A Review on Higher Order Spline Techniques for Solving Burgers Equation Using B-Spline Methods and Variation of B-Spline Techniques

Maryam Khazaei Pool, Lori Lewis

Abstract—This is a summary of articles based on higher order B-splines methods and the variation of B-spline methods such as Quadratic B-spline Finite Elements Method, Exponential Cubic B-Spline Method Septic B-spline Technique, Quintic B-spline Galerkin Method, and B-spline Galerkin Method based on the Quadratic B-spline Galerkin method (QBGM) and Cubic B-spline Galerkin method (CBGM). In this paper we study the B-spline methods and variations of B-spline techniques to find a numerical solution to the Burgers’ equation. A set of fundamental definitions including Burgers equation, spline functions, and B-spline functions are provided. For each method, the main technique is discussed as well as the discretization and stability analysis. A summary of the numerical results is provided and the efficiency of each method presented is discussed. A general conclusion is provided where we look at a comparison between the computational results of all the presented schemes. We describe the effectiveness and advantages of these methods.

Keywords—Burgers’ Equation, Septic B-spline, Modified Cubic B-Spline Differential Quadrature Method, Exponential Cubic B-Spline Technique, B-Spline Galerkin Method, and Quintic B-Spline Galerkin Method.

I. INTRODUCTION

Due to the great usefulness of spline functions in applications, scientists have used spline functions for various applications. Spline functions have applications in various fields such as applied mathematics and engineering. Spline methods are often used when solving Ordinary Differential Equations (ODEs) and Partial Differential Equations (PDEs). Spline [1]–[4] methods have played an important role in computational mathematics, mathematical physics and mechanics. Geyikli and Karakoc applied septic B-spline collocation method for the numerical solution of the modified equal width wave equation [5]. Study of solving singular boundary value problems with third and fourth degree B-spline functions have been done in [6]–[11]. A quintic non-polynomial spline method for solving fourth order two-point boundary value problems is presented by Ramadan [12] which gives better approximations and generalizes all the existing polynomial spline methods up to order four. A non-polynomial quintic spline function for numerical solution of third-order BVPs associated with odd-order obstacle problems is obtained by Khan [13], Kalyani and Lemma [14] use a ninth degree spline function as well as an eighth degree spline to solve a seventh order boundary value problem. Authors obtained an approximate solution that very closely matches the exact solutions. Rashidinia and Khazaeei solved a fifth degree and eight order boundary value problems with eight degree B-Spline [15]. A low absolute error is obtained for their results which indicates that the presented numerical method is effective for solving high order boundary value problems. From these authors we get an understanding that spline methods produce solutions that are highly accurate. Numerical approximation for the solution of linear sixth order boundary value problems by cubic B-spline is obtained by Khalid and Naeem [16]. The work presented by Roul and Goura [17] shows the construction and convergence analysis of two B-spline collocation methods for a class of nonlinear derivative dependent singular boundary value problems (DDSBVP). The first method is based on uniform mesh, while the second method is based on non-uniform mesh. For the second method, we use a grading function to construct the non-uniform grid. They proved that the method based on uniform mesh is of second-order accuracy and the method based on non-uniform mesh is of fourth-order accuracy. A differential quadrature method based on quintic B-spline functions is presented by Bashan [18] for solving Korteweg–de Vries–Burgers (KdVB) equation.

Many efforts have been enhanced to evaluate the numerical solution of Burgers’ equation in the past few years. The analytic solution of a two dimensional coupled Burgers’ equation was first given by Fletcher [19] using the Hopf-Cole transformation. A variety of studies have been developed for the various forms of nonlinear PDEs, as model problems in fluid dynamical systems [20], [21]. Spline methods are commonly used to approximate a solution to Burgers’ equation.

Numerical solution of the Burger’s equation using collocation method and finite element methods has been studied to generate accurate numerical results [22]–[26]. A survey of higher order splines for boundary value problems by Srivastava can be found which gives a summary [27] of higher order spline methods.

Several efficient methods including implicit finite difference scheme [28], group explicit methods [29], explicit methods [30], [31] are presented for solution of Berger’s equation. Zaki [32] shows an algorithm based on the collocation method with quintic B-spline finite element for solutions of the Burgers’ equation with higher accuracy. The Quintic B-Spline Galerkin
Method for Numerical Solutions of non-linear Burgers’ Equation is presented by Dag [33].

In order to study the interactions of multi-shocks in thin viscoelastic tube filled, Akter and Hafez [34] presented an analytic wave solutions of beta space fractional Burgers equation. This presented work investigates the single and overtaking collision of multi-shock wave excitations having space fractional evolution in a thin viscoelastic tube filled with incompressible inviscid fluid. The computational wave and numerical solutions of the Atangana conformable derivative (1 + 3)-Zakharov-Kuznetsov (ZK) equation with power-law non-linearity are investigated via the modified Khater method and septic-B-spline scheme by Khater and Chu [35]. This model is formulated and derived by employing the well-known reductive perturbation method.

