Abstract

It has been shown that non-Abelian solitonic vortex strings supported in four-dimensional (4D) $\mathcal{N} = 2$ supersymmetric QCD (SQCD) with the $U(N = 2)$ gauge group and $N_f = 4$ quark flavors behave as critical superstrings. In addition to four translational moduli non-Abelian strings under consideration carry six orientational and size moduli. Together they form a ten-dimensional space required for a superstring to be critical. The target space of the string sigma model is a product of the flat four-dimensional space $\mathbb{R}^4$ and a Calabi-Yau non-compact threefold $Y_6$, namely, the conifold. The spectrum of low lying closed string states in the associated type IIA string theory was found and interpreted as a spectrum of hadrons in 4D $\mathcal{N} = 2$ SQCD. In particular, the lowest string state appears to be a massless BPS baryon associated with the deformation of the complex structure modulus $b$ of the conifold. Here we address a problem of switching on quark masses in 4D SQCD, which classically breaks the world sheet conformal invariance in the string sigma model. To avoid this problem we follow a standard string theory approach and use a flux ”compactification” to lift the complex structure modulus of the conifold. Namely, we find a solution of supergravity equations of motion with non-zero NS 3-form flux. It produces a potential for the baryon $b$, which leads to the run-away vacuum. Using field theory arguments we interpret 3-form flux in terms of a particular choice of quark masses in 4D SQCD. At the run-away vacuum the conifold degenerates to lower dimensions. We interpret this as a flow from a non-Abelian string to an Abelian one.
1 Introduction

It was shown in [1] that the non-Abelian solitonic vortex string in 4D $\mathcal{N} = 2$ supersymmetric QCD (SQCD) with the U(N=2) gauge group and $N_f = 4$ flavors of quark hypermultiplets becomes a critical superstring. Non-Abelian vortices were first found in $\mathcal{N} = 2$ SQCD with the gauge group U($N$) and $N_f \geq N$ flavors of quarks [2, 3, 4, 5]. The non-Abelian vortex string is 1/2 BPS saturated and, therefore, has $\mathcal{N} = (2, 2)$ supersymmetry on its world sheet. In addition to four translational moduli characteristic of the Abrikosov-Nielsen-Olesen (ANO) strings [6], the non-Abelian string carries orientational moduli, as well as the size moduli if $N_f > N$ [2, 3, 4, 5] (see [7, 8, 9, 10] for reviews). Their dynamics are described by the effective two-dimensional (2D) sigma model on the string world sheet with the target space

$$\mathcal{O}(-1)^{\oplus(N_f-N)}_{\text{CP}^1},$$

(1.1)

to which we will refer to as to the weighted CP model ($\mathbb{WCP}(N,N_f-N)$).

For $N_f = 2N$ the world sheet sigma model becomes conformal. Moreover, for $N = 2$ the number of the orientational/size moduli is six and they can be combined with four translational moduli to form a ten-dimensional (10D) space required for a superstring to become critical [1, 11]. In this case the target space of the world sheet 2D theory on the non-Abelian vortex string is $\mathbb{R}^4 \times Y_6$, where $Y_6$ is a non-compact six dimensional Calabi-Yau (CY) manifold, the conifold [12, 13].

Non-Abelian vortices in U($N$) theories are topologically stable and cannot be broken. In particular, monopoles confined by the non-Abelian string are junctions of two strings with different orientations rather than string endpoints, see review [9]. Therefore the finite-length strings are closed.

Thus, we focus on the closed strings and consider CY "compactification" (Kaluza-Klein reduction) of 10D string theory associated with the non-Abelian vortex to 4D on the conifold $Y_6$ [1]. The goal is to identify the closed string states with the hadrons of 4D $\mathcal{N} = 2$ SQCD. The vortex string theory at hand was identified as the type IIA string theory [11].

The first step of this program, namely, identifying massless string states was carried out in [11, 14] using supergravity approximation. It turns out that most of massless modes have non-normalizable wave functions over the

\footnote{Here and below we use the term "compactification" in quotation marks because the conifold is a non-compact CY space.}
non-compact conifold $Y_6$, i.e. they are not localized in 4D and, hence, cannot be interpreted as dynamical states in 4D SQCD. In particular, the 4D graviton and unwanted vector multiplet associated with deformations of the Kähler form of the conifold are absent. However, a single massless BPS hypermultiplet was found at the self-dual point at strong coupling. It is associated with deformations of a complex structure of the conifold and was interpreted as a composite 4D baryon $b_2^2$.

Later low lying massive non-BPS 4D states were found in [15, 16] using the little string theory approach, see [17] for a review.

In this paper we consider 4D $\mathcal{N} = 2$ SQCD with non-zero quark masses. Quark masses are the only deformations of the 4D SQCD with given gauge and flavor groups allowed by $\mathcal{N} = 2$ supersymmetry, which do not involve higher derivative operators. It is interesting to study the string theory response to these deformations. However, making quarks massive lifts some of orientational and size moduli of the non-Abelian string. Generically, this breaks the conformal invariance of the world sheet $\mathcal{WCP}(2,2)$ model (at least classically) preventing the formulation of the string theory in this case. This problem is puzzling because from the standpoint of 4D SQCD switching on quark masses is physically the most natural deformation one can consider.

To overcome this difficulty instead of attempting to interpret mass terms for orientational/size moduli in $\mathcal{WCP}(2,2)$ model in terms of 10D supergravity we propose from very beginning to use a flux "compactification" to describe 4D quark masses in the string theory framework. The motivation is that fluxes generically induce a potential for CY moduli lifting flat directions, see, for example, [18] for a review. On the other hand, in 4D theory we expect that quark masses also induce a potential for the massless baryon $b$ associated with the conifold complex structure modulus. In particular, we know that it acquires the mass

$$m_b = |m_1 + m_2 - m_3 - m_4|$$

(1.2)

at non-zero $m_A$ dictated for a BPS state by its baryonic charge [19], where $m_A, A = 1, ..., 4$ are quark masses. Thus, we expect that fluxes in 10D supergravity can be interpreted in terms of quark masses of 4D SQCD.

Generically, fluxes modify the metric so that the deformed background is a solution of 10D supergravity equations of motion. This guarantees the conformal invariance of the deformed world sheet sigma model.

---

2 The definition of the baryonic charge is non-standard and will be given below in Sec. 2.
It is known that for type IIA CY compactifications the potential for the Kähler form moduli arise from RR even-form fluxes, while the potential for complex structure moduli is induced by NS 3-form flux $H_3$ \cite{20,21}. Since we are interested in the potential for the conifold complex structure modulus $b$ we consider the NS 3-form $H_3$. It does not break $\mathcal{N} = 2$ supersymmetry in 4D theory \cite{20}.

We use a perturbation theory to solve 10D gravity equations solving first equations of motion for $H_3$ using the conifold metric. The back reaction on the metric and the dilaton arise in the quadratic order in $H_3$ and we neglect this effect to the leading order at small $H_3$.

Note that if we keep the vacuum expectation value (VEV) of the baryon $b$ large the curvature of the conifold is everywhere small and the gravity approximation is justified.

It turns out that $H_3$ flux does not generate a mass term \eqref{1.2} for the baryon $b$. Mass term vanishes due to the non-compactness of the conifold. Instead, $H_3$ flux produces a potential leading to a run-away vacuum for $b$. We still look for the interpretation of $H_3$ flux in terms of quark masses. The reason for this is that there is no other deformation in 4D SQCD (preserving $\mathcal{N} = 2$ supersymmetry), which produces a scalar potential except mass deformation. Using field theory arguments we relate $H_3$ to a particular choice of quark masses in 4D SQCD. At the run-away vacuum the deformed conifold degenerates to lower dimensions. We interpret this as a flow from a non-Abelian string to an Abelian one.

