classes defined up to modular deformations. We start the discussion with a short extraction of the necessary concepts for toroidal orbifolds, mainly from the physics literature.

2.1 Concepts in toroidal- and orbifold compactifications

Let \( \Lambda = \{ \sum_{i=1}^{6} n^i e_i \mid n_i \in \mathbb{Z} \} \) be a lattice embedded in Euclidean space \( \mathbb{R}^6 \). Due to the canonical isomorphism we denote the basis of the tangent space also by \( e_i \) and define the induced metric as \( g_{ij} = \langle e_i, e_j \rangle \), where \( \langle \cdot, \cdot \rangle \) is the Euclidean scalar product. We denote the dual lattice w.r.t. \( \langle \cdot, \cdot \rangle \) by \( \Lambda^* \). The six torus is defined as the quotient of \( \mathbb{R}^6 \) w.r.t. \( \Lambda \),

\[ T^6 := \mathbb{R}^6 / \Lambda. \tag{1} \]

One may also introduce an antisymmetric background field \( B = b_{ij} e^i \wedge e^j \) as a geometrical data of the torus. The allowed momenta for the left and right movers of strings compactified on the torus with this background field are given by [7]

\[ P_L = \frac{1}{2} m + gn - bn, \quad P_R = \frac{1}{2} m - gn - bn, \tag{2} \]

where \( n \) and \( m \) are integer six vectors describing the winding and momentum quantum numbers of the string state. They label the elements of \( \Lambda \) and its dual \( \Lambda^* \) respectively. The geometry of the underlying torus, i.e. the so called modular parameters\(^4\) \( g_{ij} \) and \( b_{ij} \), enters string theory only via bilinear forms of \((m, n)\) describing the scaling dimension,

\[ H_{(g, b)}(m, n; m, n) = P_L g^{-1} P_L + P_R g^{-1} P_R \]

\[ = \frac{1}{2} m^T g^{-1} m + 2 n^T g n - m^T g^{-1} b n + n^T b g^{-1} m + 2 n^T b^{-1} g n \tag{3} \]

\(^4\)In the heterotic theory other modular parameters appear in form of Wilson lines \( A_i^I \).
and the spin,

\[ S(m, n; m, n) = P_Lg^{-1}P_L - P_Rg^{-1}P_R = 2m^Tn, \]  

of the physical vertex operators, up to geometry independent oscillator contributions. A linear relabeling of \((n, m)\) leaving invariant the bilinear form \(\mathbb{P}\) can be accompanied by a relabeling of the the modular parameters \(g\) and \(b\) such that also the scaling dimensions \((3)\) of the vertex operators are invariant. That is, string theory is the same for geometrically different tori and this leads us to following definition:

**Definition 1** The bijective linear integer transformations of \((n, m) \mapsto gl(n, m)\), which leave \((4)\) invariant, generate an invariance group \(G\) for string theory on the torus.

The requirement that \(H\) stays invariant \(H(g, b)(n, m; n, m) = H(g', b')(gl(n, m); gl(n, m))\) induces a representation of \(G\) as transformations of the moduli \(\rho(gl) : (g, b) \mapsto (g', b')\), which is not \(5\) faithful. The group generated by this transformations is called modular symmetry group \(G\).

Setting the \(B\)-field to zero and restricting to a subgroup of \(G\), which do not mix windings and momenta \(4\) we have the following

**Lemma 1** Let \(M \in GL(6, \mathbb{Z})\). The string theory on \(T^6\) remains invariant under the simultaneous transformations \(n \to M n, m \to M^Tm\) and \(g \to M^Tg M^{-1}\).

An orbifold is defined by a finite group \(T\) generated by elements \(\Theta_i\) of \(G\), all of which leave \(H \mapsto \Theta g_o \) of \((g_o, b_o) \neq \emptyset\) invariant. The latter requirement defines \((g_o, b_o)\) the untwisted moduli space of the orbifold, which is a subspace of the moduli space \((g, b)\) of the torus. \((g_o, b_o)\) might be a point in moduli space, but in general the \(\Theta_i\) specify the orbifold only up to modular deformations.

The symmetric \(Z_N\) orbifolds with vanishing discrete \(B\)-field, which we want to classify amount to the simplest possible choice for \(\Theta\). Namely we pick an element \(\theta \in GL(6, \mathbb{Z})\) with \(\theta^N = 1\) and transform simultaneously \(6\) \(n \to \theta n\) and \(m \to \theta^Tm\). The spin \(S\) is invariant by construction and requiring invariance of \(H_{g_o}\) we get

\[ \theta^Tg_o \theta = g_o. \]  

Condition \(6\) ensures that the lattice automorphism acts crystallographically.

The basis transformation on \((n, m)\) of Lemma 1 accompanied with a transformation of \(g \mapsto M^Tg M^{-1}\) does not change the string theory on the torus and if we transform a given twist covariantly we also define the same orbifold thereof. We have therefore the following equivalence relation for the twist matrices \(7\):

**Definition 2** Two twist matrices \(\theta\) and \(\theta'\) are equivalent in the sense that they define the same orbifold string theory, if and only if \(\exists M \in GL(6, \mathbb{Z})\) such that \(\theta = M\theta'M^{-1}\).
The modular group of the orbifold can be described as follows\footnote{By \footnote{5} all powers of $\theta$ are in the kernel of $\rho$.}

**Corollary 1** The $M \in GL(6, \mathbb{Z})$ which fulfill $\theta^n = M \theta M^{-1}$ ($n \in \mathbb{Z}_+$) generate a symmetry group of the orbifold, which induces a non\footnote{\det(1-\theta) = 0 in \footnote{7} signals the occurrence of fixed sublattices.} faithful representation on the orbifold moduli $\rho(M) : g_o \mapsto g'_o$ by the requirement $H_{g_o}(n,m;n,m) = H_{g'_o}(Mn,M^{-1}m;Mn,M^{-1}m)$.

### 2.2 Description of the Classification

We start the classification of the symmetric $Z_N$ twists by analysing their possible eigenvalues. Let $\theta$ be a $Z_N$ twist in an $n$-dimensional lattice. By a transformation matrix $B \in GL(n, \mathbb{C})$ we can pass from the lattice basis where the twist $\theta$ is integer valued to a basis where it is diagonal

$$
\theta_d = B^{-1} \theta B = \text{diag}(\xi^{a_1}, \ldots, \xi^{a_n}).
$$

Here $\xi = e^{2\pi i/N}$ is the $N$'th order root of unity and $a_i \in \mathbb{N}_0$, $a_i < N$. Since we wish $\theta$ to act as an integer matrix in some lattice we get as a necessary condition on the exponents $\lambda_i = a_i/N$ of $\theta_d$ that they define a characteristic polynomial $P(x)$ over the integers. Especially the Lefschetz Fixed Point Theorem which gives the number of fixed points $\chi_F$ of a lattice automorphism $\theta$ as

$$
\chi_F = \det(1-\theta),
$$

implies $P(1) \in \mathbb{Z}$.

First we search for $\theta_d$, which fulfill the necessary condition above. Let us denote by $(a,b)$ the greatest common divisor of $a$ and $b$. We call $\theta_d$ proper, if $(a_i, N) = 1$ for all $i$. Obviously all $\theta_d$ can be constructed from proper subblocks $\theta_d'$. The Euler function is defined $\phi(N)$ as the number of integers $0 < l < N$ with $(l, N) = 1$. The characteristic polynomial for a proper twist is a so called cyclotomic polynomial of degree $\phi(N)$

$$
P_N(x) = \prod_{0 < a < N \atop (a, N) = 1} (x - \xi^a),
$$

which enjoys the following properties

1. $P_N(x)$ is in the polynom ring over the integers: $P_N(x) \in \mathbb{Z}[x]$.
2. $P_N(x)$ is irreducible in $\mathbb{Z}[x]$.
3. $P_N(1) = \begin{cases} p & \text{if } N = p^r \text{ with } p \text{ prime}, \\ 1 & \text{otherwise.} \end{cases}$

1. ensures our necessary condition for $\theta'$ to act as a lattice automorphism. Due to 2. the minimal dimension in which a $Z_N$ twist can be realised crystallographically and proper is given by $\phi(N)$. Finally, 3. provides us with an effective method for computing the number of fixed points. The dimensions of the proper blocks are given by

$$
\phi(N) = N \prod_i \frac{p_i - 1}{p_i}, \quad \text{where } p_i \text{ are the distinct prime factors of } N,
$$

\footnote{\det(1-\theta) = 0 in \footnote{7} signals the occurrence of fixed sublattices.}
which reduces to $N - 1$ for prime $N$. From that we see that for $d = 1$ only $Z_2$ with 2 fixed points is allowed and furthermore that no other block can be defined properly in odd dimensions. We can easily construct a table of exponents up to $d = 6$. Because all $\xi^{a_i}$ appear together with $\xi^{a_i}$, we only list half of them. Using (9) it is easy to see that no higher orders are possible.

