Symplectic homology and the Eilenberg–Steenrod axioms

KAI CIELIEBAK
ALEXANDRU OANCEA

APPENDIX WRITTEN JOINTLY WITH PETER ALBERS

We give a definition of symplectic homology for pairs of filled Liouville cobordisms, and show that it satisfies analogues of the Eilenberg–Steenrod axioms except for the dimension axiom. The resulting long exact sequence of a pair generalizes various earlier long exact sequences such as the handle attaching sequence, the Legendrian duality sequence, and the exact sequence relating symplectic homology and Rabinowitz Floer homology. New consequences of this framework include a Mayer–Vietoris exact sequence for symplectic homology, invariance of Rabinowitz Floer homology under subcritical handle attachment, and a new product on Rabinowitz Floer homology unifying the pair-of-pants product on symplectic homology with a secondary coproduct on positive symplectic homology.

In the appendix, joint with Peter Albers, we discuss obstructions to the existence of certain Liouville cobordisms.

1 Introduction

To begin with, a story. At the Workshop on conservative dynamics and symplectic geometry held at IMPA, Rio de Janeiro in August 2009, the participants had seen in the course of a single day at least four kinds of Floer homologies for noncompact objects, among which were wrapped Floer homology, symplectic homology, Rabinowitz–Floer homology and linearized contact homology. The second author was seated in the audience next to Albert Fathi, who at some point suddenly turned to him and exclaimed: "There are too many such homologies!". Hopefully this paper can serve as a structuring answer: although there are indeed several versions of symplectic homology (non-equivariant, \(S^1\)-equivariant, Lagrangian, each coming in several flavours determined by suitable action truncations), we show that they all obey the same axiomatic pattern, very much similar to that of the Eilenberg–Steenrod axioms for singular homology.

In order to exhibit such a structured behaviour we need to extend the definition of symplectic homology to pairs of cobordisms endowed with an exact filling.

We find it useful to explain immediately our definition, although there is a price to pay regarding the length of this introduction.

We need to first recall the main version of symplectic homology that is currently in use, which can be interpreted as dealing with cobordisms with empty negative end. This construction associates to a Liouville domain — meaning an exact symplectic manifold \((W^{2n}, \omega, \lambda)\), \(\omega = d\lambda\) such that \(\alpha = \lambda|_{\partial W}\) is a positive contact form (see Section 2.1) — a symplectic homology group \(\text{SH}_*(W)\) which is an invariant of the symplectic completion \((\hat{W}, \hat{\omega}) = (W, \omega) \cup ([1, \infty) \times \partial W, d(\tau \alpha))\). The generators of the underlying chain complex can be thought of as being either the critical points of a Morse function on \(W\) which is increasing towards the boundary, or the positively parametrized closed orbits of the Reeb vector field \(R_\alpha\) on \(\partial W\) defined by \(d\alpha(R_\alpha, \cdot) = 0\) and \(\alpha(R_\alpha) = 1\). Since the generators of the underlying complex are closed Hamiltonian orbits, we also refer to symplectic homology as being a theory of closed strings (compare with the discussion of Lagrangian symplectic homology, or wrapped Floer homology, below). We interpret a Liouville domain \((W, \omega, \lambda)\) as an exact symplectic filling of its contact boundary \((M, \xi = \ker \alpha)\), or as an exact cobordism from the empty set to \(M\), which we call the positive boundary of \(W\), also denoted by \(M = \partial^+ W\).

The implementation of this setup is the following. One considers on \(\hat{W}\) (smooth time-dependent 1–periodic approximations of) Hamiltonians \(H_\tau\) which are identically zero on \(W\) and equal to the linear function \(\tau r - \tau\) for \(r \in [1, \infty)\) on the symplectization.
part \([1, \infty) \times M\), where \(\tau > 0\) is different from the period of a closed Reeb orbit on \(M\). One then sets

\[
\text{SH}_*(W) = \lim_{\tau \to \infty} \text{FH}_*(H_\tau),
\]

where \(\text{FH}_*(H_\tau)\) stands for Hamiltonian Floer homology of \(H_\tau\), which is generated by closed Hamiltonian orbits of period 1, and the direct limit is considered with respect to continuation maps induced by increasing homotopies of Hamiltonians. The dynamical interpretation of these homology groups reflects the fact that the Hamiltonian vector field of a function \(h(r)\) defined on the symplectization part \([1, \infty) \times M\) is equal to \(X_h(r, x) = h'(r) R_\alpha(x)\). A schematic picture for the Hamiltonians underlying symplectic homology of such cobordisms with empty negative end is given in Figure 1, in which the arrows indicate the location of the two kinds of generators for the underlying complex, constant orbits in the interior of the cobordism and nonconstant orbits located in the “bending” region near the positive boundary. The vertical thick dotted arrow in Figure 2 indicates that we consider a limit over \(\tau \to \infty\).

![Figure 1: Symplectic homology of a domain](image)

Key to our construction is the notion of \textit{Liouville cobordism with filling}. The definition of a Liouville cobordism \(W^{2n}\) is similar to that of a Liouville domain, with the notable difference that we allow the volume form \(\alpha \wedge (d\alpha)^{n-1}\) determined by \(\alpha\) on \(\partial W\) to define the opposite of the boundary orientation on some of the components of \(\partial W\), the collection of which is called \textit{the negative boundary of} \(W\) and is denoted by \(\partial^- W\), while \textit{the positive boundary of} \(W\) is \(\partial^+ W = \partial W \setminus \partial^- W\). In addition, we assume that one is given a Liouville domain \(F\) whose positive boundary is isomorphic to the contact negative boundary of \(W\), so that the concatenation \(F \circ W\) is a Liouville domain with positive boundary \(\partial^+ W\).

Given a Liouville cobordism \(W\) with filling \(F\), the output of the closed theory is a symplectic homology group \(\text{SH}_*(W)\). Although we drop the filling \(F\) from the notation for the sake of readability, this homology group does depend on \(F\). The
dependence is well understood in terms of the geometric augmentation of the contact homology algebra of $\partial^- W$ induced by the filling; see Bourgeois and Oancea [15]. Symplectic homology $\text{SH}_*(W)$ is an invariant of the Liouville homotopy class of $W$ with filling, and the generators of the underlying chain complex can be thought of as being of one of the following three types: negatively parametrized closed Reeb orbits on $\partial^- W$, constants in $W$, and positively parametrized closed Reeb orbits on $\partial^+ W$.

To implement this setup one considers (smooth time-dependent 1–periodic approximations of) Hamiltonians $H_{\mu, \tau}$ described as follows: they are equal to the linear function $\tau r - \tau$ on the symplectization part $[1, \infty) \times \partial^+ W$, they are identically equal to 0 on $W$, they are equal to the linear function $-\mu r + \mu$ on some finite but large part of the negative symplectization $(\delta, 1] \times \partial^- W \subset F$ with $\delta > 0$, and finally they are constant on the remaining part of $F$. Here $\tau > 0$ is required not to be equal to the period of a closed Reeb orbit on $\partial^+ W$, and $\mu > 0$ is required not to be equal to the period of a closed Reeb orbit on $\partial^- W$. Finally, one sets

$$\text{SH}_*(W) = \lim_{b \to \infty} \lim_{a \to -\infty} \lim_{\mu, \tau \to \infty} \text{FH}^{(a, b)}_*(H_{\mu, \tau}),$$

where $\text{FH}^{(a, b)}_*$ denotes Floer homology \textit{truncated in the finite action window} $(a, b)$.

Though the definition may seem frightening when compared to the one for Liouville domains, it is actually motivated analogously by the dynamical interpretation of the groups that we wish to construct. Let us consider the corresponding shape of Hamiltonians depicted in Figure 2. (The vertical thick dotted arrows in Figure 2 indicate that we consider limits over $\mu \to \infty$ and $\tau \to \infty$.) A Hamiltonian $H_{\mu, \tau}$ has 1–periodic orbits either in the regions where it is constant, or in the small “bending” regions near $\{\delta\} \times \partial^- W$ and $\partial^\pm W$ where it acquires some derivative with respect to the symplectization coordinate $r$. The role of the finite action window $(a, b)$ in the definition is to take into account only the orbits located in the areas indicated by arrows in Figure 2: as $\mu$ and $\tau$ increase, the orbits located deep inside the filling $F$ have very negative action and naturally fall outside the action window. The order of the limits on the extremities of the action window, first an inverse limit on $a \to -\infty$ and then a direct limit on $b \to \infty$, is important. It has two motivations:

(i) The inverse limit functor is not exact except when applied to an inverse system consisting of finite-dimensional vector spaces. Should one wish to exchange the order of the limits on $a$ and $b$, such a finite-dimensionality property would
typically not hold on the inverse system indexed by $a \to -\infty$, and this would have implications on the various exact sequences that we construct in the paper.

(ii) With this definition, symplectic homology of a cobordism is a ring with unit (see Section 10). Should one wish to reverse the order of the limits on $a$ and $b$, this would not be true anymore.

![Figure 2: Symplectic homology of a cobordism](image)

It turns out that the full structure of symplectic homology involves in a crucial way a definition that is yet more involved, namely that of symplectic homology groups of a pair of filled Liouville cobordisms. To give the definition of such a pair it is important to single out the operation of composition of cobordisms, which we already implicitly used above. Given cobordisms $W$ and $W'$ such that $\partial^+ W = \partial^- W'$ as contact manifolds, one forms the Liouville cobordism $W \circ W' = W_{\partial_+ W \cup \partial^- W'}$ by gluing the two cobordisms along the corresponding boundary. The resulting Liouville structure is well-defined up to homotopy. A pair of Liouville cobordisms $(W, V)$ then consists of a Liouville cobordism $(W, \omega, \lambda)$ together with a codimension-0 submanifold with boundary $V \subset W$ such that $(V, \omega|_V, \lambda|_V)$ is a Liouville cobordism and $(W \setminus V, \omega|_W, \lambda|$) is the disjoint union of two Liouville cobordisms $W^{\text{bottom}}$ and $W^{\text{top}}$ such that $W = W^{\text{bottom}} \circ V \circ W^{\text{top}}$. We allow any of the cobordisms $W^{\text{bottom}}$, $W^{\text{top}}$ or $V$ to be empty. If $V = \emptyset$, we think of the pair $(W, \emptyset)$ as being the cobordism $W$ itself. A convenient abuse of notation is to allow $V = \partial^+ W$ or $V = \partial^- W$, in which case we think of $V$ as being a trivial collar cobordism on $\partial^{\pm} W$. This setup does not allow for $V = \partial W$ in case the latter has both negative and positive components, but one can extend it in this direction without much difficulty at the price of somewhat burdening the notation; see Remark 1.1 and Section 2.6. A pair of Liouville cobordisms with filling is a pair $(W, V)$ as above, together with an exact filling $F$ of $\partial^- W$. In this case the cobordism $V$ inherits a natural filling $F \circ W^{\text{bottom}}$. See Figure 3.

Given a cobordism pair $(W, V)$ with filling $F$, we define a symplectic homology group $\text{SH}_*(W, V)$ by a procedure similar to the above, involving suitable direct and inverse
limits and based on Hamiltonians that have the more complicated shape depicted in Figure 4. The Hamiltonians depend now on three parameters $\mu, v, \tau > 0$ and the vertical thick dotted arrows in Figure 4 indicate that we consider limits over $\mu, v, \tau \to \infty$. One sets

$$SH_\ast(W, V) = \lim_{b \to \infty} \lim_{a \to -\infty} \lim_{\mu, \tau \to \infty} \lim_{v \to \infty} FH_\ast(a, b)(H_{\mu, v, \tau}).$$

This is as complicated as it gets. The definition is again motivated by the dynamical interpretation of the groups that we wish to construct. For a given finite action window and for suitable choices of the parameters, the orbits that are taken into account in $FH_\ast(H_{\mu, v, \tau})$ are located in the regions indicated by arrows in Figure 4. They correspond (from left to right in the picture) to negatively parametrized closed Reeb orbits on $\partial^- W$, to constants in $W_{\text{bottom}}$, to negatively parametrized closed Reeb orbits on $\partial^- V$, to positively parametrized closed Reeb orbits on $\partial^+ V$, to constants in $W_{\text{top}}$, and finally to positively parametrized closed Reeb orbits on $\partial^+ W$ (see Section 6).

We wish to emphasize at this point the fact that the above groups of periodic orbits cannot be singled out solely from action considerations. Filtering by the action and considering suitable subcomplexes or quotient complexes is the easiest way to extract useful information from some large chain complex, but this is not enough for our purposes here. Indeed, getting hold of enough tools in order to single out the desired groups of orbits was one of the major difficulties that we encountered. We gathered these tools in Section 2.3, and there are no fewer than four of them: a robust maximum principle (Lemma 2.2) due to Abouzaid and Seidel [3], an asymptotic behaviour lemma (Lemma 2.3) which appeared for the first time in Bourgeois and Oancea [15], a new stretch-of-the-neck argument tailored to the situation at hand (Lemma 2.4), and a new mechanism to exclude certain Floer trajectories asymptotic to constant orbits (Lemma 2.5). The simultaneous use of these tools is illustrated by the proof of the excision theorem, Theorem 6.8.
Important particular cases of such relative symplectic homology groups are the *symplectic homology groups of a filled Liouville cobordism relative to (a part of) its boundary*. Recalling that we think of a contact-type hypersurface in \( W \) as a trivial collar cobordism, we obtain groups \( \text{SH}_*(W, \partial W) \). It turns out that these can be equivalently defined using Hamiltonians of a much simpler shape, as shown in Figure 5. It is then straightforward to define also symplectic homology groups \( \text{SH}_*(W, \partial W) \), which play a role in the formulation of Poincaré duality; see Section 3.2. We refer to Section 2.4 for the details of the definitions.

**Remark 1.1** Our previous conventions for Liouville pairs do not allow us to interpret \( \text{SH}_*(W, \partial W) \) as symplectic homology of the pair \((W, [0, 1] \times \partial W)\) if \( \partial W \) has both negative and positive components. To remedy for this one needs to further extend the setup to *pairs of multilevel Liouville cobordisms with filling*; see Section 2.6.

The mnemotechnic rule for all these constructions is the following:
To compute $\text{SH}_*(W, V)$ one must use a family of Hamiltonians that vanish on $W \setminus V$, that go to $-\infty$ near $\partial V$ and that go to $+\infty$ near $\partial W \setminus \partial V$.

Some of these shapes of Hamiltonians already appeared, if only implicitly, in Viterbo’s foundational paper [68], as well as in Cieliebak [24]. We make their use systematic.

These constructions have Lagrangian analogues, which we will refer to as the open theory. The main notion is that of an exact Lagrangian cobordism with filling, meaning an exact Lagrangian submanifold $L \subset W$ of a Liouville cobordism $W$ which intersects $\partial W$ transversally and is such that $\partial^- L = L \cap \partial^- W$ is the Legendrian boundary of an exact Lagrangian submanifold $L_F \subset F$ inside the filling $F$ of $W$. We call $L_F$ an exact Lagrangian filling. There is also an obvious notion of exact Lagrangian pair with filling. The open theory associates to such a pair $(L, K)$ a Lagrangian symplectic homology group $\text{SH}_*(L, K)$, which is an invariant of the Hamiltonian isotopy class preserving boundaries of the pair $(L, K)$ inside the Liouville pair $(W, V)$. (In the case of a single Lagrangian $L$ with empty negative boundary this is known under the name of wrapped Floer homology of $L$.) Formally the implementation of the Lagrangian setup is the same, using exactly the same shapes of Hamiltonians for a Lagrangian Floer homology group. The generators of the relevant chain complexes are then Hamiltonian chords which correspond either to Reeb chords with endpoints on the relevant Legendrian boundaries, or to constants in the interior of the relevant Lagrangian cobordisms. One can also mix the closed and open theories together as in Ekholm and Oancea [39] — see Section 8.3 — and there are also $S^1$–equivariant closed theories; see Section 8.2. In order to streamline the discussion, we shall restrict in this introduction to the nonequivariant closed theory described above.

Remark (grading) For simplicity we shall restrict in this paper to Liouville domains $W$ whose first Chern class vanishes. In this case the filtered Floer homology groups are $\mathbb{Z}$–graded by the Conley–Zehnder index, where the grading depends on the choice of a trivialization of the canonical bundle of $W$ for each free homotopy classes of loops. If $c_1(W)$ is nonzero, the groups are only graded modulo twice the minimal Chern number.

As announced in the title, one way to state our results is in terms of the Eilenberg–Steenrod axioms for a homology theory. We define a category, which we call the Liouville category with fillings, whose objects are pairs of Liouville cobordisms with filling, and whose morphisms are exact embeddings of pairs of Liouville cobordisms.
with filling. Such an exact embedding of a pair \((W, V)\) with filling \(F\) into a pair \((W', V')\) with filling \(F'\) is an exact codimension-0 embedding \(f: W \hookrightarrow W'\), meaning that \(f^*\lambda' - \lambda\) is an exact 1–form, together with an extension \(\overline{f}: F \circ W \hookrightarrow F' \circ W'\) which is also an exact codimension-0 embedding, such that \(f(V) \subset V'\). A cobordism triple \((W, V, U)\) (with filling) is a topological triple such that \((W, V)\) and \((V, U)\) are cobordism pairs (with filling).

**Theorem 1.2**  Symplectic homology with coefficients in a field \(\mathbb{K}\) defines a contravariant functor from the Liouville category with fillings to the category of graded \(\mathbb{K}\)–vector spaces. It associates to a pair \((W, V)\) with filling the symplectic homology groups \(\text{SH}_*(W, V)\), and to an exact embedding \(f: (W, V) \hookrightarrow (W', V')\) between pairs with fillings a linear map

\[ f_!: \text{SH}_*(W', V') \rightarrow \text{SH}_*(W, V), \]

called the Viterbo transfer map or shriek map. This functor satisfies the following properties:

(i) **Homotopy**  If \(f\) and \(g\) are homotopic through exact embeddings, then

\[ f_! = g_!. \]

(ii) **Exact triangle of a pair**  Given a pair \((W, V)\) for which we have the inclusions \(V \hookrightarrow W \hookrightarrow (W, V)\), there is a functorial exact triangle in which the map \(\partial\) has degree \(-1\):

\[
\begin{array}{ccc}
\text{SH}_*(W, V) & \xrightarrow{j!} & \text{SH}_*(W) \\
\downarrow{\partial} & & \downarrow{i!} \\
\text{SH}_*(V) & \xleftarrow{\partial} & \text{SH}_*(W, V)
\end{array}
\]

(Here we identify as usual a cobordism \(W\) with the pair \((W, \emptyset)\).)

(iii) **Excision**  For any cobordism triple \((W, V, U)\), the transfer map induced by the inclusion \((W \setminus \text{int}(U), V \setminus \text{int}(U)) \hookrightarrow (W, V)\) is an isomorphism

\[ i_!: \text{SH}_*(W, V) \xrightarrow{\cong} \text{SH}_*(W \setminus \text{int}(U), V \setminus \text{int}(U)). \]

These are symplectic analogues of the first Eilenberg–Steenrod axioms [34] for a homology theory. The one fact that may be puzzling about our terminology is that we insist on calling this a homology theory, though it defines a contravariant functor. Our arguments are the following. The first one is geometric: With \(\mathbb{Z}/2\)–coefficients we have
an isomorphism $\text{SH}_*(T^*M) \simeq H_*(\mathcal{LM})$ between the symplectic homology of the cotangent bundle of a closed manifold $M$ and the homology of $\mathcal{LM}$, the space of free loops on $M$. Moreover, the product structure on $\text{SH}_*(T^*M)$ is isomorphic to the Chas–Sullivan product structure on $H_*(\mathcal{LM})$, and the latter naturally lives on homology since it extends the intersection product on $H_*(M) \cong H_{n+*}(T^*M, T^*M \setminus M)$. The second one is algebraic and uses the $S^1$–equivariant version of symplectic homology (see Section 8.2): We wish that $S^1$–equivariant homology with coefficients in any ring $R$ be naturally a $R[u]$–module, with $u$ a formal variable of degree $-2$, and that multiplication by $u$ be nilpotent. In contrast, $S^1$–equivariant cohomology should naturally be a $R[u]$–module, with $u$ of degree $+2$, and multiplication by $u$ should typically not be nilpotent. This is exactly the kind of structure that we have on the $S^1$–equivariant version of our symplectic homology groups. The third one is an algebraic argument that refers to the $0$–level part of the $S^1$–equivariant version of a filled Liouville cobordism: Given such a cobordism $W^{2n}$, this $0$–level part is denoted by $\text{SH}^{S^1,=0}_k(W)$ and can be expressed either as the degree $n+k$ part of $H_*(W, \partial W) \otimes R[u^{-1}]$, with $R$ the ground ring and $u$ of degree $-2$, or as the degree $n-k$ part of $H^*(W) \otimes R[u]$. Since $H^*(W) \otimes R[u]$ is nontrivial in arbitrarily negative degrees, it is only the first expression that allows the interpretation of $\text{SH}^{S^1,=0}_k(W)$ as the singular (co)homology group of a topological space via the Borel construction. This natural emphasis on homology determines our interpretation of the induced maps as shriek or transfer maps.

Our bottom line is that the theory is homological in nature, but contravariant because the induced maps are shriek maps.

Note that in the case of a pair $(W, V)$ the simplest expression for $\text{SH}^{S^1,=0}_k(W, V)$ is obtained by identifying it with the degree $n-k$ part of the cohomology group $H^*(W, V) \otimes R[u^{-1}]$. To turn this into homology one needs to use excision followed by Poincaré duality, and the expression gets more cumbersome. A similar phenomenon happens for the nonequivariant version $\text{SH}^{=0}_*(W, V)$. In order to simplify the notation we identify the $0$–level part of symplectic homology with singular cohomology.

Remark (coefficients) The symplectic homology groups are defined with coefficients in an arbitrary ring $R$, and statement (i) in Theorem 1.2 is valid with arbitrary coefficients too. Field coefficients are necessary only for statements (ii) and (iii). As a general fact, the statements in this paper which involve exact triangles are only valid with field coefficients, and the proof of excision does require such an exact triangle;
see Section 6. The reason is that we define our symplectic homology groups as a first-inverse-then-direct-limit over symplectic homology groups truncated in a finite action window. The various exact triangles involving symplectic homology are obtained by passing to the limit in the corresponding exact triangles for such finite action windows, at which point the question of the exactness of the direct limit functor and of the inverse limit functor arises naturally. While the direct limit functor is exact, the inverse limit functor is not. Nevertheless, the inverse limit functor is exact when applied to inverse systems consisting of finite-dimensional vector spaces, which is the case for symplectic homology groups truncated in a finite action window. In order to extend the exact triangle of a pair (and also the other exact triangles which we establish in this paper) to arbitrary coefficients one would need to modify the definition of our groups by passing to the limit at chain level and use a version of the Mittag-Leffler condition, a path that we shall not pursue here. See also the discussion of factorization homology below, the discussion in Section 4 and Remark 8.2. More generally, one can define symplectic homology with coefficients in a local system with fibre $\mathbb{K}$ — see Abouzaid [1] and Ritter [63] — and most of the results of this paper adapt in a quite straightforward way to that setup. One notable exception is the duality results in Section 3, in which the treatment of local coefficients would be more delicate.