The paper is organized as follows. In Sec. 2 we briefly review 4D $\mathcal{N} = 2$ SQCD and the world sheet sigma model on the non-Abelian string. Next we review massless baryon $b$ as a deformation of the complex structure of the conifold and present the conifold metric. In Sec. 3 we solve equations of motion for the 3-form $H_3$ and show that $H_3$ does not induce a mass \eqref{1.2} for $b$-baryon. Also we derive the potential for $b$ leading to the run-away vacuum. To understand better the behavior of the potential at large $b$ in Sec. 4 we solve the equations of motion for $H_3$ using deformed conifold metric and calculate the potential at large $b$. In Sec. 5 we interpret $H_3$-form in terms of quark masses in 4D SQCD. We also discuss the interpretation of the degeneration of the conifold at the run-away vacuum as a flow from a non-Abelian string to an Abelian one. Sec. 6 summarizes our conclusions.
2 Non-Abelian critical vortex string

2.1 Four-dimensional $\mathcal{N} = 2$ SQCD

As was already mentioned, non-Abelian vortex-strings were first found in 4D $\mathcal{N} = 2$ SQCD with the gauge group $U(N)$ and $N_f \geq N$ quark flavors supplemented by the Fayet-Iliopoulos (FI) [22] term with parameter $\xi$ [23, 4, 5], see for example, [9] for a detailed review of this theory. Here, we just mention that at weak coupling $g^2 \ll 1$, this theory is in the Higgs phase in which the scalar components of the quark multiplets (squarks) develop vacuum expectation values (VEVs). These VEVs break the $U(N)$ gauge group Higgsing all gauge bosons. The Higgsed gauge bosons combine with the screened quarks to form long $\mathcal{N} = 2$ multiplets with mass $m_G \sim g\sqrt{\xi}$.

The global flavor $SU(N_f)$ is broken down to the so-called color-flavor locked group. The resulting global symmetry is

$$SU(N)_{C+F} \times SU(N_f - N) \times U(1)_B,$$

(2.1)

see [9] for more details.

The unbroken global $U(1)_B$ factor above is identified with a baryonic symmetry. Note that what is usually identified as the baryonic $U(1)$ charge is a part of our 4D theory gauge group. "Our" $U(1)_B$ is an unbroken by squark VEVs combination of two $U(1)$ symmetries; the first is a subgroup of the flavor $SU(N_f)$, and the second is the global $U(1)$ subgroup of $U(N)$ gauge symmetry.

As was already noted, we consider $\mathcal{N} = 2$ SQCD in the Higgs phase: $N$ squarks condense. Therefore, non-Abelian vortex strings confine monopoles. In the $\mathcal{N} = 2$ 4D theory these strings are 1/2 BPS-saturated; hence, their tension is determined exactly by the FI parameter,

$$T = 2\pi \xi.$$

(2.2)

However, as we already mentioned, the monopoles cannot be attached to the string end points. In fact, in the $U(N)$ theories confined monopoles are junctions of two distinct elementary non-Abelian strings [23, 4, 5] (see [9] for a review). As a result, in four-dimensional $\mathcal{N} = 2$ SQCD we have monopole-anti-monopole mesons in which the monopole and anti-monopole are connected by two confining strings. In addition, in the $U(N)$ gauge theory we can have baryons appearing as a closed “necklace” configurations.
of $N \times \text{(integer)}$ monopoles \cite{9}. For the U(2) gauge group the important example of a baryon consists of four monopoles \cite{19}.

Below we focus on the particular case $N = 2$ and $N_f = 4$ because, as was mentioned in the Introduction, in this case 4D $\mathcal{N} = 2$ SQCD supports non-Abelian vortex strings which behave as critical superstrings \cite{11}. Also, for $N_f = 2N$ the gauge coupling $g^2$ of the 4D SQCD does not run; the $\beta$ function vanishes. However, the conformal invariance of the 4D theory is explicitly broken by the FI parameter $\xi$, which defines VEV’s of quarks. The FI parameter is not renormalized.

Both stringy monopole-antimonopole mesons and monopole baryons with spins $J \sim 1$ have masses determined by the string tension, $\sim \sqrt{\xi}$ and are heavier at weak coupling $g^2 \ll 1$ than perturbative states with masses $m_G \sim g \sqrt{\xi}$. Thus, they can decay into perturbative states and in fact at weak coupling we do not expect them to appear as stable states.

Only in the strong coupling domain $g^2 \sim 1$ we expect that (at least some of) stringy mesons and baryons become stable. These expectations were confirmed in \cite{11, 15} where low lying string states in the string theory for the critical non-Abelian vortex were found at the self-dual point at strong coupling.

Below in this paper we introduce small quark masses $m_A$, $A = 1, \ldots, 4$ assuming that two first squark flavors with masses $m_1$ and $m_2$ develop VEVs.

### 2.2 World-sheet sigma model

The presence of the color-flavor locked group $SU(N)_{C+F}$ is the reason for the formation of non-Abelian vortex strings \cite{2, 3, 4, 5}. The most important feature of these vortices is the presence of the orientational zero modes. As was already mentioned, in $\mathcal{N} = 2$ SQCD these strings are 1/2 BPS saturated.

Let us briefly review the model emerging on the world sheet of the non-Abelian string \cite{9}.

The translational moduli fields are described by the Nambu—Goto action and decouple from all other moduli. Below we focus on internal moduli.

If $N_f = N$ the dynamics of the orientational zero modes of the non-Abelian vortex, which become orientational moduli fields on the world sheet, are described by 2D $\mathcal{N} = (2, 2)$ supersymmetric $\mathbb{C}P(N-1)$ model.

\footnote{Their quantum numbers with respect to the global group \cite{2, 11} allow these decays, see \cite{9}.}
If one adds additional quark flavors, non-Abelian vortices become semi-local – they acquire size moduli \([24]\). In particular, for the non-Abelian semi-local vortex in U(2) \(\mathcal{N} = 2\) SQCD with four flavors, in addition to the complex orientational moduli \(n^P\) (here \(P = 1, 2\)), we must add two complex size moduli \(\rho^K\) (where \(K = 3, 4\)), see \([5, 2, 24, 25, 26, 27]\).

The effective theory on the string world sheet is a two-dimensional \(\mathcal{N} = (2, 2)\) supersymmetric WCP\((2, 2)\) model \([1, 11, 14]\). This model describes internal dynamics of the non-Abelian semilocal string. For details see e.g. the review \([9]\).

The WCP\((2, 2)\) sigma model can be defined as a low energy limit of the U(1) gauge theory \([28]\), which corresponds to taking the limit of infinite gauge coupling, \(e^2 \rightarrow \infty\) in the action below. The bosonic part of the action reads

\[
S = \int d^2x \left\{ \left| \nabla_\alpha n^P \right|^2 + \left| \tilde{\nabla}_\alpha \rho^K \right|^2 + \frac{1}{4e^2} F_{\alpha\beta}^2 + \frac{1}{e^2} |\partial_\alpha \sigma|^2 \right. \\
+ 2 \left| \sigma + \frac{m_P}{\sqrt{2}} \right|^2 |n^P|^2 + 2 \left| \sigma + \frac{m_K}{\sqrt{2}} \right|^2 \left| \rho^K \right|^2 + e^2 \left( |n^P|^2 - |\rho^K|^2 - \text{Re} \beta \right)^2 \left. \right\},
\]

\[P = 1, 2, \quad K = 3, 4.\]  \(2.3\)

Here, \(m_A\) (\(A = 1, .., 4\)) are the so-called twisted masses (they coincide with 4D quark masses), while \(\text{Re} \beta\) is the inverse coupling constant (2D FI term). More exactly it is the real part of the complexified coupling constant introduced in Eq. (2.7) below.

The fields \(n^P\) and \(\rho^K\) have charges +1 and −1 with respect to the auxiliary U(1) gauge field, and the corresponding covariant derivatives in \(2.3\) are defined as

\[
\nabla_\alpha = \partial_\alpha - iA_\alpha, \quad \tilde{\nabla}_\alpha = \partial_\alpha + iA_\alpha,
\]

\(2.4\)

respectively. The complex scalar field \(\sigma\) is a superpartner of the U(1) gauge

---

\(4\)Both the orientational and the size moduli have logarithmically divergent norms, see e.g. \([25]\). After an appropriate infrared regularization, logarithmically divergent norms can be absorbed into the definition of relevant two-dimensional fields \([25]\). In fact, the worldsheet theory on the semilocal non-Abelian string is not exactly the WCP\((N, \tilde{N})\) model \([27]\), there are minor differences. The actual theory is called the \(zn\) model. Nevertheless it has the same infrared physics as the model \([2.3, 29]\), see also \([30]\).

\(5\)Equation \([23]\) and similar expressions below are given in Euclidean notation.
Apart from the U(1) gauge symmetry, the sigma model (2.3) in the massless limit has a global symmetry group

$$SU(2) \times SU(2) \times U(1)_B,$$

(2.5)
i.e. exactly the same as the unbroken global group in the 4D theory at $N = 2$ and $N_f = 4$. The fields $n$ and $\rho$ transform in the following representations:

$$n: \ (2, \ 1, \ 0), \quad \rho: \ (1, \ 2, \ 1).$$

(2.6)

Here the global “baryonic” $U(1)_B$ symmetry is a classically unbroken (at $\beta > 0$) combination of the global $U(1)$ group which rotates $n$ and $\rho$ fields with the same phases plus $U(1)$ gauge symmetry which rotates them with the opposite phases, see [11] for details. Non-zero twisted masses $m_A$ break each of the SU(2) factors in (2.5) down to U(1).