The Burgers equation involves both non-linear propagation effects and diffusive effects. This equation is similar to the Navier–Stokes equation without the pressure term. Therefore, it is a simpler model to analyze fluid turbulence [36]. For this paper we consider variations of B-spline methods including Quadratic B-Spline Finite Elements Method, Exponential-Cubic B-Spline Method and B-spline Galerkin methods for numerical solutions of Burgers equation. A summary of different methods for solving burgers’ equation is presented. Using B-spline functions in different methods demonstrates efficient techniques in terms of time and cost in each approach. High accuracy solutions and stability and convergence analysis of the methods show efficiency and effectively of the discussed techniques.

In Section II, we provide fundamental definitions of Burgers equation, spline, and B-spline functions. Section III presents the quadratic B-spline finite element method which includes some remarks about the method and its advantages. In Section IV, the exponential-cubic B-spline method is summarized. Sections V and VI present the quintic B-spline Galerkin method and the septic B-spline techniques respectively. In Section VII, we look at the B-spline Galerkin methods to find a numeric solution to Burgers’ equation by considering two time splitting techniques. The final Section VIII includes the conclusion and final thoughts about these methods.

II. DEFINITIONS

A. Burgers’ Equation

Burgers’ equation is a fundamental partial differential equation [37]. Here we will use the following form

\[ u_t + uu_x = \lambda u_{xx} \]  

where \( \lambda > 0 \) is a constant which is known as the diffusion coefficient, and \( u \) is an arbitrary function.

For each paper we describe the initial conditions and boundary conditions that are considered for each method.

B. Spline Functions

A spline is a piece-wise polynomial function defined in region \( D = [a, b] \), such that there exists a decomposition of \( D \) into sub-regions. In each sub-region of \( D \), the function is a polynomial of some degree \( k \). The term "spline" is used to refer to a wide class of functions that are used in applications requiring data interpolation or smoothing. A function \( S(x) \) is a spline of degree \( k \) on \([a, b]\) if

\[ S \in C^{k-1}[a, b] \]

\[ a = t_0 < t_1 < \ldots < t_n = b \]

and

\[ S(x) = \begin{cases} S_0(x), & t_0 < x < t_1 \\ S_1(x), & t_1 < x < t_2 \\ \vdots \\ S_{n-1}(x), & t_{n-1} < x < t_n \end{cases} \]

where \( S_i(x) \in P^k, \ i = 0, 1, \ldots, n-1 \).

C. B-Spline

The B-spline is defined as a basis function of degree \( k \) which is denoted by \( \varphi_i^k(x) \), where \( i \in \mathbb{Z} \). In order to define B-spline basis functions, we need to define the degree of these basis functions, \( p \). The \( i \)-th B-spline basis function of degree \( p \) is written as \( N_{i,p}(u) \) and it is defined as follows:

\[ N_{i,p}(u) = \begin{cases} 1, & \text{if } u_{i+1} > u \geq u_i \\ 0, & \text{otherwise} \end{cases} \]  

\[ N_{i,p}(u) = \frac{u - u_{i+p+1}}{u_{i+p+1} - u_{i+p-1}} N_{i+1,p-1}(u) + \frac{u_{i+p} - u}{u_{i+p} - u_{i+p-1}} N_{i,p-1}(u) \]  

Equation (4) is known as the Cox-de Boor recursion formula. To understand how the formula works, we can start by assuming that the degree is zero (i.e., \( p = 0 \)) then all the basis functions are considered as step functions. That is, basis function \( N_{i,0}(u) \) is 1, if \( u \) is in the \( i \)-th knot span \([u_i, u_{i+1}]\). Here, we denote the B-spline of degree \( k \) by \( B_i^k(x) \), where \( i \) is an element in \( Z \) with the following properties [38]:

1) \( N_{i,p}(u) \) is a degree \( p \) polynomial in \( u \).
2) Non-negativity: for all \( i, p \) and \( u \), \( N_{i,p}(u) \) is non-negative.
3) Local support: \( N_{i,p}(u) \) is a nonzero polynomial on \([u_i, u_{i+p+1}]\).
4) At most \( p + 1 \) degree of the basis functions are nonzero on any span \([u_i, u_{i+p+1}]\), namely: \( N_{i-p,p}(u), N_{i-p+1,p}(u), N_{i-p+2,p}(u), \ldots, N_{i,p}(u) \). This property shows that the following basis functions are nonzero on \([u_i, u_{i+p+1}]\): \( N_{i-p,p}(u), N_{i-p+1,p}(u), N_{i-p+2,p}(u), \ldots, N_{i,p}(u) \).
5) Partition of unity: The sum of all nonzero degree \( p \), basis functions on span \([u_i, u_{i+p+1}]\) are 1 which states that the sum of these \( p + 1 \) basis functions is 1.