In view of the above discussion, we henceforth adopt the following convention:

**Convention** (coefficients) *In this paper we use constant coefficients in a field $\mathbb{K}$.*

Let us now discuss briefly the two other Eilenberg–Steenrod axioms, namely the direct sum axiom and the dimension axiom, and explain why they do not, and indeed cannot, have a symplectic counterpart.

(I) The *direct sum axiom* expresses the fact that the homology of an arbitrary disjoint union of topological spaces is naturally isomorphic to the direct sum of their homologies, whereas in contrast a cohomology theory would involve a direct product. The distinction between direct sums and direct products is not relevant in the setup of Liouville domains, which are by definition compact and therefore consist of at most finitely many connected components. Passing to arbitrary disjoint unions would mean to go from Liouville domains to Liouville manifolds as in Seidel [66], and the contravariant nature of the functor would imply that it behaves as a direct product. This is one of the reasons why [66] refers to the same object as “symplectic cohomology”. However, in view of the extension of the definition to cobordisms this appears to be only a superficial
distinction. The deeper fact is that, whichever way one turns it around, symplectic homology of a cobordism with nonempty negative boundary is an object of a mixed homological–cohomological nature because its definition involves both a direct limit (on \( b \to \infty \)) and an inverse limit (on \( a \to -\infty \)). We actually present in Section 3.3 an example showing that algebraic duality fails already in the case of symplectic homology of a trivial cobordism.

(II) The dimension axiom of Eilenberg and Steenrod expresses the fact that the value of the functor on any pair homotopy equivalent to a pair of CW–complexes is determined by its value on a point. This fact relies on the homotopy axiom and illustrates the strength of the latter: since any ball is homotopy equivalent to a point, the homotopy axiom allows one to go up in dimension for computations. As a matter of fact, the dimension of a space plays no role in the definition of a homology theory in the sense of Eilenberg and Steenrod, although it is indeed visible homologically via the fact that the homology of a pair consisting of an \( n \)–ball and of its boundary is concentrated in degree \( n \). In contrast, symplectic homology is a dimension-dependent theory. Moreover, it cannot be determined by its value on a single object. No change in dimension is possible, and no dimension axiom can exist. For example, symplectic homology vanishes on the \( 2n \)–dimensional ball since the latter is subcritical, but the theory is nontrivial. The symplectic analogue of the class of CW–complexes is that of Weinstein manifolds, and the whole richness of symplectic homology is encoded in the way it behaves under critical handle attachments; see Bourgeois, Ekholm and Eliashberg [13]. One could say that it is determined by its value on the elementary cobordisms corresponding to a single critical handle attachment, but that would be an essentially useless statement, since it would involve all possible contact manifolds and all their possible exact fillings. The complexity of symplectic homology reflects that of Reeb dynamics and is such that there is no analogue of the dimension axiom.

We show in Section 3.2 how to interpret Poincaré duality by defining an appropriate version of symplectic cohomology, and we establish in Section 7.4 a Mayer–Vietoris exact triangle.

It is interesting to note at this point a formal similarity with the recent development of factorization homology; see Ayala and Francis [7]. Roughly speaking, a factorization homology theory is a graded vector space valued monoidal functor defined on some category of open topological manifolds of fixed dimension \( n \), with morphism spaces given by topological embeddings and which obeys a dimension axiom involving the notion of an \( E_n \)–algebra. (Such a category includes in particular that of closed
manifolds of dimension $n - 1$, which are identified with open trivial cobordisms of one dimension higher, a procedure very much similar to our viewpoint on contact hypersurfaces as trivial cobordisms.) If one forgets the monoidal property then one essentially recovers the restriction of an Eilenberg–Steenrod homology theory to a category of manifolds of fixed dimension. Conjecturally, the symplectic analogue of a factorization homology theory should involve some differential graded algebra (DGA) enhancement of symplectic homology in the spirit of Ekholm and Oancea [39], and the axioms satisfied by factorization homology should provide a reasonable approximation to the structural properties satisfied by such a DGA enhancement.

One other lesson that the authors have learned from Ayala and Francis [7] is that the Eilenberg–Steenrod axioms can, and probably should, be formulated at chain level. More precisely, the target of a homological functor is naturally the category of chain complexes up to homotopy rather than that of graded $R$–modules. This kind of formulation in the case of symplectic homology seems to lie at close hand using the methods of our paper, but we shall not deal with it.

A fruitful line of thought, pioneered by Viterbo [68] in the case of Liouville domains, is to compare the symplectic homology groups of a pair $(W, V)$ with the singular cohomology groups, the philosophy being that the difference between the two measures the amount of homologically interesting dynamics on the relevant contact boundary. The singular cohomology $H^{n-*}(W, V)$ is visible through the Floer complex generated by the constant orbits in $W \setminus V$ of any of the Hamiltonians $H_{\mu, v, \tau}$ (see Figure 4) with the degree shift being dictated by our normalization convention for the Conley–Zehnder index, and this Floer complex coincides with the Morse complex since we work on symplectically aspherical manifolds and the Hamiltonian is essentially constant in the relevant region; see Salamon and Zehnder [65]. Note also that these constant orbits are singled out among the various types of orbits involved in the computation of $\text{SH}_*(W, V)$ by the fact that their action is close to zero, whereas all the other orbits have negative or positive action bounded away from zero. Accordingly, we denote the resulting homology group by $\text{SH}_*^{=0}(W, V)$, with the understanding that we have an isomorphism

$$\text{SH}_*^{=0}(W, V) \simeq H^{n-*}(W, V).$$

In the case of a Liouville domain (Figure 1) we see that these constant orbits form a subcomplex since all the other orbits have positive action. As such, for a Liouville domain there is a natural map $H^{n-*}(W) \to \text{SH}_*(W)$. In the case of a cobordism or of a pair of cobordisms such a map does not exist anymore since the orbits on level
zero do not form a subcomplex. The correct way to heal this apparent ailment is to consider symplectic homology groups *truncated in action with respect to the zero level*, which we denote by

\[
\text{SH}^<_{*0}(W, V), \quad \text{SH}^>_{*0}(W, V), \quad \text{SH}^{\leq 0}_{*0}(W, V), \quad \text{SH}^{\geq 0}_{*0}(W, V).
\]

Their meaning is the following: each of them, respectively, takes into account, *among the orbits involved in the definition of SH_{*}(W, V)*, the ones which have strictly positive action (on $\partial^+ V$ and $\partial^+ W$), nonnegative action (on $\partial^+ V$, $\partial^+ W$ and $W \setminus V$), non-positive action (on $\partial^- V$, $\partial^- W$ and $W \setminus V$), and negative action (on $\partial^- V$ and $\partial^- W$). We refer to Sections 2.4 and 2.5 for the definitions.

We have maps $\text{SH}^<_{*0}(W, V) \to \text{SH}^{\leq 0}_{*0}(W, V) \to \text{SH}^>_{*0}(W, V)$ induced by inclusions of subcomplexes, and also maps $\text{SH}^{\leq 0}_{*}(W, V) \to \text{SH}^{> 0}_{*}(W, V) \to \text{SH}^{= 0}_{*}(W, V)$ induced by projections onto quotient complexes. The group $\text{SH}^{= 0}_{*}(W, V)$ can be thought of as a homological cone since it completes the map $\text{SH}^<_{*0}(W, V) \to \text{SH}^{\leq 0}_{*0}(W, V)$ to an exact triangle. The various maps which connect these groups are conveniently depicted as forming an octahedron as in

\[
\begin{array}{ccc}
\text{SH}^<_{*0} & \xrightarrow{[-1]} & \text{SH}^<=_{*0} \\
& \searrow & \\
\text{SH}^{= 0}_{*} & \xrightarrow{[-1]} & \text{SH}^>_{*0} \\
\end{array}
\]

The continuous arrows preserve the degree, whereas the dotted arrows decrease the degree by 1. Among the eight triangles forming the surface of the octahedron, the four triangles whose sides consist of one dotted arrow and two continuous arrows are exact triangles (see Proposition 2.18), and the four triangles whose sides consist either of three continuous arrows or of one continuous arrow and two dotted arrows are commutative. The structure of this octahedron is exactly the same as the one

*Algebraic & Geometric Topology, Volume 18 (2018)*
involved in the octahedron axiom for a triangulated category — see Kashiwara and Schapira [54, Chapter 1] — and for a good reason: this tautological octahedron can be deduced from the octahedron axiom of a triangulated category starting from (the chain level version of) a commuting triangle which involves $\text{SH}_<^0$, $\text{SH}_>^0$ and $\text{SH}_*$, and in which the composition of the natural maps $\text{SH}_<^0 \to \text{SH}_>^0 \to \text{SH}_*$ is the natural map $\text{SH}_<^0 \to \text{SH}_*$. Turning this around, this action-filtered octahedron can serve as an interpretation of the octahedron axiom for a triangulated category fit for readers with a preference for variational methods over homological methods.

Our uniform and emotional notation for these groups is

$\text{SH}_{\heartsuit}^\land(W, V), \quad \heartsuit \in \{\emptyset, > 0, \geq 0, = 0, \leq 0, < 0\},$

with the meaning that $\text{SH}_{\emptyset}^\land = \text{SH}_*$.

**Definition 1.3** A functor from the Liouville category with fillings to the category of graded $\mathbb{K}$–vector spaces satisfying the conclusions of Theorem 1.2 is called a **Liouville homology theory**.

**Theorem 1.4** For $\heartsuit \in \{\emptyset, > 0, \geq 0, = 0, \leq 0, < 0\}$ the action-filtered symplectic homology group $\text{SH}_{\heartsuit}^\land$ with coefficients in a field $\mathbb{K}$ defines a Liouville homology theory.

The octahedron (1) defines a diagram of natural transformations which is compatible with the functorial exact sequence of a pair.

In particular, each of the symplectic homology groups $\text{SH}_{\heartsuit}^\land$ defines a Liouville homotopy invariant of the pair $(W, V)$. Note that such an invariance statement can only hold provided we truncate the action with respect to the zero value, which is the level of constant orbits. Indeed, answering a question of Polterovich and Shelukhin, we can define symplectic homology groups $\text{SH}_{(a, b)}^\land(W, V)$ truncated in an arbitrary action interval $(a, b) \subset \mathbb{R}$ (see Section 2.5) and the exact triangle of a pair still holds for $\text{SH}_{(a, b)}^\land$. However, the homotopy axiom would generally break down and the resulting homology groups would not be Liouville homotopy-invariant, except if the interval is either small and centred at 0, or semi-infinite with the finite end close enough to 0, which are the cases that we consider. Failure of Liouville homotopy-invariance for most truncations by the action can be easily detected by rescaling the symplectic form. We believe this action filtration carries interesting information for cobordisms in the form of spectral invariants, or more generally persistence modules; see Polterovich and Shelukhin [62].
What do we gain from this extension of the theory of symplectic homology from Liouville domains to Liouville cobordisms, and from having singled out the action-filtered symplectic homology groups $\text{SH}_{\ast, ?}$? Firstly, a broad unifying perspective. Secondly, new computational results. We refer to Sections 8, 9 and 10 for a full discussion, and give here a brief overview.

(a) Our point of view encompasses symplectic homology, wrapped Floer homology, Rabinowitz–Floer homology, $S^1$–equivariant symplectic homology, linearized contact homology and nonequivariant linearized contact homology. Indeed:

In view of Cieliebak, Frauenfelder and Oancea [29], Rabinowitz–Floer homology of a separating contact hypersurface $\Sigma$ in a Liouville domain $W$ is $\text{SH}_{\ast}(\Sigma)$, understood to be computed with respect to the natural filling $\text{int}(\Sigma)$.

We show in Section 8.2 that Viterbo’s $S^1$–equivariant symplectic homology $\text{SH}_{\ast}^{S^1}$ and its flavours $\text{SH}_{\ast, \lozenge}^{S^1}$ define Liouville homology theories, and the same is true for negative and periodic cyclic homology. The Gysin exact sequences are diagrams of natural transformations which are compatible with the exact triangles of pairs and with the octahedron (1).

In view of Bourgeois and Oancea [18, Theorem 1.3], linearized contact homology is encompassed by $\text{SH}_{\ast}^{S^1, \geq 0}$ and nonequivariant linearized contact homology is encompassed by $\text{SH}_{\ast}^{> 0}$. Moreover, our enrichment of symplectic homology to (pairs of) cobordisms indicates several natural extensions of linearized contact homology theories which blend homology with cohomology and whose definition involves the “banana”, ie the genus-zero curve with two positive punctures; see also Bourgeois, Ekholm and Eliashberg [12] and Remark 9.22. Indeed, such an enrichment should exist at the level of contact homology too, ie nonlinearized.

(b) Most of the key exact sequences established in recent years for symplectic invariants involving pseudoholomorphic curves appear to us as instances of the exact triangle of a pair. Examples are the critical handle attaching exact sequence (see Bourgeois, Ekholm and Eliashberg [13]), the new subcritical handle attaching exact sequence of Section 9.6 (see also Bourgeois and Koert [19]), the exact sequence relating Rabinowitz–Floer homology and symplectic homology (see Cieliebak, Frauenfelder and Oancea [29]), and the Legendrian duality exact sequence (see Ekholm, Etnyre and Sabloff [36]). We discuss these in detail in Section 9. Our point of view embeds all these isolated results into a much larger framework and establishes compatibilities between exact triangles, eg with Gysin exact triangles; see Section 8.2.
(c) Since our setup covers Rabinowitz–Floer homology, it clarifies in particular its functorial behaviour. Unlike for symplectic homology, a cobordism does not give rise to a transfer map but rather to a correspondence

$$\text{SH}_*(\partial^- W) \leftarrow \text{SH}_*(W) \rightarrow \text{SH}_*(\partial^+ W).$$

This allows us in particular to prove invariance of Rabinowitz–Floer homology under subcritical handle attachment and understand its behaviour under critical handle attachment as a formal consequence of [13]. See Section 9.

(d) We describe in Section 10 which of the symplectic homology groups carry product structures, with respect to which transfer maps are ring homomorphisms as in the classical case of symplectic homology of a Liouville domain. As a consequence we construct a degree $-n$ product on Rabinowitz–Floer homology which induces a degree $1-n$ coproduct on positive symplectic homology.

(e) We give a uniform treatment of vanishing and finite-dimensionality results in Section 9.3.

(f) We establish in Section 7.4 Mayer–Vietoris exact triangles for all flavours $\text{SH}_*^{\triangleright}$. To the best of our knowledge such exact triangles have not appeared previously in the literature.

A word about our method of proof. We already mentioned the confinement lemmas of Section 2.3. There are two other important ingredients in our construction: continuation maps and mapping cones. We now describe their roles. It turns out that the key map of the theory is the transfer map

$$i^!: \text{SH}_*^{\triangleright}(W) \rightarrow \text{SH}_*^{\triangleright}(V)$$

induced by the inclusion $i: V \hookrightarrow W$ for a pair of Liouville cobordisms $(W, V)$ with filling; see Section 5.1. It is instrumental for our constructions to interpret this transfer map as a continuation map determined by a suitable increasing homotopy of Hamiltonians. (Compare with the original definition of Viterbo [68] of the transfer map for Liouville domains, where its continuation nature is only implicit and truncation by the action plays the main role.) The next step is to interpret the homological mapping cone of the transfer map as being isomorphic to the group $\text{SH}_*^{\triangleright}(W, V)$ shifted in degree down by 1 (Proposition 7.13). This is achieved via a systematic use of homological algebra for mapping cones (see Section 4) in which a higher homotopy-invariance property of the Floer chain complex plays a key role (Lemma 4.7). While it is possible
to show directly, starting from the definitions, that the groups $\text{SH}_*(W, V)$, $\text{SH}_*(W)$ and $\text{SH}_*(V)$ fit into an exact triangle, we did not succeed in proving this directly for the truncated versions $\text{SH}_*^\Omega$. The situation was unlocked and the arguments were streamlined upon adopting the continuation map and mapping cone point of view.

We implicitly described the structure of the paper in the body of the introduction, so we shall not repeat it here. The titles of the sections should now be self-explanatory. We end the introduction by mentioning two further directions that unfold naturally from the present paper. The first one is to extend symplectic homology, which is a linear theory in the sense that its output is valued in graded $R$–modules, possibly endowed with a ring structure, to a nonlinear theory at the level of DGAs. This is accomplished for $\text{SH}_*^{>0}$ in Ekholm and Oancea [39], but the other flavours may admit similar extensions too. The second one is a further categorical extension of the theory to the level of the wrapped Fukaya category, in the spirit of Abouzaid and Seidel [3], where this is again accomplished for Liouville domains. We expect in particular a meaningful theory of wrapped Fukaya categories for cobordisms, with interesting applications.

**Acknowledgements**  Thanks to Grégory Ginot for inspiring discussions on factorization homology, to Mihai Damian for having kindly provided the environment that allowed us to overcome one last obstacle in the proof, to Stéphane Guillermou and Pierre Schapira for help with correcting a sign error in Section 4, and to the referee for valuable suggestions. The authors acknowledge the hospitality of the Institute for Advanced Study, Princeton, NJ in 2012 and of the Simons Center for Geometry and Physics, Stonybrook, NY in 2014, when part of this work was carried out. Cieliebak was supported by DFG grant CI 45/6-1. Oancea was supported by the European Research Council via the Starting Grant StG-259118-STEIN and by the Agence Nationale de la Recherche, France via the project ANR-15-CE40-0007-MICROLOCAL. Oancea acknowledges support from the School of Mathematics at the Institute for Advanced Study in Princeton, NJ during the Spring Semester 2017, funded by the Charles Simonyi Endowment.

## 2 Symplectic (co)homology for filled Liouville cobordisms

Symplectic homology for Liouville domains was introduced by Floer and Hofer [42; 26] and Viterbo [68]. In this section we extend their definition to filled Liouville cobordisms. Since symplectic homology is a well-established theory, we will omit many details of
the construction and concentrate on the new aspects. For background we refer to the excellent account [1].

2.1 Liouville cobordisms

A Liouville cobordism \((W, \lambda)\) consists of a compact manifold with boundary \(W\) and a 1–form \(\lambda\) such that \(d\lambda\) is symplectic and \(\lambda\) restricts to a contact form on \(\partial W\). We refer to \(\lambda\) as the Liouville form. If the dimension of \(W\) is \(2n\), the last condition means that \(\lambda \wedge (d\lambda)^{n-1}\) defines a volume form on \(\partial W\). We denote by \(\partial^+ W \subset \partial W\) the union of the components for which the orientation induced by \(\lambda \wedge (d\lambda)^{n-1}\) coincides with the boundary orientation of \(W\) and call it the convex boundary of \(W\). We call \(\partial^- W = \partial W \setminus \partial^+ W\) the concave boundary of \(W\). The convex/concave boundaries of \(W\) are contact manifolds. We refer to [25, Chapter 11] for an exhaustive discussion of Liouville cobordisms and their homotopies. A Liouville domain is a Liouville cobordism such that \(\partial W = \partial^+ W\).

Example 2.1 Given a Riemannian manifold \((N, g)\), its unit codisk bundle \(D^*_r N := \{(q, p) \in T^* N : \|p\|_g \leq r\}\) is a Liouville domain with the canonical Liouville form \(\lambda = p \, dq\), whereas \(T^*_r, R N := D^*_r N \setminus \text{int} \, D^*_r N\) for \(r < R\) is a Liouville cobordism with concave boundary given by \(S^*_r N := \partial D^*_r N\).

Define the Liouville vector field \(Z \in \mathcal{X}(W)\) by \(\iota_Z \, d\lambda = \lambda\) and denote by \(\alpha^\pm\) the restriction of \(\lambda\) to \(\partial^\pm W\). It is a consequence of the definitions that \(Z\) is transverse to \(\partial W\) and points outwards along \(\partial^+ W\), and inwards along \(\partial^- W\). The flow \(\phi^t_Z\) of the vector field \(Z\) defines Liouville trivializations of collar neighbourhoods \(N^\pm\) of \(\partial^\pm W\),

\[
\Psi^+ : ((1 - \varepsilon, 1] \times \partial^+ W, r \alpha^+) \to (N^+, \lambda),
\]

\[
\Psi^- : ([1, 1 + \varepsilon] \times \partial^- W, r \alpha^-) \to (N^-, \lambda),
\]

via the map

\[
(r, x) \mapsto \phi^{ln r}_Z(x).
\]

Given a contact manifold \((M, \alpha)\), its symplectization is given by \((0, \infty) \times M\) with the Liouville form \(r \alpha\). We call \((0, 1] \times M\) and \([1, \infty) \times M\) (both equipped with the form \(r \alpha\)) the negative and positive parts, respectively, of the symplectization.

---

\(^1\)Unless otherwise stated our contact manifolds will be always cooriented and equipped with chosen contact forms.
Given a Liouville cobordism \((W, \lambda)\), we define its *completion* by
\[
\hat{W} = ((0, 1] \times \partial^- W) \sqcup \psi^- W \sqcup [1, \infty) \times \partial^+ W,
\]
with the obvious Liouville form still denoted by \(\lambda\).

Given a contact manifold \((M, \alpha)\) we define a *(Liouville) filling* to be a Liouville domain \((F, \omega)\) together with a diffeomorphism \(\phi: \partial F \to M\) such that \(\phi^* \alpha = \lambda|_{\partial F}\).

We view a Liouville cobordism \((W, \omega, \lambda)\) as a morphism from the concave boundary to the convex boundary, \(W: (\partial^- W, \alpha^-) \to (\partial^+ W, \alpha^+)\). We view a Liouville domain \(W\) as a cobordism from \(\emptyset\) to its convex boundary. Given two Liouville cobordisms \(W\) and \(W'\) together with an identification \(\phi: (\partial^- W, \alpha^-) \cong (\partial^+ W', \alpha'^+)\), we define their *composition* by
\[
W \circ W' = W \sqcup \phi^*: \partial^- W \cong \partial^+ W', W'.
\]
The gluing is understood to be compatible with the trivializations \(\Psi^-\) and \(\Psi'^+\), so that the Liouville forms glue smoothly.

### 2.2 Filtered Floer homology

A contact manifold \((M, \alpha)\) carries a canonical *Reeb vector field* \(R_\alpha \in \mathcal{X}(M)\) defined by the conditions \(i_{R_\alpha} d\alpha = 0\) and \(\alpha(R_\alpha) = 1\). We refer to the closed integral curves of \(R_\alpha\) as *closed Reeb orbits*, or just *Reeb orbits*. We denote by \(\text{Spec}(M, \alpha)\) the set of periods of closed Reeb orbits. This is the critical value set of the action functional given by integrating the contact form on closed loops, and a version of Sard’s theorem shows that \(\text{Spec}(M, \alpha)\) is a closed nowhere dense subset of \([0, \infty)\). If \(M\) is compact, the set \(\text{Spec}(M, \alpha)\) is bounded away from 0 since the Reeb vector field is nonvanishing.