The 2D coupling constant $\Re \beta$ can be naturally complexified if we include the $\theta$ term in the action,

$$\beta = \Re \beta + i \frac{\theta_{2D}}{2\pi},$$

(2.7)

where $\theta_{2D}$ is the 2D $\theta$ angle.

The number of real bosonic degrees of freedom in the model (2.3) is $8 - 1 - 1 = 6$. Here 8 is the number of real degrees of freedom of $n^P$ and $\rho^K$ fields and we subtracted one real constraint imposed by the the $D$ term condition in (2.3)

$$|n^P|^2 - |\rho^K|^2 = \Re \beta,$$

(2.8)
in the limit $\epsilon^2 \rightarrow \infty$ and one gauge phase eaten by the Higgs mechanism. As we already mentioned, these six internal degrees of freedom in the massless limit can be combined with four translational moduli to form a 10D space needed for a superstring to be critical.

At the quantum level, the coupling $\beta$ does not run in this theory. Thus, the $\mathbb{CP}(2, 2)$ model is superconformal at zero masses $m_A = 0$. Therefore, its target space is Ricci flat and (being Kähler due to $N = (2, 2)$ supersymmetry) represents a non-compact Calabi-Yau manifold, namely the conifold $Y_6$, see [13] for a review.

The $\mathbb{CP}(2, 2)$ model (2.3) with $m_A = 0$ was used in [11] to define the critical string theory for the non-Abelian vortex at hand.
Typically solitonic strings are "thick" and the effective world sheet theory like the one in (2.3) has a series of unknown high derivative corrections in powers of $\partial/m_G$. The string transverse size is given by $1/m_G$, where $m_G \sim g\sqrt{\xi}$ is a mass scale of the gauge bosons and quarks forming the string. The string cannot be thin in a weakly coupled 4D SQCD because at weak coupling $m_G \sim g\sqrt{T}$ and $m_G^2/\xi$ is always small in the units of the string tension $T$, see (2.2).

A conjecture was put forward in [1] that at strong coupling in the vicinity of a critical value $g_c^2 \sim 1$ the non-Abelian string in the theory at hand becomes thin, and higher-derivative corrections in the world sheet theory (2.3) are absent. This is possible because the low energy sigma model (2.3) already describes a critical string and higher-derivative corrections are not required to improve its ultra-violet behavior, see [31] for the discussion of this problem. The above conjecture implies that $m_G(g^2) \to \infty$ at $g^2 \to g_c^2$. As expected the thin string produces linear Regge trajectories even for small spins [16].

It was also conjectured in [11] that $g_c$ corresponds to the value of the 2D coupling constant $\beta = 0$. The motivation for this conjecture is that this value is a self-dual point for the WCP$(2, 2)$ model (2.3). Also $\beta = 0$ is a natural choice because at this point we have a regime change in the WCP$(2, 2)$ model. The resolved conifold defined by the $D$ term condition (2.8) develops a conical singularity at this point. The point $\beta = 0$ corresponds to $\tau_{SW} = 1$ in the 4D SQCD, where $\tau_{SW}$ is the complexified inverse coupling, $\tau_{SW} = i\pi g^2 + \theta_{4D}/\pi$, where $\theta_{4D}$ is the 4D $\theta$ angle [19].

A version of the string-gauge duality for 4D SQCD was proposed [1]: at weak coupling this theory is in the Higgs phase and can be described in terms of quarks and Higgsed gauge bosons, while at strong coupling hadrons of this theory can be understood as string states formed by the non-Abelian vortex string.

At non-zero quark masses $m_A \neq 0$ the model (2.3) is a mass deformation of the superconformal CY theory on the conifold. Generically quark masses break the world sheet conformal invariance. The WCP$(2, 2)$ model in (2.3) can no longer be used to define a string theory for the non-Abelian vortex in the massive 4D SQCD.
2.3 Massless 4D baryon

In this section we briefly review the only 4D massless state found in the string theory of the critical non-Abelian vortex in the massless limit [11]. It is associated with the deformation of the conifold complex structure. As was already mentioned, all other massless string modes have non-normalizable wave functions over the conifold. In particular, 4D graviton associated with a constant wave function over the conifold \( Y_6 \) is absent [11]. This result matches our expectations since we started with \( \mathcal{N} = 2 \) SQCD in the flat four-dimensional space without gravity.

We can construct the U(1) gauge-invariant “mesonic” variables

\[
w^{PK} = n^P \rho^K. \tag{2.9}\]

These variables are subject to the constraint

\[
det w^{PK} = 0. \tag{2.10}\]

Equation (2.10) defines the conifold \( Y_6 \). It has the Kähler Ricci-flat metric and represents a non-compact Calabi-Yau manifold [12, 13, 28]. It is a cone which can be parametrized by the non-compact radial coordinate

\[
\tilde{r}^2 = \text{Tr} \bar{w} w \tag{2.11}\]

and five angles, see [12]. Its section at fixed \( \tilde{r} \) is \( S_2 \times S_3 \).

At \( \beta = 0 \) the conifold develops a conical singularity, so both spheres \( S_2 \) and \( S_3 \) can shrink to zero. The conifold singularity can be smoothed out in two distinct ways: by deforming the Kähler form or by deforming the complex structure. The first option is called the resolved conifold and amounts to keeping a non-zero value of \( \beta \) in (2.8). This resolution preserves the Kähler structure and Ricci-flatness of the metric. If we put \( \rho^K = 0 \) in (2.3) we get the \( \mathbb{C}P(1) \) model with the sphere \( S_2 \) as a target space (with the radius \( \sqrt{\beta} \)). The resolved conifold has no normalizable zero modes. In particular, the modulus \( \beta \) which becomes a scalar field in four dimensions has non-normalizable wave function over the \( Y_6 \) and therefore is not dynamical [11].

If \( \beta = 0 \) another option exists, namely a deformation of the complex structure [13]. It preserves the Kähler structure and Ricci-flatness of the conifold and is usually referred to as the deformed conifold. It is defined by deformation of Eq. (2.10), namely,

\[
det w^{PK} = b, \tag{2.12}\]

9
where \( b \) is a complex parameter. Now the sphere \( S_3 \) can not shrink to zero, its minimal size is determined by \( b \).

The modulus \( b \) becomes a 4D complex scalar field. The effective action for this field was calculated in [11] using the explicit metric on the deformed conifold [12, 32, 33],

\[
S_{\text{kin}}(b) = T \int d^4x |\partial_\mu b|^2 \log \frac{\tilde{R}_{\text{IR}}^2}{|b|},
\]

(2.13)

where \( \tilde{R}_{\text{IR}} \) is the maximal value of the radial coordinate \( \tilde{r} \) introduced as an infrared regularization of the logarithmically divergent \( b \)-field norm. Here the logarithmic integral at small \( \tilde{r} \) is cut off by the minimal size of \( S_3 \), which is equal to \(|b|\).

We see that the norm of the modulus \( b \) turns out to be logarithmically divergent in the infrared. The modes with the logarithmically divergent norm are at the borderline between normalizable and non-normalizable modes. Usually such states are considered as “localized” ones. We follow this rule. This scalar mode is localized near the conifold singularity in the same sense as the orientational and size zero modes are localized on the vortex-string solution.

The field \( b \) being massless can develop a VEV. Thus, we have a new Higgs branch in 4D \( \mathcal{N} = 2 \) SQCD which is developed only for the critical value of the 4D coupling constant \( \tau_{\text{SW}} = 1 \) associated with \( \beta = 0 \).

In [11] the massless state \( b \) was interpreted as a baryon of 4D \( \mathcal{N} = 2 \) QCD. Let us explain this. From Eq. (2.12) we see that the complex parameter \( b \) (which is promoted to a 4D scalar field) is a singlet with respect to both SU(2) factors in (2.5), i.e. the global world-sheet group. What about its baryonic charge? From (2.6) and (2.12) we see that the \( b \) state transforms as

\[(1, 1, 2).
\]

(2.14)

In particular it has the baryon charge \( Q_B(b) = 2 \).