An alternative approach to drive the B-Spline relations: Here we consider equally-spaced knots of a partition \( \pi : \alpha = x_0 < x_1 < \ldots < x_n \) on \([a, b]\). This will be an alternative approach for deriving the B-splines which are more applicable with respect...
to the recurrence relation for the formulations of B-splines of higher degrees. Firstly, we recall that the \( k - 1 \)th forward difference \( f(x_0) \) of a given function \( f(x) \) at \( x_0 \) is defined recursively by [39] and [40] and is given as follows:

\[
\nabla f(x_0) = \nabla(x_1) - \nabla f(x_0),
\]

**Definition:** The function \((x - t)_m^n\), details given in [15],

\[
(x - t)_m^n = \begin{cases} 
(x - t)^m & x \leq t_0 \\
0 & x < t 
\end{cases}
\]

It is clear that \((x - t)_m^n\) is \((m - 1)\) times continuously differentiable with respect to \( t \) and \( x \). The B-spline of order \( m \) is defined as follows:

\[
B_i^m(t) = \frac{1}{h^m} \sum_{j=0}^{m+1} \binom{m+1}{j} (-1)^{m+1-j}(x_{i+j} - t)_+^m
\]

Here, we obtain the B-spline of various orders by taking various values of \( m \). Let \( m = 1 \) so that

\[
\frac{1}{h^m} \nabla^2(x_{i-1} - t)_+^1 = \frac{1}{h^2}[(x_{i-1} - t)_+^1
\]

\[
-2(x_{i-1} - t)_+^1 + (x_{i-1} - t)_+^1] = \frac{1}{h^2}[(x_{i-1} - t)_+^1
\]

\[
-2(x_{i-1} - t)_+^1 + (x_{i-1} - t)_+^1]
\]

By considering different values for \( m \), different degree of B-Spline can be obtained, including septic B-Spline.

**III. QUADRATIC B-SPLINE FINITE ELEMENT METHOD**

For the quadratic B-spline finite element method presented in [41], the collocation method and a central difference with respect to time is used. This method is used to find a solution to the Burgers’ equation (1) with homogeneous boundary conditions that are

\[
u(a, t) = \mu(b, t) = 0.
\]

Since the finite element method used in the region is partitioned into \( N \) finite elements with equal length \( h \) and knots \( x_i \) are used such that \( a = x_0 < x_1 < ... < x_N = b \). The quadratic B-spline properties are defined as follows for \( B_m \),

\[
B_m(x) = \frac{1}{h^2} \begin{cases} 
(x - x_{m-1})^2, & \text{if } x_{m-1} \leq x \leq x_m \\
2h^2 - (x_{m+1} - x)^2 - (x - x_m)^2, & \text{if } x_{m} \leq x \leq x_{m+1} \\
(x_{m+2} - x_m)^2, & \text{if } x_{m+1} \leq x \leq x_{m+2} \\
0, & \text{otherwise}
\end{cases}
\]

The goal is to approximate \( u(x, t) \) of the form,

\[
u(x, t) = \sum_{m} \xi_m(t) B_m(x)
\]

Here \( \xi_m \) is given as a time dependent quantity and the numerical solution \( u(x, t) \) is given in mid knots such as \( y_m = (x_m + x_{m+1})/2 \). The values of \( u \) and the principal derivatives are calculated from the quadratic B-spline definitions,

\[
u = u(x_m) = \frac{1}{4} \xi_{m-1} + \frac{3}{2} \xi_m + \frac{1}{4} \xi_{m+1}
\]

\[
u' = u'(x_m) = -\frac{1}{h} \xi_{m-1} + \frac{1}{h} \xi_{m+1}
\]

\[
u'' = u''(x_m) = \frac{2}{h^2} \xi_{m-1} - \frac{4}{h^2} \xi_m + \frac{2}{h^2} \xi_{m+1}
\]

To implement the collocation points, mid knots are used to evaluate \( u \) so that (14) is obtained

\[
\frac{1}{4} \xi_{m-1} + \frac{3}{2} \xi_m + \frac{1}{4} \xi_{m+1} = u \left( \frac{2}{h^2} \xi_{m-1} - \frac{4}{h^2} \xi_m + \frac{2}{h^2} \xi_{m+1} \right)
\]

Here the \( + \) represents the differentiation with respect to time. Interpolating between \( n \) and \( n + 1 \) and using the central difference operator for time, \( \xi \) gives

\[
\xi = \frac{\xi_n^+ + \xi_n^-}{2}, \quad \xi^* = \frac{\xi_n^{+1} - \xi_n^{-1}}{2\Delta t}
\]

where \( \xi^n \) are parameters at the time \( n\Delta t \). A system is then obtained and written as

\[
A(\xi) \xi^{n+1} = B(\xi) \xi^n + C(\xi) \xi^{n-1}
\]

here \( A(\xi) \), \( B(\xi) \) are tridiagonal matrices with two initial time levels. The exact solution at \( t = t_0 \) and \( t = t_0 + \Delta t \) is used to obtain the initial conditions.

