Open-air oxidative Mizoroki–Heck reaction of arylsulfonfyl hydrazides with alkenes†

On Ying Yuen, Chau Ming So* and Fuk Yee Kwong*

A palladium(II)-catalyzed oxidative Mizoroki–Heck reaction of arylsulfonfyl hydrazides with alkenes was developed employing atmospheric air as the sole oxidant in an open-vessel manner. By using palladium(II) acetate associating with inexpensive, air-stable and moisture stable pyridine ligand L9 as the catalyst system, the efficiency of the reaction could be significantly enhanced. A wide range of arylsulfonfyl hydrazides underwent the oxidative Mizoroki–Heck reaction with alkenes smoothly. Good-to-excellent product yields and excellent regio- and stereoselectivity were achieved. Functional groups such as halo, ester etc. were well-tolerated under these optimized reaction conditions.

Introduction

The palladium-catalyzed Mizoroki–Heck reaction is one of the most powerful tools for incorporating a C–C double bond in organic synthesis1 and plays an important role in both synthetic laboratories and industrial applications.2 In the traditional Heck reaction, aryl halides act as electrophiles and couple with alkenes in the presence of palladium catalysts under basic conditions to produce higher substituted alkenes.3 Apart from aryl halides, aryl sulfonates,4 aryl diazonium salts,5 arylsulfonfyl halides,6 and arylerboxylic acid derivatives7 are also effective aryl sources in the Mizoroki–Heck type reactions.

The oxidative Heck reaction is also an excellent pathway to access substituted alkene products.8 The most striking difference between traditional Heck reaction and oxidative Heck reaction is the reaction mechanism. The former is that electrophiles act as self-oxidant for carrying out oxidative addition to palladium(0) species to form arylpalladium(II) intermediates. The latter is that extra oxidants such as oxygen or copper(II) salts are required to re-oxidize palladium(0) species to palladium(II) complexes. Aromatics,9 arylcarboxylic acids,10 aryboronic acid derivatives,11 arylyphosphonic acids,12 arylsulfonfyl acids13 and its sodium salts,14 arylhydrazines,15 carbazates16 and aroyl hydrazides17 were shown to effectively couple with alkenes in the oxidative reactions (Scheme 1).

Arylsulfonfyl hydrazides are recently rising electrophiles which are readily accessible solids, stable in air and moisture conditions and can be easily prepared in one step from arylsulfonfyl chlorides and hydrazine hydrates.18 Particular noteworthy is that they can serve as arylating agents, which are subjected to denitrogenation and desulfitation to generate the aryl source for the oxidative palladium-catalyzed coupling reactions.19 Oxidative Heck reaction,19a oxidative direct arylation of heteroarenes,19b,d oxidative conjugate addition reaction,19e oxidative homo-coupling reaction,19f oxidative Suzuki reaction19g and oxidative Hiyama reaction19h have been reported.

Currently, most of these reactions are using excess amount of Cu(OAc)2 or pure oxygen as oxidant. We envision that the use of the atmospheric air in open-vessel manner is one of the most attractive protocols for the oxidative Heck reaction because of the following advantages: (1) avoid the handling of dangerous and hazardous pressurized gas tube, (2) allow to release the extra gaseous pressure generates from denitrogenation (N2) and desulfitation (SO2) of arylsulfonfyl hydrazides under high temperature, (3) can provide a constant oxygen concentration over the whole reaction period which may maximize the utility of this technology for genuine applications. However, in general, only inferior yields were obtained when air is used as the reaction atmosphere especially for the Heck-type

a Reaction condition: 4-methylbenzenesulfonyl hydrazide (0.45 mmol), styrene (0.3 mmol), Pd source (10 mol%) and solvent (3.0 mL) were stirred at 90 °C for 16 h under air. b Calibrated GC yields were reported using dodecane as internal standard.

Results and discussion

In order to test the feasibility of palladium-catalyzed oxidative Mizoroki–Heck reaction of arylsulfonyl hydrazides with alkenes, a series of screenings was conducted (Table 1). 4-Methylbenzenesulfonyl hydrazide and styrene were used as the benchmark substrates. In surveying of common solvents, DMF gave the best result (Table 1, entry 2 and entries 1–11). The initial screening of palladium sources (Table 1, entries 12–18) indicated that Pd(OAc)2 was the suitable Pd source for this coupling reaction.