Table 1: Exponents of proper $Z_N$ twists

| $d = 2$ | $d = 4$ | $d = 6$ |
|---------|---------|---------|
| twist   | $\chi_F$ | twist   | $\chi_F$ | twist   | $\chi_F$ |
| \(1/3\)(1) | 3 | \(1/5\)(1, 2) | 5 | \(1/7\)(1, 2, 3) | 7 |
| \(1/4\)(1) | 2 | \(1/8\)(1, 3) | 2 | \(1/9\)(1, 2, 4) | 3 |
| \(1/6\)(1) | 1 | \(1/10\)(1, 3) | 1 | \(1/14\)(1, 3, 5) | 1 |
|         |     | \(1/12\)(1, 5) | 1 | \(1/18\)(1, 5, 7) | 1 |

The allowed sets of exponents in dimensions less than 6 can now be obtained by building all possible combinations of the proper ones. From the table we see e.g. that crystallographic automorphisms in $d = 6$ can only exist for $N = 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 14, 15, 18, 20, 24, 30$. Indeed this list agrees with the one given e.g. in [1].

All eigenvalues appear with their complex conjugate so that we can define a complex coordinate system

$$z_i = \frac{1}{\sqrt{2}}(x_i + ix_{i+1}), \quad i = 1, 2, 3$$

on which $\theta$ acts holomorphically. The condition for obtaining a supersymmetric orbifold can be formulated in different ways. We follow the geometric approach [11] and require invariance of the holomorphic $(3,0)$ form of the complex torus ([18] II.6)

$$\omega = dz_1 \wedge dz_2 \wedge dz_3,$$

which implies $a_1 + a_2 + a_3 = 0 \text{ mod } N$. If we furthermore restrict our attention to models which have exactly $N = 1$-supersymmetry, i.e. no fixtorus in the first twisted sector, we get the following 9 sets of allowed exponents:

Table 2: Eigenvalues of $Z_N$ twists leaving $N = 1$ supersymmetry.

| twist | $\chi_F$ | twist | $\chi_F$ | twist | $\chi_F$ |
|-------|---------|-------|---------|-------|---------|
| $Z_3$ : \(1/3\)(1, 1, −2) | 27 | $Z'_6$ : \(1/5\)(1, 2, −3) | 12 | $Z_8$ : \(1/8\)(1, 3, −4) | 8 |
| $Z_4$ : \(1/4\)(1, 1, −2) | 16 | $Z_7$ : \(1/6\)(1, 2, −3) | 7 | $Z_{12}$ : \(1/12\)(1, −5, 4) | 3 |
| $Z_6$ : \(1/6\)(1, 1, −2) | 3 | $Z_8$ : \(1/8\)(1, −3, 2) | 4 | $Z'_{12}$ : \(1/12\)(1, 5, −6) | 4 |

One approach to find $Z_N$ orbifolds, which was carried out in [11], is to start with a lattice and consider the compatible $Z_N$ automorphisms. In contrast we will start with the twist matrix and then specify the lattice metric as solution to (3). In virtue of the equivalence
relation Definition 2 the action of an irreducible block of a $Z_N$ twist can be brought into the canonical form

$$
\theta = \begin{pmatrix}
0 & \ldots & 0 & v_1 \\
1 & 0 & \ldots & 0 & v_2 \\
0 & 1 & 0 & \ldots & 0 & v_3 \\
\vdots & \ddots & \ddots & \ddots & \ddots & \vdots \\
0 & \ldots & 1 & v_n
\end{pmatrix},
$$

where $v_1 = \pm 1$ such that $|\det(\theta)| = 1$. Note that the form of (11) alone does not imply that the block is not further reducible. We calculate the $N$th power of (11) according to our list of possible orders in the given dimension and search for integer $\vec{v}$ such that this is the unit matrix. The corresponding twist matrices can easily be found by means of a computer program. It turns out that $|v_i| \leq 3$. In the following table we list only the vectors $\vec{v}$ which specify irreducible twist matrices relevant for the $N = 1$ supersymmetric $Z_N$-orbifolds:

Table 3: Irreducible building blocks for $Z_N$ twists relevant for $N = 1$ supersymmetry.

| $d = 1$ | $d = 2$ | $d = 3$ | $d = 4$ |
|---------|---------|---------|---------|
| $Z_2^{(1)} : (-1)$ | $Z_3^{(2)} : (-1, -1)$ | $Z_4^{(3)} : (-1, -1, -1)$ | $Z_3^{(4)} : (-1, 0, -1, 0)$ |
| $Z_4^{(2)} : (-1, 0)$ | $Z_6^{(3)} : (-1, 0, 0)$ | $Z_8^{(4)} : (-1, 0, 0, 0)$ |
| $Z_6^{(2)} : (-1, 1)$ | | $Z_{12}^{(4)} : (-1, 0, 1, 0)$ |

| $d = 5$ | $d = 6$ |
|---------|---------|
| $Z_6^{(5)} : (-1, -1, -1, -1, -1)$ | $Z_7^{(6)} : (-1, -1, -1, -1, -1, -1)$ |
| $Z_8^{(5)} : (-1, -1, 0, 0, -1)$ | $Z_8^{(6)} : (-1, 0, -1, 0, -1, 0)$ |
| | $Z_{12}^{(6)} : (-1, -1, 0, 1, 0, -1)$ |

Now we combine these irreducible blocks to $(6 \times 6)$ twist matrices giving rise to $N = 1$ supersymmetric orbifolds.

To make contact with the classification of Coxeter orbifolds in [11, 14], we use the equivalence relation in Definition 2 to rewrite our twists as Coxeter automorphisms, if possible. A Weyl reflection $^{12}$ is a reflection on the hyperplane perpendicular to a simple root

$$S_i(x) = x - 2\frac{\langle x, e_i \rangle}{\langle e_i, e_i \rangle} e_i.$$

A Coxeter automorphism $c$ in a Lie algebra lattice is defined by successive Weyl reflections w.r.t. all simple roots $c = S_1 \cdot \ldots \cdot S_{\text{rank}}$. Automorphisms are called outer if they cannot be generated by Weyl reflections. They are generated by transpositions of roots which are symmetries of

---

9In the following irreducibility is to be understood over $\mathbb{Z}$.

10In this form $\chi_F$ is simply given by $1 - \sum_i v_i$.

11It also turned out that the cases with $v_1 = +1$ exactly correspond to fixed tori.

12For the following definitions concerning Lie algebras [23] is the standard reference.
the Dynkin diagram. Generalised Coxeter automorphisms can be obtained by combining Weyl reflections with outer automorphisms. We denote a transposition which exchange the roots \(i \leftrightarrow j\) by \(P_{ij}\). In [11] generalised Coxeter automorphisms were only considered if they act in one semisimple factor, e.g. in the lattice \(A_2 \times D_4\) the automorphism \(S_1S_2S_3P_{36}P_{35}\) (cyclic permutation of the roots (3,5,6)).

There is no reason for this restriction and in fact the full classification involves transpositions between the semisimple factors, e.g. in \(A_3 \times A_3\) the automorphism \(S_1S_2S_3P_{16}P_{25}P_{34}\).