In type IIA superstring compactifications the complex scalar associated with deformations of the complex structure of the Calabi-Yau space enters as a 4D \( \mathcal{N} = 2 \) BPS hypermultiplet, see [18] for a review. Other components of this hypermultiplet can be restored by \( \mathcal{N} = 2 \) supersymmetry. In particular, 4D \( \mathcal{N} = 2 \) hypermultiplet should contain another complex scalar \( \tilde{b} \) with

\[\text{which is isomorphic to the 4D global group (2.1) for } N = 2, N_f = 4.\]
baryon charge $Q_B(\tilde{b}) = -2$. In the stringy description this scalar comes from ten-dimensional three-form, see [18] for a review, as well as Sec. 3.3 and Appendix.

To conclude this section let us present the explicit metric of the singular conifold (with both $\beta$ and $b$ equal to zero), which will be used in the next section. It has the form [12]

$$ds_6^2 = dr^2 + \frac{r^2}{6}(e^2_{\theta_1} + e^2_{\varphi_1} + e^2_{\theta_2} + e^2_{\varphi_2}) + \frac{r^2}{9}e^2_\psi, \quad (2.15)$$

where

$$e_{\theta_1} = d\theta_1, \quad e_{\varphi_1} = \sin \theta_1 d\varphi_1,$$

$$e_{\theta_2} = d\theta_2, \quad e_{\varphi_2} = \sin \theta_2 d\varphi_2,$$

$$e_\psi = d\psi + \cos \theta_1 d\varphi_1 + \cos \theta_2 d\varphi_2. \quad (2.16)$$

Here $r$ is another radial coordinate on the cone while the angles above are defined at $0 \leq \theta_{1,2} < \pi$, $0 \leq \varphi_{1,2} < 2\pi$, $0 \leq \psi < 4\pi$.

The volume integral associated with this metric is

$$\text{(Vol)}_6 = \frac{1}{108} \int r^5 dr d\psi d\theta_1 \sin \theta_1 d\varphi_1 d\theta_2 \sin \theta_2 d\varphi_2. \quad (2.17)$$

The radial coordinate, $\tilde{r}$ defined in terms of matrix $w^{PK}$, see (2.11) is related to $r$ in (2.15) via [12]

$$r^2 = \frac{3}{2} \tilde{r}^{4/3}. \quad (2.18)$$

### 3 NS 3-form

Now we switch on small quark masses $m_A$, $A = 1, \ldots, 4$. We will use the effective 10D supergravity approach to find the deformed background for our non-Abelian vortex string. As we already explained in the Introduction, instead of attempting to interpret twisted mass terms in (2.3) in terms of 10D gravity we take a different route. We exploit the standard string theory approach of flux compactifications to 4D. Namely, we look for the solution of 10D gravity equations of motion with non-zero NS 3-form $H_3$ and then interpret $H_3$ in terms of quark masses. Note that the 3-form $H_3$ flux does not break $\mathcal{N} = 2$ supersymmetry in 4D [20].
The motivation to consider the NS 3-form $H_3$ is as follows. We expect that quark masses should lift the Higgs branch associated with the massless baryon $b$. In particular, the mass term (1.2) for the baryon $b$ appears for generic values of quark masses as dictated for a BPS state with non-zero baryonic charge [19]. On the other hand, generically, in type IIA compactifications a potential for Kähler moduli is generated by even-form RR fluxes, while the potential for complex structure moduli (like our $b$-modulus) is induced by the NS 3-form flux [20].

As we already mentioned, solving gravity equations of motion we will use the perturbation theory at small $H_3$. Namely, we will solve equations of motion for $H_3$ using the conifold metric neglecting the back reaction on the metric and the dilaton. These effects appear in the quadratic order in $H_3$. We also assume that VEV of the baryon $b$ is large to make sure that the curvature of the conifold is everywhere small. This justify the gravity approximation.

### 3.1 Solution for NS 3-form at large $r$

The bosonic part of the action of the type IIA supergravity in the Einstein frame is given by

$$S_{10D} = \int d^{10}x \sqrt{-G} \left\{ R - \frac{1}{2} G^{MN} \partial_M \Phi \partial_N \Phi - \frac{e^{-\Phi}}{12} H_{MNL} H^{MNL} - \frac{1}{2} e^\frac{\Phi}{2} F_4^2 \right\} + T^2 \int \frac{1}{2} H_3 \wedge C_3 \wedge dC_3, \quad (3.1)$$

where $G_{MN}$ and $\Phi$ are 10D metric and dilaton, the string coupling $g_s = e^\Phi$. We also keep only NS 2-form $B_2$ with the field strength $H_3 = dB_2$ and RR 3-form $C_3$ with the field strength $F_4 = dC_3$. We will need RR 3-form $C_3$ below to introduce the complex scalar $\tilde{b}$, the bosonic superpartner of $b$ in the 4D baryonic hypermultiplet.

In this section we will find a solution for the NS 3-form $H_3$ at large values of the radial coordinate $r$. Large means that $\tilde{r}$ is much larger then the minimal radius of the $S_3$ of the deformed conifold, which is equal to $\sqrt{|b|}$, see (2.12). This translates into $r \gg |b|^{1/3}$, see (2.13). At large $r$ we can neglect the deformation of the conifold and use the metric of the singular conifold. Thus, the 10D space has the structure $\mathbb{R}^4 \times Y_6$ with the metric

$$ds_{10}^2 = T \left[ -(dt)^2 + (dx^1)^2 + (dx^2)^2 + (dx^3)^2 \right] + ds_6^2, \quad (3.2)$$
where the metric of $Y_6$ is given by (2.15) and $T$ is the string tension (2.2).

For 2-form $B_2$ we use the ansatz introduced in \cite{34, 35, 33, 36} for type IIB "compactifications" on the conifold. Namely, we write

$$B_2 = f_1(r) e_{\theta_1} \wedge e_{\varphi_1} + f_2(r) e_{\theta_2} \wedge e_{\varphi_2}, \quad (3.3)$$

where $f_1(r)$ and $f_2(r)$ are functions of the radial coordinate $r$, while angle differentials are defined in (2.16). This gives for the 3-form field strength

$$H_3 = f'_1 dr \wedge e_{\theta_1} \wedge e_{\varphi_1} + f'_2 dr \wedge e_{\theta_2} \wedge e_{\varphi_2}, \quad (3.4)$$

where prime denotes the derivative with respect to $r$. This 3-form is closed so the Bianchi identity is satisfied.

In order to find a non-zero solution for $H_3$ we have to either introduce a source like a D-brane or impose a non-trivial boundary condition for $H_3$. We use the latter option and specify the boundary condition for $H_3$ at small $r$ in Sec. 4.2.

The equation of motion for $H_3$ reads

$$d(e^{-\Phi} \ast H_3) = e^{-\Phi} d(\ast H_3) = 0, \quad (3.5)$$

where $\ast$ denotes the Hodge star and, as we explained above, we neglect the back reaction on the dilaton to the leading order in small $H_3$ and assumed that the dilaton is constant.

The 10D-dual of $H_3$ is given by

$$\ast H_3 = \frac{T^2}{3} dx'^0 \wedge dx'^1 \wedge dx'^2 \wedge dx'^3 \wedge e_\psi \wedge (e_{\theta_2} \wedge e_{\varphi_2} r f'_1 + e_{\theta_1} \wedge e_{\varphi_1} r f'_2). \quad (3.6)$$

Substituting this into equation of motion (3.5) we find three equations,

$$\partial_r (r f'_1) = 0, \quad \partial_r (r f'_2) = 0 \quad (3.7)$$

and

$$f'_1 + f'_2 = 0. \quad (3.8)$$

The non-zero solution to these equations has the form

$$f_1 = -f_2 = \mu_1 \log r, \quad (3.9)$$

where $\mu_1$ is a small real parameter which we will interpret in terms of quark masses in Sec. 5.
This gives for the 3-form $H_3$

$$H_3 = \mu_1 \frac{dr}{r} \wedge (e_{\theta_1} \wedge e_{\varphi_1} - e_{\theta_2} \wedge e_{\varphi_2}).$$  \hfill (3.10)

Essentially, this coincides with the solution obtained in [34, 35, 33] for NS 3-form in type IIB "compactifications" on the conifold.

