Effects of diets with whole plant-origin proteins added with different ratios of taurine:methionine on the growth, macrophage activity and antioxidant capacity of rainbow trout (Oncorhynchus mykiss) fingerlings

Omar Ezequiel Aguillón Hernández, Luis Héctor Hernández Hernández, Armando Shimada Miyasaka, Mario Garduño Lugo

ABSTRACT

A 70-days feeding trial was performed to determine the effect of diets with whole plant-origin proteins added with different ratios of taurine:methionine on the growth, macrophage burst activity and antioxidant capacity of rainbow trout (Oncorhynchus mykiss) fingerlings. Triplicated groups of 70 fingerlings of an initial weight of 0.54 ± 0.1 g (mean ± ± SD) were fed diets with soy protein isolate and Spirulina powder as protein sources (46% crude protein) and added (10 g/kg diet) with different taurine and methionine ratios: 0.0 and 10.0 (diet T100/M0), 2.5 and 7.5 (diet T25/M75), 5.0 and 5.0 (diet T50/M50), 7.5 and 2.5 (diet T75/M25) and 10.0 and 0.0 (diet T100/M0), respectively. At the end of the trial, growth performance, lipid and protein contents in liver and muscle, macrophage burst activity and liver antioxidant activity, were determined. The growth performance, macrophage burst activity and antioxidant activity were improved as the taurine increased in the diets. The ratio of 7.5 and 2.5 g/kg of taurine:methionine in diets with SPI and Spirulina powder as protein sources (diet T75/M25), seems to be the best inclusion for rainbow trout fingerlings.

1. Introduction

The rapid growth of the aquaculture during the last 20 years has been accompanied by an increasing demand for aquafeeds (Gatlin et al., 2007). Fishmeal is still the main source of protein in commercial diets and with no expectations to increase the production beyond the current levels (Tacon & Metian, 2008). Plant-origin meals are pointed out as an alternative to fishmeal and particularly, the protein concentrates from whole plant proteins will exceed the supply in the near future (Hardy, 1996). The demand for fishmeal will exceed the supply in the next few years (Tacon & Metian, 2008). Plant-origin meals are pointed out as an alternative to fishmeal and particularly, the protein concentrates from whole plant proteins will exceed the supply in the near future. The growth and well-being of fish (Bañuelos-Vargas, López, Pérez-Jiménez & Peres, 2014).

Methionine is a sulfur-containing amino acid and it has several metabolic roles, such as being a precursor in the protein synthesis, production of S-adenosylmethionine (SAM), L-cystein, glutathione, taurine, phosphatidylcholine and other phospholipids. On the other hand, taurine is a non-proteic amino acid (2-aminoethanosulfonic acid), which is involved in several physiological processes: bile acid conjugation, osmoregulation and membrane stabilization and antioxidant activity (Divakaran, 2006; Salze & Davis, 2015). The taurine biosynthesis starts with the methionine conversion to cysteine, which is oxidized to cysteine sulfonic acid mediated by cysteine dioxygenase (CDO), then a decarboxylation to hypotaurine mediated by the cysteine sulfonate decarboxylase (CDS) and a final step of oxidation to taurine (Salze & Davis, 2015; Wang, He, Mai, Xu & Zhou, 2015). The taurine...
biosynthesis from methionine, has been detected in the rainbow trout (Oncorhynchus mykiss) (Yokoyama, Takeuchi, Park & Nakazoe, 2001); but, it seems not to occur at adequate levels when plant proteins sources are used to substitute fish meal (Boonyoung, Haga & Satoh, 2013; Gaylord, Teague & Barrows, 2006) and might be a conditionally indispensable amino acid (Takeuchi, Park, Seiki & Yokoyama, 2001). It has been reported that inclusion of taurine to diets with plant-origin protein sources improved the growth of rainbow trout (Gaylord et al., 2006). Gaylord et al. (2007) found that supplement diets with three levels of taurine and/or three levels of DL-methionine to diets with soy protein concentrate fed to rainbow trout juvenile showed an improved of growth performance and that methionine supplementation above the requirement did not influence spare taurine. Boonyoung et al. (2013) reported a that methionine hydroxy-analog might be converted to taurine and improve the growth of rainbow trout fingerlings when fed a diet with soy protein concentrate. So far, there is no information available about the inclusion of methionine and/or taurine in diets with soy protein isolate. In addition to these, the importance of methionine as a precursor of taurine, the role of the latter in the immune and antioxidant activity, as well the necessity to include them in diets with plant-origin proteins, the aims of the present work is to determine the effect of diet with soy protein isolate and Spirulina powder as protein sources added with different ratios of taurine: methionine on the growth, macrophage burst activity and antioxidant capacity of rainbow trout (Oncorhynchus mykiss) fingerlings.