Consider the symplectization \(((0, \infty) \times M, r\alpha)\) and let \(h: (0, \infty) \times M \to \mathbb{R}\) be a function that depends only on the radial coordinate, ie \(h(r, x) = h(r)\). Its Hamiltonian vector field, defined by \(d(r\alpha)(X_h, \cdot) = -dh\), is given by
\[
X_h(r, x) = h'(r) R_\alpha(x).
\]
The 1–periodic orbits of \(X_h\) on the level \([r] \times M\) are therefore in one-to-one correspondence with the closed Reeb orbits with period \(h'(r)\). Here we understand that a Reeb orbit of negative period is parametrized by \(-R_\alpha\), whereas a 0–periodic Reeb orbit is by convention a constant.
Let \((W, \lambda)\) be a Liouville domain and \(\hat{W}\) its completion. We define the class
\[ \mathcal{H}(\hat{W}) \]
of admissible Hamiltonians on \(\hat{W}\) to consist of functions \(H: S^1 \times \hat{W} \to \mathbb{R}\) such that in the complement of some compact set \(K \supset W\) we have \(H(r,x) = ar + c\) with \(a, c \in \mathbb{R}\) and \(a \notin \text{Spec}(\partial W, \alpha) \cup \{0\}\). In particular, \(H\) has no \(1\)–periodic orbits outside the compact set \(K\).

An almost complex structure \(J\) on the symplectization \((0, \infty) \times M, r\lambda\) is called cylindrical if it preserves \(\xi = \ker \alpha\), if \(J|_\xi\) is independent of \(r\) and compatible with \(d(r\alpha)|_\xi\), and if \(J(r\partial_r) = R\alpha\). Such almost complex structures are compatible with \(d(r\alpha)\) and are invariant with respect to dilations \((r,x) \mapsto (cr, x)\) for \(c > 0\). In the definition of Floer homology for admissible Hamiltonians on \(\hat{W}\) we shall use almost complex structures which are cylindrical outside some compact set that contains \(W\), which we call admissible almost complex structures on \(\hat{W}\).

Consider an admissible Hamiltonian \(H\) and an admissible almost complex structure \(J\) on the completion \(\hat{W}\) of a Liouville domain \(W\). To define the filtered Floer homology we use the same notation and sign conventions as in [29], which match those of [24; 3; 39]:
\[
\begin{align*}
  d\lambda(\cdot, J\cdot) &= g_J \quad \text{(Riemannian metric)}, \\
  d\lambda(X_H, \cdot) &= -dH, \quad X_H = J \nabla H \quad \text{(Hamiltonian vector field)}, \\
  \mathcal{L}\hat{W} := C^\infty(S^1, \hat{W}), \quad S^1 = \mathbb{R}/\mathbb{Z} \quad \text{(loop space)}, \\
  A_H: \mathcal{L}\hat{W} \to \mathbb{R}, \quad A_H(x) := \int_{S^1} x^*\lambda - \int_{S^1} H(t,x(t)) \, dt \quad \text{(action)}, \\
  \nabla A_H(x) &= -J(x)(\dot{x} - X_H(t,x)) \quad \text{\((L^2\text{-gradient})\)}, \\
  u: \mathbb{R} \to \mathcal{L}W, \quad \partial_s u = \nabla A_H(u(s, \cdot)) \quad \text{(gradient line)},
\end{align*}
\]
where the last equation is equivalent to
\[
(2) \quad \partial_s u + J(u)(\partial_t u - X_H(t,u)) = 0 \quad \text{(Floer equation)},
\]
and
\[
\mathcal{P}(H) := \text{Crit}(A_H) = \{1\text{-periodic orbits of the Hamiltonian vector field } X_H\}, \\
\mathcal{M}(x_-, x_+; H, J) = \{u: \mathbb{R} \times S^1 \to W \mid \partial_s u = \nabla A_H(u(s, \cdot)), \ u(\pm \infty, \cdot) = x_{\pm}/\mathbb{R} \} \quad \text{(moduli space of Floer trajectories connecting } x_{\pm} \in \mathcal{P}(H)\).
\]
Here the formula expressing the dimension of the moduli space in terms of Conley–Zehnder indices is to be understood with respect to a symplectic trivialization of $u^*TW$.

Let $\mathbb{K}$ be a field and $a < b$ with $a, b \not\in \text{Spec}(\partial W, \alpha)$. We define the filtered Floer chain groups with coefficients in $\mathbb{K}$ by

$$FC^\leq b_*(H) = \bigoplus_{x \in \mathcal{P}(H), A_H(x) < b} \mathbb{K} \cdot x,$$

$$FC^{(a,b)}_*(H) = FC^\leq b_*(H)/FC^{<a}_*(H),$$

with the differential $\partial : FC^{(a,b)}_*(H) \to FC^{(a,b)-1}_*(H)$ given by

$$\partial x_+ = \sum_{CZ(x_-) = CZ(x_+)-1} #\mathcal{M}(x_-, x_+; H, J) \cdot x_-.$$

Here $#$ denotes the signed count of points with respect to suitable orientations. We think of the cylinder $\mathbb{R} \times S^1$ as the twice-punctured Riemann sphere, with the positive puncture at $+\infty$ as incoming, and the negative puncture at $-\infty$ as outgoing. This terminology makes reference to the corresponding asymptote being an input and an output, respectively, for the Floer differential. Note that the differential decreases both the action $A_H$ and the Conley–Zehnder index. The filtered Floer homology is now defined as

$$FH^{(a,b)}_*(H) = \ker \partial / \text{im} \partial.$$

Note that for $a < b < c$ the short exact sequence

$$0 \to FC^{(a,b)}_*(H) \to FC^{(a,c)}_*(H) \to FC^{(b,c)}_*(H) \to 0$$

induces a tautological exact triangle

$$(3) \quad FH^{(a,b)}_*(H) \to FH^{(a,c)}_*(H) \to FH^{(b,c)}_*(H) \to FH^{(a,b)}_*(H)[-1].$$

**Remark** We will suppress the field $\mathbb{K}$ from the notation. As noted in the introduction, the definition can also be given with coefficients in a commutative ring, and more generally with coefficients in a local system as in [63; 1].
2.3 Restrictions on Floer trajectories

We shall frequently make use of the following three lemmas to exclude certain types of Floer trajectories. The first one is an immediate consequence of Lemma 7.2 in [3]; see also [64, Lemma 19.3]. Since our setup differs slightly from the one there, we include the proof for completeness.

**Lemma 2.2** (no escape lemma) Let $H$ be an admissible Hamiltonian on a completed Liouville domain $(\hat{W}, \omega, \lambda)$. Let $V \subset \hat{W}$ be a compact subset with smooth boundary $\partial V$ such that $\lambda|_{\partial V}$ is a positive contact form, $J$ is cylindrical near $\partial V$ and $H = h(r)$ in cylindrical coordinates $(r, x)$ near $\partial V = \{r = 1\}$. If both asymptotes of a Floer cylinder $u: \mathbb{R} \times S^1 \to \hat{W}$ are contained in $V$, then $u$ is entirely contained in $V$.

The result continues to hold if $H_s$ depends on the coordinate $s \in \mathbb{R}$ on the cylinder $\mathbb{R} \times S^1$ such that $\partial_s H_s \leq 0$ and the action $A_{h_s}(r) = r h'_s(r) - h_s(r)$ satisfies $\partial_s A_{h_s}(r) \leq 0$ for $r$ near 1.

**Proof** Assume first that $H$ is $s$–independent. Arguing by contradiction, suppose that $u$ leaves the set $V$. After replacing $V$ by the set $\{r \leq r_0\}$ for a constant $r_0 > 1$ close to 1, we may assume that $u$ leaves $V$ and is transverse to $\partial V$. In cylindrical coordinates near $\partial V$ we have $X_H = h'(r)R$ and $\lambda = r\alpha$, where $R$ is the Reeb vector field of $\alpha = \lambda|_{\partial V}$, so the functions $H = h(r)$ and $\lambda(X_H) = r h'(r)$ are both constant along $\partial V$. Note that their difference equals the action $A_h(r)$.

Now $S := u^{-1}(\hat{W} \setminus \text{int} V)$ is a compact surface with boundary. We denote by $j$ and $\beta$ the restrictions of the complex structure and the 1–form $dt$ from the cylinder $\mathbb{R} \times S^1$ to $S$, so that on $S$ the Floer equation for $u$ can be written as $(du - X_H(u) \otimes \beta)^{0,1} = 0$. We estimate the energy of $u|_S$:

$$E(u|_S) = \frac{1}{2} \int_S |du - X_H \otimes \beta|^2 \text{vol}_S$$

$$= \int_S (u^* d\lambda - u^* dH \wedge \beta)$$

$$= \int_S d(u^* \lambda - (u^* H) \beta) + \int_S (u^* H) \ d\beta$$

$$= \int_{\partial S} (u^* \lambda - (u^* H) \beta)$$

$$= \int_{\partial S} \lambda (du - X_H(u) \otimes \beta)$$
\[
= \int_{\partial S} \lambda (J \circ (du - X_H(u) \otimes \beta) \circ (-j)) \\
= \int_{\partial S} dr \circ du \circ (-j) \\
\leq 0.
\]

Here the equality in the 4th line follows from Stokes’ theorem and \( d\beta \equiv 0 \). The equality in the 5th line holds because the \( r \)-component of \( u|_{\partial S} \) equals \( r_0 \) and thus

\[
\int_{\partial S} u^*(\lambda(X_H) - H)\beta = \int_{\partial S} A_h(r_0)\beta = \int_S A_h(r_0) d\beta = 0.
\]

The equality in the 6th line follows from the Floer equation, and the equality in the 7th line from \( \lambda \circ J = dr \) and \( dr(X_H) = 0 \) along \( \partial V \). The last inequality follows from the fact that for each tangent vector \( \xi \) to \( \partial S \) defining its boundary orientation, \( j_\xi \) points into \( S \), so \( du(j_\xi) \) points out of \( V \) and \( dr \circ du(j_\xi) \geq 0 \). Since \( E(u|_S) \) is nonnegative, it follows that \( E(u|_S) = 0 \), and therefore \( du - X_H(u) \otimes \beta \equiv 0 \). So each connected component of \( u|_S \) is contained in an \( X_H \)-orbit, and since \( X_H \) is tangent to \( \partial V \), \( u(S) \) is entirely contained in \( \partial V \). This contradicts the hypothesis that \( u \) leaves \( V \) and the lemma is proved for \( s \)-independent \( H \).

If \( H_s \) is \( s \)-dependent, we get an additional term \( \int_S (u^* \partial_s H_s) ds \wedge dt \leq 0 \) in the 3rd line, so the equality in the 4th line becomes an inequality \( \leq \). The equality in the 5th line also becomes an inequality \( \leq \) due to the nonpositive additional term in

\[
\int_{\partial S} A_{h_s}(r_0)\beta = \int_S A_{h_s}(r_0) d\beta + \int_S \partial_s A_{h_s}(r_0) ds \wedge dt \leq 0.
\]

This proves the lemma for \( s \)-dependent \( H_s \).

\[\square\]

**Remark**  The proof shows that Lemma 2.2 continues to hold if the cylinder \( \mathbb{R} \times S^1 \) is replaced by a general Riemann surface \( S \) with a 1-form \( \beta \) satisfying \( H d\beta \leq 0 \) and \( A_h(r) d\beta \leq 0 \) for all \( r \) near 1. In this case we can allow \( H \) to depend on \( s \) in holomorphic coordinates \( s + it \) on a region \( U \subset S \) in which \( \beta = c \, dt \) for a constant \( c \geq 0 \), with the requirements \( \partial_s H_s \leq 0 \) and \( \partial_s A_{h_s}(r) \leq 0 \) as before. This generalization underlies the definition of product structures in Section 10.

The second lemma summarizes an argument that appeared first in [15, pages 654–655]. Since the conventions in [15] differ from ours, we include the short proof for completeness.
Lemma 2.3 (asymptotic behaviour lemma) Let \((\mathbb{R}_+ \times M, r\alpha)\) be the symplectization of a contact manifold \((M, \alpha)\). Let \(H = h(r)\) be a Hamiltonian depending only on the radial coordinate \(r \in \mathbb{R}_+\), and let \(J\) be a cylindrical almost complex structure. Let \(u = (a, f): \mathbb{R}_\pm \times S^1 \to \mathbb{R}_+ \times M\) be a solution of the Floer equation (2) with 
\[ \lim_{s \to \pm \infty} u(s, \cdot) = (r_\pm, \gamma_\pm(\cdot)) \]
for suitably parametrized Reeb orbits \(\gamma_\pm\).

(i) Assume \(h''(r_-) > 0\). Then either there exists \((s_0, t_0) \in \mathbb{R} \times S^1\) such that \(a(s_0, t_0) > r_-\), or \(u\) is constant equal to \((r_-, \gamma_-)\).

(ii) Assume \(h''(r_+) < 0\). Then either there exists \((s_0, t_0) \in \mathbb{R} \times S^1\) such that \(a(s_0, t_0) > r_+\), or \(u\) is constant equal to \((r_+, \gamma_+)\).

Proof In coordinates \((s, t) \in \mathbb{R}_\pm \times S^1\), the Floer equation for \(u = (a, f)\) with Hamiltonian \(H = h(r)\) expands to

\[ \begin{aligned}
\partial_s a - \alpha(\partial_t f) + h'(a) &= 0, \\
\partial_t a + \alpha(\partial_s f) &= 0, \\
\pi_\xi &\partial_s f + J(f)\pi_\xi \partial_t f = 0,
\end{aligned} \]

where \(\pi_\xi: TM \to \xi = \ker \alpha\) is the projection along the Reeb vector field \(R\). In case (i), suppose \(h''(r_-) > 0\) and \(a(s, t) \leq r_-\) for all \((s, t) \in \mathbb{R}_- \times S^1\). After replacing \(\mathbb{R}_- \times S^1\) by a smaller half-cylinder we may assume that \(h''(a(s, t)) \geq 0\) for all \((s, t) \in \mathbb{R}_- \times S^1\). Then the average \(\overline{a}(s) := \int_0^1 a(s, t)\ dt\) satisfies

\[ \begin{aligned}
\overline{a}'(s) &= \int_0^1 \partial_s a(s, t)\ dt \\
&= \int_0^1 \alpha(\partial_s f)(s, t)\ dt - \int_0^1 h'(a(s, t))\ dt \\
&\geq \int_0^1 f^* \alpha(s) - \int_0^1 h'(r_-)\ dt \\
&\geq \int_{\gamma_-} \alpha - h'(r_-) = h'(r_-) - h'(r_-) = 0.
\end{aligned} \]

Here the second equality follows from the first equation in (4), the first inequality from \(a(s, t) \leq r_-\) and \(h''(a(s, t)) \geq 0\), and the second inequality from Stokes’ theorem and \(f^* d\alpha \geq 0\). For the third equality observe that \(x_-(t) = (r_-, \gamma_-(t))\) is a 1–periodic orbit of \(X_H = h'(r) R\) if and only if \(\dot{y}_- = h'(r_-) R\), so that \(\int_{\gamma_-} \alpha = h'(r_-)\).

Now \(\overline{a}'(s) \geq 0\) and \(\overline{a}(-\infty) = r_-\) imply that \(\overline{a}(s) \geq r_-\) for all \(s\), which is compatible with \(a(s, t) \leq r_-\) only if \(a(s, t) = r_-\) for all \((s, t)\). Then all of the preceding inequalities are equalities; in particular, \(f^* d\alpha \equiv 0\), and therefore \(u(s, t) = (r_-, \gamma_1(t))\) for all \((s, t)\). This proves case (i). Case (ii) follows from case (i) by replacing \(h\) by \(-h\) and \(u(s, t)\) by \(u(-s, -t)\).

\[ \square \]
Lemma 2.3 can be rephrased by saying that nonconstant Floer trajectories must rise above their output asymptote if the Hamiltonian is convex at the asymptote, and they must rise above their input asymptote if the Hamiltonian is concave at the asymptote. Combined with Lemma 2.2, it forbids Floer trajectories of the kind shown in Figure 6.

Figure 6: Such Floer trajectories are forbidden by Lemma 2.3 in combination with Lemma 2.2.

The third lemma follows from a neck-stretching argument using the compactness theorem in symplectic field theory (SFT). We refer to Figure 7 for a sketch of a situation in which a certain kind of Floer trajectory is forbidden by this technique.

**Lemma 2.4** (neck-stretching lemma) Let $H$ be an admissible Hamiltonian on a completed Liouville domain $(\hat{W}, \lambda)$. Let $V \subset \hat{W}$ be a compact subset with smooth boundary $\partial V$ such that $H \equiv c$ near $\partial V$ and $\lambda|_{\partial V}$ is a positive contact form. Let $J_R$ be the compatible almost complex structure on $\hat{W}$ obtained from $J$ by inserting a cylinder of length $2R$ around $\partial V$. Then for sufficiently large $R$ there exists no $J_R$–Floer cylinder $u: \mathbb{R} \times S^1 \to \hat{W}$ with asymptotic orbits $x_\pm$ at $\pm \infty$ such that

1. $x_- \subset \text{int } V$ and $x_+ \subset \hat{W} \setminus V$ with $A_H(x_+) < -c$, or
2. $x_+ \subset V$ and $x_- \subset \hat{W} \setminus V$ with $A_H(x_-) > -c$.

**Proof** Let us first describe more precisely the neck-stretching along $M = \partial V$. Pick a tubular neighbourhood $[-\varepsilon, \varepsilon] \times M$ of $M$ in $\hat{W}$ on which $H \equiv c$ and $\lambda = e^{\rho} \alpha$, where $\alpha = \lambda|_M$ and $\rho$ denotes the coordinate on $\mathbb{R}$. Let $J$ be a compatible almost complex structure on $\hat{W}$ whose restriction $J_0$ to $[-\varepsilon, \varepsilon] \times M$ is independent of $\rho$ and maps $\xi = \ker \alpha$ to $\xi$ and $\partial \rho$ to $\partial \alpha$. Let $\phi_R$ be any diffeomorphism $[-R, R] \to [-\varepsilon, \varepsilon]$ with derivative 1 near the boundary. Then we define $J_R$ on $\hat{W}$ by $(\phi_R \times \text{id})_* J_0$ on $[-\varepsilon, \varepsilon] \times M$, and by $J$ outside $[-\varepsilon, \varepsilon] \times M$. 

*Algebraic & Geometric Topology, Volume 18 (2018)*
Consider a \( J_R \)-Floer cylinder \( u: \mathbb{R} \times S^1 \to \hat{W} \) with asymptotic orbits \( x_{\pm} \). Its Floer energy is given by

\[
A_H(x_+) - A_H(x_-) = \int_{\mathbb{R} \times S^1} |\partial_s u|^2 ds \, dt = \int_{\mathbb{R} \times S^1} u^* (d\lambda - dH \wedge dt).
\]

Set \( \Sigma = u^{-1}([-\epsilon, \epsilon] \times M) \) and write the restriction of \( u \) to \( \Sigma \) as

\[
u|_{\Sigma} = (\phi_R \circ a, f), \quad (a, f): \Sigma \to [-R, R] \times M.
\]

Let \( \psi: [-R, R] \to [e^{-\epsilon}, e^{\epsilon}] \) be any nondecreasing function which equals \( e^{\phi_R} \) on the boundary. Using nonnegativity of the integrand in the Floer energy, vanishing of \( dH \) on \([-\epsilon, \epsilon] \times M \) and Stokes’ theorem, we obtain

\[
A_H(x_+) - A_H(x_-) \geq \int_{\Sigma} u^* (d\lambda - dH \wedge dt) = \int_{\Sigma} u^* \, d\lambda
\]  
\[
= \int_{\Sigma} (a, f)^* d(e^{\phi_R} \alpha) = \int_{\Sigma} (a, f)^* d(\psi \alpha)
\]  
\[
= \int_{\Sigma} (\psi'(a) \, da \wedge f^* \alpha + \psi(a) f^* d\alpha).
\]

Since \( (a, f) \) is \( J_0 \)-holomorphic, \( da \wedge f^* \alpha \) and \( f^* d\alpha \) are nonnegative 2–forms on \( \Sigma \). Since \( \psi'(a) \geq 0 \) and \( \psi(a) \geq e^{-\epsilon} \), and \( \psi \) was arbitrary with the given boundary conditions, this yields a uniform bound (independent of \( R \)) on the Hofer energy of \( (a, f) \) (see [14, Section 5.3; 30, Section 4.1]).
lie on different sides of $M$, the punctures asymptotic to $x_{\pm}$ lie on different components. Hence, for large $k$ there exists a separating embedded loop $\delta_k \subset \mathbb{R} \times S^1$ such that $u_k \circ \delta_k$ is $C^1$–close to a (positively parametrized) closed Reeb orbit $\gamma$ on $M$ (which we view as a loop in $\hat{W}$ lying on $\partial V$). Here $\delta_k$ is parametrized as a positive boundary of the component of $\mathbb{R} \times S^1$ that is mapped to $\hat{V}$. Now we distinguish two cases.

**Case (i)** $(x_- \subset V \text{ and } x_+ \subset \hat{W} \setminus V)$ Then $\delta_k$ winds around the cylinder in the positive $S^1$–direction, and since the Hamiltonian action increases along Floer cylinders we conclude

$$A_H(x_+) \geq A_H(\gamma) \geq A_H(x_-).$$

Since $\int_{\gamma} \lambda = \int_{\gamma} \alpha \geq 0$, we obtain $A_H(\gamma) = \int_{\gamma} \lambda - \int_0^1 c \, dt \geq -c$ and thus $A_H(x_+) \geq -c$.

**Case (ii)** $(x_+ \subset V \text{ and } x_- \subset \hat{W} \setminus V)$ Then $\delta_k$ winds around the cylinder in the negative $S^1$–direction, and since the Hamiltonian action increases along Floer cylinders we conclude

$$A_H(x_+) \geq A_H(-\gamma) \geq A_H(x_-).$$

Since $\int_{\gamma} \lambda = \int_{\gamma} \alpha \geq 0$, we obtain $A_H(-\gamma) = -\int_{\gamma} \lambda - \int_0^1 c \, dt \leq -c$ and hence $A_H(x_-) \leq -c$.

Our fourth lemma prohibits certain trajectories asymptotic to constant Hamiltonian orbits. We consider the setup consisting of a completed Liouville domain $\hat{W}$, a cobordism $V \subset W$ such that $(W, V)$ is a Liouville pair, ie $W = W^{\text{bottom}} \circ V \circ W^{\text{top}}$, and a Hamiltonian $H: \hat{W} \to \mathbb{R}$ which is constant on $V$, which depends only on the radial coordinate $r$ in an open neighbourhood of $\partial V$ and which is either strictly convex or strictly concave as a function of $r$ outside $V$ in each component of the given neighbourhood of $\partial V$. Denote by $c$ the value of $H$ on $V$.