As the result of our classification we have the following

**Theorem 1** There exist 18 inequivalent \(N = 1\) supersymmetric string theories on symmetric \(Z_N\) orbifolds of \((2,2)\)-type without discrete background all having at least one representative in the class of generalised Coxeter orbifolds. More precisely we have 15 ordinary Coxeter orbifolds realized on the lattices

\[
\begin{array}{cccc}
A_2 \times A_2 \times A_2, & A_1 \times A_1 \times B_2 \times B_2, & A_1 \times A_3 \times B_2, & A_3 \times A_3, \\
A_2 \times G_2 \times G_2, & A_1 \times A_1 \times A_2 \times G_2, & A_2 \times D_4, & A_1 \times A_5, \\
A_6, & B_2 \times B_4, & A_1 \times A_1 \times B_4, & A_1 \times D_5, \\
A_2 \times F_4, & E_6, & D_2 \times F_4, & \\
\end{array}
\]

and 3 involving outer automorphisms, namely \(A_1 \times A_1 \times A_2 \times A_2\) with \(S_1S_2S_3S_4P_{36}P_{45}\), \(G_2 \times A_2 \times A_2\) with \(S_1S_2S_3S_4P_{36}P_{45}\) and finally \(A_3 \times A_3\) with \(S_1S_2S_3P_{16}P_{25}P_{34}\).

This result is to be compared with the result of [11], which was the basis for further investigations [14, 16, 22]. Here the authors give in Table 1 of their classification theorem 13 examples. They suggest that only 9 are inequivalent, namely the one which have different twist eigenvalues (cf table 2 above). Three pairs of orbifolds which are identified in [11], are inequivalent in the sense of Definition 2. In fact they have different hodge numbers, as we will explain below. We agree on the other hand with the identification of the models \(A_2 \times D_4^{[3]}\) (with automorphism \(S_1S_2S_3P_{36}P_{35}\)) and \(A_2 \times F_4\) (with Coxeter automorphism) in Table 1 of [11]. Finally we have found six new examples which are inequivalent to the ones appearing in [11], three of them as mentioned involve outer automorphisms between semi simple factors.

### 3 Partition Functions

In this section we discuss the construction of one loop partition functions, which allows for a survey of all string states. For the \(E_8 \times E_8\) heterotic string before compactification it is given

\[13\text{The relevant combinations of the twist matrices specified in Table 3 and the Hodge numbers for the 18 models can be found in table }\]
by \[15\]
\[
Z(\tau, \bar{\tau}) = \frac{1}{8} \frac{(2\pi \text{Im} \tau)^4}{[\eta(\tau)]^{16}} \frac{[\theta^6_2(\tau) + \theta^6_4(\tau) + \theta^6_2(\bar{\tau})]^2 [\theta^4_4(\tau) - \theta^4_1(\tau) - \theta^4_1(\bar{\tau})]}{\eta^{16}(\tau) \eta^4(\bar{\tau})},
\]
where the first factor refers to ten dimensional Minkowski space in light cone gauge, the part holomorphic in the complex world sheet parameter \(\tau\) describes the gauge part of the left handed bosonic string and the antiholomorphic part account for the right handed superfermions. We introduced Dedekind’s \(\eta\)-function

\[
\eta(\tau) = q^{1/24} \prod_{n=1}^{\infty} (1 - q^n)
\]
and Jacobi’s \(\theta\)-functions

\[
\theta \left[ \begin{array}{c} \alpha \\ \beta \end{array} \right] (\tau) = \sum_{n \in \mathbb{Z}} q^{\frac{1}{2}(n+\alpha)^2} e^{2\pi i(n+\alpha)\beta}
\]
with \(q = e^{2\pi i \tau}\). In the context of toroidal orbifolds each part can be realized as free world sheet bosons. Thus the \(\theta\)-functions will be regarded as the instanton part whereas the \(\eta\)-functions describe quantum oscillations. Factors like \((2\pi \text{Im} \tau)\) arise after integrating out continuous momentum states. After compactifying on \(T^6\) this integration transmutes to a sum over discrete momenta \(p^\mu\) characterized by elements of the dual torus lattice \(\Lambda^*\). Modular invariance requires the appearance of an additional sum over elements of \(\Lambda\) itself interpreted as winding states \(w^\mu\). These two lattices can be combined to define an even self-dual lattice \(\Lambda_N\) with Lorentzian signature \([14]\)

\[
(+, +, +, +, +, +, +, +, +, +, +, +, +, +, +, +, +)
\]
and elements \(P = (P_L, P_R)\), defined in \([2]\).

Again we used the freedom of turning on an antisymmetric background field \(b_{ij}\) which corresponds to considering all even, self-dual lattices in \(6 + 6\) dimensions\([3]\). The partition function now reads

\[
Z(\tau, \bar{\tau}) = \frac{1}{8(2\pi \text{Im} \tau)|\eta(\tau)|^{16}} \frac{[\theta^6_2(\tau) + \theta^6_4(\tau) + \theta^6_2(\bar{\tau})]^2 [\theta^4_4(\tau) - \theta^4_1(\tau) - \theta^4_1(\bar{\tau})]}{\eta^{16}(\tau) \eta^4(\bar{\tau})},
\]
The orbifold projection can be performed yielding the *untwisted partition function*

\[
\sum_{n=0}^{N-1} Z_{\text{(1,0)}}(\tau, \bar{\tau}) = \frac{1}{4} \sum_{n=0}^{N-1} \text{Tr} \theta^n q^{L_0} \bar{q}^{\bar{L}_0},
\]
where the trace is to be taken over all states of the torus theory\([3]\) with conformal dimensions \(L_0\) and \(\bar{L}_0\). The projection is such that oscillator states in the quantum part are multiplied by phases \(e^{2\pi i/N}\) and powers thereof, whereas instantons are organized in *orbit sums* with definite twist eigenvalues. In other words, orbit sums are linear combinations of states

\[\text{not just the ones subject to physical state conditions}\]

\[\text{Similarly, it is possible to add the } E_8 \times E_8 \text{ gauge lattice as well and to allow for the most general lattice in } 22 + 6 \text{ dimensions of even and self-dual type, what in turn corresponds to turning on Wilson lines.}\]
of toroidal Hilbert space diagonalizing the twist. We conclude that \( Z_{(1,1)} \) is simply given by \( 1/N \) times the torus function and thus clearly contains the full instanton part. If the defining twist matrix \( \theta \) fixes the origin of the lattice only, as is the case for all our models, \( Z_{(1,\theta)} \) will not contain any instantons from the six dimensional part, since the phases of the orbits add up to zero. Clearly, the same is true for all \( Z_{(1,\theta^n)} \), where \( n \) is not a divisor of \( N \). In all other cases the appearance of an instanton sum precisely depends on the question whether the corresponding power of \( \theta \) leaves fixed tori or not. Namely, if it does give rise to fixed directions the corresponding instantons are (like the origin) not organized in orbit sums. It is this fact where our disagreement with the literature stems from. For instance, in formulae (3.3a) and (3.3c) of reference [14] there is no such sum. In these formulae there appear correctly the instanton sums coming from the gauge part. The remark to make is simply that instanton sums can appear in parts of \( Z_{(1,\theta^n)} \) even if the lattice is not invariant under \( \theta \) itself.

The twisted sectors of the orbifold can be obtained by successive \( S \) and \( T \) transformations\(^{16} \), which then ensure one loop modular invariance by construction \([20]\). For symmetric \( Z_N \)-orbifolds these transformations close after having created \( N(N-1) \) new terms labeled by \( Z_{(\theta^m,\theta^n)} \), with \( 1 \leq m < N \) and \( 0 \leq n < N \). For these world sheet modular transformations we will need the identities

\[
\theta \left[ \begin{array}{c} \alpha \\ \beta \end{array} \right] (-1/\tau) = e^{2\pi i\alpha\beta} \sqrt{-i\tau} \theta \left[ \begin{array}{c} \beta \\ -\alpha \end{array} \right] (\tau),
\]

\[
\theta \left[ \begin{array}{c} \alpha \\ \beta \end{array} \right] (\tau + 1) = e^{i\pi\alpha(1-\alpha)} \theta \left[ \begin{array}{c} \alpha \\ \alpha + \beta - \frac{1}{2} \end{array} \right] (\tau).
\]

(17) (18)

The question arises whether the invariant lattice we had argued for in the last paragraph has implications on the spectrum of twisted states and in particular on the generalized GSO-projection established in \([6]\). Concerning massive states the answer is certainly yes, since the lattice dual to the invariant lattice contributes. Massless states are never built up by states of this dual lattice, so how can the number of massless matter multiplets depend on it? The important point is that the invariant lattice lowers the degeneracy factors of \( Z_{(\theta^m,\theta^n)} \) iff its volume differs from one. As a corollary of our classification in the proceeding section we can state that for any configuration of twist eigenvalues there exist a model where the volume of the invariant lattice is one. In the remaining 9 cases \( h_{1,1} \) is reduced.