2. Materials and methods

2.1. Experimental diets

A basal diet was formulated with a minimum content of 45% of crude protein and 10% of lipids to cover the requirements previously reported for the species (NRC, 2011). Fishmeal was substituted at 100% with a mixture of soy protein isolate (SPI, crude protein 90 ± 1%, Pronaquim, S.A. de C.V., Mexico) and soybean lecithin (Abastecedora de Productos Naturales, S.A. de C.V., México) and wheat gluten (Sigma Aldrich Co., USA) as carbohydrate source. A mixture of vitamins and minerals (Micro Rovimix for carnivorous fish, DSM Nutritional Products of Mexico, Mexico) and wheat gluten (Sigma Aldrich Co., USA) were used. Diets were prepared according to Cruz, Hernández, Fernández, Ramírez and Angeles (2011) by mixing all the powered ingredients for a period of 20 min and then, the oils and purified water (40%) were added and mixed again for another 20 min. The resulting wet dough was passed through a meat chopper to obtain 5-mm diameter pellets, which were dried at 60 °C in a constant temperature oven for 60 min and then, store at −24 °C until used.

2.2. Experimental fish

Eyed eggs of rainbow trout (Oncorhynchus mykiss) were obtained from the “Centro Acuícola de Calimaya” (municipality of Calimaya, State of Mexico, Mexico) and translated to the farm “Los Alevines” (municipality of Amalanco de Becerra, State of Mexico, Mexico) and incubated there. After reabsorbing the egg yolk, fingerlings were fed on a commercial diet (Api-trucha-1, crumble, 50% protein and 15% lipid, Malta-Cleyton de Mexico) until the beginning of the feeding trial.

2.3. Feeding trial

The feeding experiment was conducted in 24 glass-fiber tanks of 1000 L. Seventy fingerlings of an initial weight of 0.54 ± 0.1 g (mean ± standard deviation) were randomly stocked in each tank. Each test diet was fed to triplicate groups of fingerlings. Fish were fed the respective diet at 7% of their body weight and the daily ration size was adjusted accordingly. Water parameters (mean ± SD) were: dissolved oxygen 4.5 ± 1.0 mg/L, pH 7.2 ± 0.5 and water temperature of 13 ± 1 °C. Water flow in each tank was of 5 L/min during the entire experiment. All tanks were maintained under natural photoperiod, which was of 11 h light, 13 h dark during March and April. The feeding trail using the diets was conducted for a period of 70 days. At the end of the feeding experiment, fish were maintained un-fed for 24 h. To obtain the growth performance, they were weighed and measured for total length. Five organisms form each were sacrificed with an overdose (300 mg/L, Popovic et al., 2012) of MS-222 (ethyl 3-aminobenzoate, methanesulfonic acid, Sigma Aldrich Comp., USA) and were dissected to obtain the samples of liver and muscle for the lipid and protein contents analysis. As well, another 5 fingerlings for each tank were sacrificed as previously described and the kidneys were dissected asepctically and put into sterile test tubes containing 5 ml Leibovitz L-15 medium (Sigma Aldrich Co., USA) supplemented with 0.1% fetal bovine serum (FBS, Biovest SAS, France) (Burrells, Williams, Southgate & Crampton, 1999). Then, the liver was also dissected and put into sterile plastic tubes and frozen on liquid N2. All samples were transported to the Laboratorio de Producción Acuícola, Facultad de Estudios Superiores Iztacala, UNAM, where the analysis were performed.

2.4. Chemical analysis

The contents of protein and lipid in the diets, muscle and liver were determined with the technique reported by AOAC (1990) and the Blight

| Table 1 Basal formulation of the test diets fed to fingerlings of rainbow trout. |
|------------------------|--------|------------------------|------------------------|------------------------|------------------------|------------------------|------------------------|------------------------|------------------------|

Different ratios of the taurine and methionine was added at the expense of 10 g of the α-cellulose.
and Dyer (1959) of chloroform and methanol extraction, respectively. The amino acid profile of the basal diet was performed in triplicate by Evonik Mexico S.A de C.V., by using a HPLC, after a protein digestion.