### 3.2 A generalization

In this section we make a generalization of our solution (3.10) for $H_3$. Let us define two real 3-forms on $Y_6$,

$$\alpha_3 \equiv \frac{dr}{r} \wedge (e_{\theta_1} \wedge e_{\varphi_1} - e_{\theta_2} \wedge e_{\varphi_2})$$  \hfill (3.11)

and

$$\beta_3 \equiv e_\psi \wedge (e_{\theta_1} \wedge e_{\varphi_1} - e_{\theta_2} \wedge e_{\varphi_2})$$  \hfill (3.12)

They are both closed [34, 35],

$$d\alpha_3 = 0, \quad d\beta_3 = 0,$$  \hfill (3.13)

Moreover, using the conifold metric (2.15) one can check that their 10D-duals are given by

$$*\alpha_3 = -\frac{T^2}{3} dx^0 \wedge dx^1 \wedge dx^2 \wedge dx^3 \wedge \beta_3,$$

$$*\beta_3 = 3T^2 dx^0 \wedge dx^1 \wedge dx^2 \wedge dx^3 \wedge \alpha_3,$$  \hfill (3.14)

where the first relation was already shown in the previous section, see (3.6).

The above relations ensure that both 10D-dual forms satisfy equations of motion

$$d * \alpha_3 = 0, \quad d * \beta_3 = 0.$$  \hfill (3.15)

Therefore, we can generalize our solution (3.10) for $H_3$ writing

$$H_3 = \mu_1 \alpha_3 + \frac{\mu_2}{3} \beta_3,$$  \hfill (3.16)

where $\mu_2$ is another real parameter, while the factor $\frac{1}{3}$ is introduced for convenience. This $H_3$-form satisfy both Bianchi identity and equations of motion (3.5).
3-Forms (3.11) and (3.12) form a basis similar to the simplectic basis of harmonic $\alpha$ and $\beta$ 3-forms for compact CYs, see for example review [18]. In particular,

$$\int_{Y_6} \alpha_3 \wedge \alpha_3 = \int_{Y_6} \beta_3 \wedge \beta_3 = 0,$$

while

$$\int_{Y_6} \alpha_3 \wedge \beta_3 \sim -\int \frac{dr}{r} \sim -\log \frac{R_{\IR}^2}{|b|}.$$  (3.18)

Here $R_{\IR}$ is the maximal value of the radial coordinate $r$ introduced to regularize the infrared logarithmic divergence, while at small $r$ the integral is cut off by the minimal size of $S_3$ which is equal to $|b|$. This logarithmic behavior will play an important role below. Note that this logarithm is similar to the one, which determines the metric for the $b$-baryon in (2.13).  

### 3.3 Mass term for $\tilde{b}$-baryon

Generically in type IIA compactifications the potential for complex structure moduli comes from two sources: the topological term and the kinetic term for $B_2$ in the 10D action, namely, the last and the first terms in the second line in (3.1) respectively [20]. In this section we consider the topological term.

Following the standard procedure for compactifications on CY 3-folds [18] we expand the 10D potential $C_3$ as

$$C_3 = C_3^{4D} + \tilde{b}_1 \alpha_3 + \frac{1}{3} \tilde{b}_2 \beta_3.$$  (3.19)

Here $C_3^{4D}(x)$ is the part of the 10D potential $C_3$ oriented in 4D which depends only on 4D coordinates $x_\mu$. Real 4D scalar fields $\tilde{b}_1$ and $\tilde{b}_2$ can be combined into a complex scalar $\tilde{b}(x) = \tilde{b}_1(x) + i\tilde{b}_2(x)$ which together with the complex scalar $b$ form a bosonic part of the 4D baryonic hypermultiplet.

In Appendix we calculate kinetic terms for 4D scalars $\tilde{b}_{1,2}$ using two last terms in (3.19) to calculate 4-form field strength $F_4 = dC_3$. We show that scalars $\tilde{b}_{1,2}$ acquire the same logarithmic metric as the complex scalar $b$, see (2.13) as dictated by $\mathcal{N} = 2$ supersymmetry in 4D.

In order to obtain mass term for $\tilde{b}$ we following [20] saturate the last factor $dC_3$ in the topological term in (3.1) by the 4D potential $C_3^{4D}(x)$. Dualizing

\[\text{Note that } R_{\IR}^3 \sim R_{\IR}^2, \text{ see (2.18).}\]
it to a 4D scalar \( e(x) \), \( dC_{3}^{4D}(x)_{\mu_\nu_\rho_\gamma} = e(x) \varepsilon_{\mu_\nu_\rho_\gamma} \) we get

\[
\int \frac{1}{2} H_3 \wedge C_3 \wedge dC_3 = \frac{1}{2} \int d^4x \left\{ e \int_{Y_6} H_3 \wedge C_3 \right\}.
\] (3.20)

Now we substitute here our solution for \( H_3 \)-form (3.16) and the expansion (3.19). This gives the contribution to the 4D action

\[
T^2 \int d^4x \left( \mu_2 \tilde{b}_1 - \mu_1 \tilde{b}_2 \right) \log \frac{R^3_{\text{IR}}}{|b|},
\] (3.21)

where we used (3.17), (3.18).

Combining this with the kinetic term for \( C_{3}^{4D} \) in (3.1) we get the part of the 4D action depending on the scalar \( e \)

\[
S_{1D}^{e} = T^2 \int d^4x \left\{ \frac{1}{2} (\text{Vol})_6 e^{\Phi/2} e^2 + e \left( \mu_2 \tilde{b}_1 - \mu_1 \tilde{b}_2 \right) \log \frac{R^3_{\text{IR}}}{|b|} \right\}
\] (3.22)

Here \( (\text{Vol})_6 \sim P^6_{\text{IR}} \) is the infinite volume of the conifold, see (2.17). Integrating the scalar \( e \) out we finally get the mass term for \( \tilde{b} \)

\[
S_{\text{mass}}^{\tilde{b}} = -\frac{T^2 e^{\Phi/2}}{2(\text{Vol})_6} \int d^4x \left( \mu_2 \tilde{b}_1 - \mu_1 \tilde{b}_2 \right)^2 \left( \log \frac{R^3_{\text{IR}}}{|b|} \right)^2 \left| R_{\text{IR}} \rightarrow \infty \rightarrow 0 \right.
\] (3.23)

We see that the mass term for the baryon \( \tilde{b} \) vanishes. In contrast to type IIA compactifications on compact CY spaces, where the topological term in (3.1) produces mass terms for scalar superpartners of complex structure moduli [20], in our case it goes to zero due to the non-normalizability of \( C_{3}^{4D} \). In terms of quark masses we interpret the result in (3.23) as follows. NS 3-form \( H_3 \) corresponds to a particular choice of quark masses for which \( m_b = 0 \), see (1.2). We will come back to the interpretation of \( H_3 \) in terms of quark masses later in Sec. 5.

In fact this result is a test of the consistency of our approach. To see this note that the mass term (3.23) gives mass to a particular combination of \( \tilde{b}_1 \) and \( \tilde{b}_2 \), while the orthogonal combination remains massless. If this term were nonzero this would signal the breaking of \( \mathcal{N} = 2 \) supersymmetry in 4D. On the other hand, we know that quark masses do not break \( \mathcal{N} = 2 \) supersymmetry in 4D SQCD.
### 3.4 The potential for the baryon $b$

As we already mentioned in the type IIA compactifications another source of the potential for complex structure moduli come from the kinetic term for $B_2$ in (3.1). Writing this term as

$$-\frac{e^{-\Phi}}{12} \int H_3 \wedge \ast H_3$$

and substituting here our solution (3.16) we get

$$-T^2 e^{-\Phi} (\mu_1^2 + \mu_2^2) \int d^4x \log \frac{R^3_{\text{IR}}}{|b|},$$

where we used (3.14) and (3.18). Thus, the scalar potential has the form

$$V(b) = \text{const} T^2 e^{-\Phi} (\mu_1^2 + \mu_2^2) \log \frac{R^3_{\text{IR}}}{|b|},$$

(3.26)

The potential (3.26) is proportional to the same infrared logarithm which enters the metric (2.13) for the baryon $b$. We see that the Higgs branch for $b$ is lifted and we have a run-away vacuum with VEV

$$\langle |b| \rangle \to R^3_{\text{IR}} \to \infty.$$  

(3.27)

In fact our solution (3.16) is found using the metric of the singular conifold and therefore is valid at $r \gg |b|^{1/3}$. Thus, the potential (3.26) can be trusted at small $|b|$ where the logarithm is large and we cannot really use it at $|b| \sim R^3_{\text{IR}}$. In the next section we consider the case of large $|b|$ and confirm our conclusion in (3.27) that the VEV of the baryon $b$ tends to infinity.