We don’t need to worry whether we really obtain a sensible string theory after dividing the degeneracy factors by the volume of the invariant sublattice, i.e. whether we get an integer number of states. As shown in \([24, 25]\) this is guaranteed due to the fact that \( \Lambda_N \) appearing in \([13]\) is even and self-dual.

In order to illustrate all this, we now discuss as an example the \( Z_4 \) case in more detail. In particular, we compare models 2 and 4 in our list. These are also the most explicit ones of reference \([22]\), where for the first time such a comparative study of different lattices in a somewhat different context was undertaken.

First we give the partition functions. In order to keep the formulae readable we will now restrict ourselves to the twisted bosons of internal space. I.e., the holomorphic gauge and antiholomorphic superfermionic parts as well as uncompactified space time dimensions are

\(^{16} S: \tau \to -1/\tau; T: \tau \to \tau + 1.\)
disregarded and can be found in [14].

\[ Z_{(1,1)}^{\text{int.}} = \sum_{P \in \Lambda_N^\perp} \frac{q^{P_L^2}q^{P_R^2}}{|\eta(\tau)|^2} \]

\[ Z_{(1,\theta^2)}^{\text{int.}} = 16 \sum_{P \in \Lambda_N^\perp} \frac{q^{P_L^2}q^{P_R^2}}{|\theta^2[1/2] \theta[0,1/2]|^2} \]

\[ Z_{(\theta,1)}^{\text{int.}} = 16 \frac{|\eta(\tau)|^6}{|\theta^2[3/4] \theta[0,1/2]|^2} \]

\[ Z_{(\theta,\theta^2)}^{\text{int.}} = 16 \frac{|\eta(\tau)|^6}{|\theta^2[3/4] \theta[0,1/2]|^2} \]

\[ Z_{(\theta^2,\theta)}^{\text{int.}} = 16 \frac{|\eta(\tau)|^6}{|\theta^2[3/4] \theta[0,1/2]|^2} \]

\[ Z_{(\theta^2,\theta^2)}^{\text{int.}} = 16 \frac{|\eta(\tau)|^6}{|\theta^2[3/4] \theta[0,1/2]|^2} \]

\[ Z_{(\theta^3,1)}^{\text{int.}} = 16 \frac{|\eta(\tau)|^6}{|\theta^2[1/4] \theta[0,1/2]|^2} \]

\[ Z_{(\theta^3,\theta)}^{\text{int.}} = 16 \frac{|\eta(\tau)|^6}{|\theta^2[1/4] \theta[0,1/2]|^2} \]

\[ Z_{(\theta^3,\theta^2)}^{\text{int.}} = 16 \frac{|\eta(\tau)|^6}{|\theta^2[1/4] \theta[0,1/2]|^2} \]

\[ Z_{(\theta^3,\theta^3)}^{\text{int.}} = 16 \frac{|\eta(\tau)|^6}{|\theta^2[1/4] \theta[0,1/2]|^2} \]

We denoted the invariant part of the self-dual lattice by \( \Lambda_N^\perp \). The numerical factors in the untwisted sector arise when expressing infinite products in terms of \( \theta \)-functions. They carry over to the twisted parts, but they are implicitly lowered whenever a function \( \theta^{1/2} \) appears.

In our case the actual degeneracy factor in \( Z_{(\theta^2,\theta)} \) and \( Z_{(\theta^2,\theta^3)} \) are thus reduced to 4. Recalling that the whole partition function is multiplied by the inverse twist order this yields projectors for massless twisted states of the form (compare [14]):

\[ \frac{1}{4}(16 + 16\Delta_{\theta} + 16\Delta_{\theta^2} + 16\Delta_{\theta^3}) \]

\[ \frac{1}{4} \left( \frac{16}{\text{vol } \Lambda_N^\perp} + \frac{16}{\text{vol } \Lambda_N^\perp} \Delta_{\theta^2} + 4\Delta_{\theta} + 4\Delta_{\theta^3} \right) \]

\[ \frac{1}{4} (16 + 16\Delta_{\theta^3} + 16\Delta_{\theta} + 16\Delta_{\theta^3}) \]
where $\Delta = \pm 1$ for generations and antigenerations, respectively. As mentioned earlier the only difference to the corresponding projector in [14] is the appearance of the volume factors. It differs from one exactly in the cases where $\Lambda_N^\perp$ does not factorize trivially. For model 2 it is just given by a two-dimensional torus lattice and its dual. Being self-dual such a lattice transforms into itself under the Poisson resummation.

connected with the $S$ transformation and we conclude $\text{vol } \Lambda_N^K = 1$. Expressed in more formal terms for the torus lattice we have the relation

\[(\Lambda^K)^\perp = (\Lambda^K)^*\]  \tag{22}

The same is true for the first model of each $Z_N$ $(Z'_N)$ in table (3), respectively. The corresponding values $h_{(1,1)}$ and $h_{(1,2)}$ are the ones stated in the literature. In contrast, the other cases no longer satisfy (22) as will now be illustrated with help of model 4.

The $Z_4$-twist matrix and its dual in an $SU(4)$-lattice are

\[
\theta = \begin{pmatrix}
0 & 0 & -1 \\
1 & 0 & -1 \\
0 & 1 & -1
\end{pmatrix}, \quad \theta^* = \begin{pmatrix}
-1 & -1 & -1 \\
1 & 0 & 0 \\
0 & 1 & 0
\end{pmatrix}.
\]

(23)

In solving the equations

\[\theta^2 n = n, \quad \theta^{T-1^2} m = m,\]  \tag{24}

we find the fixed directions

\[(n_1, 0, n_1), \quad (m_1, -m_1, m_1).\]  \tag{25}

To find the volume factor of $\Lambda_N^K$ in this case, we consider one of the two scalar products in (3) or (4). It is convenient to take the latter one, since it does not depend on the background parameters. We just compute the quantity $2m^T n$ for the sublattices defined in (25) and normalize the result w.r.t. to a (self-dual) circle theory,

\[\text{vol } \Lambda_N^K = \frac{4 m_1^T n_1}{2 m_1^T n_1}.\]  \tag{26}

Since model 4 is a product of two $SU(4)$-lattices, we finally find a volume factor of four and we can read off from the projector in (20), that four generations and no antigeneration survive in the double twisted sector of this model. Comparing with model 2, where ten generations and six antigenerations survive the projection, we make two observations which in fact turn out to be general rules. First, the number of chiral generations is unchanged when considering different lattices but the same twist eigenvalues. This one indeed expects, since this number can be computed by a formula conjectured by Dixon, Harvey, Vafa and Witten [1] and proved by Markushevich, Olshanetsky and Perelomov [11], which only uses twist eigenvalues. Second, the total number of generations is lowered when one considers cases where formula (22) is no

\[17\text{The Poisson resummation formula reads}
\]

\[
\sum_{w \in \Lambda} \exp[-\pi(w + \epsilon)^T A(w + \epsilon) + 2\pi i \phi^T (w + \epsilon)] = \frac{1}{\text{vol } \Lambda \sqrt{\det A}} \sum_{p \in \Lambda^*} \exp[-\pi(p + \phi)^T A^{-1}(p + \phi) - 2\pi i \epsilon^T p],
\]

where $\epsilon$ and $\phi$ are constant vectors and $A$ is an invertible matrix.
longer fulfilled. For the projector of massive states the phase factor \(e^{2\pi i P_L - P_R^2} \in \mathbb{Z}_{(g^2, g^2)}^{int.}\) has to be taken into account in case of non-trivial instanton contributions.

The list of the basic degeneracy factors for all twist eigenvalue configurations can be found in [16]. Here, we give the volume factors \(V_i\) for all our models, where the subscript denotes the sector in which the fixed torus appears.