2.5. Macrophage burst activity

The isolation and culture of the kidney macrophages was after Chung and Secombes (1988) and Secombes (1990). The macrophage superoxide anion activity (respiratory burst) of the macrophages was determined by the reduction of the redox dye nitro-blue tetrazolium (NBT) by using a Sunrise microplate reader (Tecan Group Ltd., Switzerland) at a wavelength of 620 nm (OD_{620}). Later, the macrophage number in each well was determined. Results are expressed as OD_{620} per 10^5 cells.

2.6. Hepatocyte antioxidant capacity

Livers were homogenized in cold (4 °C) phosphate-buffered saline solution (Sigma Aldrich Comp., USA). Samples were centrifuged for 10 min at 14,000 rpm and 20 μl of the supernatant were used. The antioxidant capacity was measured after Cao, Alessio, and Cutler (1993) by using a Quantichrom antioxidant assay kit (BioAssay Systems, USA) and optical density was determined with a Sunrise microplate reader (Tecan Group Ltd., Switzerland) at a wavelength of 570 nm. Results are expressed as μM Trolox equivalents per mg per ml.

2.7. Statistical analysis

Data on final body weight (FW), weight gain (WG), specific growth rate (SGR), feed intake (FI), total length (TL), condition factor (K), survival, contents of lipid and protein in muscle and liver, macrophage burst activity and hepatocyte antioxidant capacity were tested for normality with the Shapiro and Wilk W tests and the Barletts’s test, respectively. Since all data showed to be normal and homocedastic, a one-way ANOVA test was used (Prism for Mac, Graph Pad Software Inc., USA). Significant differences among the treatments were determined by a Fisher LSD test (Zar, 1999), with a significance level of 5% (p < 0.05) for each set of comparisons.

3. Results

Means of final body weight (FW), weight gain (WG), specific growth rate (SGR), total length (TL) and condition factor (K) are show in Table 3. There was a trend in which FW, WG and SGR increased with the increasing level of taurine. These indices increased until the treatment T75/M25, beyond which they decreased significantly. The WG and SGR were the lowest in treatments T100/M0 and T0/M0. No significant differences were observed among the fingerling fed diet T75/M25 and the commercial diet. Regarding TL, a significantly lower value was observed in the fingerlings fed the diet T100/M0. The K values were not significantly different among the treatments. Survival rates were higher than 95% in all the groups and no significant differences were observed among the treatments. Survival rates of all the groups was higher than 95% and no significant differences were observed among the groups (T100/M0, 100%; T75/M25 100%; T50/M50, 95 ± 7%; T25/M75, 98 ± 3%; T0/M100, 97 ± 4%; T0/M0, 100%; Comm, 95 ± 7%).

Lipid contents in the liver (Fig. 1A) were significantly lower in the fish fed the diets with the inclusion of taurine and/or methionine than those observed in the fish fed diets T0/M0 and commercial diet. Regarding the lipid contents in muscle (Fig. 1B), a tendency to lower values was observed as the methionine level decreased in the diet, but significant differences were only observed between fish fed the diets T25/M75 and those fed T50/M50 and T75/M25.

The Fig. 2A shows the protein content in liver and a tendency of decreasing values was observed as the methionine concentration lowered in the diets. The lowest value was observed in the fish fed the commercial diet. Muscle protein content (Fig. 2B) did not show significant differences among the treatments.

The antioxidant capacity of hepatocytes is show in Fig. 3 and a trend of increasing values was observed as the taurine concentration increase in the diets. The highest value among the experimental diets was observed in the fish fed the diet T75/M25. Significant higher value was observed in the fish fed the commercial diet when compared with the diets with the other diets, except for that observed in T75/M25.

There was a tendency of increased values of the macrophage burst activity with the increment of taurine in the diets (Fig. 4). The burst activity of the fish fed the diet T100/M0 was significantly higher than the other groups, including the fish fed the commercial diet.

4. Discussion

For the first time, here is reported the effect of different ratios of methionine:taurine included in diets with SPI and SP as the main sources of protein in rainbow trout of such small size (0.54 g of initial weight). According to our results, an inclusion of 10 g/kg diet at the ratio of 7.5:2.5 taurine-methionine improved the growth performance and the antioxidant activity in liver, while decreasing the lipid content in the liver. The SPI is considered a good protein source for fish (Glencross et al., 2005), but lacks certain nutrients that are conditionally indispensable when used as a protein sources in formulated diets (Takeuchi et al., 2001).