Let $f: V \to \mathbb{R}$ be a Morse function which depends only on the radial coordinate $r$ in some neighbourhood of $\partial V$ and such that $\partial^\pm V$ are regular level sets. We require the gradient of $f$ to point inside/outside $V$ along $\partial^- V$ if $H$ is concave/convex near $\partial^- V$, and to point inside/outside $V$ along $\partial^+ V$ if $H$ is concave/convex near $\partial^+ V$.

Given $\varepsilon > 0$ we denote by $V^{\varepsilon} = ([1 - \varepsilon, 1] \times \partial^- V) \cup V \cup ([1, 1 + \varepsilon] \times \partial^+ V)$ an $\varepsilon$–thickening of $V$ inside $\hat{W}$. For $\varepsilon > 0$ small enough let

$$H_{f, \varepsilon}: S^1 \times \hat{W} \to \mathbb{R}$$

be a smooth Hamiltonian which is equal to $c + \varepsilon^2 f$ on $V$, which is equal to $H$ outside $V^{\varepsilon}$ and which smoothly interpolates between $H$ and $c + \varepsilon^2 f$ on $[1-\varepsilon, 1] \times \partial^- V$. 

and $[1, 1 + \varepsilon] \times \partial^+ V$ as a function of $r$ which is either concave or convex, according to $H$ being concave or convex on each of these regions.

We consider admissible almost complex structures on $\hat{W}$ which are time-independent on $V$, cylindrical near $\partial V$, and such that the gradient flow of $f$ is Morse–Smale.

**Lemma 2.5** Let $f: V \to \mathbb{R}$ be a Morse function and $H_{f, \varepsilon}$ a Hamiltonian as above. For $\varepsilon > 0$ small enough the following hold:

1. If the gradient of $f$ points inside $V$ along $\partial^- V$, then there is no Floer trajectory for $H_{f, \varepsilon}$ which is asymptotic at the positive end to a constant orbit given by a critical point of $f$ and which is asymptotic at the negative end to an orbit in $W_{\text{bottom}}$.

2. If the gradient of $f$ points outside $V$ along $\partial^- V$, then there is no Floer trajectory for $H_{f, \varepsilon}$ which is asymptotic at the negative end to a constant orbit given by a critical point of $f$ and which is asymptotic at the positive end to an orbit in $W_{\text{bottom}}$.

**Proof** To prove (1) we argue by contradiction and assume without loss of generality that there is a sequence of positive real numbers $\varepsilon_n \to 0$ and a sequence of Floer trajectories $u_n: \mathbb{R} \times S^1 \to \hat{W}$ solving $\partial_s u_n + J_t(u_n)(\partial_t u_n - X_{H_{f, \varepsilon_n}}(u_n)) = 0$ such that $\lim_{s \to \infty} u_n(s, t) = p_+$ and $\lim_{s \to -\infty} u_n(s, t) = x_-(t)$, with $p_+$ a critical point of $f$, $x_-: S^1 \to \hat{W}$ a 1-periodic orbit of $H$ inside $W_{\text{bottom}}$ and $J = (J_t)$ an admissible almost complex structure which is time-independent on $V$ and such that the flow of the gradient of $f$ for the corresponding Riemannian metric is Morse–Smale.

We interpret $V$ as a Morse–Bott critical manifold with boundary for the action functional $A_H$ and we view $H_{f, \varepsilon_n}$, $n \geq 1$ as determining a sequence of Morse perturbations of $A_H$ along $V$. The Morse–Bott compactness theorem, proved in a more restricted Hamiltonian setting in [16, Proposition 4.7] and in a general SFT setting in [14; 30], applies to our situation. Indeed, the fact that the Morse–Bott manifold $V$ has boundary plays no role and the proof of [16, Proposition 4.7] carries over mutatis mutandis.

It follows that, up to extracting a subsequence, the sequence $u_n$ converges in the terminology of [16, Definition 4.2] to a broken Floer trajectory $[u]$ with gradient fragments. The critical manifold $V$ may be disconnected, but all its components are located on the same action level $A_H = -c$. Since Floer trajectories for $H$ strictly increase the action from the asymptote at the negative puncture to the asymptote at the
positive puncture, we infer that each level of the limit \([u]\) contains at most one gradient trajectory of \(f\). Moreover, \([u]\) has a representative \(\bar{u} = (u_1, \ldots, u_l)\) described as follows: There exists \(1 \leq i \leq l\) such that:

- \(u_1, \ldots, u_{i-1}\) are Floer trajectories for \(H\), with \(u_1(-\infty) = x_-\) and \(u_j(+\infty) = u_{j+1}(-\infty)\) for \(1 \leq j \leq i-2\).
- \(u_i\) is a Floer trajectory with one gradient fragment, ie \(u_i = (u_i, \gamma_i)\) with \(u_i\) a Floer trajectory for \(H\) and \(\gamma_i\): \([0, +\infty) \rightarrow V\) a negative gradient trajectory for \(f\), ie solving \(\dot{\gamma}_i = -\nabla f(\gamma_i)\), subject to the following conditions: \(u_{i-1}(+\infty) = u_i(-\infty)\) if \(i > 1\) and \(u_i(-\infty) = x_-\) if \(i = 1\); \(u(i)(+\infty) = \gamma_i(0) \in V\); and \(\gamma_i(+\infty) = p_+\) if \(i = l\).
- \(u_{i+1}, \ldots, u_l\) are negative gradient trajectories \(u_j = \gamma_j: \mathbb{R} \rightarrow V\) for \(f\), ie solving \(\dot{\gamma}_j = -\nabla f(\gamma_j)\) for \(j = i+1, \ldots, l\) subject to the conditions \(\gamma_j(-\infty) = \gamma_{j-1}(+\infty)\) for \(j = i+1, \ldots, l\) and \(\gamma_l(+\infty) = p_+\).

We now focus on the level \(u_i = (u_i, \gamma_i)\). Three situations can arise:

**Case 1** \((\gamma(0) \in V \setminus \partial V)\) Then the Floer trajectory \(u_i\) solves the Cauchy–Riemann equation \(\partial_u J(u) \partial_t u = 0\) on some half-cylinder \([s_0, +\infty) \times S^1\) with \(s_0 \gg 0\). We identify biholomorphically \([s_0, +\infty) \times S^1\) with a punctured disc \(\hat{D}\) and, by assumption, \(u: \hat{D} \rightarrow V\) admits a continuous extension at the puncture. Thus, \(0 \in D\) is a removable singularity and we can view \(u_i: \mathbb{R} \times S^1 \rightarrow \hat{W}\) as being defined on a Riemann sphere with a single negative puncture, on which it solves a Floer equation. The asymptote at the negative puncture is located in \(W_{\text{bottom}}\) by assumption, and the image of \(u_i\) intersects \(\partial^- V\). Then Lemma 2.2 gives a contradiction.

**Case 2** \((\gamma(0) \in \partial^+ V)\) Pick \(\delta > 0\) such that \([1-\delta, 1] \times \partial^+ V\) does not contain critical points of \(f\). Since \([u]\) is the limit of the sequence \(u_n\), there exists \(n_0 \geq 1\) such that the image of \(u_n\) intersects the set \((1-\delta, 1] \times \partial^+ V\). By assumption, both asymptotes of \(u_n\) are located in \(W_{\text{bottom}} \cup V \setminus ([1-\delta, 1] \times \partial^+ V)\), and Lemma 2.2 again gives a contradiction.

**Case 3** \((\gamma(0) \in \partial^- V)\) The map \(\gamma_i: [0, \infty) \rightarrow V\) solves \(\dot{\gamma}_i = -\nabla f(\gamma_i)\) and enters \(V\) in positive time, but at the same time \(-\nabla f\) points outwards along \(\partial V\), which is a contradiction.

The proof of (2) is entirely analogous: Cases 1 and 2 are treated exactly in the same way, while Case 3 is proved similarly to (1) using that negative gradient trajectories of a Morse function on \(V\) whose gradient points outwards along \(\partial V\) must exit \(V\) in negative time. □
Remark 2.6  The conclusions of Lemma 2.5 most likely do not hold if one exchanges “positive” and “negative” in either of the statements (1) or (2). Although we do not have an explicit example involving Floer trajectories, ie twice-punctured spheres, we can easily give an example involving pairs of pants. Consider this effect a Liouville domain \( W \) and the trivial cobordism \( V = \left[ \frac{1}{2}, 1 \right] \times \partial W \) over the boundary. As discussed in Section 10, the symplectic homology group \( \text{SH}_0^\leq(V) = \text{SH}_0^\leq(\partial W) \) is a unital graded commutative ring, and the unit maps to \( 1 \in H^0(\partial W) \) under the projection \( \text{SH}_0^\leq(V) \to \text{SH}_0^\leq(\partial W) \simeq H^0(\partial W) \). Assume now that the map \( \text{SH}_0^\leq(V) \to \text{SH}_0^\leq(\partial W) \) is nontrivial — which holds for example in the case of unit cotangent bundles of closed manifolds — and consider a class \( \alpha \neq 0 \) in its image. Since \( 1 \cdot \alpha = \alpha \neq 0 \) we infer the existence of at least one solution to a Floer equation defined on a pair of pants with two positive punctures and one negative puncture, asymptotic at one of the positive punctures to a constant orbit inside \( V \), and asymptotic at each of the other punctures to orbits located in \( W_{\text{bottom}} = W \setminus V \).

2.4 Symplectic homology of a filled Liouville cobordism

Let \((W, \lambda)\) be a Liouville cobordism and \((F, \lambda)\) a Liouville filling of \((\partial^+ W, \alpha^+ = \lambda_\beta - W)\). We compose \( F \) and \( W \) to form the Liouville domain
\[
W_F := F \circ W
\]
and denote its completion by \( \hat{W}_F \). We define the class
\[
\mathcal{H}(W; F)
\]
of admissible Hamiltonians on \( \hat{W}_F \) with respect to the filling \( F \) to consist of functions \( H: S^1 \times \hat{W}_F \to \mathbb{R} \) such that \( H \in \mathcal{H}(\hat{W}_F) \) and \( H = 0 \) on \( W \). When there is no danger of confusion we shall use the notation
\[
\mathcal{H}(W)
\]
for the set \( \mathcal{H}(W; F) \) and refer to its elements as admissible Hamiltonians on \( W \).

Remark 2.7  For the purposes of this section it would have been enough to define admissible Hamiltonians by the condition \( H \leq 0 \) on \( W \). This would have allowed for cofinal families consisting of Hamiltonians with nondegenerate \( 1 \)-periodic orbits. The definition that we have adopted requires us to use small perturbations in order to define Floer homology and is slightly cumbersome in that respect. However, it will prove very convenient when we come to the definition of symplectic homology groups for pairs.
Next we consider continuation maps. Let $H_- \geq H_+$ be admissible Hamiltonians and $H_s$ for $s \in \mathbb{R}$ be a decreasing homotopy through admissible Hamiltonians such that $H_s = H_{\pm}$ near $\pm \infty$. Let $J_s$ be a homotopy of admissible almost complex structures. Solutions of the Floer equation $\partial_s u + J_s(\partial_t u - X_{H_s}(u)) = 0$ satisfy a maximum principle in the region where all the Hamiltonians $H_s$ are linear and all the almost complex structures are cylindrical, and their count defines continuation maps $FH_*^s(H_+) \to FH_*^s(H_-)$. Since the homotopy is decreasing, the action increases along solutions of the preceding $s$–dependent Floer equation, so it decreases under the continuation map. We infer from this the existence of filtered continuation maps $FH_*^{(-\infty,b)}(H_+) \to FH_*^{(-\infty,b)}(H_-)$ for $b \in \mathbb{R}$, and more generally the existence of filtered continuation maps

$$FH_*^{(a,b)}(H_+) \to FH_*^{(a,b)}(H_-), \quad a < b.$$ 

For an admissible Hamiltonian $H$ we also have natural morphisms determined by inclusions of and quotients by appropriate subcomplexes

$$FH_*^{(a,b)}(H) \to FH_*^{(a',b')}^{(a',b')} \quad a \leq a', \quad b \leq b'.$$

These morphisms commute with the continuation morphisms, and we obtain more general versions of the latter,

$$FH_*^{(a,b)}(H_+) \to FH_*^{(a',b')}^{(a',b')} \quad a \leq a', \quad b \leq b'.$$

Given real numbers $-\infty < a < b < \infty$, we define the filtered symplectic homology groups of $W$ (with respect to the filling $F$) to be

$$(5) \quad SH_*^{(a,b)}(W) = \lim_{H \in H(W;F)} FH_*^{(a,b)}(H).$$

The direct limit is taken here with respect to continuation maps and with respect to the partial order $< \text{ on } \mathcal{H}(W;F)$ defined as follows: $H \prec K$ if and only if $H(t, x) \leq K(t, x)$ for all $(t, x)$. Note that in a cofinal family the Hamiltonian necessarily goes to $+\infty$ on $F \cup ([1, \infty) \times \partial^+ W)$. Recall also that, in order to achieve nondegeneracy of the $1$–periodic orbits, the Hamiltonian $H$ needs to be perturbed on $W$, where it is constant equal to zero. Our convention is that we compute the direct limit using a cofinal family for which the size of the perturbation goes to zero.

Taking the direct limit in (3) we obtain for $a < b < c$ the tautological exact triangle

$$(6) \quad SH_*^{(a,b)}(W) \to SH_*^{(a,c)}(W) \to SH_*^{(b,c)}(W) \to SH_*^{(a,b)}(W)[-1].$$
**Definition 2.8** We define six versions of *symplectic homology groups of* $W$ (with respect to the filling $F$):

\[ \text{SH}_*(W) = \lim_{b \to \infty} \lim_{a \to -\infty} \text{SH}^{(a,b)}_*(W) \quad \text{(full symplectic homology)}, \]

\[ \text{SH}_{*}^0(W) = \lim_{b \to \infty} \lim_{a \to 0} \text{SH}^{(a,b)}_*(W) \quad \text{(positive symplectic homology)}, \]

\[ \text{SH}_{*}^{-0}(W) = \lim_{b \to \infty} \lim_{a \to 0} \text{SH}^{(a,b)}_*(W) \quad \text{(nonnegative symplectic homology)}, \]

\[ \text{SH}_{*}^0(W) = \lim_{b \to 0} \lim_{a \to 0} \text{SH}^{(a,b)}_*(W) \quad \text{(zero-level symplectic homology)}, \]

\[ \text{SH}_{*}^{-0}(W) = \lim_{b \to 0} \lim_{a \to -\infty} \text{SH}^{(a,b)}_*(W) \quad \text{(nonpositive symplectic homology)}, \]

\[ \text{SH}_{*}^{-}(W) = \lim_{b \to -\infty} \lim_{a \to -\infty} \text{SH}^{(a,b)}_*(W) \quad \text{(negative symplectic homology)}. \]

Since the actions of Reeb orbits are bounded away from zero, the direct/inverse limits as $a$ (or $b$) goes to zero stabilize for $a$ (respectively $b$) sufficiently close to zero, so they are not actual limits. Note that the actual inverse limits as $a \to -\infty$ in these definitions are always applied to finite-dimensional vector spaces when considering field coefficients. This ensures that the inverse and direct limits preserve exactness of sequences; see [28] for further discussion of the order of limits, and also [34, Chapter 8] for a discussion of exactness.

The geometric content of the definition is the following: Let $H$ be a Hamiltonian as depicted in Figure 8, which is constant and very positive on $F \setminus ([\delta, 1] \times \partial F)$ with $0 < \delta < 1$, which is linear of negative slope with respect to the $r$–coordinate on $[\delta, 1] \times \partial F$, which vanishes on $W$, and which is linear of positive slope with respect to the $r$–coordinate on $[1, \infty) \times \partial^+ W$. The 1–periodic orbits of $H$ fall in four classes, denoted by $F$ (orbits in the filling), $I^-$ (orbits that correspond to negatively parametrized closed Reeb orbits on $\partial^- W$), $I^0$ (constant orbits in $W$), and $I^+$ (orbits that correspond to positively parametrized closed Reeb orbits on $\partial^+ W$). As $\delta \to 0$ and as the absolute values of the slopes go to $\infty$, Hamiltonians of this type form a cofinal family in $\mathcal{H}(W; F)$. The action of orbits in the class $F$ becomes very negative and falls outside any fixed and finite action window $(a, b)$, so the homology groups $\text{SH}_{*}^{(a,b)}(W)$ take into account only orbits of type $I^{-0}$. Each flavour of symplectic homology group $\text{SH}_{*}^{\Phi}(W)$ for $\Phi \in \{\emptyset, > 0, \geq 0, = 0, \leq 0, < 0\}$, with $\text{SH}_{*}^{\emptyset}(W)$ as
a notation for $\text{SH}_*(W)$, takes into account orbits in the class $I^{-0+}$, $I^+$, $I^{0+}$, $I^0$, $I^{-0}$, $I^-$, respectively, for arbitrarily large values of the slope. As such, each of these symplectic homology groups corresponds to a certain count of negatively parametrized closed Reeb orbits on $\partial^- W$, of constant orbits in $W$, and of positively parametrized closed Reeb orbits on $\partial^+ W$.

![Figure 8: Cofinal family of Hamiltonians for $\text{SH}_*(W)$](image)

The next proposition will be proved as Proposition 5.5 below.

**Proposition 2.9** Each of the above six versions of symplectic homology is an invariant of the Liouville homotopy type of the pair $(W; F)$.

The following computation is fundamental in applications.

**Proposition 2.10** Let $\dim W = 2n$. Then we have a canonical isomorphism

$$\text{SH}_*^{=0}(W) \cong H^{n-*}(W).$$

**Proof** Consider a Hamiltonian $K$ of the shape as in Figure 8. Since $\hat{W}_F$ is symplectically aspherical, it follows from [65, Theorem 7.3] (see also [68, Proposition 1.4]) that if $K$ is sufficiently $C^2$–small on $W$, then its Floer chain complex reduces to the Morse cochain complex for an appropriate choice of almost complex structure. Fix such a $K$ and denote by $c > 0$ its constant value on the filling $F$. Pick $\varepsilon$ with $0 < \varepsilon < c$, so that the constant orbits in $F$ have action $-c < -\varepsilon$. Since the Conley–Zehnder index of a critical point is related to its Morse index by $\text{CZ} = n - \text{Morse}$, we get a canonical isomorphism $\text{FH}_*^{(-\varepsilon, \varepsilon)}(K) \cong H^{n-*}(W)$.

Consider any other Hamiltonian $H$ of the shape as in Figure 8 with $K \leq H$. We choose $\varepsilon$ smaller than the smallest action of a closed Reeb orbit on $\partial W$. Then all nonconstant
orbits of $H$ have action outside $(-\varepsilon, \varepsilon)$ and a monotone homotopy from $K$ to $H$ yields a continuation isomorphism $\text{FH}^{(-\varepsilon,\varepsilon)}_*(K) \cong \text{FH}^{(-\varepsilon,\varepsilon)}_*(H)$, which induces in the direct limit over $H$ a canonical isomorphism

$$\text{FH}^{(-\varepsilon,\varepsilon)}_*(K) \cong \text{SH}^{(-\varepsilon,\varepsilon)}_*(W) = \text{SH}^{=0}_*(W).$$

\[\square\]

**Remark 2.11** If $W$ is a Liouville domain, we have

$$\text{SH}^{<0}_*(W) = 0, \quad \text{SH}^{=0}_*(W) = \text{SH}^{=0}_*(W), \quad \text{SH}^{\geq 0}_*(W) = \text{SH}^{=0}_*(W),$$

and the group $\text{SH}^{>0}_*(W)$ coincides by definition with the group $\text{SH}^{\div}_*(W)$ of [15]. If $W$ is a Liouville cobordism with Liouville filling $F$, we have (by a standard continuation argument)

$$\text{SH}^{>0}_*(W) \cong \text{SH}^{>0}_*(WF).$$

**Proposition 2.12** The following “tautological” exact triangles hold for the symplectic homology groups of $W$:

$$
\begin{array}{ccc}
\text{SH}^{<0}_* & \to & \text{SH}^{=0}_* \\
\text{SH}^{\geq 0}_* \downarrow & & \downarrow \\
\text{SH}^{>0}_* \\
\end{array}
$$

$$
\begin{array}{ccc}
\text{SH}^{<0}_* & \to & \text{SH}^{=0}_* \\
\text{SH}^{\geq 0}_* \downarrow & & \downarrow \\
\text{SH}^{>0}_* \\
\end{array}
$$

**Proof** We prove the exactness of the triangle

$$\text{SH}^{<0}_*(W) \to \text{SH}^{=0}_*(W) \to \text{SH}^{>0}_*(W) \to \text{SH}^{=0}_*(W)[-1].$$

The proofs for the other three triangles are similar and left to the reader.

Let $\varepsilon > 0$ be smaller than the minimal period of a closed characteristic on $\partial^+ W$. It follows from the definitions that

$$\text{SH}^{<0}_*(W) = \lim_{a \to -\infty} \text{SH}^{(a,\varepsilon)}_*(W)$$

and

$$\text{SH}^{>0}_*(W) = \lim_{b \to \infty} \text{SH}^{(\varepsilon,b)}_*(W).$$
For fixed $a, b \in \mathbb{R}$ such that $-\infty < a < 0 < \varepsilon < b < \infty$ we have from (6) an exact triangle
\[ \text{SH}^{(a, \varepsilon)}_*(W) \to \text{SH}^{(a, b)}_*(W) \to \text{SH}^{(\varepsilon, b)}_*(W) \to \text{SH}^{(a, \varepsilon)}_*(W)[-1]. \]

All the terms in this exact triangle are finite-dimensional vector spaces. The inverse limit functor is exact on directed systems consisting of finite-dimensional vector spaces, and the direct limit functor is always exact. We then obtain (7) by first taking the inverse limit on $a \to -\infty$, and then taking the direct limit on $b \to \infty$. \hfill \Box

**Symplectic homology groups relative to boundary components** Let $A \subset \partial W$ be a union of boundary components of $W$ and write
\[ A^\pm = A \cap \partial^\pm W. \]

We further assume that $A^-$ is a union of boundaries of components of $F$. We refer to such an $A$ as an admissible subset of $\partial W$.

**Examples** One obvious choice is $A^- = \partial^- W$, which satisfies the assumption for any $F$. If each component of $F$ has connected boundary then one can take $A^- \subset \partial^- W$ arbitrarily. If $F$ consists of a single connected component then the only possible choices are $A^- = \partial^- W$ or $A^- = \emptyset$. Note also that, if $A$ satisfies the assumption, then $A^c := \partial W \setminus A$ also does.