Table 4: Volume factors \(V_i\) for twist sectors with fixed tori.

| model | volume factors |
|-------|----------------|
| 1     | —              |
| 2     | \(V_2 = 1\)   |
| 3     | \(V_2 = 2\)   |
| 4     | \(V_2 = 4\)   |
| 5     | \(V_3 = 1\)   |
| 6     | \(V_3 = 4\)   |
| 7     | \(V_2 = 1\) \(V_3 = 1\) |
| 8     | \(V_2 = 1\) \(V_3 = 4\) |
| 9     | \(V_2 = 3\) \(V_3 = 1\) |
| 10    | \(V_2 = 3\) \(V_3 = 4\) |
| 11    | —              |
| 12    | \(V_4 = 1\)   |
| 13    | \(V_4 = 4\)   |
| 14    | \(V_2 = 1\) \(V_4 = 1\) |
| 15    | \(V_2 = 2\) \(V_4 = 2\) |
| 16    | \(V_3 = 1\) \(V_6 = 1\) |
| 17    | \(V_3 = 4\) \(V_6 = 4\) |
| 18    | \(V_2 = 1\) \(V_4 = 1\) \(V_6 = 1\) |

For the resulting generation numbers we refer to table 5.

4 Geometrical Resolution of the Orbifold Singularities

In this section we will calculate the Hodge numbers for the Calabi-Yau manifold which is constructed by resolving the orbifold singularities. As it was conjectured in [1] there exists a resolution \(\hat{T}/G\) of the toroidal orbifold \(T/G\) to a Calabi-Yau manifold, if the group action leave the holomorphic three form of the torus invariant. The prediction for the Euler number was extracted from the partition function [1] and stated in form of the famous orbifold formula

\[
\chi(\hat{T}/G) = \frac{1}{|G|} \sum_{\{g, h\}=0} \chi_{g,h},
\]

where the sum is taken over all commuting elements of the group and \(\chi_{g,h} = \chi(Fix(g) \cap Fix(h))\) is the Euler number of the intersection of the fixed sets under \(g\) and \(h\), respectively. For the special case of \(\mathbb{Z}_N\) actions the corresponding Calabi-Yau spaces were constructed explicitly [11, 12] confirming (27).
4.1 The fixed sets

In our examples we have only fixed points $P$ ($\chi(P) = 1$) and fixed tori $T$ ($\chi(T) = 0$). The application of (27) is simplified by the fact that $\chi_{g,h} = \chi(Fix(gh))$. Because $\chi(T) = 0$ the precise number of fixed tori in the higher sectors does not affect the Euler number. Using the numbers of fixed points which depend only on the eigenvalues of the twist matrix (cf. section 2 table 2) we see that $\chi = 72$ in the $Z_3$ case and $\chi = 48$ in all other cases.

In contrast to the Euler number the numbers of independent (1,1)-forms and (1,2)-forms in Hodge cohomology depend on the fixed tori and their intersection pattern and hence on the lattice. Let us illustrate this point with help of a series of examples, namely three $Z_6'$ models with twist exponents $\frac{1}{6}(1, 2, 3)$. As the first model we consider case 7 of table 5 which is equivalent to the Coxeter twist in the lattice $A_1 \times A_1 \times A_2 \times G_2$. An explicit twist matrix can be obtained by combining the irreducible blocks ($Z_2^{(1)}$, $Z_2^{(1)}$, $Z_6^{(2)}$, $Z_3^{(2)}$) specified by the vectors in table 3. This matrix has the following fixed sets in the first, second and third twist sector respectively:

$\theta$: 12 fixed points: $v_i \otimes (0,0) \otimes w_j$, $i = 1, 2, 3, 4$; $j = 1, 2, 3$
- $v_1 = (0,0)$, $v_2 = (\frac{1}{2}, 0)$, $v_3 = (0, \frac{1}{2})$, $v_4 = (\frac{1}{2}, \frac{1}{2})$;
- $w_1 = (0,0)$, $w_2 = (\frac{1}{3}, \frac{2}{3})$, $w_3 = (\frac{2}{3}, \frac{1}{3})$

$\theta^2$: 9 fixed tori: invariant subspace: $n_1 = (1, 0, 0, 0, 0, 0)$, $n_2 = (0, 1, 0, 0, 0, 0)$;
- $[m_1 = (1, 0, 0, 0, 0, 0), m_2 = (0, 1, 0, 0, 0, 0)]$
- basepoints: $(0,0) \otimes v_i \otimes w_j$, $i, j = 1, 2, 3$
  - $v_1 = (0,0)$, $v_2 = (\frac{1}{2}, \frac{1}{2})$, $v_3 = (\frac{2}{3}, \frac{2}{3})$;
  - $w_1 = (0,0)$, $w_2 = (\frac{1}{3}, \frac{2}{3})$, $w_3 = (\frac{2}{3}, \frac{1}{3})$

$\theta^3$: 16 fixed tori: invariant subspace: $n_1 = (0, 0, 1, 0, 0, 0)$, $n_2 = (0, 0, 0, 1, 0, 0)$;
- $[m_1 = (0, 0, 1, 0, 0, 0), m_2 = (0, 0, 0, 1, 0, 0)]$
- base points: $v_i \otimes (0,0) \otimes w_j$, $i, j = 1, 2, 3, 4$
  - $v_1 = (0,0)$, $v_2 = (\frac{1}{2}, 0)$, $v_3 = (0, \frac{1}{2})$, $v_4 = (\frac{1}{2}, \frac{1}{2})$

The vectors $n_i$ span an invariant subspace of the matrix $\theta^s$ from the given base points. These data define the corresponding fixed tori. The vectors $m_i$ span the invariant subspace of $(\theta^{T-1})^s$; their significance is explained below. Note that all base points given, lie in fact on different tori, as their only non vanishing entries are perpendicular to the $n_i$. The schematic view of the intersection pattern can be found in figure 1. Let us compare this situation with the one of case 8, which may be defined as the the Coxeter twist in the lattice $A_2 \times D_4$

$$\theta = \begin{pmatrix}
0 & -1 & 0 & 0 & 0 & 0 \\
1 & -1 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & -1 & -1 \\
0 & 0 & 1 & 1 & -1 & -1 \\
0 & 0 & 0 & 1 & -1 & 0 \\
0 & 0 & 0 & 1 & 0 & -1
\end{pmatrix} \quad (28)$$

This matrix and has the following fixed sets
\( \theta: \) 12 fixed points: \( v_i \otimes w_j, i = 1, 2, 3; j = 1, 2, 3, 4 \)
\[ v_1 = (0, 0), \quad v_2 = (\frac{1}{3}, \frac{2}{3}), \quad v_3 = (\frac{2}{3}, \frac{1}{3}) \]
\[ w_1 = (0, 0, 0, 0), \quad w_2 = (0, 0, \frac{1}{3}, \frac{2}{3}), \quad w_3 = (\frac{1}{3}, 0, 0, \frac{1}{3}), \quad w_4 = (\frac{1}{3}, 0, \frac{1}{3}, 0) \]

\( \theta^2: \) 3 fixed tori: invariant subspace: \( n_1 = (0, 0, 1, 0, 0, 1), \quad n_2 = (0, 0, 1, 0, 1, 0), \quad m_1 = (0, 0, 1, -1, 0, 1) \)
basepoints: \( v_i \otimes (0, 0, 0, 0), \quad i = 1, 2, 3 \)
\[ v_1 = (0, 0), \quad v_2 = (\frac{1}{3}, \frac{2}{3}), \quad v_3 = (\frac{2}{3}, \frac{1}{3}) \]

\( \theta^3: \) 16 fixed tori: invariant subspace: \( n_1 = (1, 0, 0, 0, 0, 0), \quad n_2 = (0, 1, 0, 0, 0, 0) \)
basepoints: \( (0, 0) \otimes v_i \otimes v_j, \quad i, j = 1, 2, 3, 4 \)
\[ v_1 = (0, 0), \quad v_2 = (\frac{1}{2}, 0), \quad v_3 = (0, \frac{1}{2}), \quad v_4 = (\frac{1}{2}, \frac{1}{2}) \]

This model was investigated in detail in [13], however here the author claims that there are 9 instead of 3 fixed tori in the second twisted sector and the conclusion about the massless spectrum is therefore not completely correct. The reason for the difference seems to be due to an improper use of the Lefschetz Fixed Point Theorem. In the second twist sector the exponents of \( \theta^2 \) are \( \frac{1}{3} (1, 2, 0) \), so that the coordinate plane \( \bar{I} \) spanned by \( z_3 \) ([10]), is fixed. In order to calculate the multiplicity of the corresponding fixed tori, the authors of [11, 13] apply now the Lefschetz Fixed Point Theorem ([7]) to the action of \( \theta^2 \) on the subspace \( \bar{J} \), spanned by the first and second coordinate plane. The result is \( n_F = \det(1 - \theta^2)|_\bar{J} = (1 - \exp[2\pi i / 3]^2 (1 - \exp[4\pi i / 3])^2 = 9 \). This is inadequate, because the splitting of \( \mathbb{R}^6 \) in \( \bar{I} \) and \( \bar{J} \) does not correspond to a splitting of the lattice \( \Lambda \) into sublattices on which \( \theta^2 \) acts as an automorphism. Let us pass to the lattice basis and denote the sublattice fixed w.r.t. to the lattice automorphism \( \theta^2 \) by \( I \). The Lefschetz Fixed Point Theorem could be utilized in the above sense, if there would be a sublattice \( \bar{J} \) invariant under \( \theta^2 \), which is complementary to \( I \), i.e. \( \Lambda = I \oplus \mathbb{Z} J \). This is not the case because \( \theta^2 \) has no block structure w.r.t. \( I \).