**Stability Analysis:** Since the finite element method is used, which is explained in [42], an investigation of the stability of the numerical scheme is required. The Von-Neumann method is used to find the stability which is defined as

\[
\xi^m = \xi^n e^{im \Delta k}
\]

Here \( k \) is the mode number and \( h \) is the element size. The following equations are then solved and the roots \( g_1 \) and \( g_2 \) are found as

\[
g_1 = -1, \quad g_2 = \frac{3 + \cos \theta}{\frac{3 + \cos \theta + 4\alpha \cos \theta + 2\beta}}
\]

where \( \alpha = \Delta z/4 - 2\Delta t/h^2 \), \( \beta = 3\Delta t z/2 + 4\Delta t/v/h^2 \).

Modules of growth are taken to obtain \( |g| \leq 1 \), which means that the scheme is unconditionally stable.

**Remarks:** The \( L_2 \) and \( L_\infty \) error norms are used to compare the analytical and numerical solutions. Different examples with different initial conditions are analyzed. Here we focus on the initial condition of an exponential form for which the exact solution is known to be

\[
u(x, t) = \frac{x/t}{1 + \left(t/t_0 e^{2x/t(t_0)}\right)} , \quad t \geq 1.
\]
The results are compared with the exact solution for different \( h \) and \( k \) values. The algorithm is compared with the exact solutions and it is shown that the method produces accurate results for small viscosity values. The quadratic B-spline method is easy to implement and can be generalized with higher order spline methods. Because of the flexibility and accuracy of this method the quadratic B-spline finite element method is advantageous when finding a solution to the Burgers’ equation.

IV. EXPONENTIAL-CUBIC B- SPLINE METHOD

The exponential cubic B-spline functions are used to set up the collocation method to solve Burgers’ Equation by [20]. The initial conditions and boundary conditions considered are as follows:

The initial condition
\[
 u(x, 0) = f(x), \quad a \leq x \leq b 
\]
and the boundary conditions
\[
 u(a, t) = \alpha_1, \quad u(b, t) = \alpha_2 
\]
Here \( \alpha_1, \alpha_2 \) are constants, \( u = u(x, t) \) is a sufficiently differentiable unknown function and \( f(x) \) which is bounded.

Exponential Cubic B-spline Collocation Method: For this method the nodes are equally distributed for the domain so that
\[
 \pi: \quad a = x_0 < x_1 < \ldots < x_N = b 
\]
and a mesh with spacing \( h = (b - a)/N \) is used. The exponential cubic b-splines, \( B_i(x) \), at the points of \( \pi \) are defined as
\[
 B_i(x) = \begin{cases} 
 b_2((x_{i-2} - x) - \frac{1}{4}[(\sinh(p(x_{i-2} - x))] & \text{for } [x_{i-2}, x_{i-1}], \\
 a_1 + b_1(x_{i} - x_{i-1}) + c_1 \exp(p(x_{i} - x)) + d_1 \exp(-p(x_{i} - x)) & \text{for } [x_{i-1}, x_{i}], \\
 a_1 + b_1(x_{i+1} - x_{i}) + c_1 \exp(p(x_{i+1} - x_{i})) + d_1 \exp(-p(x_{i+1} - x_{i})) & \text{for } [x_{i}, x_{i+1}], \\
 b_2((x - x_{i+2}) - \frac{1}{4}[(\sinh(p(x - x_{i+2})])] & \text{for } [x_{i+1}, x_{i+2}], \\
 0 \text{ otherwise} 
\end{cases} 
\]
where
\[
 a_1 = \frac{phc}{phc - s}, \quad b_1 = \frac{p}{2} \frac{c(c - 1) + s^2}{(phc - s)(1 - c)}, \\
 c_1 = \frac{1}{4} \frac{\exp(-ph)(1 - c) + s(\exp(-ph) - 1)}{(phc - s)(1 - c)} \\
 d_1 = \frac{1}{4} \frac{\exp(ph)(c - 1) + s(\exp(ph) - 1)}{(phc - s)(1 - c)} 
\]
and \( c = \cosh(ph), s = \sinh(ph), p \) is a free parameter. A basis is formed for the functions over the interval. Each basis function \( B_i(x) \) is twice continuously differentiable and \( B_i, \ B_i'(x) \) and \( B_i''(x) \) [20]. To approximate the unknown \( u, u_N \) is used which is in the form of
\[
 u_N(x, t) = \sum_{i=1}^{N+1} \delta_i B_i(x) 
\]
Here \( \delta_i \) is a time dependent parameter. The first and second derivatives are calculated at Knots, \( x_i \), and the Crank-Nicolson scheme is used to discretize time variables of the initial conditions are modified known \( u \) in the Burgers’ equation. After some substitution, the initial conditions at the boundaries are obtained and used to find an approximation to the Burgers’ equation.