Let $F_{A^-}$ denote the filling of $(A^-, \alpha^-)$ consisting of the union of the components of $F$ with boundary contained in $A^-$. Let
\[ (\hat{W}_F \setminus W)_A = \text{int} F_{A^-} \cup ((1, \infty) \times A^+). \]
so that
\[ \hat{W}_F \setminus W = (\hat{W}_F \setminus W)_A \cup (\hat{W}_F \setminus W)_{A^c}. \]

Given real numbers $-\infty < a < b < \infty$, we define the filtered symplectic homology groups of $W$ relative to $A$ (with respect to the filling $F$) to be
\[ \text{SH}^{(a, b)}_*(W, A) = \lim_{H \in \mathcal{H}(W; F) \to \infty \text{ on } (\hat{W}_F \setminus W)_{A^c}} \lim_{H \in \mathcal{H}(W; F) \to -\infty \text{ on } (\hat{W}_F \setminus W)_A} \text{FH}^{(a, b)}_*(H). \]

**Definition 2.13** We define six flavours of symplectic homology groups of $W$ relative to $A$, or symplectic homology groups of the pair $(W, A)$,
\[ \text{SH}_{\heartsuit}^\varnothing(W, A), \quad \heartsuit \in \{\varnothing, > 0, \geq 0, = 0, \leq 0, < 0\}. \]
by the formulas in Definition 2.8 with $\mathcal{SH}^{(a,b)}_*(W)$ replaced by $\mathcal{SH}^{(a,b)}_*(W, A)$. The notation $\mathcal{SH}^\bigcirc_*$ with $\bigcirc = \varnothing$ refers to $\mathcal{SH}_*$.

We refer to Figure 9 for an illustration of several significant cases of Hamiltonians used in the computation of relative symplectic homology groups. The case $A = \varnothing$ corresponds to Figure 8. In each case, in the limit the orbits that appear in the filling either fall below or fall above any fixed and finite action window, so that only orbits appearing near $W$ are taken into account. As an example, $\mathcal{SH}_*(W, \partial^- W)$ corresponds to a certain count of positively parametrized closed Reeb orbits on $\partial^- W$, of constant orbits in $W$ and of positively parametrized closed Reeb orbits on $\partial^+ W$. Similar interpretations hold for $\mathcal{SH}_*(W, \partial^+ W)$ and $\mathcal{SH}_*(W, \partial W)$, and also for all their $\bigcirc$–flavours. In Figure 9 we encircled with a dashed line the region which contains the orbits that are taken into account. The mnemotechnic rule is the following:

*To compute $\mathcal{SH}^\bigcirc_*(W, A)$ one must use a family of Hamiltonians that go to $-\infty$ near $A$ and that go to $+\infty$ near $\partial W \setminus A$.***
Our notation is motivated by the following analogue of Proposition 2.10, which is proved in the same way.

**Proposition 2.14** Let \( \dim W = 2n \) and \( A \subset \partial W \) be admissible. Then we have a canonical isomorphism

\[
\operatorname{SH}_{*}^{<0} (W, A) \cong H^{n-*} (W, A).
\]

The tautological exact triangles described in Proposition 2.12 also exist for the relative symplectic homology groups \( \operatorname{SH}_{*}^{\omega} (W, A) \) (same proof). Also, the relative symplectic homology groups \( \operatorname{SH}_{*}^{\omega} (W, A) \) are invariants of the Liouville homotopy type of the pair \( (W, F) \) (see Section 7.3; compare Propositions 2.9 and 2.16).

### 2.5 Symplectic homology groups of a pair of filled Liouville cobordisms

A **Liouville pair, or pair of Liouville cobordisms**, is a triple \( (W, V, \lambda) \) where \( (W, \lambda) \) is a Liouville cobordism and \( V \subset W \) is a codimension-0 submanifold with boundary such that

1. \((V, \lambda|_V)\) is a Liouville cobordism;
2. \(\overline{W \setminus V}\) is a disjoint union of two (possibly empty) Liouville cobordisms \( W^{\text{bottom}} \) and \( W^{\text{top}} \) such that
   \[
   W = W^{\text{bottom}} \circ V \circ W^{\text{top}}.
   \]

We fix a filling \( F \) of \( W \) and define \( W_F \) and \( \hat{W}_F \) as above. We define the class

\[
\mathcal{H}(W, V; F)
\]

of **admissible Hamiltonians on** \( (W, V) \) (with respect to the filling \( F \)) to consist of elements \( H : S^1 \times \hat{W}_F \to \mathbb{R} \) such that \( H \in \mathcal{H}(\hat{W}_F) \) and \( H = 0 \) on \( W \setminus V \) (see Figure 14). Given real numbers \(-\infty < a < b < \infty\), we define the **action-filtered symplectic homology groups of** \( (W, V) \) (with respect to the filling \( F \)) to be

\[
\operatorname{SH}_{*}^{(a,b)} (W, V) = \lim_{H \in \mathcal{H} (W, V; F)} \lim_{H \in \mathcal{H} (W, V; F)} \lim_{H \to \infty \text{ on } \hat{W}_F \setminus W} \lim_{H \to -\infty \text{ on } \text{int } V} \operatorname{FH}_{*}^{(a,b)} (H).
\]

**Definition 2.15** We define six flavours of **symplectic homology groups of the Liouville pair** \( (W, V) \),

\[
\operatorname{SH}_{*}^{\omega} (W, V), \quad \omega \in \{\varnothing, > 0, \geq 0, = 0, \leq 0, < 0\}.
\]
by the formulas in Definition 2.8 with \( \text{SH}_*^{(a,b)}(W) \) replaced by \( \text{SH}_*^{(a,b)}(W, V) \). The notation \( \text{SH}_*^{\bigcirc} \) with \( \bigcirc = \emptyset \) refers to \( \text{SH}_* \).

To describe the geometric content of the definition we consider a cofinal family of Hamiltonians \( H \) of the shape described in Figure 14. Heuristically, each of the groups \( \text{SH}_*^{\bigcirc}(W, V) \) represents a certain count of negatively parametrized closed Reeb orbits on \( \partial^-W \) and \( \partial^-V \), of constant orbits in \( \overline{W \setminus V} \), and of positively parametrized closed Reeb orbits on \( \partial^+V \) and \( \partial^+W \), which correspond to generators of type \( I^{-0+} \) and \( III^{-0+} \) in Figure 14. However, unlike in the case of (relative) symplectic homology groups for a single cobordism, it is not possible to arrange the parameters of the Hamiltonians in the cofinal family so that for a fixed and finite value of the action window \( (a, b) \) the group \( \text{FH}_*^{(a,b)}(H) \) takes into account only orbits of types \( I^{-0+} \) and \( III^{-0+} \). Instead, we will use in Section 6 an indirect argument relying on the confinement lemmas in Section 2.3 and on the properties of continuation maps in order to prove an isomorphism between \( \text{SH}_*^{\bigcirc}(W, V) \) and \( \text{SH}_*^{\bigcirc}(W_{\text{bottom}}, \partial^-V) \oplus \text{SH}_*^{\bigcirc}(W_{\text{top}}, \partial^+V) \) (Theorem 6.8). There we will also see (Corollary 6.9) that Definition 2.13 is a special case of Definition 2.15 by taking for \( V \) a tubular neighbourhood of a union of boundary components \( A \).

The following three results generalize the corresponding ones for a single cobordism.

**Proposition 2.16** Each of the above six versions of symplectic homology is an invariant of the Liouville homotopy type of the triple \((W, V, F)\).

**Proof** See Proposition 7.14.

**Proposition 2.17** Let \( \dim W = 2n \). Then we have a canonical isomorphism

\[
\text{SH}_*^{\bigcirc=0}(W, V) \cong H^{n-*}(W, V).
\]

**Proof** The proof of Proposition 2.10 does not carry over to this situation because Hamiltonians as in Figure 14 may have nonconstant orbits of action zero of type \( II^- \). Instead, we combine the excision theorem, Theorem 6.8, with Proposition 2.14 and excision in singular cohomology to obtain canonical isomorphisms

\[
\text{SH}_*^{\bigcirc=0}(W, V) \cong \text{SH}_*^{\bigcirc=0}(W_{\text{bottom}}, \partial^-V) \oplus \text{SH}_*^{\bigcirc=0}(W_{\text{top}}, \partial^+V) \cong H^{n-*}(W_{\text{bottom}}, \partial^-V) \oplus H^{n-*}(W_{\text{top}}, \partial^+V) \cong H^{n-*}(W, V).
\]
The proof of the following proposition is verbatim the same as that of Proposition 2.12. Recall to this effect that we are using field coefficients, and note that $\text{SH}_{*,(a,b)}(W, V)$ is finite-dimensional for any choice of parameters $-\infty < a < b < \infty$. This holds because in the nondegenerate case there are only a finite number of closed Reeb orbits on $\partial(W \setminus V)$ with action smaller than $\max(|a|, |b|)$, and only these orbits contribute to the relevant Floer complex for the cofinal family of Hamiltonians described in Section 6.

**Proposition 2.18**  *The tautological exact triangles*

\[
\begin{align*}
\text{SH}^0_* & \to \text{SH}_* & \text{SH}_{*,0}^0 & \to \text{SH}_* \\
\text{SH}^0_* & \to \text{SH}^{<0}_* & \text{SH}_{*,0}^{<0} & \to \text{SH}_* \\
\text{SH}^0_* & \to \text{SH}^{<0}_* & \text{SH}_{*,0}^{<0} & \to \text{SH}_* \\
\text{SH}^0_* & \to \text{SH}^{<0}_* & \text{SH}_{*,0}^{<0} & \to \text{SH}_* \\
\text{SH}^0_* & \to \text{SH}^{<0}_* & \text{SH}_{*,0}^{<0} & \to \text{SH}_*
\end{align*}
\]

*hold for the symplectic homology groups of a pair $(W, V)$.*

---

2.6 Pairs of multilevel Liouville cobordisms with filling

As mentioned in the introduction, according to our conventions for pairs of Liouville cobordisms the symplectic homology group $\text{SH}_*(W, \partial W)$ cannot be interpreted as $\text{SH}_*(W, [0, 1] \times \partial W)$ if $\partial W$ has both negative and positive components. We explain in this section a further extension of the setup which removes this limitation.

Let $l \geq 0$ be an integer. A *Liouville cobordism with $l$ levels* is, if $l \geq 1$, a disjoint union $W = W_1 \sqcup W_2 \sqcup \cdots \sqcup W_l$ of Liouville cobordisms, called *levels*, and is the empty set if $l = 0$. We think of $W_1$ as being the “bottom-most” level, and of $W_l$ as being the “top-most” level. Each $W_i$ may itself be disconnected. Our previous definition of Liouville cobordisms corresponds to the case $l = 1$. We also refer to such a $W$ as being a *multilevel Liouville cobordism*.

Let $V$ and $W$ be two Liouville cobordisms with $l$ levels. We say that $V$ and $W$ can be *interweaved* if $\partial^+ V_i = \partial^- W_i$ for $i = 1, \ldots, l$ and $\partial^+ W_i = \partial^- V_{i+1}$ for $i = 1, \ldots, l-1$. The *interweaving of $V$ and $W$*, denoted by $V \circ W$, is the Liouville cobordism with one level $V_1 \circ W_1 \circ \cdots \circ V_l \circ W_l$. We allow in the definition the bottom-most or the top-most level of $V$ or $W$ to be empty, and in that case the condition for interweaving
Symplectic homology and the Eilenberg–Steenrod axioms

1993

Figure 10: Interweaving of two multilevel cobordisms

$V$ and $W$ which involves that level has to be understood as being void. In the case of cobordisms with one level, interweaving specializes to composition. See Figure 10.

Given a Liouville cobordism $W$ with $l \geq 1$ levels, a Liouville filling for $W$ is a Liouville cobordism with $l$ levels $F = F_1 \cup \cdots \cup F_l$ such that $F_1$ is a nonempty Liouville domain and $F$ and $W$ can be interweaved. In the case $l = 1$, this notion specializes to our previous notion of a Liouville filling.

Given a Liouville cobordism $W$ with one level, a Liouville subcobordism $V \subset W$ is a codimension-0 submanifold such that, with respect to the induced Liouville form, $V$ and $V^c = \overline{W \setminus V}$ are multilevel Liouville cobordisms that can be interweaved. If $V$ has only one level then $(W, V)$ is a Liouville pair in the sense of Section 2.5.

Given a multilevel Liouville cobordism $W$, a Liouville subcobordism $V \subset W$ consists of a collection of (possibly empty) multilevel Liouville subcobordisms, one for each of the levels of $W$. We speak in such a situation of a pair of multilevel Liouville cobordisms. If $W$ has a filling, we speak of a pair of multilevel Liouville cobordisms with filling.

Let $(W, V)$ be a pair of multilevel Liouville cobordisms with filling $F$. Let $W_F = F \circ W$ and consider the symplectization $\hat{W}_F$. We define the class

$$\mathcal{H}(W, V; F)$$

of admissible Hamiltonians on $(W, V)$ (with respect to the filling $F$) to consist of elements $H: S^1 \times \hat{W}_F \to \mathbb{R}$ such that $H \in \mathcal{H}(\hat{W}_F)$ and $H = 0$ on $W \setminus V$ (see Figure 11). Given real numbers $-\infty < a < b < \infty$, we define the action-filtered symplectic homology groups of $(W, V)$ (with respect to the filling $F$) to be

$$SH_*^{(a, b)}(W, V) = \lim_{H \to \infty \text{ on } \hat{W}_F \setminus W} \lim_{H \to \infty \text{ on } \text{int } V} \lim_{H \to \infty \text{ on } \hat{W}_F \setminus W} \lim_{H \to \infty \text{ on } \text{int } V} FH_*^{(a, b)}(H).$$
We define six flavours of symplectic homology groups of the multilevel Liouville pair \((W, V)\),

\[ \text{SH}_*^\bigcirc(W, V), \quad \heartsuit \in \{\varnothing, > 0, \geq 0, = 0, \leq 0, < 0\}, \]

by the formulas in Definition 2.8 with \(\text{SH}^{(a,b)}_*(W)\) replaced by \(\text{SH}^{(a,b)}_*(W, V)\). The notation \(\text{SH}_*^\bigcirc\) with \(\heartsuit = \varnothing\) refers to \(\text{SH}_*\).

The above definition obviously specializes to Definition 2.15 when \(W\) is a filled Liouville cobordism with one level.

Within the paper we state and prove all the results for pairs of one-level Liouville cobordisms with filling. However, all these results hold more generally for pairs \((W, V)\) of multilevel Liouville cobordisms with filling. The formulation of these more general statements is verbatim the same. The proofs are only superficially more involved: a repeated application of the excision theorem, Theorem 6.8, allows one to restrict to the case where \(W\) is a one-level cobordism with filling, and the case of a multilevel subcobordism \(V\) is treated in exactly the same way as that of a one-level subcobordism. For these reasons, we will not give in the sequel any more details regarding multilevel Liouville cobordisms and will restrict to one-level pairs.

### 3 Cohomology and duality

#### 3.1 Symplectic cohomology for a pair of filled Liouville cobordisms

We continue with the notation of the previous section. Our definition of symplectic cohomology for a pair of filled Liouville cobordisms extends the one for Liouville domains used in [29, Section 2.5].
The starting point of the definition is the dualization of the Floer chain complex with coefficient field $K$. We write

$$FC^*_a(H) = \prod_{x \in P(H), A_H(x) > a} K \cdot x.$$ 

The grading is given by the Conley–Zehnder index, and the differential $\delta: FC^k_a(H) \to FC^{k+1}_a(H)$ is defined by

$$\delta x_- = \sum_{CZ(x_+) = CZ(x_-) + 1} #M(x_-, x_+; H, J) \cdot x_+.$$ 

The differential increases the action, so $FC^*_b(H) \subset FC^*_a(H)$ is a subcomplex if $a < b$. We define filtered Floer cochain groups

$$FC^{*, (a, b)}(H) = FC^*_a(H)/FC^*_b(H).$$

We have a natural identification

$$FC^{*, (a, b)}(H) \cong FC^*_*(H)^\vee, \quad \delta = \partial^\vee,$$

where $FC^{*, (a, b)}(H)^\vee = \text{Hom}_R(FC^*_*(H), R)$.

We have natural morphisms at the filtered cochain level defined by shifting the action window

$$FC^{*, (a', b')}(H) \to FC^{*, (a, b)}(H), \quad a \leq a', \ b \leq b'.$$

These morphisms are dual to the ones defined on Floer chain groups. Also, given admissible Hamiltonians $H_- \geq H_+$ and a decreasing homotopy from $H_-$ to $H_+$, we have filtered continuation maps, which commute with the differentials,

$$FC^{*, (a, b)}(H_-) \to FC^{*, (a, b)}(H_+).$$

These continuation maps are dual to the ones defined on Floer chain groups, and commute with the morphisms defined by shifting the action window. The homotopy type of the continuation maps does not depend on the choice of decreasing homotopy with fixed endpoints.

Let $W$ be a Liouville cobordism with filling $F$, and let $A \subset \partial W$ be an admissible union of boundary components as in Section 2.4. Recall also the notation $A^c = \partial W \setminus A$ and $(\hat{W}_F \setminus W)_A = \text{int} F_A \cup ((1, \infty) \times A^+)$, and recall also the class $\mathcal{H}(W; F)$ of admissible Hamiltonians from Section 2.4. Let $-\infty < a < b < \infty$ be real numbers.
We define the \textit{filtered symplectic cohomology groups of $W$ relative to $A$} (with respect to the filling $F$) to be

$$\text{(11)} \quad \text{SH}^*_{(a,b)}(W, A) = \lim_{H \in \mathcal{H}(W; F)} \lim_{a \to -\infty \text{ on } (\tilde{W}_F \setminus W)_A} \lim_{b \to \infty \text{ on } (\tilde{W}_F \setminus W)_A} \text{FH}^*_{(a,b)}(H).$$

The mnemonic rule is the same as in the case of symplectic homology:

\textit{To compute $\text{SH}^*_{(a,b)}(W, A)$ one must use a family of Hamiltonians that go to $-\infty$ near $A$ and that go to $+\infty$ near $\partial W \setminus A$.}

\textbf{Definition 3.1} We define six \textit{flavours} of \textit{symplectic cohomology groups of $W$ relative to $A$}, or \textit{symplectic cohomology groups of the pair $(W, A)$},

$$\text{SH}^*_{\varnothing}(W, A), \quad \varnothing \in \{\emptyset, \geq 0, > 0, = 0, \leq 0, < 0\},$$

by the following formulas (the notation $\text{SH}^*_{\varnothing}$ refers to $\text{SH}^*$):

$$\begin{align*}
\text{SH}^*(W, A) &= \lim_{a \to -\infty} \lim_{b \to \infty} \text{SH}^*_{(a,b)}(W, A) \quad \quad \quad \text{(full symplectic cohomology)}, \\
\text{SH}^{*}_{<0}(W, A) &= \lim_{a \to -\infty} \lim_{b \not> 0} \text{SH}^*_{(a,b)}(W, A) \quad \text{(negative symplectic cohomology)}, \\
\text{SH}^{*}_{\leq 0}(W, A) &= \lim_{a \to -\infty} \lim_{b \not< 0} \text{SH}^*_{(a,b)}(W, A) \quad \text{(nonpositive symplectic cohomology)}, \\
\text{SH}^{*}_{=0}(W, A) &= \lim_{a \not> 0} \lim_{b \not< 0} \text{SH}^*_{(a,b)}(W, A) \quad \text{(zero-level symplectic cohomology)}, \\
\text{SH}^{*}_{\geq 0}(W, A) &= \lim_{a \not> 0} \lim_{b \to \infty} \text{SH}^*_{(a,b)}(W, A) \quad \text{(nonnegative symplectic cohomology)}, \\
\text{SH}^{*}_{>0}(W, A) &= \lim_{a \not< 0} \lim_{b \to \infty} \text{SH}^*_{(a,b)}(W, A) \quad \text{(positive symplectic cohomology)}.
\end{align*}$$

Now let $(W, V)$ be a pair of Liouville cobordisms with filling $F$ as in Section 2.5, and recall the class $\mathcal{H}(W, V; F)$ of admissible Hamiltonians for the pair $(W, V)$ with respect to the filling $F$. Let $-\infty < a < b < \infty$ be real numbers. We define the \textit{filtered symplectic cohomology groups of $(W, V)$} (with respect to the filling $F$) to be

$$\text{(12)} \quad \text{SH}^*_{(a,b)}(W, V) = \lim_{H \in \mathcal{H}(W, V; F)} \lim_{H \to -\infty \text{ on } V} \lim_{h \to \infty \text{ on } (\tilde{W}_F \setminus W)} \text{FH}^*_{(a,b)}(H).$$
Definition 3.2  We define six flavours of symplectic cohomology groups of the Liouville pair \((W, V)\),

\[ \text{SH}_{\bigtriangleup}^*(W, V), \quad \bigtriangleup \in \{ \emptyset, > 0, \geq 0, = 0, \leq 0, < 0 \}, \]

by the formulas in Definition 3.1 with \(\text{SH}^*_{(a,b)}(W, A)\) replaced by \(\text{SH}^*_{(a,b)}(W, V)\). The notation \(\text{SH}_{\bigtriangleup}^*\) refers to \(\text{SH}^*\).

The discussion from Section 2.5 regarding the geometric content of the definition holds for cohomology as well. The following proposition is proved similarly to Proposition 2.17.

Proposition 3.3  Let \((W, V)\) be a pair of Liouville cobordisms with filling of dimension \(2n\). Then we have a canonical isomorphism

\[ \text{SH}_{=0}^*(W, V) \cong H_{n-*}(W, V). \]

3.2 Poincaré duality

The differences and the similarities between symplectic homology and symplectic cohomology are mainly dictated by the order in which we consider direct and inverse limits. We illustrate this by the following theorem, which was one of our guidelines for the definitions.

Theorem 3.4  (Poincaré duality)  Let \(W\) be a filled Liouville cobordism and \(A \subset \partial W\) be an admissible union of connected components. Then we have a canonical isomorphism

\[ \text{SH}_{\bigtriangleup}^*(W, A) \cong \text{SH}_{-\bigtriangleup}^*(W, A^c). \]

Here the symbol \(\bigtriangleup\) takes the values \(\emptyset, > 0, \geq 0, = 0, \leq 0, < 0\) and \(-\bigtriangleup\) is by convention equal to \(\emptyset, < 0, \leq 0, = 0, \geq 0\) and \(> 0\), respectively.

Proof  Given a time-dependent 1-periodic Hamiltonian \(H: S^1 \times \hat{W} \to \mathbb{R}\) we define \(\bar{H}: S^1 \times \hat{W} \to \mathbb{R}, \quad \bar{H}(t, x) = -H(-t, x)\). Given a time-dependent 1-periodic family of almost complex structures \(J = (J_t)_{t \in S^1}\) on \(\hat{W}\), we define \(\bar{J} = (\bar{J}_t)\) for \(t \in S^1\), where \(\bar{J}_t = J_{-t}\). Given a loop \(x: S^1 \to \hat{W}\), we define \(\bar{x}: S^1 \to \hat{W}, \quad \bar{x}(t) = x(-t)\). Given a cylinder \(u: \mathbb{R} \times S^1 \to \hat{W}\), we define \(\bar{u}: \mathbb{R} \times S^1 \to \hat{W}, \quad \bar{u}(s, t) = u(-s, -t)\).