In the third twisted sector \( \theta^3 \) has block structure w.r.t. its invariant sublattice \( I \) so the reasoning of the authors [11, 13] yields the correct result. Similarly it applies to the second and third twisted sector of example 7.

Instead of calculating the fixed sets explicitly the Fixed Point Theorem can be modified by taking into account volume factors in the Poisson resumation formula which reduces the multiplicity of the twisted states as it was explained in the previous section. Let \( \Theta \) be the action of the twist in the Narain lattice labeled by \( (n, m) \) and \( I \) the invariant subspace in this lattice. The number of connected fixed sets is then given by [25]

\[ n_F = \sqrt{\frac{\det' (1 - \Theta)}{\text{Vol}_N[I]}}, \quad (29) \]

where the evaluation of \( \det' \) is defined by taking the product over the nonzero eigenvalues only. The volume is with respect to the Narain scalar product ([4]) and normalized such that the unit cell has volume 1. In order to cover also the case of fixed points we define \( \text{Vol}_N \) of any number of discrete points to be 1. In the cases at hand we have

\[ \Theta = \begin{pmatrix} \theta & 0 \\ 0 & \theta^{T-1} \end{pmatrix}. \]
Let \( m_i \) be the vectors which span the sublattice invariant under \( \theta^T^{-1} \). The formula (29) simplifies to
\[
n_F = \frac{\det'(1 - \theta)}{\det'(n_i^T m_j)}.
\]
e.g. for the \( \theta^2 \) sector of the case above we get indeed the reduction factor \( \det'(n_i^T m_j) = 3 \).
For the other volume factors see table 4.

As the last example in our series we consider the case 10 which can be realised as the Coxeter twist in \( A_1 \times A_5 \). Our canonical twist \( (Z_{2}^{(1)}, Z_{6}^{(0)}) \) has the following fixed sets (cf. figure 1)
\[
\theta: \quad 12 \text{ fixed points: } v_i \otimes w_j, \ i = 1, 2; j = 1, 2, 3, 4, 5, 6
\]
\[
v_1 = (0), \ v_2 = (\frac{1}{2})
\]
\[
w_1 = (0, 0, 0, 0, 0) \quad w_2 = \frac{1}{6}(1, 2, 3, 4, 5), \ w_3 = \frac{1}{6}(2, 4, 0, 2, 4),
\]
\[
w_4 = \frac{1}{6}(3, 0, 3, 0, 3), \ w_5 = \frac{1}{6}(4, 2, 0, 4, 2), \ w_6 = \frac{1}{6}(5, 4, 3, 2, 1)
\]
\[
\theta^2: \quad 3 \text{ fixed tori: } \text{invariant subspace: } n_1 = (0, 1, 0, 1, 0, 1), \ n_2 = (1, 0, 0, 0, 0, 0);
\]
\[
[m_1 = (0, 1, -1, 1, -1, 1), \ m_2 = (1, 0, 0, 0, 0, 0)]
\]
base points: \( (0, 0) \times v_i, \ i = 1, 2, 3 \)
\[
v_1 = (0, 0, 0, 0), \ v_2 = (\frac{1}{3}, \frac{1}{3}, \frac{1}{3}, \frac{1}{3}), \ v_3 = (\frac{1}{3}, \frac{1}{3}, \frac{1}{3}, \frac{1}{3})
\]
\[
\theta^3: \quad 4 \text{ fixed tori: } \text{invariant subspace: } n_1 = (0, 1, 0, 1, 0, 1), \ n_2 = (0, 0, 1, 0, 1);
\]
\[
[m_1 = (0, 1, 0, -1, 1, 0), \ m_2 = (0, 0, 1, -1, 0, 1)]
\]
base points: \( v_i \otimes w_j, \ i, j = 1, 2 \)
\[
v_1 = (0), \ v_2 = (\frac{1}{2})
\]
\[
w_1 = (0, 0, 0, 0, 0), \ w_2 = (\frac{1}{4}, \frac{1}{4}, \frac{1}{4}, \frac{1}{4})
\]

The fixed sets where e.g. calculated in the appendix of [22], however here the conclusion was again that there are 9 tori in the second twisted sector and 16 fixed tori in the third twisted sector. The authors have correctly calculated the vectors \( n_i \) of the invariant lattice, but as one can check, from the 9 (16) base points they give, groups of 3 (4) lie on the same torus, respectively.

### 4.2 Description of the desingularisations

Let us now count the numbers of (1,1)-form introduced by the resolutions of the fixed points and the fixed tori singularities. By Poincaré duality it is equivalent to count the irreducible components of the exceptional divisors, which are introduced by the resolution process. Below we review the necessary facts about the resolutions for the kind of singularities we encounter.

In the case of fixed tori we have singularities due to the action of a discrete \( Z_k \) subgroup of \( G \) on the \( \Theta^2 \) fibres of the bundle normal to the fixed tori \( T^2 \). This action can locally always be recasted in the form
\[
(z_1, z_2) \mapsto (\exp \frac{2\pi i q}{k} z_1, \exp \frac{2\pi i}{k} z_2)
\]
The singularity of \( \mathbb{C}^2/Z_k \) at the origin can be described by the constraint
\[
y^k = xz^{1-q},
\]
in \( \mathbb{C}^3 \), where in our cases we have always \( q = k - 1 \). The resolution of this type of singularity, known as the \textit{rational double point} of type \( A_{k-1} \), is given \cite{20} by a Hirzebruch-Jung sphere tree.

The number of spheres and their self intersection numbers \( -b_i \) in the resolved manifold can be obtained by an Euclidean algorithm \cite{20, 23}. In the cases at hand \cite{23} one gets a sequence of \( k - 1 \) projective spaces \( \mathbb{P}_1 \vee \ldots \vee \mathbb{P}_{k-1} \) joined in one point with self intersection numbers \( \mathbb{P}_i \cap \mathbb{P}_i = -2 \). The resolution replaces the fibers in the normal bundle over a \textit{generic point} on the fixed torus with a sphere tree. It introduces an \textit{exceptional divisor} of the form \( T \times (\mathbb{P}_1 \vee \ldots \vee \mathbb{P}_{k-1}) \).

The new \( h_{1,1} \) forms correspond to the number of irreducible components of these exceptional divisors, which is \( k - 1 \).

In the case of fixed points the singularities are locally of the form \( \mathbb{C}^3/G \). If \( G \) is abelian as in our examples \textit{toric geometry} is a suitable framework to describe \( \mathbb{C}^3/G \) singularities and their resolutions. In this sense it allows for a generalisation of the above treatment of the \( A_{k-1} \) singularities to higher dimensions. In order to avoid lengthy repetitions we refer to the book of Oda \cite{27} and the appendix of Markushevich in \cite{11} for the precise definitions and proofs of the properties of \textit{convex rational polyhedral cones}, \textit{fans} and \textit{toric varieties}.