Remarks: In a similar approach with the previous sections, the discrete \( L_2 \) and \( L_{\infty} \) error norms are used to compare the analytical and numerical solutions. Similar to the quadratic B-spline finite element method, an example considered is a particular solution to Burgers equation which has the following initial condition
\[
 u(x, 1) = \exp\left(\frac{1}{8\lambda}\right), \quad 0 \leq x \leq 1, 
\]
with boundary conditions \( u(0, t) = 0 \) and \( u(1, t) = 1 \). The reason why this example is chosen is because the analytical solution is known to be \( (19) \). It is mentioned that the solution to this specific example will be successful for a small \( \lambda \) which results in a steep shock solution. The propagation of the shock is studied with \( \lambda = 0.005 \) and \( \lambda = 0.0005 \). The results are compared with other papers: [23] and [1]. The exponential cubic B-spline collocation method provides better results than the cubic B-spline collocation method and the B-spline Galerkin finite element method. Note that the cost of the cubic B-spline Galerkin method is higher than the exponential cubic B-spline method. Over all the test runs of the exponential cubic B-spline method had the best results for finding the free parameter \( p = 1 \).

V. QUINTIC B- SPLINE GALERKIN METHOD

Now we look into the quintic B-splines method to find solutions of a time-split Burgers equation over finite intervals with the help of [43]. The Burgers equation studied has the following boundary conditions
\[
 u(a, t) = \alpha_1, \quad u(b, t) = \alpha_2, \\
 u_x(a, t) = 0, \quad u_x(b, t) = \alpha_2, \quad t \in (0, T], \\
 u_{xx}(a, t) = 0, \quad u_{xx}(b, t) = \alpha_2 
\]
The paper explores both solutions for the Burgers and time-split Burgers equation, but here we focus on the solution of the Burgers equation.

Quintic B-spline Galerkin method: The method begins by applying the Galerkin technique [1] to add the weighted functions and a mesh \( a = x_0 < x_1 < \ldots < x_N = b \) as a uniform partition. Here the knots \( x_m \) and \( h = x_m - x_{m-1}, m = 1, \ldots, N \).
\[ h^5 \cdot Q_m(x) = \begin{cases} w_3, & \text{if } [x_{m-3}, x_{m-2}], \\ w_3 - 6w_2, & \text{if } [x_{m-2}, x_{m-1}], \\ w_3 - 6w_2 + 15w_1, & \text{if } [x_{m-1}, x_m], \\ w_3 - 6w_2 + 15w_1 - 20w_0, & \text{if } [x_m, x_{m+1}], \\ w_3 - 6w_2 + 15w_1 - 20w_0 + 15w_{-1}, & \text{if } [x_{m+1}, x_{m+2}], \\ w_3 - 6w_2 + 15w_1 - 20w_0 + 15w_{-1} - 6w_{-2}, & \text{if } [x_{m+2}, x_{m+3}], \\ 0, & \text{otherwise} \end{cases} \] (28)

where \( w_i = (x - x_{m-i})^5 \). The quintic B-splines with knots \( x_m, m = -5, \ldots, N + 5 \) and bases on \( a \leq x \leq b \) with the global approximation defined as

\[ u_N(x, t) = \sum_{m=-2}^{N+2} \delta_m(t)Q_m(x) \] (29)

where \( \delta_m(t) \) is a time dependent parameter.

A local coordinate system is used. It is defined by the mapping the relationship \( \xi = x - x_m \) to obtain a global and local coordinates using transformations of finite element \([x_m, x_{m+1}]\) into interval \([0, h]\).

The approximation is reduced over the element \([x_m, x_{m+1}]\) as follows

\[ u_N = u(\xi, t) = \sum_{i=-2}^{m+3} \delta_i(t)Q_i(\xi), \] (30)

where \( \delta_i, i = m - 2, \ldots, m + 3 \) are element parameters. The weighted function with the quintic B-spline and \( U_N \) over the element \([0, h]\) gives a weighted function as a matrix form

\[ A^e\delta^e + (\delta^e)^T L^e \delta^e - \lambda D^e \delta^e \] (31)

It is noted that the matrices \( A, D \) are 6 by 6 and the matrix \( L \) is a 6 by 6 by 6 which \( \delta^e \) is defined as follows:

\[ \delta^e = (\delta_{m-2}, \delta_{m-1}, \delta_m, \delta_{m+1}, \delta_{m+2}, \delta_{m+3}) \] (32)

The matrix \( L \) is organized as the following

\[ B_{i,j} = \sum_{k=m-2}^{m+3} L_{i,j,k} \delta_k \] (33)

After combining all element matrices as a system of nonlinear ordinary differential equations with a global parameter \( \delta \), (34) is obtained:

\[ A\delta^o + (B - \nu D)\delta = 0 \] (34)