The key to the proof of Poincaré duality for symplectic homology is the canonical isomorphism, which will be also referred to as Poincaré duality,

\[ (13) \quad \text{FC}^*_{(a,b)}(H, J) \cong \text{FC}^*_{(-b,-a)}(\bar{H}, \bar{J}), \]
obtained by mapping each 1–periodic orbit $x$ of $H$ to the 1–periodic orbit of $\bar{H}$ given by the oppositely parametrized loop $\bar{x}$, and each Floer cylinder $u$ for $(H, J)$ to the cylinder $\tilde{u}$, which is a Floer cylinder for $(\bar{H}, \bar{J})$. Note that the positive and negative punctures get interchanged when passing from $u$ to $\tilde{u}$, so that a chain complex is transformed into a cochain complex. It is straightforward that $A_H(x) = -A_H(\bar{x})$. It is less straightforward, but true, that $CZ(\bar{x}) = -CZ(x)$. The proof follows from [29, Lemma 2.3], taking into account that the flows of $\bar{H}$ and $H$ satisfy the relation $\phi_H^t = \phi_{\bar{H}}^{-t}$. We refer to [29, Proposition 2.2] for a discussion of this Poincaré duality isomorphism in the context of autonomous Hamiltonians, and for a precise statement of its compatibility with continuation maps.

The isomorphism (13) directly implies a canonical isomorphism

$$\text{SH}^\times(a, b)(W, A) \cong \text{SH}^{-\times}_{(b, -a)}(W, A^c).$$

To see this, note that the class of admissible Hamiltonians $\mathcal{H}(W; F)$ is stable under the involution $H \mapsto \bar{H}$. It follows that we can present $\text{SH}^{-\times}_{(b, -a)}(W, A^c)$ as a first-inverse-then-direct limit on $FH^{-\times}_{(b, -a)}(\bar{H})$ for $H \in \mathcal{H}(W; F)$, whereas $\text{SH}^\times(a, b)(W, A)$ is presented as a first-inverse-then-direct limit on $FH^\times(a, b)(H)$. In view of (13) it is enough to see that the inverse and direct limits in the definitions are taken over the same sets. Indeed, for $\text{SH}^\times(a, b)(W, A)$ the inverse limit is taken over Hamiltonians $H$ that go to $-\infty$ on $(\tilde{W}_F \setminus W)_A$, which is equivalent to $\bar{H}$ going to $\infty$ on $(\tilde{W}_F \setminus W)_A$, and this is precisely the directed set for the inverse limit in the definition of $\text{SH}^{-\times}_{(b, -a)}(W, A^c)$. A similar discussion holds for the direct limit.

The isomorphisms $\text{SH}^\diamondsuit(W, A) \cong \text{SH}^{-\diamondsuit}(W, A^c)$ follow from (14) and from the definitions. We analyze the case that $\diamondsuit$ is “$>$ 0” and leave the other cases to the reader. In the definition of $\text{SH}^{\ast 0}(W, A)$ the inverse limit is taken over $a \searrow 0$ and the direct limit is taken over $b \to \infty$, which is equivalent to $-a \nearrow 0$ and $-b \to -\infty$. After relabelling $(-b, -a) = (a', b')$, this is the same as $b' \nearrow 0$ and $a' \to -\infty$, which corresponds to the definition of $\text{SH}^{-\diamondsuit}(W, A^c)$.

3.3 Algebraic duality and universal coefficients

We discuss in this section the algebraic duality between homology and cohomology in the symplectic setting that we consider. Recall that we use field coefficients.

The starting observation is that, given a degree $k$, real numbers $a < b$, admissible Hamiltonians $H \leq H'$, an admissible decreasing homotopy $(H_s)$ for $s \in \mathbb{R}$ connecting
H’ to H, and a regular homotopy of almost complex structures (Js) for s ∈ ℝ connecting an almost complex structure J’ which is regular for H’ to an almost complex structure J which is regular for H, there are canonical identifications

$$FC^{(a,b)}_k(H, J) \cong FC^{(a,b)}_k(H, J)^\vee, \quad \sigma^k \cong (\sigma_k)^\vee,$$

where $\sigma_k: FC^{(a,b)}_k(H, J) \to FC^{(a,b)}_k(H', J')$ and $\sigma^k: FC^{(a,b)}_k(H', J') \to FC^{(a,b)}_k(H, J)$ are the continuation maps induced by the homotopy $(H_s, J_s)$. These identifications follow from the definitions and hold with arbitrary coefficients.

We now turn to the relationship between $SH^{(a,b)}_k(W, V)$ and $SH^{(a,b)}_k(W, V)$. Since we work in a finite action window $(a, b)$, both the direct and the inverse limits in the definition of $SH^{(a,b)}_k(W, V)$ and $SH^{(a,b)}_k(W, V)$ eventually stabilize, so that we can compute these groups using only one suitable Hamiltonian. The universal coefficient theorem then implies with coefficients in a field $\mathbb{K}$ the existence of a canonical isomorphism (see for example [20, Section V.7])

$$SH^{(a,b)}_k(W, V; \mathbb{K}) \cong SH^{(a,b)}_k(W, V; \mathbb{K})^\vee. \tag{15}$$

The issue of comparing $SH^{(a,b)}_k(W, V)$ and $SH^{(a,b)}_k(W, V)$ becomes therefore a purely algebraic one, as it amounts to comparing via duality the various double limits involved in Definitions 2.8 and 3.1 (see also Definitions 2.15 and 3.2). The key property is the following: given a direct system of modules $M_\alpha$ and a module $N$ over some ground ring $R$, the natural map

$$\text{Hom}_R(\lim R M_\alpha, N) \cong \lim R \text{Hom}_R(M_\alpha, N) \tag{16}$$

is an isomorphism. However, it is generally not true that, given an inverse system $M_\alpha$, the natural map

$$\text{Hom}_R(\lim R M_\alpha, N) \leftarrow \lim R \text{Hom}_R(M_\alpha, N)$$

is an isomorphism (the two sets actually have different cardinalities in general). In our situation, $N' = R$ is the coefficient field $\mathbb{K}$.

We omit in the sequel the field $\mathbb{K}$ from the notation.

**Proposition 3.5** Let $(W, V)$ be a pair of Liouville cobordisms with filling. Using field coefficients we have canonical isomorphisms

$$SH^\heartsuit_k(W, V) \cong SH^\heartsuit_k(W, V)^\vee, \quad \heartsuit \in \{> 0, ≥ 0, = 0\},$$

and

$$SH^\heartsuit_k(W, V) \cong SH^\heartsuit_k(W, V)^\vee, \quad \heartsuit \in \{< 0, ≤ 0, = 0\}.$$
Proof Assume first $\diamondsuit \in \{> 0, \geq 0, = 0\}$. In all three cases, the limit over $a \to 0$ in the definition of $\text{SH}_*(W,V)$ and $\text{SH}_*^\diamondsuit(W,V)$ stabilizes, and the result follows from (15) and (16) applied to the limit $b \to \infty$.

Assume now $\diamondsuit \in \{< 0, \leq 0, = 0\}$. In all three cases, the limit over $b \to 0$ in the definition of $\text{SH}_*^\diamondsuit(W,V)$ and $\text{SH}_*^\diamondsuit(W,V)$ stabilizes, and the result follows again from (16) applied to the limit $a \to -\infty$, by rewriting (15) as

$$\text{SH}_k^{(a,b)}(W,V) \cong \text{SH}_k^{(a,b)}(W,V)^\vee.$$  

This holds because the vector spaces which are involved are finite-dimensional. □

Corollary 3.6 (a) Let $(W,V)$ be a pair of filled Liouville cobordisms with vanishing first Chern class. Suppose that $\partial V$ and $\partial W$ carry only finitely many closed Reeb orbits of any given degree. Then with field coefficients we have for all flavours of $\diamondsuit$ canonical isomorphisms

$$\text{SH}_0^\diamondsuit(W,V) \cong \text{SH}_k^\diamondsuit(W,V)^\vee$$  and  $$\text{SH}_k^\diamondsuit(W,V) \cong \text{SH}_0^\diamondsuit(W,V)^\vee.$$  

(b) Let $W$ be a Liouville domain. Then with field coefficients we have canonical isomorphisms

$$\text{SH}_k(W) \cong \text{SH}_k(W)^\vee.$$  

Proof Part (a) follows from the proof as Proposition 3.5, using that all inverse limits remain finite-dimensional. Part (b) holds because for a Liouville domain we have $\text{SH}_k(W) = \text{SH}_k^{\geq 0}(W)$. □

Remark 3.7 Proposition 3.5 illustrates the fact that the full symplectic homology and cohomology groups of a cobordism or of a pair of cobordisms are of a mixed homological–cohomological nature. This is due to the presence of both a direct and an inverse limit in the definitions. As such, the full version $\text{SH}_*(W,V)$ does not satisfy in general any form of algebraic duality. In fact, in Example 9.8 we construct a Liouville cobordism $W$ for which, in some degree $k$ (and with $\mathbb{Z}_2$–coefficients), neither $\text{SH}_k(W) \cong \text{SH}_k(W)^\vee$ nor $\text{SH}_k(W) \cong \text{SH}_k(W)^\vee$ holds.

4 Homological algebra and mapping cones

4.1 Cones and distinguished triangles

Let $R$ be a ring. Let Ch denote the category of chain complexes of $R$–modules. The objects of this category are chain complexes of $R$–modules, and the morphisms
are chain maps of degree 0. Let $\text{Kom}$ denote the category of chain complexes of $\mathbb{R}$–modules up to homotopy. The objects are the same as the ones of $\text{Ch}$, and the morphisms are equivalence classes of degree 0 chain maps with respect to the equivalence relation given by homotopy equivalence. We use homological $\mathbb{Z}$–grading, and we use the following notational conventions:

(i) Given a morphism $X \to Y$ in $\text{Kom}$, we use the notation $X \xrightarrow{f} Y$ for a specific representative $f$ of this morphism. Thus $f$ is a morphism in $\text{Ch}$.

(ii) All diagrams are understood to be commutative in $\text{Kom}$. If we specify representatives in $\text{Ch}$ for the morphisms, we say that a diagram is strictly commutative if it commutes in $\text{Ch}$.

(iii) We use the notation

$$
\begin{array}{c}
X \\
\phi \\
\downarrow \\
X'
\end{array} 
\xrightarrow{f} 
\begin{array}{c}
Y \\
\psi \\
\downarrow \\
Y'
\end{array}
$$

for a diagram in $\text{Ch}$ which is commutative modulo a specified homotopy $s$, ie such that $\psi f - g \phi = s \partial X + \partial Y : s$. In particular, the diagram

$$
\begin{array}{c}
X \\
\phi \\
\downarrow \\
X'
\end{array} 
\xrightarrow{f} 
\begin{array}{c}
Y \\
\psi \\
\downarrow \\
Y'
\end{array}
$$

is commutative in $\text{Kom}$.

(iv) Given a chain complex $X = \{(X_n), \partial_X\}$ and $k \in \mathbb{Z}$, we define the shifted complex $X[k]$ by

$$
X[k]_n = X_{n+k}, \quad n \in \mathbb{Z}, \quad \partial_X[k] = (-1)^k \partial_X.
$$

Given a morphism $f : X \to Y$, we define $f[k] : X[k] \to Y[k]$ by $f[k] = f$.

Our conventions for cones and distinguished triangles follow the ones of Kashiwara and Schapira [54, Chapter 1], except that we use dual homological grading. Given a chain map $f : X \to Y$, we define its cone to be the chain complex

$$
C(f) = Y \oplus X[-1], \quad \partial_{C(f)} = \begin{pmatrix} \partial_Y & f \\ 0 & \partial_X[-1] \end{pmatrix} = \begin{pmatrix} \partial_Y & f \\ 0 & \partial_X \end{pmatrix}.
$$
We have in particular a short exact sequence of chain complexes
\[ 0 \to Y \overset{\alpha(f)}{\to} C(f) \overset{\beta(f)}{\to} X[-1] \to 0, \]
where
\[ \alpha(f) = \begin{pmatrix} \text{Id}_Y \\ 0 \end{pmatrix} \]
is the canonical inclusion and \( \beta(f) = (0 \ \text{Id}_{X[-1]}) \) is the canonical projection. For simplicity we abbreviate in the sequel the identity maps by 1, e.g. we write \( \alpha(f) = (1) \) and \( \beta(f) = (0 \ 1) \).

One of the key features of the cone construction is that the connecting homomorphism in the homology long exact sequence associated to the short exact sequence (17) is equal to \( f_* \), the morphism induced by \( f \).

By definition, a triangle in \( \text{Kom} \) is a sequence of morphisms
\[ X \overset{f}{\to} Y \overset{g}{\to} Z \overset{h}{\to} X[-1]. \]
A distinguished triangle is a triangle which is isomorphic in \( \text{Kom} \) to a triangle of the form
\[ X \overset{f}{\to} Y \overset{\alpha(f)}{\to} C(f) \overset{\beta(f)}{\to} X[-1]. \]
We call (19) a model distinguished triangle.

It follows from the definition that a distinguished triangle (18) induces a long exact sequence in homology
\[ \cdots \overset{f_*}{\to} H_*(X) \overset{g_*}{\to} H_*(Y) \overset{h_*}{\to} H_*(Z) \overset{h_*}{\to} H_{*-1}(X) \overset{f_*}{\to} \cdots. \]

We shall often represent such a long exact sequence as
\[ \begin{array}{c}
    H(X) \xleftarrow{[1]} \quad f_* \\
    h_*\\n\end{array} \begin{array}{c}
    \overleftarrow{H(Y)} \\
    g_*
\end{array} \]

We call such a diagram an exact triangle.

The above definition of the class of distinguished triangles makes \( \text{Kom} \) into a triangulated category in the sense of Verdier. This means that the class of distinguished triangles satisfies Verdier’s axioms (TR0)–(TR5) (see for example [54, Sections 1.4–1.5]). One
of the essential axioms is (TR3): a triangle (18) is distinguished if and only if the triangle
\[ Y \xrightarrow{g} Z \xrightarrow{h} X[-1] \xrightarrow{-f[-1]} Y[-1] \]
is distinguished. This follows from Lemma 4.1(i); see also [54, Lemma 1.4.2].

**Lemma 4.1** Let \( f : X \to Y \) be a morphism in \( \text{Ch} \).

(i) [54, Lemma 1.4.2] There exists a morphism in \( \text{Ch} \)
\[
\Phi : X[-1] \to C(\alpha(f))
\]
which is an isomorphism in \( \text{Kom} \), with an explicit homotopy inverse in \( \text{Ch} \), denoted by
\[
\Psi : C(\alpha(f)) \to X[-1],
\]
and such that the diagram below commutes in \( \text{Kom} \):
\[
\begin{array}{ccc}
Y & \xrightarrow{\alpha(f)} & C(f) \\
\downarrow & & \downarrow \\
Y & \xrightarrow{\alpha(f)} & C(f)
\end{array}
\begin{array}{ccc}
& \xrightarrow{\beta(f)} & X[-1] \\
& \downarrow{\Phi} & \downarrow{\Psi} \\
& \xrightarrow{\alpha(\alpha(f))} & C(\alpha(f))
\end{array}
\begin{array}{ccc}
& & \xrightarrow{-f[-1]} \\
& & \downarrow \\
& & \xrightarrow{-\alpha(f)[-1]} \\
& & \downarrow{\beta(\alpha(f))} \\
& & \xrightarrow{Y[-1]}
\end{array}
\]

(ii) There exists a morphism in \( \text{Ch} \)
\[
\tau : Y[-1] \to C(\beta(f))
\]
which is an isomorphism in \( \text{Kom} \), with an explicit homotopy inverse in \( \text{Ch} \), denoted by
\[
\sigma : C(\beta(f)) \to Y[-1],
\]
and such that the diagram below commutes in \( \text{Kom} \):
\[
\begin{array}{ccc}
C(f) & \xrightarrow{\beta(f)} & X[-1] \\
\downarrow & & \downarrow \\
C(f) & \xrightarrow{\beta(f)} & X[-1]
\end{array}
\begin{array}{ccc}
& \xrightarrow{-f[-1]} & Y[-1] \\
& \downarrow{\sigma} & \downarrow{\tau} \\
& \xrightarrow{-\alpha(f)[-1]} & C(f)[-1]
\end{array}
\begin{array}{ccc}
& & \xrightarrow{-\alpha(f)[-1]} \\
& & \downarrow \\
& & \xrightarrow{-\beta(\beta(f))} \\
& & \downarrow{\beta(\beta(f))} \\
& & \xrightarrow{C(f)[-1]}
\end{array}
\]
Proof

(i) (following [54]) Taking into account that \(C(\alpha(f)) = Y \oplus X[-1] \oplus Y[-1]\), we define in matrix form

\[
\Phi = \begin{pmatrix} 0 & 0 \\ 1 & 1 \\ -f & 1 \end{pmatrix}, \quad \Psi = \begin{pmatrix} 0 & 1 & 0 \end{pmatrix}.
\]

(Here 1 stands for \(\text{Id}_{X[-1]}\), according to our convention.) A direct verification shows that these are chain maps, and also that the third square in the diagram commutes in \(\text{Ch}\), i.e. \(\beta(\alpha(f)) \Phi = -f[-1]\). Such verifications formally amount to elementary multiplications of matrices. For example,

\[
\partial_{C(\alpha(f))} \Phi = \begin{pmatrix} \partial_Y & f & 1 \\ 0 & \partial_X[-1] & 0 \\ 0 & 0 & \partial_Y[-1] \end{pmatrix} \begin{pmatrix} 0 \\ 1 \\ -f \end{pmatrix} = \begin{pmatrix} 0 \\ \partial_X[-1] \\ \partial_Y[-1]f \end{pmatrix}
\]

and

\[
\beta(\alpha(f)) \Phi = \begin{pmatrix} 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} 0 \\ 1 \\ -f \end{pmatrix} = -f.
\]

The second square in the diagram is commutative in \(\text{Kom}\). Indeed, direct verification shows that \(\Psi \alpha(\alpha(f)) = \beta(f)\). On the other hand, the maps \(\Phi\) and \(\Psi\) are homotopy inverses to each other. Indeed, direct verification shows that \(\Psi \Phi = \text{Id}_{X[-1]}\) and

\[
\text{Id}_{C(\alpha(f))} - \Phi \Psi = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & f & 1 \end{pmatrix} = \partial_{C(\alpha(f))} K + K \partial_{C(\alpha(f))},
\]

where \(K: C(\alpha(f)) \to C(\alpha(f))[1]\) is a homotopy given in matrix form by

\[
K = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 1 & 0 & 0 \end{pmatrix}.
\]

(ii) Taking into account that \(C(\beta(f)) = X[-1] \oplus Y[-1] \oplus X[-2]\), we define in matrix form

\[
\tau = \begin{pmatrix} 0 & 0 \\ -1 & 0 \\ 0 & -f \end{pmatrix}, \quad \sigma = \begin{pmatrix} -f & -1 & 0 \end{pmatrix}.
\]

Here 1 stands for \(\text{Id}_{Y[-1]}\). Direct verification shows that these are chain maps, that \(\beta(\beta(f)) \tau = -\alpha(f)[-1]\), so that the third square is commutative in \(\text{Ch}\), and that \(\sigma \alpha(\beta(f)) = -f[-1]\).
Commutativity in $\text{Kom}$ of the second square follows again from the fact that $\sigma$ and $\tau$ are homotopy inverses to each other. Indeed, we have $\sigma \tau = \text{Id}_{Y[-1]}$, whereas

$$\text{Id}_{C(\beta(f))} - \tau \sigma = \begin{pmatrix} 1 & 0 & 0 \\ -f & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix} = \partial_{C(\beta(f))} L + L \partial_{C(\beta(f))},$$

where $L: C(\beta(f)) \to C(\beta(f))[1]$ is a homotopy defined in matrix form by

$$L = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 1 & 0 & 0 \end{pmatrix}.$$ 

Remark 4.2 One consequence of Lemma 4.1 (ie axiom (TR3)) is that a triangle

$$X \xrightarrow{f} Y \xrightarrow{g} Z \xrightarrow{h} X[-1]$$

is distinguished if and only if the triangle

$$X[-1] \xrightarrow{-f[-1]} Y[-1] \xrightarrow{-g[-1]} Z[-1] \xrightarrow{-h[-1]} X[-2]$$

is distinguished. The triangle

$$X[-1] \xrightarrow{f[-1]} Y[-1] \xrightarrow{g[-1]} Z[-1] \xrightarrow{h[-1]} X[-2]$$

is in general not distinguished, but rather antidistinguished in the sense of [54, Definition 1.5.9]. The class of distinguished triangles is distinct from that of antidistinguished triangles, as explained to us by S Guillermou.

We use Lemma 4.1 in order to replace by cones in $\text{Kom}$ the kernels and cokernels of certain maps in $\text{Ch}$.

Lemma 4.3 Let

$$0 \to A \xrightarrow{i} B \xrightarrow{p} C \to 0$$

be a short exact sequence in $\text{Ch}$ which is split as a short exact sequence of $R$–modules.

(i) Given a splitting $s: C \to B$, ie a degree 0 map such that $ps = \text{Id}_C$, there is a canonical chain map $f: C[1] \to A$ and there are canonical identifications in $\text{Ch}$

$$B = C(f), \quad i = \alpha(f), \quad p = \beta(f).$$

Algebraic & Geometric Topology, Volume 18 (2018)
The maps

\[ \Phi: C \xrightarrow{\cong} C(i), \quad \tau: A[-1] \xrightarrow{\cong} C(p) \]

defined in Lemma 4.1(i)–(ii) are isomorphisms in \( \text{Kom} \) and they determine isomorphisms of distinguished triangles

\[
\begin{array}{ccc}
A & \xrightarrow{i} & B \\
\downarrow & & \downarrow \\
A & \xrightarrow{i} & B
\end{array}
\begin{array}{ccc}
& \xrightarrow{p} & C \\
& \xrightarrow{\alpha} & C(i) \\
& \downarrow & \downarrow \\
& \xrightarrow{\beta} & A[-1]
\end{array}
\begin{array}{ccc}
& \xrightarrow{-f[-1]} & A[-1] \\
\xrightarrow{\Phi} & & \xrightarrow{\Phi} \\
& & \xrightarrow{\Phi}
\end{array}
\]

and

\[
\begin{array}{ccc}
B & \xrightarrow{p} & C \\
\downarrow & & \downarrow \\
B & \xrightarrow{p} & C
\end{array}
\begin{array}{ccc}
& \xrightarrow{-f[-1]} & A[-1] \\
& \xrightarrow{\alpha} & C(i) \\
& \downarrow & \downarrow \\
& \xrightarrow{\beta} & B[-1]
\end{array}
\begin{array}{ccc}
& \xrightarrow{-i[-1]} & A[-1] \\
\xrightarrow{\tau} & & \xrightarrow{\tau} \\
& & \xrightarrow{\tau}
\end{array}
\]

In particular, the homology long exact sequences determined by the top and bottom line in each of the above diagrams are isomorphic.