### 4 Deformed conifold

In the previous section we have seen that the 3-form $H_3$ lifts the Higgs branch for the baryon $b$ and pushes the VEV of $b$ towards large $|b|$, $|b| \sim R^3_{\text{IR}}$. To study the behavior of the potential $V(b)$ in this case we have to find the solution for $H_3$ on the deformed conifold assuming that the radial coordinate $r \sim |b|^{1/3}$. First, we briefly review the metric of the deformed conifold and then solve equations of motion for $H_3$. 
4.1 Metric of the deformed conifold

The metric of the deformed conifold has the form \[ ds^2 = \frac{1}{2} |b|^{2/3} K(\tau) \left\{ \frac{1}{3K^3(\tau)} (d\tau^2 + e^2_{\psi}) + \cosh^2 \frac{\tau}{2} (g_3^2 + g_4^2) \ight. \]

\[ + \sinh^2 \frac{\tau}{2} (g_1^2 + g_2^2) \right\}, \quad (4.1) \]

where angle differentials are defined as

\[ g_1 = -\frac{1}{\sqrt{2}} (e_{\phi_2} + e_3), \quad g_2 = \frac{1}{\sqrt{2}} (e_{\theta_1} - e_4), \]

\[ g_3 = -\frac{1}{\sqrt{2}} (e_{\phi_1} - e_3), \quad g_4 = \frac{1}{\sqrt{2}} (e_{\theta_1} + e_4), \quad (4.2) \]

while

\[ e_3 = \cos \psi \sin \theta_2 \, d\phi_2 - \sin \psi \, d\theta_2, \quad e_4 = \sin \psi \sin \theta_2 \, d\phi_2 + \cos \psi \, d\theta_2, \quad (4.3) \]

see also \((2.16)\).

Here

\[ K(\tau) = \frac{(\sinh 2\tau - 2\tau)^{1/3}}{2^{1/3} \sinh \tau} \quad (4.4) \]

and the new radial coordinate \(\tau\) is defined as

\[ \tilde{r}^2 = |b| \cosh \tau = \left( \frac{2}{3} \right)^{\frac{3}{2}} r^3. \quad (4.5) \]

In the limit of large \(\tau\) the metric \((4.1)\) reduces to the metric \((2.15)\) of the singular conifold.

Results of the previous section show that we have a run-away vacuum with \(|b| \sim R_{IR}^3\) so we are interested in the metric \((4.1)\) in the limit of small \(\tau, \tau \ll 1\). In this limit the metric of the deformed conifold takes the form

\[ ds^2 |_{\tau \to 0} = \frac{1}{2} |b|^{2/3} \left( \frac{2}{3} \right)^{1/2} \left\{ \frac{1}{2} d\tau^2 + \frac{1}{2} e^2_{\psi} + g_3^2 + g_4^2 \right. \]

\[ + \left. \frac{\tau^2}{4} (g_1^2 + g_2^2) \right\}. \quad (4.6) \]

The last term here corresponds to the collapsing sphere \(S_2\), while the sphere \(S_3\) associated with three angular terms in the first line has a fixed radius in
the limit $\tau \to 0$ \[12, 33\]. The radial coordinate $r$ approaches its minimal value with

$$r^3|_{\text{min}} = \left(\frac{3}{2}\right)\frac{3}{2}|b|$$  \hspace{1cm} (4.7)

at $\tau = 0$.

The square root of the determinant of the metric

$$\sqrt{g_6} \sim |b|^2 \cosh^2 \frac{\tau}{2} \sinh^2 \frac{\tau}{2}|_{\tau \to 0} \sim |b|^2 \tau^2$$  \hspace{1cm} (4.8)

vanishes at $\tau = 0$, which shows the degeneration of the conifold metric.

### 4.2 NS 3-form at small $\tau$

In this section we consider an extrapolation of our solution for $H_3$ obtained for large $r$ to the region of small values of $\tau$. For simplicity we will consider an extrapolation of the solution (3.10) taking $\mu_2 = 0$ in (3.16).

At large values of the radial coordinate $\tau$ the 2-form potential $B_2$ is proportional to

$$B_2 \sim e_{\theta_1} \wedge e_{\varphi_1} - e_{\theta_2} \wedge e_{\varphi_2}$$  \hspace{1cm} (4.9)

see (3.3) and (3.9). The closed 2-form on the r.h.s can be rewritten in terms of angular differentials $g$. Explicitly, we have

$$e_{\theta_1} \wedge e_{\varphi_1} - e_{\theta_2} \wedge e_{\varphi_2} = g_1 \wedge g_2 + g_3 \wedge g_4.$$  \hspace{1cm} (4.10)

Therefore, it is natural to look for a solution for $B_2$ at arbitrary $\tau$ using the ansatz,

$$B_2 = p(\tau) g_1 \wedge g_2 + k(\tau) g_3 \wedge g_4,$$  \hspace{1cm} (4.11)

where $p$ and $k$ are functions of the radial coordinate $\tau$. This ansatz was used in \[33\] for the type IIB ”compactification” on the deformed conifold.

The ansatz (4.11) gives for the field strength

$$H_3 = p' \, d\tau \wedge g_1 \wedge g_2 + k' \, d\tau \wedge g_3 \wedge g_4 - \frac{1}{2} (p - k) \, e_\psi \wedge (g_1 \wedge g_3 + g_2 \wedge g_4),$$  \hspace{1cm} (4.12)

where we used the identity \[33\]

$$d(g_1 \wedge g_2 - g_3 \wedge g_4) = -e_\psi \wedge (g_1 \wedge g_3 + g_2 \wedge g_4).$$  \hspace{1cm} (4.13)

Here primes denote derivatives with respect to $\tau$. 

19
In particular, at large $\tau$ we have $p = k = \mu_1 / 3$, where we rewrite solution (3.10) in terms of $\tau$ using relation (4.5) at $\tau \to \infty$.

Calculating the 10D-dual of (4.12) we get
\begin{align}
\ast H_3 &= T^2 dx^0 \wedge dx^1 \wedge dx^2 \wedge dx^3 \wedge \left\{ p' \coth^2 \left( \frac{\tau}{2} \right) e_\psi \wedge g_3 \wedge g_4 \\
&\quad + k' \tanh^2 \left( \frac{\tau}{2} \right) e_\psi \wedge g_1 \wedge g_2 \\
&\quad - \frac{1}{2} (p - k) d\tau \wedge (g_1 \wedge g_3 + g_2 \wedge g_4) \right\}. 
\end{align}

(4.14)

Then the equation of motion (3.5) gives two equations
\begin{align}
4 \partial_\tau \left( \frac{p'}{\tau^2} \right) - \frac{1}{2} (p - k) &= 0, \\
\frac{1}{2} \partial_\tau \left( \tau^2 k' \right) + (p - k) &= 0, 
\end{align}

(4.15)

which we write down in the limit of small $\tau$. To derive (4.15) we used the identity
\begin{align}
d(g_1 \wedge g_3 + g_2 \wedge g_4) &= e_\psi \wedge (g_1 \wedge g_2 - g_3 \wedge g_4). 
\end{align}

(4.16)

The solution of these equations at small $\tau$ has the form
\begin{align}
k(\tau) \approx \mu_1 \tau, \quad p(\tau) \approx - \frac{\mu_1}{80} \tau^5, 
\end{align}

(4.17)

up to an overall constant.

To conclude this section, we note that at $\tau = 0$ our solution (4.12) tends to a constant
\begin{align}
H_3(\tau = 0) = \mu_1 d\tau \wedge g_3 \wedge g_4, 
\end{align}

(4.18)

which we impose as boundary conditions at $S_3$, which does not shrinks at $\tau = 0$. These boundary conditions ensure a non-zero solution for $H_3$.

4.3 The potential for the baryon $b$ at large $|b|$

Substituting solutions for $H_3$ and its 10D-dual given by (4.12) and (4.14) to the kinetic term (3.24) we get
\begin{align}
-\frac{e^{-\Phi}}{12} \int H_3 \wedge \ast H_3 - \mu_1^2 T^2 e^{-\Phi} \int d^4x d\tau \tau^2, 
\end{align}

(4.19)
where only the function \( k(\tau) \) (4.17) contributes to the leading order in \( \tau \). Thus, the potential for \( b \) takes the form

\[
V(b) = \text{const} \mu_1^2 T^2 e^{-\Phi} \tau_{\text{max}}^3, \tag{4.20}
\]

where \( \tau_{\text{max}} \) is the infrared cutoff with respect to the radial coordinate \( \tau \) related to \( R_{\text{IR}} \) as follows

\[
|b| \cosh(\tau_{\text{max}}) = \left( \frac{2}{3} \right)^{\frac{3}{2}} R_{\text{IR}}^3, \tag{4.21}
\]

see (4.15).