Using the Crank-Nicolson discretization formula for the vector of element parameter \( \delta \) and the finite difference equation for the time derivatives parameters \( \delta^o \), a nonlinear recurrence relation for the time parameters \( \delta \) with the following form is obtained:

\[ (2A + \nabla(t)B - \nu \nabla(t)D)\delta^{n+1} = (2A - \nabla(t)B + \nu \nabla(t)D)\delta^n \] (35)

Boundary conditions at the left end of the region and at the right end of the region are applied as well as some terms of the global parameter so that a solvable system made of \( N + 5 \) equations and \( N + 5 \) unknown parameters is obtained. An 11-banded matrix system at every time step is solved. To start the iteration of the recurrence relation of the above system, the initial parameter vector \( \delta^0 \) is obtained and time evaluation of \( u_N \) can be evaluated from the time evolution of the vector \( \delta^n \), which is found by solving the recurrence relation of the system above.

**Remarks:** The \( L_2 \) and \( L_\infty \) error norms are used to compare the analytical and numerical solutions. Just like other methods here we focus on the first test problem with an exponential initial condition (27) which the analytical solution to Burgers’ equation is known (19). Here, the parameters used are \( \lambda = 0.005, h = 0.005 \) and \( \Delta t = 0.01 \) over the problem domain \([0, 1]\). This method shows accuracy in the \( L_2 \) norm. When compared to the cubic spline methods [23, 20] it is noted that the method shows small improvement for the \( L_2 \) and \( L_\infty \) norms.

The quintic B-spline method provides high accuracy results for finding the solution of Burgers’ equation. The time splitting does not affect the method. It was concluded that the method is efficient and reliable.

**VI. SEPTIC B-SPLINE TECHNIQUES TO SOLVE BURGERS EQUATION**

The septic B-spline method over finite elements [44] is used to obtain a numerical solutions to the nonlinear Burgers’ equation by considering [24]. The papers focus on obtaining a solution for Burgers equation (1) with the initial condition,

\[ u(x, 0) = f(x) \] (36)

and the following boundary conditions

\[ u(a, t) = c_1, \quad u(b, t) = c_2, \] (37)

\[ u_x(a, t) = u_x(b, t) = 0, \] (38)

\[ u_{xx}(a, t) = u_{xx}(b, t) = 0, \] (39)

\[ u_{xxx}(a, t) = u_{xxx}(b, t) = 0, \] (40)

where \( c_1, c_2 \) are constants as the problem need, \( u = u(x, t) \) is a sufficiently-often differentiable function, and \( f(x) \) is bounded.

The authors [24] discussed about finding approximate solution \( u_N(x, t) \) which satisfies the following conditions: (a) It must agree with the initial condition \( u(x, 0) \) at the knots \( x_j \). (b) The first, second and third derivatives of the approximate initial condition agree with the exact initial conditions at both
ends of the range \([a, b]\). The approximate solution to \(u(x, t)\) is in the form of a collocation method:

\[
u_N(x, t) = \sum_{i=0}^{N+3} B_i(x_j) \omega_i(t), \quad j = 0, 1, \ldots, N
\]  

(41)

where \(x_i(t)\) are time dependent quantities to be determined. Using the boundary conditions where \(\Phi_i(x_j)\) is the values of the septic B-spline function forms a basis for the functions defined over \([a, b]\), and all its first, second, and third derivatives vanish outside the interval \([x_{i-4}, x_{i+4}]\). Here \(\omega_i(t)\) is a time dependent quantity that is determined by using the given boundary conditions in the paper. Using values of the bases in the collocation method and its derivatives with knots at the shown points produces a matrix system that consists of \(N + 1\) equations with \(N + 7\) unknowns. This requires six additional constraints which are obtained from the boundary conditions. The presented matrix system equation has the following form:

\[
A(\omega^n)\omega^{n+1} = B(\omega^n)\omega^n + r
\]  

(42)

where the matrices \(A(\omega^n)\), and \(B(\omega^n)\) are septa-diagonal \((N + 1) \times (N + 1)\) matrices and \(r\) is the \(N + 1\) dimensional column vector. The septa-diagonal algorithm is then used to solve the derived system to obtain a solution.

**Stability Analysis:** Stability analysis is done by using the Von-Neumann stability analysis for the linear system. An amplification factor \(g\) is obtained for mode \(k\) and results produce \(|g| \leq 1\) which means that the linearized numerical scheme for the Burger’s equation is conditionally stable.

**Remarks:** The numerical solutions of Burger’s equation and modified Burger’s equations are analyzed by computing the difference between the analytic and numerical solutions at each mesh point. The \(L_2\) and \(L_{\infty}\) norms are used for comparison of the results. The results of the nonlinear Burger’s equation by Septic B-spline technique are given as follows:

1. As the viscosity value \(\lambda\) is increased the errors tend to increase, but for all the values of used here, the errors are acceptable.
2. It is discussed that as the time increases, the curve of numerical solution decays.
3. The numerical solutions obtained exhibit to maintain good accuracy compared with the exact solution, especially for small values of the viscosity parameter. Using a collocation method with the septic B-splines gives an accurate approximation, particularly for small values of the viscosity parameter.