Let \( N \simeq \mathbb{Z}^r \) be a lattice in an \( \mathbb{R} \) vector space \( V \), which is the completion of \( N \) over \( \mathbb{R} \), i.e. \( V = N \otimes \mathbb{R} \), and \( n_1, \ldots, n_s \) elements of \( N \). A \textit{strongly convex rational polyhedral cone} with apex at the origin \( O \) is defined as
\[
\tau := \mathbb{R}_0^+ n_1 + \ldots + \mathbb{R}_0^+ n_s = \{ a_1 n_1 + \ldots + a_s n_s | a_i \in \mathbb{R}_0^+ \},
\]
where \( \tau \cap (-\tau) = O \). Let \( n^{(1)}, \ldots, n^{(N)} \) be a set of generators of the \textit{semi group} \( S_\tau = (\tau \cap N) \), i.e. every lattice site in \( (\tau \cap N) \) can be reached by a linear combination of the \( n^{(i)} \) with positive integer coefficients and let
\[
\begin{align*}
a_{11} n^{(1)} + \ldots + a_{1N} n^{(N)} &= 0 \\
\cdots & \cdots \\
a_{t1} n^{(1)} + \ldots + a_{tN} n^{(N)} &= 0
\end{align*}
\]
be a maximal set of linear relations among the \( n^{(1)}, \ldots, n^{(N)} \) over \( \mathbb{Z} \). We can define from the above data an \textit{affine toric variety} \( X^{(V,N,\tau)} \) as follows
\[
X^{(V,N,\tau)} := \{ (z_1, \ldots, z_N) \in \mathbb{C}^N | F_i(z_1, \ldots, z_N) = 0, i = 1, \ldots, t \},
\]
where the \( F_i(z_1, \ldots, z_N) = 0 \) are \textit{monomial equations} of the form
\[
z_1^{a_{11}} \cdots z_N^{a_{1N}} = 1.
\]

\textsuperscript{19}The \( b_i \) correspond to a representation of \( k/q \) as continued fraction of the following form
\[
\frac{k}{q} = b_1 - \frac{1}{b_2 - \cdots - \frac{1}{b_s}}.
\]

\textsuperscript{20}The finite subgroups \( G \) of \( SU(2) \) fall into an \textit{ADE} classification. For this groups the intersection patterns of the spheres in the resolutions of the singularities \( \mathbb{C}^2/G \) correspond to the Dynkin diagrams, where points represent \( \mathbb{P} \)'s and links represent intersections, i.e. the intersection matrix equals the negative Cartan matrix.
**Example 1** \( N \simeq \mathbb{Z}^r \) is a lattice in \( \mathbb{R}^r \) spanned by \( n_i, i = 1, \ldots, r \). \( \tau = \mathbb{R}_0^+ n_1 + \ldots + \mathbb{R}_0^+ n_r = (\mathbb{R}_0^+)^r \). Then we have no relation of the type \((\ref{14})\) for the generators of the semi group so \( X^{(\mathbb{R}^r, N, \tau)} = \mathbb{Q}^r \).

**Example 2** Let \( N \simeq \mathbb{Z}^2 \) be a lattice and \( \tau = \mathbb{R}_0^+ (kn_1 - n_2) + \mathbb{R}_0^+ n_2 \). We have \( n^{(1)} = n_1 \), \( n^{(2)} = n_2 \) and \( n^{(3)} = (kn_1 - n_2) \) (compare figure 2 a.), so that \( X^{(\mathbb{R}^2, N, \tau)} = \{ (x, y, z) \in \mathbb{Q}^3 | x^k = yz \} \) is the rational double point of type \( A_{k-1} \) encountered above.

More generally \([11, 27]\)

**Example 3** Let \( G \) be a finite abelian group acting on \( \mathbb{Q}^r \). Elements \( g \in G \) of order \( k \) map \( (z_1, \ldots, z_r) \mapsto (\exp[\frac{2\pi i}{k} a_1] z_1, \ldots, \exp[\frac{2\pi i}{k} a_r] z_r) \). We have \( \mathbb{Q}^r / G = X^{(\mathbb{R}^n, N, \tau)} \), with \( \tau = (\mathbb{R}_0^+)^n \) and the lattice is defined as \( N = \bigcap_{g \in G} N_g \), where the lattice \( N_g \) is spanned by the minimal set of vectors \( n = (n^{(1)}, \ldots, n^{(r)}) \) with

\[ n^{(1)} a_1 + \ldots + n^{(r)} a_r \equiv 0 \text{ mod } k. \]

The constructive power of toric geometry lies in the fact that one can glue together affine toric varieties in a natural way. For this it is convenient to pass first to the dual cone. Denote by \( W = V^\vee \) the dual of \( V \) and by \( M \) the dual lattice to \( N \) w.r.t. the bilinear form

\[ \langle \cdot, \cdot \rangle : M \times N \to \mathbb{Z}. \]  

(37)

The dual cone \( \sigma = \tau^\vee \) is defined by

\[ \sigma := \{ x \in W | \langle x, y \rangle \geq 0, \ \forall y \in \tau \}. \]  

(38)

Defining

\[ X_\sigma = X_{(W,M,\sigma)} := X^{(V,N,\tau)} \]  

(39)

has the advantage that \( X_{\sigma \cap \sigma'} = X_\sigma \cap X_{\sigma'} \). This property, which does not hold for \( X^\tau = X^{(V,N,\tau)} \), allows to visualize gluing of toric varieties by gluing of cones. Faces \( \phi \) of a cone \( \sigma \) are subsets which are defined via an element of the dual cone \( n_0 \)

\[ \phi := \{ y \in \sigma | \langle y, n_0 \rangle = 0 \}. \]  

(40)

Faces of strongly convex rational cones are strongly convex rational cones. Fans \( \Delta \) are made by sticking together cones \( \sigma \) such that

1. Every face of any \( \sigma \) is in \( \Delta \).
2. Every intersection \( \sigma \cap \sigma' \) is a face of \( \sigma \) and \( \sigma' \).
Let now $X_{\sigma} = X^{(V,N,\tau)}$ and $X_{\sigma'} = X^{(V,N',\tau')}$ be affine varieties associated to cones $\sigma, \sigma' \in \Delta$ and $n^{(1)}, \ldots, n^{(N)}, n'^{(1)}, \ldots, n'^{(N)}$, generators of the semi groups $S_\sigma$ and $S_{\sigma'}$ respectively. The transition functions between affine coordinates $z_i$ and $z'_i$ are defined by the maximal set of linear relations $j = 1, \ldots, s$ between these generators

$$l_{1j} n^{(1)} + \ldots + l_{Nj} n^{(N)} + l'_{1j} n'^{(1)} + \ldots + l'_{Nj} n'^{(N)} = 0,$$

over $\mathbb{Z}$, as

$$z_1^{l_{1j}} \ldots \ldots z_m^{l_{Nj}} z_1^{l'_{1j}} \ldots \ldots z_m^{l'_{Nj}} = 1. \quad (41)$$

Using this transition functions one can associate to a fan $\Delta$ a general toric variety $X_\Delta := \bigcup_{\sigma \in \Delta} X_\sigma$.

**Example 4** Let $M \simeq \mathbb{Z}^2$ be lattice spanned by in $\mathbb{R}^2$. The fan $\Delta$ made by sticking together $\sigma_1 = R_0^+ m_1 + R_0^+ m_2$, $\sigma_2 = R_0^+ (-m_1 - m_2) + R_0^+ m_2$ and $\sigma_2 = R_0^+ (-m_1 - m_2) + R_0^+ m_1$ defines $X_\Delta = \mathbb{P}^2$. The affine planes ($\{ z_i \neq 0 \}$ in homogeneous coordinates) correspond to the $X_\sigma$.

Note that the fan above covers the whole two plane. As shown e.g. in Theorem 1.11. of [27] we have in general that $X_\Delta$ is compact if and only if $\Delta$ covers $W$.

Crucial for the resolution of singularities is the following

**Theorem 1** The toric variety $X_\Delta$ associated to a fan $\Delta$ in $M \simeq \mathbb{Z}^r$ is nonsingular if and only if each $\sigma \in \Delta$ is nonsingular in the following sense: $\exists$ a $\mathbb{Z}$ basis $\{ m_1, \ldots, m_r \}$ of $M$ such that $\sigma = R_0^+ m_1 + \ldots + R_0^+ m_s$. Such cones are called basic cones.