As we already explained, we expect that in our run-away vacuum \( b \) is large, close to \( R_{\text{IR}} \), therefore \( \tau_{\text{max}} \) is small. Expanding \( \cosh \tau \) at small \( \tau \) we get

\[
\tau_{\text{max}} \sim \sqrt{\frac{R_{\text{IR}}^3 - \left( \frac{3}{2} \right)^{\frac{3}{2}} |b|}{|b|}}. \tag{4.22}
\]

This gives the potential for the baryon \( b \) at large \( |b| \)

\[
V(b) = \text{const} \mu_1^2 T^2 e^{-\Phi} \left[ \frac{R_{\text{IR}}^3 - \left( \frac{3}{2} \right)^{\frac{3}{2}} |b|}{|b|} \right]^{\frac{3}{2}}. \tag{4.23}
\]

We see that to minimize the potential \( |b| \) becomes large and approaches the infrared cutoff,

\[
\langle |b| \rangle = \left( \frac{2}{3} \right)^{\frac{3}{2}} R_{\text{IR}}^3 \rightarrow \infty. \tag{4.24}
\]

As we expected earlier in Sec. 3.4, we get a run-away vacuum.

In fact, \( \tau_{\text{max}}^3 \) which enters (4.20) is the volume of the three dimensional ball bounded by the sphere \( S_2 \) of the conifold with the maximum radius \( \tau_{\text{max}} \). It shrinks to zero as \( b \) tends to its VEV (4.24). To avoid singularities we can regularize the size of \( S_2 \) introducing small non-zero \( \beta \), which makes the conifold ”slightly resolved”, see (2.8). We take the limit \( \beta \rightarrow 0 \) at the last step. Then the value of the potential and all its derivatives vanish in the vacuum (4.24) at \( |b| = \langle |b| \rangle \), for example

\[
V(b)|_{|b|=\langle |b| \rangle} = \text{const} \mu_1^2 T^2 e^{-\Phi} \frac{\beta^3}{R_{\text{IR}}^{3/2}} \rightarrow 0. \tag{4.25}
\]
In particular, the mass term for \( b \) is zero. This is in accordance with \( \mathcal{N} = 2 \) supersymmetry in 4D SQCD, since the mass of \( \bar{b} \) is zero, see (3.23).

To summarize, the \( H_3 \)-form flux produces following effects.

- The Higgs branch of the baryon \( b \) in 4D SQCD is lifted.
- The vacuum is of a run-away type \( \langle |b| \rangle \to \infty \).
- At the run-away vacuum the sphere \( S_2 \) of the conifold degenerates, while the radius of the sphere \( S_3 \) tends to infinity.

We will interpret this degeneration in terms of \( \mathcal{N} = 2 \) SQCD in Sec. 5.2.

## 5 Interpretation in terms of 4D SQCD

### 5.1 3-form flux in terms of quark masses

In this section we interpret the NS 3-form \( H_3 \) in terms of quark masses of 4D \( \mathcal{N} = 2 \) SQCD. For \( N_f = 4 \) we have four complex mass parameters. However, a shift of the complex scalar \( a \), a superpartner of the U(1) gauge field, produces an overall shift of quark masses. This can be also seen in the \( \mathbb{W}\mathbb{C}\mathbb{P}(2,2) \) model (2.3) on the world sheet of the non-Abelian string; a constant shift of the scalar \( \sigma \) makes an overall shift of quark masses. Thus, in fact we have three independent complex mass parameters in our 4D SQCD.

For example, we can choose three mass differences

\[
m_1 - m_2, \quad m_3 - m_4, \quad m_1 - m_3
\]

as independent parameters.

On the string theory side our solution (3.16) for the 3-form \( H_3 \) is parametrized by two real parameters \( \mu_1 \) and \( \mu_2 \). Thus, we expect that non-zero \( H_3 \)-flux can be interpreted in terms of a particular choice of quark masses, subject to two complex constraints.

One constraint we already discussed. We know that \( H_3 \) does not produces a mass term for the \( b \)-baryon. This ensures that

\[
m_1 + m_2 - m_3 - m_4 = 0,
\]

see (1.2).
To derive the second constraint we consider the exact twisted superpotential for the $\mathbb{WCP}(2,2)$ model (2.3) obtained by integrating out $n$ and $\rho$ supermultiplets. It is a generalization [37, 38] of the CP$(N-1)$ model superpotential [39, 40, 28, 41] of the Veneziano-Yankielowicz type [42]. In the present case $N_f = 2N = 4$ it reads:

$$W_{\mathbb{WCP}}(\sigma) = \frac{1}{4\pi} \left\{ \sum_{P=1,2} \left( \sqrt{2} \sigma + m_P \right) \ln \left( \sqrt{2} \sigma + m_P \right) 
- \sum_{K=3,4} \left( \sqrt{2} \sigma + m_K \right) \ln \left( \sqrt{2} \sigma + m_K \right) + 2\pi \sqrt{2} \sigma \beta + \text{const} \right\}, \tag{5.3}$$

where we use one and the same notation $\sigma$ for the twisted superfield [28] and its lowest scalar component.

To study the vacuum structure of the theory we minimize this superpotential with respect to $\sigma$ to obtain the 2D vacuum equation

$$\prod_{P=1,2} \left( \sqrt{2} \sigma + m_P \right) = e^{-2\pi \beta} \prod_{K=3,4} \left( \sqrt{2} \sigma + m_K \right). \tag{5.4}$$

Consider the limit $\beta \to 0$ in this equation. In this limit (5.4) reduces to the following quadratic equation

$$2\pi \beta (\sqrt{2} \sigma)^2 + (\sqrt{2} \sigma)(m_1 + m_2 - m_3 - m_4) + m_1 m_2 - m_3 m_4 = 0. \tag{5.5}$$

The second term here is zero due to the constraint (5.2). Two roots of (5.5) read

$$\sqrt{2} \sigma = \pm \left[ \frac{1}{2\pi \beta} (m_1 m_2 - m_3 m_4) \right]^{1/2} \bigg|_{\beta \to 0} \to \infty \tag{5.6}$$

However, infinite VEVs of $\sigma$ cost an infinite energy for non-zero $H_3$. To see this, observe that from the string theory side we learned that the VEV of $b$ goes to infinity, see (4.24). Then eq. (4.5) shows that the radial coordinate $\tilde{r}$ is very large, which means that (some of) $n$’s and $\rho$’s become infinitely large, see (2.11). Given the infinite VEV of $\sigma$ this makes first two terms in the second line of the $\mathbb{WCP}(2,2)$ action (2.3) infinite.

To avoid this we impose the second constraint, namely

$$m_1 m_2 - m_3 m_4 = 0. \tag{5.7}$$
Now, let us solve two constraints in (5.2) and (5.7) for masses $m_3$ and $m_4$ as functions of $m_1$ and $m_2$. Finding, say, $m_4$ from (5.2) and substituting it into (5.7) we get a quadratic equation for $m_3$,

$$m_3^2 - m_3(m_1 + m_2) + m_1m_2 = 0. \quad (5.8)$$

Two roots of this equation read

$$m_3 = m_1, \quad m_4 = m_2 \quad (5.9)$$

and

$$m_3 = m_2, \quad m_4 = m_1. \quad (5.10)$$

These two options are essentially the same, up to permutation of quarks $q^3$ and $q^4$. Let us choose the first option in (5.9).

The above arguments lead us to the conclusion that the $H_3$-flux can be interpreted in terms of the single mass difference $(m_1 - m_2)$. Thus, we complexify parameters $\mu_{1,2}$ and identify

$$\mu \equiv \mu_1 + i\mu_2 = \sqrt{\frac{g_s}{T}} (m_1 - m_2), \quad m_3 = m_1, \quad m_4 = m_2. \quad (5.11)$$

Now, in terms of quark masses our solution (3.16) for the NS 3-form reads

$$H_3 = \sqrt{\frac{g_s}{T}} \left[ \text{Re}(m_1 - m_2) \alpha_3 + \frac{1}{3} \text{Im}(m_1 - m_2) \beta_3 \right], \quad (5.12)$$

while the potential (3.26) for the baryon $b$ becomes

$$V(b) = \text{const} T |m_1 - m_2|^2 \log \frac{R^3_{IR}}{|b|}. \quad (5.13)$$

Similarly we can rewrite our solution (4.12) for $H_3$ obtained at large $|b|$ in terms of $(m_1 - m_2)$.