After the detailed optimization of solvents and Pd sources, we still found that the product yield was unsatisfactory. Inspired by the poor result of Pd(OAc)2/DMSO system which is one of the well-known catalyst systems for the palladium-catalyzed oxidative reactions and also analogy to the aerobic alcohol oxidation reaction and oxidative amination of olefins reaction, we were intrigued that the inferior yield may result from the slow aerobic oxidation of Pd(0) species to Pd(n), especially under air atmosphere which is low oxygen concentration. Pd(0) species easily aggregate and agglomerate to unreactive palladium black and retard the coupling catalysis in the ligand-free Heck reactions. Oxidatively stable ligands have been identified to enhance the rate of Pd(0) oxidation particularly with respect to competing Pd(0) aggregation so as to promote catalyst turnover, improve catalyst stability and increases regio- and stereoselectivity of the reaction.

Herein, we attempted to advance this oxidative Heck reaction by using atmospheric air in open air manner.

The reaction was conducted at 90 °C.

In order to have a better understanding of the effect of pyridine ligand towards the reaction rate of palladium-catalyzed oxidative Mizoroki–Heck reaction, 4-methylbenzenesulfonyl hydrazide and styrene were selected as substrates for kinetic studies. Two sets of parallel experiment in the presence of L9 and absence of L9 were conducted which was represented by blue line and red line in Scheme 2 respectively. The reaction rates in both cases were essentially the same within the first 30 min, which indicated the reaction rate was not obviously promoted by the presence of L9. At 45 min, on the wall of the reaction tube, a small amount of palladium black was observed in the absence of L9 while palladium black was not observed in the presence of L9. In the absence of the L9, the reaction rate decreased more significantly at 90 min and the reaction rate became steady after 180 min. In contrast, in the presence of L9, the reaction rate decreased relatively slower in the first 120 min and the reaction rate became steady after 240 min. Furthermore, in the presence of the L9, a higher turnover number could be obtained within the same reaction period. This kinetic result implied that the coordination of the pyridine ligand to the Pd center may reduce the possibility of the formation of inactive Pd black so that the reaction can be promoted by a higher concentration of the active Pd species during the course of the reaction.

A proposed catalytic cycle, as adapted from the mechanistic studies performed on the Pd-catalyzed coupling reactions of arylsulfonyl hydrazides and Pd(OAc)$_2$/pyridine oxidation reaction mechanism, is shown in Scheme 3.$^{18,20}$ The coordination of the pyridine ligand to Pd(OAc)$_2$ generate complex I which is subsequently converted to complex II and HOAc by deprotonation with arylsulfonyl hydrazide. Complex II undergoes β-hydride elimination to give complex III and sulfonyl diazene. Displacement of complex I with sulfonyl diazene gives complex IV. Liberation of N$_2$ with complex IV provides the complex V, and successive extrusion of SO$_2$ affords complex VI. The coordination of alkene to complex VI followed by alkene insertion generates complex VII. Complex VII undergoes β-hydride elimination to generate complex III. Reductive elimination of complex III generates complex VIII, and the complex I is regenerated by oxidation.
Conclusions

In summary, we have reported the first examples of oxidative Mizoroki–Heck reaction of arylsulfonyl hydrazides with alkenes in an open-air manner using the stable and inexpensive pyridine ligand L9. The Pd(OAc)₂/L9 catalyst system was effective for the coupling of a wide range of arylsulfonyl hydrazides and alkenes. It was noteworthy that the reaction was conducted under atmospheric air. The preliminary kinetic study result showed that pyridine ligand L9 may reduce the Pd(0) aggregation so as to promote catalyst turnover. We expect this convenient synthetic method will be useful in the organic synthesis.

Experimental section

General procedure for the oxidative heck reaction of arylsulfonyl hydrazides with alkenes

All reagents were weighted in air and the reactions were performed in an open vessel. Pd(OAc)₂ (0.0068 g, 0.03 mmol) and phenyl isonicotinate (Pd : L = 1 : 2) were loaded into a 40 mL vial equipped with a Teflon-coated magnetic stir bar. Precomplexation was applied by adding DMF (1 mL) in to the vial. The palladium complex stock solution was stirred for 10 minutes. Arylsulfonyl hydrazide (0.45 mmol) and alkenes (0.3 mmol) were loaded into the vial. DMF (2 mL) was added with continuous stirring at room temperature. The vial was fitted with an air condenser as cooler and then placed into a preheated oil bath which the temperature was indicated in the table and vigorously stirred for 16 h. After the completion of reaction, the reaction vial was allowed to cool at room temperature. Ethyl acetate (~10 mL) was added. The organic layer was subjected to GC analysis. After analyzing GC spectra, the crude product in the organic layer was extracted and the vial was washed with ethyl acetate. The filtrate was concentrated under reduced pressure. The crude product was purified by flash column chromatography on silica gel (230–400 mesh) to afford the desired product.

Only poor to fair yields could be observed when non-terminal and aliphatic alkenes were used as substrates in this oxidative Heck reaction. The isolation of the desired products from the complicated reaction mixtures containing the homo-coupling by-products and the regioisomers were unsuccessful.