A proof can be found in [27]. If we consider the lattice $M = \mathbb{Z}^2$ and the cone $\sigma = R_0^+ m_1 + R_0^+ (k m_2 + m_2)$ with $N = M^\vee = M$ and $\tau = \sigma^\vee$ as in Example 2, one sees that one has to subdivide $\sigma$ into a fan of $k$ basic cones in order to meet the requirement of Theorem 1. The $k-1$ inner faces spanned by $\alpha_i$ by which this is achieved correspond to the $k-1$ exceptional $\mathbb{P}$ curves necessary to resolve the $A_{k-1}$ singularity, see figure 2 b.) below.

**Figure 2:** Resolution of the $A_{k-1}$ rational double point ($k=3$):
Theorem 2 Let $X_{W,M,\sigma}$ be a toric variety. Let $\sigma_i i = 1,\ldots,r$ a subdivision of $\sigma$ in the sense of Theorem 1. The canonical bundle of $X_\Delta = X_{W,M,\cup_{i=1}^r \sigma_i}$ is trivial if and only if the generators of $S_{\sigma_i}$ lie on a hyperplane $H_N$ in $W$.

Moreover the additional lattice vectors $\alpha_i$, which are needed to define the subdivision, can be associated in a one to one way to the compact divisors on $X_\Delta$.

Now consider the $\mathbb{Z}_k$ actions whose exponents, see table 2, are of the form $\frac{1}{k}(1,a_2,a_3)$ with $1 + a_2 + a_3 = 0 \mod k$. (42)

In accordance with Example 3 we define the lattices $N, M$ by

$$N = \langle n_1, n_2, n_3 \rangle \mathbb{Z} = \begin{pmatrix} k & -a_2 & -a_3 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \quad M = \langle m_1, m_2, m_3 \rangle \mathbb{Z} = \begin{pmatrix} \frac{1}{k} & 0 & 0 \\ \frac{a_2}{k} & 1 & 0 \\ \frac{a_3}{k} & 0 & 1 \end{pmatrix}. \quad (43)$$

The cone $\sigma = \langle e_1, e_2, e_3 \rangle_{\mathbb{R}_3^+}$ is spanned by an orthonormal vectors as:

$$e_1 \quad H_N \quad m_1 \quad e_3 = m_3 \quad e_2 = m_2$$

Due to (42) the lattice vector $m_1 = \alpha_1$ lies indeed on the hyper plane $H_N$. The other lattice vectors $\alpha_i = (\alpha_i^{(1)}, \alpha_i^{(2)}, \alpha_i^{(3)})$, which define the resolution according to Theorem 1 can be easily obtained as set of three tuples :

$$\{k(\alpha_i^{(1)}, \alpha_i^{(2)}, \alpha_i^{(3)}) = (j \mod k, ja_2 \mod k, ja_3 \mod k)\mid \sum_{l=1}^3 \alpha_i^{(l)} = k, j = 1, \ldots, k-1 \}. \quad (44)$$

We have drawn in figure 3 the trace of a resolving fan $X_\Delta$ in the hyper plane $H_N$ for the 9 different types of fixed point singularities. To obtain a Kählerian manifold we have also to make sure that the corresponding resolutions are projective algebraic. Indeed the necessary conditions given in II.2.3 of [27] are fulfilled.

The dots on the edges and in the interior of the the triangles $(e_1, e_2, e_3)$ correspond to $\alpha_i$ and hence to exceptional divisors of $X_\Delta$. In the case of non prime $k$ the fixed points of the $\mathbb{Z}_k$ actions lie always on a fixed torus. Note that the exceptional divisors associated to the points on the edges of the triangle coincide with the exceptional divisors present over the generic points of the fixed torus. From figures 1 and 3 we can easily count the exceptional divisors. E.g. consider the $\mathbb{Z}_{12}'$ case 18.), here we have two tori fixed under a group action of order three, each gives rise to a divisor $T \times (\mathbb{P} \vee \mathbb{P})$, i.e. we get 4 (1,1)-forms from that resolution.
The resolutions of three fixed tori of order two and one of order six add 3 and 5 (1,1)-forms, respectively. The four fixed points of order four on the $Z_2$ fixed torus are of type $\frac{1}{4}(1,1,2)$ and hence introduce 4 new exceptional divisors (cf. figure 3). Likewise the resolution of the four $Z'_2$ fixed points on the $Z_6$ torus give rise to 12 exceptional divisors according to the inner points in the trace of the last fan in figure 3.

A basis for the 9 (1,1)-forms of the complex torus is given by $dz_j \wedge d\bar{z}_j \ i, j = 1, 2, 3 \ (\text{II.6})$. From this we see that three (1,1)-forms are invariant if all twist exponents are different. If two(three) twist exponents are equal we have five(nine) invariant (1,1)-forms. Adding in the above example the three invariant (1,1)-forms from the torus we arrive $h_{1,1} = 31$ the number given in table 5. Similarly the reader might use figures 2 and 3 to count all (1,1)-forms of all other Coxeter orbifolds. As $\chi = 2(\chi_{1,1} - \chi_{2,1})$ for Calabi-Yau manifolds $h_{2,1}$ follows. Alternatively the additional (1,2)-forms can be obtained from the properties of the resolving spaces [27]. Concerning the Hodge numbers we disagree in eight of the twelve cases given in Table 1 of [11]. We agree with the Hodge numbers given in [12] for the prime cases $Z_3$ and $Z_7$.

While the location of the the $\alpha_i$ is fixed by the requirements of theorem 1 and 2, there is some freedom in the triangulisation which lead to the actual choice of the $\sigma_i$ and hence the resolving space. Namely, whenever there is a quadruple of points $\alpha_1, \ldots, \alpha_4$ in general position, the diagonal of the quadrangle can be flipped by an elementary transformation.

Given a triangulisation the triple intersection numbers of the irreducible hypersurfaces can be calculated [11]. Especially the intersection of three exceptional divisors can be obtained by a simple algebraic prescription [28]. Note that these numbers correspond to the Yukawa couplings in the large radius limit. They can be used to check the conformal field theory results for these couplings. The ambiguity in the triangulisation process leads to different couplings. This ambiguity seems to be hard in the sense that it cannot be removed by a field redefinition [13]. From the point of view of conformal field theory it might correspond to an ambiguity in taking the large radius limit in the orbifold moduli space.

5 Conclusions

We have investigated in a systematic way orbifolds with $(2,2)$ world sheet supersymmetry, which can be constructed, by modding out symmetric $Z_N$ actions from the six dimensional torus with vanishing discrete $B$-field. As a result we give a classification of these types of models. Preceding investigations [11, 14, 16, 22] in this direction have the drawback of being incomplete and more seriously of stating or using incorrect spectra. The source for the deviations is that properties of the twist, which are not directly related to the twist eigenvalues, were not taken into account properly. In the case of the $Z_4, Z_6, Z'_6, Z_8, Z'_8$ and $Z_{12}$ actions there exist, for the same twist eigenvalues, inequivalent automorphisms which are realised in different lattices. The complete reducibility of the twist over $\mathbb{C}$, which is used to define the complex planes in the space-time basis, is often confused with the reducibility of the twist over $\mathbb{Z}$, such that the authors erroneously imply that the twist can be made block diagonal in the lattice basis. Consequently their conclusions are only correct if this holds indeed, which is usually only for one of the above mentioned inequivalent automorphisms the case. Statements concerning the factorisation properties of the modular group, which have
been made in the same spirit, are also wrong in the general cases.

As the impact of the different lattices even on the spectrum was not fully understood, almost all conclusions about these non prime $Z_N$ orbifolds should be reconsidered. E.g. the couplings stated in [22] should be adapted to the correct spectrum etc.

Furthermore one should investigate how other phenomenological relevant properties such as the non perturbative potential for the moduli fields or the threshold corrections to the gauge couplings will change, when the different automorphisms with the same twist eigenvalues are considered.

Table 5: Hodge numbers of the 18 symmetric $Z_N$-orbifolds with $(2,2)$ world sheet supersymmetry and vanishing discrete $b_{\mu\nu}$-field. The corresponding twist eigenvalues are given in Table 2. The twist matrix is specified by the irreducible blocks which appear in Table 3. We also specify the Lie-algebra lattice where an equivalent twist can be realised as generalised Coxeter automorphism. If no automorphism is explicitly specified the twist is realised as ordinary Coxeter twist [19].