### 5.2 Degeneration of the conifold

If we take the limit of large $|m_1 - m_2| \gg \sqrt{\xi}$ in 4D SQCD keeping the constraint (5.9) non-Abelian degrees of freedom decouple and U(2) gauge theory flows to $N = 2$ supersymmetric Abelian theory with the gauge group U(1)$\times$U(1) and $N_f = 4$ quark flavors. For example, off-diagonal gauge fields
acquire large masses $\sim |m_1 - m_2|$ and decouple. However, in this paper we consider limit of small quark masses on the string theory side and therefore, cannot make $|m_1 - m_2|$ large. At small $|m_1 - m_2| \ll \sqrt{\xi}$ our 4D SQCD remains to be U(2) gauge theory.

On the other hand in the world sheet $\mathcal{WCP}(2,2)$ model on the non-Abelian string the story is different. This theory is conformal and has no scale. Therefore, once we switch on non-zero $(m_1 - m_2)$ there is no notion of smallness of this deformation. We see a dramatic effect as soon as $(m_1 - m_2)$ becomes non-zero.

Classically there are two branches in $\mathcal{WCP}(2,2)$ model (2.3) associated with VEVs of $\sigma$

$$\sqrt{2} \sigma = -m_1 \tag{5.14}$$

or

$$\sqrt{2} \sigma = -m_2. \tag{5.15}$$

Let us choose the first branch for definiteness. Then fields $n^{P=2}$ and $\rho^{K=4}$ acquire masses $|m_1 - m_2|$ and decouple in the infrared. The low energy effective theory at scales below $|m_1 - m_2|$ is the $\mathcal{WCP}(1,1)$ model

$$S = \int d^2 x \left\{ |n_1|^2 + |\tilde{\nabla}_\alpha n_1|^2 + |\tilde{\nabla}_\alpha \rho^3|^2 + \frac{1}{4e^2} F_{\alpha\beta}^2 + \frac{1}{e^2} |\partial_\alpha \sigma|^2 + 2 |\sigma|^2 |n_1|^2 + 2 |\sigma|^2 |\rho^3|^2 + \frac{e^2}{2} \left( |n_1|^2 - |\rho^3|^2 - \text{Re} \beta \right)^2 \right\} , \tag{5.16}$$

where much in the same way as in (2.3), the limit $e^2 \to \infty$ is assumed and we made a shift($\sqrt{2} \sigma + m_1$) $\to \sqrt{2} \sigma$.

The number of real degrees of freedom in (5.16) is $4 - 1 - 1 = 2$ where 4 is the number of real degrees of freedom of $n_1$ and $\rho^3$ and much in the same way as in (2.3), we subtract 2 due to the $D$-term constraint in (5.16) and the U(1) phase eaten by the Higgs mechanism.

Physically $\mathcal{WCP}(1,1)$ model describes an Abelian semilocal vortex string supported in $\mathcal{N} = 2$ supersymmetric U(1) gauge theory with $N_f = 2$ quark flavors. This vortex has no orientational moduli, but it has one complex size modulus $\rho^3$, see [24, 25, 26]. Thus, we can think that upon switching on $(m_1 - m_2)$ a non-Abelian string flows to an Abelian one.

---

In addition to masses $m_G \sim g \sqrt{\xi}$ due to the Higgs mechanism, see [9] for a review.
The low energy $WCP(1, 1)$ model is also conformal. Moreover, it was shown in [43] that in the non-linear sigma model formulation it flows to a free theory on $\mathbb{R}^2$ in the infrared. Thus, in fact, switching on $(m_1 - m_2)$ with constraint (5.9) does not break the conformal invariance on the world sheet.

It just reduces the number of degrees of freedom transforming a non-Abelian string into an Abelian one. The string theory which one would associate with the sigma model (5.16) is non-critical.

This supports our interpretation of the flux "compactification" on the conifold in terms of quark masses. On the string theory side switching on $(m_1 - m_2)$ is reflected in the degeneration of the conifold, which effectively reduces its dimension. Also in the limit $|b| \to \infty$ the radius of the sphere $S_3$ of the conifold becomes infinite and it tends to a flat three dimensional space. This matches the field theory result [43] that $WCP(1, 1)$ model flows to a free theory in the infrared. It would be tempting to interpret the extra coordinate of the sphere $S_3$ of the conifold in the limit $|b| \to \infty$ as a Liouville coordinate for a non-critical string associated with the sigma model (5.16). This is left for a future work.

To conclude, we note that although 4D SQCD gets just slightly deformed as we switch on small $(m_1 - m_2)$ at weak coupling, this deformation becomes much more pronounced at strong coupling. Namely, at $\tau_{SW} = 1$ (which corresponds to $\beta = 0$ in (2.3)) the non-perturbative Higgs branch gets lifted and we have a run-away vacuum (4.24) for the stringy baryon $b$.

### 6 Conclusions

In this paper we considered the NS 3-form flux "compactification" for the string theory of the critical non-Abelian vortex supported in $\mathcal{N} = 2$ SQCD with gauge group $U(2)$ and $N_f = 4$ quark flavors. Using supergravity approach we found a solution for the 3-form $H_3$ to the leading order at small $H_3$ neglecting the back reaction on the conifold metric and the dilaton. The non-zero 3-form $H_3$ generates a potential for the complex structure modulus $b$ of the conifold, which is interpreted as a BPS baryonic hypermultiplet in 4D SQCD at strong coupling. This potential lifts the Higgs branch formed by VEVs of $b$ and leads to a run-away for $b$, $\langle |b| \rangle \to \infty$.

We interpret the 3-form $H_3$ as a quark mass deformation of 4D SQCD. The reason for this interpretation is that there is no other deformation in 4D SQCD preserving $\mathcal{N} = 2$ supersymmetry, which produces a scalar potential.
We use field theory arguments to relate the 3-form $H_3$ to the quark mass difference $(m_1 - m_2)$, see (5.12), subject to the constraint (5.9).

At the runaway vacuum the conifold degenerates to lower dimensions. This qualitatively matches with a flow to the $\mathbb{CP}(1, 1)$ model (5.16) on the string world sheet, expected if one switches on the mass difference $(m_1 - m_2)$. This flow can be thought of as a flow from a non-Abelian string to an Abelian one.

As a direction of a future research we can mention the finding of exact solutions of 10D supergravity equations with non-zero NS 3-form flux. This would allow us to describe the limit of large $(m_1 - m_2)$ in terms of the string theory. In this limit non-Abelian degrees of freedom in 4D SQCD with $U(2)$ gauge group decouple and the theory flows to an Abelian $U(1) \times U(1)$ theory.

Also a challenging problem is to find a supergravity deformations associated with other choices of quark masses in 4D SQCD.

**Appendix.**

**Kinetic term for $\tilde{b}$-baryon**

In this Appendix we calculate kinetic terms for 4D scalars $\tilde{b}_{1,2}$ which arise from the expansion of the 10D 3-form potential $C_3$ in (3.19). Assuming that scalars $\tilde{b}_{1,2}$ depend only on 4D coordinates $x_\mu$ and dropping the 4D 3-form $C_3^{4D}$ (we consider it in Sec. 3.3) we write

$$F_4 = dC_3 = \partial_\mu \tilde{b}_1 \, dx^\mu \wedge \alpha_3 + \frac{1}{3} \partial_\mu \tilde{b}_2 \, dx^\mu \wedge \beta_3. \tag{6.1}$$

Calculating the 10D dual of this form we get

$$\ast F_4 = -\frac{1}{3!} T^2 \varepsilon_{\mu\nu\gamma\delta} \partial^\mu \tilde{b}_1 \, dx^\nu \wedge dx^\gamma \wedge dx^\delta \wedge \beta_3$$

$$+ \frac{1}{3!} T^2 \varepsilon_{\mu\nu\gamma\delta} \partial^\mu \tilde{b}_2 \, dx^\nu \wedge dx^\gamma \wedge dx^\delta \wedge \alpha_3, \tag{6.2}$$

27
where we used (3.14).

Now writing the kinetic term for $C_3$ in (3.1) as

$$\int F_4 \wedge * F_4$$  \hspace{2cm} (6.3)

we finally get

$$S_{\text{kin}}(\tilde{b}) = T \int d^4 x \left\{ |\partial_\mu \tilde{b}_1|^2 + |\partial_\mu \tilde{b}_2|^2 \right\} \log \frac{R_{\text{IR}}}{|b|} ,$$  \hspace{2cm} (6.4)

where we used (3.17) and (3.18).

We see that scalars $\tilde{b}_{1,2}$ have the same logarithmic metric as the complex scalar $b$. As we already mentioned, the complexified scalar $\tilde{b}$ together with $b$ form a bosonic part of the 4D baryonic hypermultiplet.