Inclusion of methionine (Espe, Hervroy, Liaset, Lemme & El-Mowafi,
2008; Mambrini, Roem, Cardevi, Lalles & Kaushik, 1999) to all-plant protein diets has been previously reported to improve the growth performance in rainbow trout. Interestingly, we observed lower values of growth performance in the fingerlings fed the diet T0/M100. Previously, the NRC (2011) reported that methionine is the most toxic of the primary amino acids, and the concentration of 10 g/kg might be toxic at some level for the fingerlings.

The inclusion of taurine has been reported (Gaylord et al., 2006, 2007) to improve the growth of fish when fed plant-protein based diets. We could see increasing values of FW, WG and SGR as the taurine increased in the diet. The role of taurine in the growth is still not clear, but according to Salze and Davis (2015), it seems to stimulate some enzymes related to the intermediary metabolism (amino acid catabolism and gluconeogenesis) and increasing the nutrient utilization (Bañuelos-Vargas et al., 2014). The inclusion of 10 g/kg of taurine (diet T100/M0) decreased significantly the growth performance of the fingerlings, which indicates that even a small quantity of methionine should be added to diets with all plant-origin proteins, which has been previously reported in rainbow trout (Boonyoung et al., 2013) and Atlantic salmon, Salmo salar (Espe et al., 2008).

Contents of lipids in liver were lower than those reported by Enriquez, Ramirez, Hernandez, and Fernandez (2015) in the rainbow trout fingerlings fed diets with soybean meal or soy protein concentrate. The inclusion of taurine and/or methionine did influence the lipid deposition in the liver, as significantly lower values of lipid content were observed when fish were fed the experimental diets. Previously, the inclusion of taurine has been reported to be related to a decrease in lipid deposition in liver of Atlantic salmon (Espe, Ruohonen & El-Mowafi, 2012) and dentex, Dentex dentex (Chatzifotis, Polemitou, Divanaach & Antonopoulou, 2008). The hypolipidemic effect of taurine seems to be related to an increased formation of bile acid synthesis (Russell, 2003) and a consequent synthesis of bile salt activated lipase (Chatzifotis et al., 2008). Still, more information is necessary to draw a conclusion on this. In the other hand, the inclusion of taurine and/or methionine did not have an effect on the lipid deposition in muscle, as previously reported for Chatzifotis et al. (2008). As for the lipid content, the protein content did not show significant difference in muscle. However, the inclusion of taurine and methionine did influence protein deposition in the liver, as the levels of taurine increased, a tendency.

Fig. 1. Lipid content (% wet basis) in liver (A) and muscle (B) of rainbow trout fingerlings fed diets with soy protein isolate and Spirulina powder as protein sources and the addition of different ratios of taurine:methionine. The bars represent the mean of three replicate groups ± standard error. Bars with different letters differ significantly (P < 0.05).

Fig. 2. Crude protein contents (% on wet basis) of liver (A) and muscle (B) of rainbow trout fingerlings fed diets with soy protein isolate and Spirulina powder as protein sources and the addition of different ratios of taurine:methionine. The bars represent the mean of three replicate groups ± standard error. Bars with different letters differ significantly (P < 0.05).
have a similar role (Takagi et al., 2006).

On the other hand, the macrophage burst activity improved as the taurine increased in the diet. The macrophages possess a variety of action mechanisms, but one of the most important is the oxygen-dependent respiratory burst which forms reactive oxygen species such as superoxide anion, hydrogen peroxide and hypochlorous acid (Rubio-Godoy, 2010), particularly with the latter one, which forms the long-lived taurine chloramine (Schulke-Levis & Park, 2004) which might be helping in the responses of the macrophages burst (Salze & Davis, 2015). In mammals, taurine has been pointed out as a potent regulator of immune responses and the present results might indicate immunoregulatory proprieties for rainbow trout, as well (Salze & Davis, 2015).

In conclusion, the ratio of 7.5 and 2.5 g/kg of taurine:methionine in diets with soy protein isolated and Spirulina powder as protein sources (diet T75/M25), did improve the growth and the antioxidant capacity of the liver in rainbow trout fingerlings. As well, the 10 g/kg inclusion of just taurine or methionine affects negatively the growth as much as not inclusion at all in plant protein based-diets. Even if the effects of the inclusion of taurine and methionine are clear, we still need to address research to understand better the modes of action.