Assume that the splitting \( s: C \to B \) is a chain map. We then have an isomorphism in \( \text{Kom} \)

\[ A \xrightarrow{\cong} C(s). \]

(The same holds if we assume that the splitting \( s \) is homotopic to a chain map.)

**Proof** For item (i) let \((i,s): C(f) = A \oplus C \xrightarrow{\cong} B\) be the isomorphism of \( R \)-modules induced by \( s \). Since \( p(\partial_B s - s \partial_C) = 0 \) and \( i \) is injective, we can define \( f': C[1] \to A \) uniquely by \( if' = \partial_B s - s \partial_C \) and one checks that this map has the desired properties.

Item (ii) is simply a rephrasing of Lemma 4.1.

Item (iii) is a consequence of (ii) as follows: Let us write \( s = \begin{pmatrix} \phi \\ 1 \end{pmatrix} \) with \( \phi: C \to A \). Viewing \( B \) as the cone of \( f \) as in (i), the condition that \( s \) is a chain map translates into \( \phi \partial_C = \partial_A \phi + f \). (This in turn can be reinterpreted as saying that \(-\phi \) is a chain homotopy between \( f \) and 0.)

We consider the map \( \pi: B = A \oplus C \to A \) given by \( \pi = \begin{pmatrix} 1 & -\phi \end{pmatrix} \). Then \( \pi \) is a chain map and \( \ker \pi = \text{im} \ s \), so we have a split short exact sequence

\[ 0 \to C \xrightarrow{s} B \xrightarrow{\pi} A \to 0 \]

and we conclude using the first assertion in (ii).
The class of chain maps is closed under homotopies: if \( s \) is homotopic to a chain map, then it is an actual chain map. □

**Remark** It is *not* true that a short exact sequence of complexes \( 0 \to A \overset{i}{\to} B \overset{p}{\to} C \to 0 \) can always be completed to a distinguished triangle \( A \overset{i}{\to} B \overset{p}{\to} C \to A[-1] \). Thus the splitting assumption in Lemma 4.3 is necessary. Indeed, consider the example of the short exact sequence of \( \mathbb{Z} \)-modules

\[
0 \to \mathbb{Z} \overset{i}{\to} \mathbb{Z} \overset{p}{\to} \mathbb{Z}/2 \to 0,
\]

where \( p \) is the canonical projection and \( i \) is multiplication by 2, thought of as an exact sequence of chain complexes supported in degree 0. The cone of \( i \) is equal to \( \mathbb{Z} \) in degrees 0 and 1, with differential \( (0 \times 2) \). The map \( (p, 0) : C(i) \to \mathbb{Z}/2 \) is a quasi-isomorphism, yet \( \mathbb{Z}/2 \) is not homotopy equivalent to \( C(i) \) since the only morphism \( \mathbb{Z}/2 \to C(i) \) is the zero map. This shows that the above short exact sequence cannot be completed to a distinguished triangle.

**Proposition 4.4** Let

\[
\begin{array}{c}
X \\ \downarrow \phi \\
X' \end{array} \quad \begin{array}{c}
Y \\ \downarrow \psi \\
Y' \end{array} \quad \begin{array}{c}
Z \\ \downarrow \chi \\
X[1] \end{array}
\]

be a commutative diagram in \( \text{Kom} \). This can be completed to a diagram whose rows and columns are distinguished triangles in \( \text{Kom} \) and in which all squares are commutative (in \( \text{Kom} \)), except the bottom-right square, which is anticommutative:

\[
\begin{array}{c}
X \\ \downarrow \phi \\
X' \\
X'' \\
X[-1]
\end{array} \begin{array}{c}
Y \\ \downarrow \psi \\
Y' \\
Y'' \\
Y[-1]
\end{array} \begin{array}{c}
Z \\ \downarrow \chi \\
Z' \\
Z'' \\
Z[-1]
\end{array} \begin{array}{c}
X[1] \\
X[2]
\end{array}
\]
Remark 4.5  This statement, attributed to Verdier, is proved in Beilinson, Bernstein and Deligne [8, Proposition 1.1.11] by a repeated use of the octahedron axiom (TR5). This is also proved in [57, Lemma 2.6] under the name “3 × 3 lemma”, where it is shown that it is actually equivalent to the octahedron axiom. The same statement appears as Exercise 10.2.6 in [69]. Our proof is more explicit and produces a diagram in which all the squares except the initial one and the bottom-right one are commutative in Ch, and in which the bottom-right square is anticommutative in Ch. This result encompasses [18, Lemma 2.18] and [17, Lemma 5.7]. For completeness, we will reprove [17, Lemma 5.7] as Lemma 4.6 below as a consequence of Proposition 4.4 (under an additional splitting assumption).

Proof of Proposition 4.4  We start with the square

\[
\begin{array}{c}
\xymatrix{ X \ar[r]^f & Y \\
\phi \ar[u] & \psi \ar[u] \\
X' \ar[r]_g & Y' 
}
\end{array}
\]

which is commutative modulo the homotopy s, meaning in our notation that

(22) \[ \psi f - g \phi = s \partial_X + \partial_Y, s. \]

We construct the grid diagram in the statement by a repeated use of the cone construction. The first two lines and the first two columns are constructed as model distinguished triangles. More precisely, we define

\[
Z = C(f) = Y \oplus X[-1], \quad Z' = C(g) = Y' \oplus X'[-1], \quad \chi = \begin{pmatrix} \psi & s \\ 0 & \phi \end{pmatrix}.
\]

The condition that \( \chi \) is a chain map is equivalent to (22), and the second and third square formed by the first two lines are then commutative in Ch:

\[
\begin{array}{c}
\xymatrix{ X \ar[r]^f & Y \ar[r]^{\alpha(f)} & Z \ar[r]^{\beta(f)} & X[-1] \\
\phi \ar[u] & \psi \ar[u] & \chi \ar[u] & \phi[-1] \\
X' \ar[r]_g & Y' \ar[r]^{\alpha(g)} & Z' \ar[r]^{\beta(g)} & X'[-1] 
}
\end{array}
\]

Similarly, we define

\[
X'' = C(\phi) = X' \oplus X[-1], \quad Y'' = C(\psi) = Y' \oplus Y[-1], \quad h = \begin{pmatrix} g & -s \\ 0 & f \end{pmatrix}.
\]
Again, the condition that $h$ is a chain map is equivalent to (22) and the first two columns determine a diagram in which the second and third square are commutative in $\text{Ch}$:

\[
\begin{array}{c}
X \xrightarrow{f} Y \\
\downarrow \phi \quad \downarrow \psi \\
X' \xrightarrow{g} Y' \\
\downarrow \alpha(\phi) \quad \downarrow \alpha(\psi) \\
X'' \xrightarrow{h} Y'' \\
\downarrow \beta(\phi) \quad \downarrow \beta(\psi) \\
X[-1] \xrightarrow{f[-1]} Y[-1]
\end{array}
\]

We define

\[Z'' = C(\chi).\]

We construct the third and fourth columns of the grid diagram as model distinguished triangles, and we are left to specify the morphisms $A$, $B$, $C$ and $D$ below:

\[
\begin{array}{c}
X \xrightarrow{f} Y \xrightarrow{\alpha(f)} C(f) \xrightarrow{\beta(f)} X[-1] \\
\downarrow \phi \quad \downarrow \psi \quad \downarrow \alpha(\phi) \quad \downarrow \alpha(\chi) \quad \downarrow \alpha(\phi[-1]) \\
X' \xrightarrow{g} Y' \xrightarrow{\alpha(g)} C(g) \xrightarrow{\beta(g)} X'[-1] \\
\downarrow \alpha(\psi) \quad \downarrow \alpha(\chi) \quad \downarrow \alpha(\phi[-1]) \\
C(\phi) \xrightarrow{h} C(\psi) \xrightarrow{A} C(\chi) \xrightarrow{B} C(\phi[-1]) \\
\downarrow \beta(\phi) \quad \downarrow \beta(\psi) \quad \downarrow \beta(\chi) \quad \downarrow \beta(\phi[-1]) \\
X[-1] \xrightarrow{f[-1]} Y[-1] \xrightarrow{C} C(f)[-1] \xrightarrow{D} X[-2]
\end{array}
\]

The key point is that we have isomorphisms of chain complexes

\[I: C(\chi) = Y' \oplus X'[-1] \oplus Y[-1] \oplus X[-2] \isom C(h) = Y' \oplus Y[-1] \oplus X'[-1] \oplus X[-2].\]

\[
I := \begin{pmatrix}
1 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 0 & -1
\end{pmatrix},
\]
and

\[ J(f) : C(f)[-1] = Y[-1] \oplus X[-2] \xrightarrow{\cong} C(f[-1]) = Y[-1] \oplus X[-2], \]

(23)

\[ J(f) := \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}. \]

One checks directly that the maps \( I \) and \( J(f) \) commute with the differentials.

The third line in our diagram, involving the maps \( A \) and \( B \), is defined using the isomorphisms \( I \) and \( J(\phi) \) from the model distinguished triangle associated to \( h \), ie \( A = I^{-1} \alpha(h) \) and \( B = J(\phi) \beta(h) I \):

\[
\begin{array}{cccccc}
C(\phi) & \xrightarrow{h} & C(\psi) & \xrightarrow{A} & C(\chi) & \xrightarrow{B} & C(\phi)[-1] \\
\| & & \| & & \| & & \| \\
C(\phi) & \xrightarrow{h} & C(\psi) & \xrightarrow{\alpha(h)} & C(h) & \xrightarrow{\beta(h)} & C(\phi)[-1] \\
\end{array}
\]

In matrix form we have

\[ A = \begin{pmatrix} 1 & 0 \\ 0 & 0 \\ 0 & 1 \\ 0 & 0 \end{pmatrix}, \quad B = \begin{pmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}. \]

The fourth line in our diagram, involving the maps \( C \) and \( D \), is defined using the isomorphism \( J(f) \) from the model distinguished triangle associated to \( f[-1] \), ie \( C = J(f)^{-1} \alpha(f[-1]) \) and \( D = \beta(f[-1]) J(f) \):

\[
\begin{array}{cccccc}
X[-1] & \xrightarrow{f[-1]} & Y[-1] & \xrightarrow{C} & C(f)[-1] & \xrightarrow{D} & X[-2] \\
\| & & \| & & \| & & \| \\
X[-1] & \xrightarrow{f[-1]} & Y[-1] & \xrightarrow{\alpha(f[-1])} & C(f[-1]) & \xrightarrow{\beta(f[-1])} & X[-2] \\
\end{array}
\]

In matrix form we have

\[ C = \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \quad D = (0 \quad -1). \]

A direct check shows that

\[ A \alpha(\psi) = \alpha(\chi) \alpha(g), \quad B \alpha(\chi) = \alpha(\phi[-1]) \beta(g), \]

\[ C \beta(\psi) = \beta(\chi) A, \quad D \beta(\chi) = -\beta(\phi[-1]) B. \]

\[ \square \]

Algebraic & Geometric Topology, Volume 18 (2018)
For later use, we recall [17, Lemma 5.7] and show how it follows from Proposition 4.4 under an additional assumption.

**Lemma 4.6** [17, Lemma 5.7] Let

\[
\begin{array}{ccccccccc}
0 & \longrightarrow & A & \longrightarrow & B & \longrightarrow & C & \longrightarrow & 0 \\
\downarrow f & & \downarrow g & & \downarrow h & & & & \\
0 & \longrightarrow & A' & \longrightarrow & B' & \longrightarrow & C' & \longrightarrow & 0
\end{array}
\]

be a morphism of short exact sequences of complexes. We then have a diagram whose rows and columns are exact and in which all squares are commutative, except the bottom-right one, which is anticommutative:

\[
\begin{array}{cccccccccccccccc}
H_*(A) & \xrightarrow{i_*} & H_*(B) & \xrightarrow{p_*} & H_*(C) & \longrightarrow & H_{*-1}(A) \\
\downarrow f_* & & \downarrow g_* & & \downarrow h_* & & \downarrow f_* \\
H_*(A') & \xrightarrow{i'_*} & H_*(B') & \xrightarrow{p'_*} & H_*(C') & \longrightarrow & H_{*-1}(A') \\
\downarrow \alpha(f)_* & & \downarrow \alpha(g)_* & & \downarrow \alpha(h)_* & & \downarrow \alpha(f)_* \\
H_*(C(f)) & \longrightarrow & H_*(C(g)) & \longrightarrow & H_*(C(h)) & \longrightarrow & H_{*-1}(C(f)) \\
\downarrow \beta(f)_* & & \downarrow \beta(g)_* & & \downarrow \beta(h)_* & & \downarrow \beta(f)_* \\
H_{*-1}(A) & \xrightarrow{i_*} & H_{*-1}(B) & \xrightarrow{p_*} & H_{*-1}(C) & \longrightarrow & H_{*-2}(A)
\end{array}
\]

**Proof** Up to changes in notation, this is exactly Lemma 5.7 in [17].

To wrap up the story, we show here how this result follows from Proposition 4.4 under the additional assumption that the short exact sequences are split as sequences of \(R\)–modules (this is always the case if \(R\) is field or, more generally, if we work with chain complexes of free \(R\)–modules).

Choose splittings \(s: C \to B\) and \(s': C' \to B'\). By Lemma 4.3, these determine canonical chain maps \(\phi: C[1] \to A\) and \(\phi': C'[1] \to A'\), together with canonical identifications \(B = C(\phi), i = \alpha(\phi), p = \beta(\phi), B' = C(\phi'), i' = \alpha(\phi')\) and \(p' = \beta(\phi')\).

The map \(g: B \to B'\) can then be identified with a map \(C(\phi) \to C(\phi')\), written in matrix form as

\[
g = \begin{pmatrix} f & t \\ 0 & h \end{pmatrix}: A \oplus C \to A' \oplus C'.
\]
The condition that \( g \) be a chain map is then equivalent to the three relations
\[
f \partial_A = \partial_{A'} f, \quad h \partial_C = \partial_{C'} h, \quad f \phi - \phi' h = \partial_{A'} t - t \partial_C.
\]
We interpret the last relation as \( f \phi - \phi' h[1] = \partial_{A'} t + t \partial_{C[1]} \), which means that the square
\[
\begin{array}{ccc}
C[1] & \xrightarrow{\phi} & A \\
\downarrow h[1] & & \downarrow f \\
C'[1] & \xrightarrow{\phi'} & A'
\end{array}
\]
(25)
is commutative up to a homotopy given by \( t: C \to A' \). The initial diagram (24) appears then as the horizontal extension of this commutative square in \( \text{Kom} \) to a map of distinguished triangles.

We now apply Proposition 4.4 to the square (25) in order to obtain the grid diagram
\[
\begin{array}{ccccccc}
C[1] & \xrightarrow{\phi} & A & \xrightarrow{i} & B & \xrightarrow{p} & C \\
\downarrow h[1] & & \downarrow t & & \downarrow g & & \downarrow h \\
C'[1] & \xrightarrow{\phi'} & A' & \xrightarrow{i'} & B' & \xrightarrow{p'} & C' \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
C(h[1]) & \xrightarrow{C(f)} & C(g) & \xrightarrow{C(h)} \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
C & \xrightarrow{A[-1]} & B[-1] & \xrightarrow{C[-1]}
\end{array}
\]

The anticommutativity of the bottom-right corner can be traded for anticommutativity of the bottom-left corner by changing the sign of the two bottom-middle vertical arrows. The grid diagram in the statement of the lemma is then obtained by passing to homology.

\[\square\]

4.2 Uniqueness of the cone

We now spell out what is the additional piece of structure that is needed in order for the cone of a map to be uniquely and canonically defined up to homotopy.
(i) **Hom complexes** Let $X$ and $Y$ be chain complexes of $R$–modules and denote by

$$\text{Hom}_d(X, Y), \quad d \in \mathbb{Z},$$

the $R$–module of $R$–linear maps of degree $d$. This is a chain complex with differential

$$\partial: \text{Hom}_d(X, Y) \to \text{Hom}_{d-1}(X, Y), \quad \partial \Phi = \partial_Y \Phi - (-1)^{|\Phi|} \Phi \partial_X,$$

where $|\Phi| = d$ denotes the degree of a map $\Phi \in \text{Hom}_d(X, Y)$. The space of degree $d$ cycles

$$Z_d(X, Y) = \ker(\partial: \text{Hom}_d(X, Y) \to \text{Hom}_{d-1}(X, Y))$$

is the space of degree $d$ chain maps $X \to Y$. Two degree $d$ chain maps are homologous, i.e. they differ by an element of

$$B_d(X, Y) := \text{im}(\partial: \text{Hom}_{d+1}(X, Y) \to \text{Hom}_d(X, Y)),$$

if and only if they are chain homotopic.

**Remark/Notation** We denote a degree $d$ map $f$ from $X$ to $Y$ by

$$f: X \overset{d}{\longrightarrow} Y.$$ We do not use the notation $f: X \to Y[d]$, which we reserve for chain maps. This distinction is relevant in practice when using cones because the differential of the complex $Y[d]$ is not $\partial_Y$, but $(-1)^d \partial_Y$.

(ii) **Chain maps between cones** Let

$$\begin{array}{ccc}
x & \xrightarrow{f} & y \\
\phi & \downarrow{s} & \psi \\
x' & \xrightarrow{g} & y'
\end{array}$$

be a diagram of degree 0 chain maps which is commutative modulo a prescribed degree 1 homotopy $s \in \text{Hom}_1(X, Y')$, meaning that $\psi f - g \phi = \partial(s)$. We have an induced chain map

$$\chi_s = \begin{pmatrix} \psi & s \\ 0 & \phi[-1] \end{pmatrix}: C(f) = Y \oplus X[-1] \to C(g) = Y' \oplus X'[-1].$$

The homotopy class of the map $\chi_s$ depends only on the equivalence class of the homotopy $s$ modulo $B_1(X, Y')$. Indeed, if $t \in \text{Hom}_1(X, Y')$ is another map such that
\( \psi f - g \phi = \partial(t) \) then \( s - t \in Z_1(X, Y') \). If \( s - t \in B_1(X, Y') \), meaning that

\[ s - t = \partial(b) \]

with \( b \in \text{Hom}_2(X, Y') \), then

\[ \chi_s - \chi_t = \partial \begin{pmatrix} 0 & b \\ 0 & 0 \end{pmatrix} \in B_0(C(f), C(g)), \]

meaning that \( \chi_s \) and \( \chi_t \) are chain homotopic.

(iii) **Lifts of** \( B_0 \) **modulo** \( B_1 \)  
Let \( B_1 = B_1(X, Y), \ Z_1 = Z_1(X, Y) \) and \( \text{Hom}_1 = \text{Hom}_1(X, Y) \). Let

\[ V_1 \subset \text{Hom}_1 \]

be a subspace such that \( V_1 \cap Z_1 = B_1 \) and \( V_1 + Z_1 = \text{Hom}_1 \). Equivalently, \( B_1 \subset V_1 \) is a subspace and \( \partial \) induces an isomorphism \( V_1/B_1 \cong B_0 \). We call \( V_1 \) a *linear lift of* \( B_0 \) *modulo* \( B_1 \).

Let such a linear lift \( V_1 \subset \text{Hom}_1(X, Y) \) be given. Given two homotopic maps \( f, g \in \text{Hom}_0(X, Y) \), ie \( f - g = \partial(s) \), we can assume without loss of generality that \( s \in V_1 \). The map \( s \) is uniquely defined modulo \( B_1 \), which implies that the homotopy class of the map \( \chi_s: C(f) \to C(g) \) is well-defined.

Thus, given a lift \( V_1 \subset \text{Hom}_1(X, Y) \), the cone of any map \( X \to Y \) is uniquely defined in \( \text{Kom} \).

### 4.3 Directed, bidirected and doubly directed systems

We now explain a setup in which one can speak of limits of ordered systems of mapping cones. The motivation for the definitions to follow lies in the definition of symplectic homology as a direct/inverse limit over directed systems in which the morphisms are Floer continuation maps in Floer homology. To this effect, the reader may find it useful to refer to Sections 4.4 and 5.1. We begin with a few definitions.

A **directed set** is a partially ordered set \((I, <)\) such that for any \( i \) and \( j \) there exists \( k \) with \( i < k \) and \( j < k \). An **inversely directed set** is a partially ordered set \((I, <)\) such that for any \( i \) and \( j \) there exists \( l \) with \( l > i, j \). Equivalently, we require that \( I \) with the opposite order be a directed set. A **bidirected set** is a partially ordered set \((I, <)\) which is both directed and inversely directed. Our typical example is \( I = \mathbb{R} \).

A **system in** \( \text{Kom} \) **indexed by** \( I \) is a collection of chain complexes \( X(i) \) for \( i \in I \) together with chain maps \( \phi_i^j : X(i) \to X(j) \) for \( i < j \) such that \( \phi_j^k \phi_i^j = \phi_i^k \) for \( i < j < k \).
and $\phi_i^j = \text{Id}_{X(i)}$ in $\text{Kom}$. More precisely, there exist maps $x_{ijk} \in \text{Hom}_1(X(i), X(k))$ for $i < j < k$ and $x_i \in \text{Hom}_1(X(i), X(i))$ such that

$$\phi_k^i - \phi_j^k \phi_i^j = \partial(x_{ijk}), \quad \text{Id}_{X(i)} - \phi_i^i = \partial(x_i).$$

We speak of a directed system, of an inversely directed system and of a bidirected system if $(I, \prec)$ is a directed set, an inversely directed set or a bidirected set, respectively. We call the maps $\phi_i^j$ structure maps.

More generally, let $(I^+, \prec)$ be a directed set and $(I^-, \prec)$ be an inversely directed set. A doubly directed set modelled on $I^\pm$ is a subset $I \subset I^- \times I^+$ with the following two properties:

- If $(i, j) \in I$ then $(i', j) \in I$ for all $i' < i$ and $(i, j') \in I$ for all $j' < j$.
- For every $j \in I^+$ there exists $i \in I^-$ such that $(i, j) \in I$.

Our typical example is $I^\pm = \mathbb{R}^*_\pm$ and $I = \{(a, b) \in \mathbb{R}^* \times \mathbb{R}^*_+: a \leq f(b)\}$, where $f: \mathbb{R}_+^* \to \mathbb{R}_+^*$ is a decreasing function such that $f(b) \to -\infty$ as $b \to \infty$.