**VII. B-SPLINE GALERKIN METHODS FOR NUMERIC SOLUTIONS OF THE BURGERS’ EQUATION**

Here we will look at one variation of B-Spline functions to solve Burger’s equation \([1]\). A solution to Burger equations is approximated using quadratic and cubic B-spline Galerkin finite element method. The Burger’s equation (1) solved has the following initial condition,

\[
u(x, 0) = f(x)
\]  

(43)

and boundary conditions

\[
u(a, t) = \alpha_1, \quad \nu(b, t) = \alpha_2, \quad \nu_x(a, t) = \nu_x(b, t) = 0 \]  

(44)

where subscripts \(x\) and \(t\), where \(t \in [0, T]\) denote differentiation.

A system of PDE’s of the first order is obtained by splitting Burgers’ equation in time as follows

\[
u_t + 2\nu\nu_x = 0, \quad \nu_t - 2\nu\nu_{xx} = 0
\]  

(45)

Applying the Galerkin technique and considering weight functions, \(w\), to the equations above lead to following integral equations,

\[
\int_a^b w(\nu_t + 2\nu\nu_x)dx = 0, \quad \int_a^b w(\nu_t - 2\nu\nu_{xx})dx = 0
\]  

(46)

The first and second order smooth solutions are provided using the quadratic and cubic B-splines functions as well as the Galerkin finite element method \([1]\).

The Quadratic B-spline Galerkin method (QBGM): Here a global approximation \(u_g\) is written in terms of B-splines \([1]\) given in the following form:

\[
u_N(x, t) = \sum_{m=-1}^{N} \delta_m(t)Q_m(x),
\]  

(47)

where \(\delta_m\) is time dependent parameter which is specified from the quadratic Galerkin method. \(Q_m(x)\) represents the quadratic B-splines at knots \(x_m\). A basis is then formed over the interval \([a, b]\). First derivatives values vanish outside the interval. An interval \([x_m, x_{m+1}]\) includes three successive quadratic B-splines.

The finite elements are identified with intervals \([x_m, x_{m+1}]\), with nodes at \(x_m\) and \(x_{m+1}\). This transforms the quadratic B-splines into element shape functions over the finite intervals \([0, h]\). A local coordinate system is used which is \(\xi = x - x_m\), where \(\xi \in [0, h]\).

We consider \(\delta^e = (\delta_{m-1}, \delta_m, \delta_{m+1})\) which are known as element parameters and \(Q^e = (Q_{m-1}, Q_m, Q_{m+1})\) are given as element shape functions. A system of algebraic equations is obtained by applying the Galerkin method, and considering both weight and approximate functions that are chosen as the quadratic B-spline shape functions:

\[
(2A + \nabla tB)\delta^{n+1/2} = (2A - \nabla tB)\delta^n
\]  

(48)

\[
(2A - v\nabla tD)\delta^{n+1} = (2A + v\nabla tD)\delta^{n+1/2}
\]  

(49)

The two pentadiagonal systems, shown above, consist of \((N + 2)\) equations of \((N + 2)\) unknown parameters \((\delta^0, \delta^1, \delta^2)\). Applying the boundary conditions \(u(a, x) = u(b, x) = 0\) at both ends of the interval and using Thomas algorithms, the solutions of the pentadiagonal matrix equations with the dimensions \(N \times N\) are obtained. After initial parameters \(\delta^0_m\) are obtained with the help of the boundary and initial conditions, time evolution of the parameters \(\delta^n_m\) are computed using the recurrence relations between time steps.
These are obtained alliteratively so that time evolution of the approximate solution \( u_N \) could be determined [1].

Cubic B-spline Galerkin method (CBGM): Cubic B-spline \( Q_m, \quad m = -1, \ldots, N + 1 \) is defined at the knots \( x_m \) and a basis is formed over \([a, b] \). An approximate solution to \( u_N(x, t) \) is obtained using the cubic B-splines [1] and element parameters \( \delta_m \) which have the following form:

\[
u_N(x, t) = \sum_{m=-1}^{N+1} \delta_m(t)Q_m(x).
\]

Using the above expression and the values of the cubic B-splines \( Q_m \) at the knots \( x_m \), the values of \( u, u' \) and \( u'' \) in terms of the element parameters are obtained and given as follows:

\[
u_m = \delta_{m-1} + 4\delta_m + \delta_{m+1},
\]

\[
u'_m = \frac{3}{h}(\delta_{m+1} - \delta_{m-1}),
\]

\[
u''_m = \frac{6}{h^2}(\delta_{m-1} - 2\delta_m + \delta_{m+1}),
\]

where time dependent parameters, \( \delta_m \), is determined from the cubic B-spline Galerkin method.

A mapping of a typical finite interval \([x_m, x_{m+1}]\) to the interval \([0, h]\) is used with local coordinates \( \xi \) to related to the global coordinates \( x = x_m, \xi \in [0, h] \). Using the given cubic B-spline shape functions \( Q_{m-1}, Q_m, Q_{m+1}, Q_{m+2} \) in terms of the \( \xi \) over the \([0, h]\) will cover a finite element \([x_m, x_{m+1}]\) which yields to a local approximation (trial solution) over the element and is given as follows,

\[
u_m(\xi) = \left(\delta_{m-1}^e, \delta_m^e, \delta_{m+1}^e, \delta_{m+2}^e\right)
\]

where the element parameters \( \delta^e = (\delta_{m-1}^e, \delta_m^e, \delta_{m+1}^e, \delta_{m+2}^e) \) and element shape functions \( \eta^e = (Q_{m-1}^e, Q_m^e, Q_{m+1}^e, Q_{m+2}^e) \). Substituting weight functions \( W \) and \( u \) by shape functions \( \eta^e \) and trial solution (54) into the main equations (45) yields to a matrix system of first order ODE’s which leads to a global matrix equation:

\[
(2A + \nabla tB)\delta^{n+1/2} = (2A - \nabla tB)\delta^n
\]

In a similar manner, by using interpolation of the parameters \( \delta_m \) and it’s time derivative between two time levels \( n + 1/2 \) and \( n + 1 \), an algebraic equation is obtained as follows:

\[
2A + \lambda \nabla tD)\delta^{n+1} = (2A + \lambda \nabla tD)\delta^{n+1/2}
\]

The equations (68) and (69) consist of two recurrence relations for the time \((N + 3)\) equations of the \((N + 3)\) unknown parameters. Applying boundary conditions produces a septa-diagonal systems which includes \((N + 1)\) unknown parameters in equations \((N + 1)\). Then the time evolution of the time parameter for the both schemes are obtained.

**Remarks:** The numerical solution of Burgers’ equation is discussed [1] for three standard problems. The \( L_2 \) and \( L_1 \) error norms are used to measure the versatility and accuracy of the proposed methods as well as \( |e_1| \) norm. The Galerkin method with both quadratic and cubic B-splines are presented as weight and trial functions which are used to obtained a solution to the time-split Burgers equation.

The first example is about Shock-like solution of the Burgers’ equation which is compared with the analytical solution (19). The propagation of the shocks is shown to be slightly smoother as time increases. A variety of boundary conditions are tested and the best result is obtained by selecting zero for initial conditions as \( u(a, t) = 0 \) and \( u(b, t) = 0 \). Both schemes show the same result for the \( L_2 \) and \( L_1 \) error norms. From the results, the present calculation produced has a larger error compared to the schemes in which the split Burgers’ equation approximation is not carried out.

For the second example the Burgers equation is discussed with the following initial condition

\[
u(x, 0) = \sin(\pi x), \quad x \in [0, 1]
\]

and boundary condition

\[
u(0, t) = u(1, t) = 0, \quad 0 \leq t.
\]

We observe the decay of sinusoidal disturbance. The parameters which are used are viscosity constant \( \nu = 1 \), time step \( \Delta t = 0.00001 \) and various space steps are considered. There is a good agreement between both numerical schemes and exact values. Numerical results for \( \lambda = 10^4 \) show a very sharp front near the left boundary at earlier times and as time increases. The sharpness and amplitude of the wave front then decays. These properties of the numerical solutions from the QBGM and CBGM produce a small error when comparing with the result obtained by Varoquaux and Finn [45], Kakuda and Tosaka [46]. For an arbitrary initial data sets, the exact solutions of Burgers equation are presented as a quasi-linear parabolic PDE. Considering the fact that the analytical solutions of Burgers equations involve Fourier series solutions for a small viscosity constant \( \nu \), the analytical solutions converge slowly.

**VIII. CONCLUSION**

We provide a summary of different methods for solving Burgers’ equation which are shown to be efficient and effective. A summary for solving time-split Burgers’ equation is presented by using quadratic and cubic B-spline Galerkin finite element techniques. Solving Quintic B-spline Galerkin Method results in an 11-banded sparse matrix system for every time step which is efficient time wise and cost wise. Two numerical algorithms based on Galerkin method with both quadratic and cubic B-splines as weight and trial functions are studied for the time-split Burgers’ equation. This technique produces a high accuracy solution for Burgers’ equation. Moreover, by selecting suitable boundary conditions for the Galerkin method with both cubic and quadratic B-splines as an approximate function will produce a similar error. Having sparse and band matrices in a linear system for the septic
B-spline function techniques [24] is more efficient and cost less computationally. Stability analysis for the methods show that the methods are stable which are great to work with. Finally we present a comparison among the numerical results of all schemes and analytical values in all methods which maintain a good accuracy compared with the exact solutions. These methods are efficient and cost effective and are a great option for solving Burgers’ equation.