A doubly directed system in $\text{Kom}$ indexed by the doubly directed set $I$ is a collection of chain complexes $X(i, j)$ for $(i, j) \in I$ together with chain maps $\phi_{i'j'}: X(i', j) \to X(i, j)$ for $i' < i$ and $\phi_{ij'}: X(i, j') \to X(i, j)$ for $j < j'$ with respect to which every $X(i, \cdot)$ is a directed system and every $X(\cdot, j)$ is an inversely directed system, and such that all diagrams

$$\begin{array}{c}
X(i', j) \quad \longrightarrow \quad X(i, j) \\
\downarrow \quad \quad \quad \downarrow \\
X(i', j') \quad \longrightarrow \quad X(i, j')
\end{array}$$

are commutative in $\text{Kom}$ for any choice of indices such that $i' < i$, $j < j'$ and $(i, j), (i', j), (i, j'), (i', j') \in I$. We call the maps $\phi_{i'j'}$ and $\phi_{ij'}$ structure maps.

Given a map of bidirected systems or a map of doubly directed systems, which means a collection of chain maps indexed by the relevant indexing set which commute in $\text{Kom}$ with the chain maps defining each of the systems, we are interested in understanding conditions under which the cone of that map is itself a bidirected or a doubly directed system, respectively. The two situations are similar, except for more cumbersome notation in the case of doubly directed systems since we need to work with two indexing variables $(i, j)$ rather than with just one index variable $i$. For this reason we
shall focus in the sequel on bidirected systems and indicate how the discussion adapts to doubly directed systems.

Let \( \{X(i), \phi^i_j\} \) and \( \{Y(i), \psi^i_j\} \) be two bidirected systems in \( \text{Kom} \) with the same index set \( I \). A map of bidirected systems in \( \text{Kom} \) is a collection of chain maps \( f_i: X(i) \to Y(i) \) for \( i \in I \) such that \( \psi^i_j f_i \) and \( f_j \phi^i_j \) are homotopic for all \( i < j \).

Given \( s^j_l \in \text{Hom}_1(X(i), Y(j)) \) for \( i < j \) such that \( \psi^j_l f_i - f_j \phi^j_l = \partial(s^j_l) \), let \( \chi^l_i = \chi^{l,j} \).

We then have a commutative diagram

\[
\begin{array}{ccc}
X(i) & \xrightarrow{f_i} & Y(i) \\
\downarrow \phi^i_j & & \downarrow \psi^j_l \\
X(j) & \xrightarrow{f_j} & Y(j)
\end{array}
\]

\[
\begin{array}{ccc}
& & C(f_i) \\
\downarrow \chi^i_j & & \downarrow \chi^j_l \\
& & C(f_j)
\end{array}
\]

We are interested in finding conditions under which \( \{C(f_i), \chi^i_j\} \) is a bidirected system in \( \text{Kom} \).

Let us consider the following condition:

(B) There exists a collection \( \{b_{ijk}\} \) for \( i < j < k \) with \( b_{ijk} \in \text{Hom}_1(X(i), Y(k)) \) such that

\[
s^k_l - \psi^k_j s^l_i - s^k_j \phi^l_i + f_k x_{ijk} - y_{ijk} f_i = \partial(b_{ijk}), \quad i, j, k.
\]

Here it is understood that \( \{x_{ijk}\}, \{y_{ijk}\} \) and \( \{s^j_l\} \) are given as above. A direct computation then shows that

\[
\chi^k_l - \chi^k_j \chi^l_i = \partial \left( \begin{array}{c} y_{ijk} \\ b_{ijk} \\ 0 \end{array} \right), \quad i, j, k.
\]

Indeed, the off-diagonal term on the left-hand side is \( s^k_l - \psi^k_j s^l_i - s^k_j \phi^l_i \), while the off-diagonal term on the right-hand side is \( \partial(b_{ijk}) - f_k x_{ijk} + y_{ijk} f_i \).

**Remark** Condition (B) is motivated both by the outcome of preliminary computations for bidirected systems in \( \text{Ch} \) and by the example of Floer continuation maps discussed below.

Condition (B) is clearly independent of the choice of \( \{s^j_l\}, \{x_{ijk}\} \) and \( \{y_{ijk}\} \) up to homotopy. This motivates the stronger condition (C) below, of a more intrinsic nature. For the statement, recall the notion of a lift of \( B_0 \bmod B_1 \) from Section 4.2(iii).
Symplectic homology and the Eilenberg–Steenrod axioms

We are given the data of collections of lifts of $B_0 \mod B_1$

\[
\{X_i^j \subset \text{Hom}_1(X(i), X(j))\}, \quad i < j,
\]

\[
\{Y_i^j \subset \text{Hom}_1(Y(i), Y(j))\}, \quad i < j,
\]

\[
\{V_i^j \subset \text{Hom}_1(X(i), Y(j))\}, \quad i < j
\]

such that $(\psi_i^k)_* V_i^j \subset V_i^k$, $(\phi_i^j)_* V_j^k \subset V_j^k$, $(f_k)_* X_i^k \subset V_i^k$ and $(f_i)_* Y_i^k \subset V_i^k$.

We claim that

\[
(C) \implies (B).
\]

For the proof we start by choosing $s_i^j \in V_i^j$, $x_{ijk} \in X_i^k$ and $y_{ijk} \in Y_i^k$. We then remark that 

\[
y_{ijk} f_i s_i^j + f_k x_{ijk} \quad \text{and} \quad \psi_i^j f_i s_i^j + s_i^j \phi_i^j
\]

are both contracting homotopies for $\psi_i^k \psi_i^j f_i - f_k \phi_i^j \phi_i^j$, so that their difference is a cycle. Now condition (C) implies that both these homotopies lie in $V_i^k$, which implies that their difference is a boundary $\partial(b_{ijk})$.

Condition (B) implies that $\{C(f_i), X_i^j\}$ is a bidirected system in $\text{Kom}$. The same holds in particular under condition (C).

We now indicate how the discussion adapts to the case of a map $f_{ij}: X(i, j) \to Y(i, j)$ between doubly directed systems indexed by the same doubly directed set $I$. Denote by $\phi_{i'j'}$ and $\phi_{ij}$ the structure maps for $\{X(i, j)\}$, and denote by $\psi_{i'j'}$ and $\psi_{ij}$ the structure maps for $\{Y(i, j)\}$. Denote by $\alpha_{i'j'}$ and $\alpha_{ij}$ the homotopies that express the commutativity in $\text{Kom}$ of the diagrams (26):

\[
\phi_{i'j'} \phi_{ij} - \phi_{i'j'} \phi_{ij} = \partial(\sigma_{ij'i'}), \quad \psi_{ij'} \psi_{ij} - \psi_{ij'} \psi_{ij} = \partial(\tau_{ij'i'}).
\]

Denote by $s_{i'j'}$ and $s_{ij}$ the homotopies that express the fact that $f_{ij}$ and $f_i$ are maps of directed systems.

The analogue of condition (B) for doubly directed systems is the following:

\[
(\tilde{B}) \quad \text{We require condition (B) to hold for each of the maps of directed systems } f_i \text{ and } f_{ij}, \text{ and in addition we require that there exists a collection } \{B_{i'j'}_{ij}\} \text{ with } B_{i'j'}_{ij} \in \text{Hom}_1(X(i', j'), Y(i', j')) \text{ such that}
\]

\[
\psi_{ij'} s_{i'j'} + s_{ij} \phi_{i'j'} - \psi_{ij'} s_{i'j'} - s_{ij} \phi_{i'j'} + f_{ij'} \sigma_{i'j'} - \tau_{i'j'} f_{ij'} = \partial(B_{i'j'}_{ij}).
\]
Similarly to the case of bidirected systems, a direct computation shows that

\[
\chi_{ij}^{ij'} - \chi_{i'j}^{ij'} - \chi_{i'j'j}^{ij'} = \partial \begin{pmatrix} \tau_{ij}^{ij'} & B_{ij}^{ij'} \\ 0 & -\sigma_{ij}^{ij'} \end{pmatrix},
\]

where \( \chi_{ab}^c : C(f_{ab}) \to C(f_{cd}) \) are the maps induced between cones, as before. It is important to note that condition (\( \widetilde{B} \)) is of the same nature as condition (B), and the only difference between the two is that condition (\( \widetilde{B} \)) takes into account the additional conditions of commutativity up to homotopy which are involved in the definition of a doubly directed system.

One can also phrase for doubly directed systems an analogue (\( \widetilde{C} \)) of condition (C) for bidirected systems, but we shall not need it and therefore we do not make it explicit.

**Limiting objects** Now let the coefficient ring be a field \( \mathbb{K} \), and recall [34] that the inverse limit functor is exact on inversely directed systems consisting of finite-dimensional vector spaces. Let \( \{ f_{ij} : X(i, j) \to Y(i, j) \} \) be a map of doubly directed systems, and assume that each \( X(i, j) \) and \( Y(i, j) \) has finite-dimensional homology in each degree. Under condition (\( \widetilde{B} \)) we obtain in the first-inverse-then-direct-limit a homology exact triangle

\[
\lim_j \lim_i H(X(i, j)) \xrightarrow{\lim_j \lim_i (f_{ij})_*} \lim_j \lim_i H(Y(i, j)) \xrightarrow{[\text{[\text{-}1]}]} \lim_j \lim_i H(C(f_{ij}))
\]

**Remark** The following question is relevant: When is

\[
\lim_j \lim_i X(i, j) \xrightarrow{\lim_j \lim_i} \lim_j \lim_i Y(i, j) \xrightarrow{\lim_j \lim_i} \lim_j \lim_i C(f_{ij}) \xrightarrow{\lim_j \lim_i} \lim_j \lim_i X(i, j)[-1]
\]

a (model) distinguished triangle? This is related to exactness criteria for the inverse limit functor and to the so-called Mittag-Leffler condition; see for example [28].

**4.4 Floer continuation maps**

We now show how condition (\( \widetilde{B} \)) above is satisfied in the case of Floer continuation maps for a doubly directed system of Hamiltonians. In order to streamline the discussion we shall actually treat the case of a directed system of Hamiltonians, the case of doubly directed systems being conceptually equivalent, except for the more complicated notation.
Higher continuation maps  Let $K \leq L$ be two Hamiltonians and let $(\text{FC}(K), \partial_K)$ and $(\text{FC}(L), \partial_L)$ be the Floer complexes for some choice of regular almost complex structures $J_K$ and $J_L$. An $s$–dependent Hamiltonian $H = H_s$ for $s \in \mathbb{R}$ such that $H_s = L$ for $s \ll 0$, $H_s = K$ for $s \gg 0$, and $\partial_s H \leq 0$, together with an $s$–dependent almost complex structure interpolating between $J_L$ and $J_K$, determines a degree 0 chain map
\[
\phi_H : \text{FC}(K) \to \text{FC}(L).
\]
We refer to $H$ as a decreasing Hamiltonian homotopy (from $L$ to $K$), and to $\phi_H$ as the associated continuation map.

Given two decreasing Hamiltonian homotopies $H^0$ and $H^1$ from $L$ to $K$, the choice of a homotopy $\{H^\lambda\}$ for $\lambda \in [0, 1]$ between the two, together with the choice of a homotopy of almost complex structures which we ignore in the notation, determines a degree 1 map
\[
\phi_{\{H^\lambda\}} : \text{FC}(K) \to \text{FC}(L).
\]
We refer to $\{H^\lambda\}$ as a homotopy of homotopies, or 1–homotopy, and to $\phi_{\{H^\lambda\}}$ as the associated degree 1 continuation map. This is in general not a chain map. However, it is a chain homotopy between $\phi_{H^0}$ and $\phi_{H^1}$:
\[
\phi_{H^1} - \phi_{H^0} = \partial(\phi_{\{H^\lambda\}}) = \partial_K \phi_{\{H^\lambda\}} + \phi_{\{H^\lambda\}} \partial_H.
\]

We now go one step further. Given two 1–homotopies $\{H^0_\mu\}$ and $\{H^1_\mu\}$ for $\mu \in [0, 1]$, the choice of a homotopy $\{H^\lambda_\mu\}$ for $\lambda \in [0, 1]$ connecting them, together with the choice of a homotopy of homotopies of almost complex structures which we ignore in the notation, determines a degree 2 map
\[
\phi_{\{H^\lambda_\mu\}} : \text{FC}(K) \to \text{FC}(L).
\]
We refer to $\{H^\lambda_\mu\}$ as a 2–homotopy, and to $\phi_{\{H^\lambda_\mu\}}$ as the associated degree 2 continuation map. This is in general not a chain map. However, if $\{H^0_\mu\}$ and $\{H^1_\mu\}$ coincide at $\mu = 0$ and at $\mu = 1$, and if $\{H^\lambda_\mu\}$ is constant at $\mu = 0$ and at $\mu = 1$, the map $\phi_{\{H^\lambda_\mu\}}$ is a contracting chain homotopy for $\phi_{\{H^1_\mu\}} - \phi_{\{H^0_\mu\}}$:
\[
\phi_{\{H^1_\mu\}} - \phi_{\{H^0_\mu\}} = \partial(\phi_{\{H^\lambda_\mu\}}).
\]

More generally, let $I = [0, 1]$ and, for $d \geq 0$, consider the $d$–dimensional cube $I^d$. (If $d = 0$ then $I^d$ consists of a single point.) A generic pair $\{H_s,z\}, \{J_s,z\}$ for $z \in I^d$ and $s \in \mathbb{R}$, consisting of an $I^d$–family of decreasing Hamiltonian homotopies from...
Let \( L \) to \( K \) and of an \( I^d \)–family of \( s \)–dependent almost complex structures which all coincide with \( J_L \) for \( s \ll 0 \) and with \( J_K \) for \( s \gg 0 \), determines a map

\[
\phi_{\{H_{s,z},J_{s,z}\}} \in \text{Hom}_d(\text{FC}(K), \text{FC}(L)).
\]

This map is defined on a generator \( x \in \text{FC}(K) \) by

\[
x \mapsto \sum_{|x|-|y|=-d} \text{#M}(y,x; \{H_{s,z}, J_{s,z}\}) y
\]

and then extended by linearity. Here \( \text{M}(y,x; \{H_{s,z}, J_{s,z}\}) \) denotes the moduli space of solutions to the Floer equation in the chosen \( I^d \)–family, asymptotic to \( y \) at \(-\infty\) and asymptotic to \( x \) at \(+\infty\). In other words, the map \( \phi_{\{H_{s,z},J_{s,z}\}} \) counts index \(-d\) solutions of the Floer equation within the \( d \)–dimensional family parametrized by \( I^d \).

We refer to \( \{H_{s,z}, J_{s,z}\} \) as a \( d \)–homotopy and to \( \phi_{\{H_{s,z},J_{s,z}\}} \) as the associated degree \( d \) continuation map.

Let \( \{H^0, J^0\} \) and \( \{H^1, J^1\} \) be two \( d \)–homotopies which are equal on \( \partial I^d \). For any choice of a \((d+1)\)–homotopy \( \{H^\lambda, J^\lambda\} \) for \( \lambda \in [0,1] \) which interpolates between the two and which is constant on \( (\partial I^d) \times I \subset I^d \times I = I^{d+1} \), the associated degree \( d+1 \) continuation map \( \phi_{\{H^\lambda, J^\lambda\}} \) is a contracting chain homotopy for \( \phi_{\{H^1, J^1\}} - \phi_{\{H^0, J^0\}} = \partial(\phi_{\{H^\lambda, J^\lambda\}}) \).

We have thus proved the following:

\[ \text{Lemma 4.7} \quad \text{The difference between any two degree } d \text{ continuation maps determined by } d \text{–homotopies which coincide on } \partial I^d \text{ is homotopic to zero. A contracting homotopy is provided by any degree } d+1 \text{ continuation map determined by an interpolating } (d+1)\text{–homotopy which is constant on } (\partial I^d) \times I \subset I^d \times I = I^{d+1}. \]  

This statement generalizes to higher homotopies the well-known fact that any two continuation maps in Floer theory are homotopic, so that the morphism that they induce in homology is independent of all choices. This last property is sometimes referred to as Floer homology being a connected simple system in the sense of Conley.

**Directed systems of continuation maps**

Let \( \{K_i\} \) and \( \{L_i\} \) be two directed systems of Hamiltonians, meaning that \( K_i \leq K_j \) and \( L_i \leq L_j \) for \( i < j \). Let \( \{K^j_i\} \) and \( \{L^j_i\} \) for \( i < j \) be decreasing homotopies from \( K_j \) to \( K_i \) and from \( L_j \) to \( L_i \), respectively, yielding continuation maps
\(\phi_i^j : \text{FC}(K_i) \to \text{FC}(K_j)\) and \(\psi_i^j : \text{FC}(L_i) \to \text{FC}(L_j)\). Then
\[
\{\text{FC}(K_i), \phi_i^j\}, \quad \{\text{FC}(L_i), \psi_i^j\}
\]
are bidirected systems in \(\text{Kom}\).

Assume further that \(K_i \leq L_i\) for all \(i\). Let \(H_i\) be a decreasing homotopy from \(L_i\) to \(K_i\), yielding continuation maps \(f_i: \text{FC}(K_i) \to \text{FC}(L_i)\). The collection \(\{f_i\}\) is then a map of bidirected systems in \(\text{Kom}\).

Indeed, the maps \(\psi_i^j f_i\) and \(f_j \phi_i^j\) are homotopic via a degree 1 continuation map
\[
s_i^j: \text{FC}(K_i) \to \text{FC}(L_j)
\]
that is associated to a 1–homotopy \(\mathcal{H}_i^j\) connecting \(L_i^j \# H_i\) and \(H_j \# K_i^j\). Here \# denotes the gluing of Hamiltonians for a large enough value of the gluing parameter.

Similarly, the maps \(\phi_i^k\) and \(\phi_j^k \phi_i^j\), and \(\psi_i^k\) and \(\psi_j^k \psi_i^j\), respectively, are homotopic via degree 1 maps
\[
x_{ijk}: \text{FC}(K_i) \to \text{FC}(K_k), \quad y_{ijk}: \text{FC}(L_i) \to \text{FC}(L_k)
\]
that are associated to 1–homotopies \(K_{ijk}\) connecting \(K_i^k\) and \(K_j^k \# K_i^j\), and \(L_{ijk}\) connecting \(L_i^k\) and \(L_j^k \# L_i^j\), respectively.

We claim that condition (B) is satisfied in this setup. In view of Lemma 4.7 it is enough to show that both \(\psi_i^j s_i^j + s_j^k \phi_i^j\) and \(f_k x_{ijk} + s_i^k - y_{ijk} f_i\) are degree 1 Floer continuation maps induced by 1–homotopies parametrized by \(\lambda \in [0, 1]\) with the same endpoints \(L_i^j \# L_i^j \# H_i\) at \(\lambda = 0\) and \(H_k \# K_i^k \# K_i^j\) at \(\lambda = 1\). Consider the following diagram, where in each entry we have indicated a composition of Floer continuation maps and the 0–homotopy which induces it, and where on each arrow we have indicated a homotopy between the target and source maps, together with the 1–homotopy which induces it:
The main point is that a concatenation of 1–homotopies induces the sum of the corresponding degree 1 maps, and the reversal of the direction of a 1–homotopy induces minus the corresponding degree 1 map. The composition of the bottom horizontal arrows is thus a degree 1–continuation map which equals $\psi_j^k s_i^j + s_j^k \phi_i^j$, while the composition of the other three arrows is a degree 1 continuation map which equals $f_k x_{ijk} + s_i^k - y_{ijk} f_i$. The corresponding 1–homotopies do have the same endpoints at $\lambda = 0$ and $\lambda = 1$, as expected.

It follows from the results in Section 4.3 that the system

$$\{C(f_i), \chi_i^j\}$$

of cones $C(f_i)$ and induced maps $\chi_i^j : C(f_i) \to C(f_i)$ is a directed system in Kom. In particular, the homotopy type of the maps $\chi_i^j$ does not depend on the choice of 1–homotopies.

Similarly, for a doubly directed system of Hamiltonians we obtain a doubly directed system

$$\{C(f_{ij}), \chi_{ab}^{cd}\}$$

in Kom, together with the fact that the homotopy type of the maps $\chi_{ab}^{cd}$ does not depend on the choice of 1–homotopies.

5 The transfer map and homotopy invariance

Given a Liouville cobordism pair $(W, V)$ we construct in this section a transfer map

$$f_\vee : \text{SH}_\vee(W) \to \text{SH}_\vee(V)$$

for $\vee \in \{\emptyset, > 0, = 0, \leq 0, < 0\}$ that is invariant under homotopy of Liouville structures. This generalizes to cobordisms the transfer map defined for Liouville domains by Viterbo [68]. The whole structure that we exhibit on symplectic homology is actually governed by the underlying chain level map. Indeed, we prove in Section 7 that the shifted symplectic homology groups of the pair $\text{SH}_\vee(W, V)[-1]$ are isomorphic to the homology of the cone of the chain level transfer map.

We recall that we use coefficients in a field $\mathbb{K}$. 

_Algebraic & Geometric Topology, Volume 18 (2018)_, Kai Cieliebak and Alexandru Oancea
5.1 The transfer map

Let \((W, V)\) be a Liouville cobordism pair with filling \(F\). Recall from Section 2.4 the definition of the symplectic homology groups

\[
\text{SH}_\ast(W) = \lim_{b} \lim_{a} \lim_{H \in \mathcal{H}(W; F)} \text{FH}_\ast(a, b)(H),
\]

where \(\mathcal{H}(W; F)\) is the class of Hamiltonians \(H: S^1 \times \hat{W}_F \to \mathbb{R}\) which are zero on \(W\) and are linear of noncritical slope in the complement of \(W_F\), and the meaning of the limits involving \(a\) and \(b\) is determined by the value of \(\vartriangleright\). In the previous formula the first direct limit is considered with respect to continuation maps \(\text{FH}_\ast(a, b)(H_\ast) \to \text{FH}_\ast(a, b)(H_-)\) for \(H_\ast \leq H_-\) induced by nonincreasing homotopies \(H_s\) for \(s \in \mathbb{R}\) which are equal to \(H_\ast\) for \(s\) near \(\pm \infty\).

The transfer map will be defined as a limit of a directed system of continuation maps. For that purpose the definition of \(\text{SH}_\ast(V)\), which involves Hamiltonians defined on \(y \subseteq W \cap V_{\text{bottom}} \to \mathbb{R}\) such that \(H = 0\) on \(V\), needs to be recast in terms of Hamiltonians defined on \(y \subseteq W \cap V_{\text{bottom}} \to \mathbb{R}\) such that \(H = 0\) on \(V\). The manifold \(\hat{W}_F\) is the domain of the Hamiltonians involved in the definition of \(\text{SH}_\ast(W)\).

Denote by \(\mathcal{H}^W(V; F)\) the space of Hamiltonians \(H: S^1 \times \hat{W}_F \to \mathbb{R}\) such that \(H \in \mathcal{H}(\hat{W}_F)\) and \(H = 0\) on \(V\).

**Lemma 5.1** For any two real numbers \(-\infty < a < b < \infty\) we have

\[
\text{SH}_\ast(a, b)(V) = \lim_{H \in \mathcal{H}^W(V; F)} \text{FH}_\ast(a, b)(H).
\]

**Proof** By definition we have

\[
\text{SH}_\ast(a, b)(V) = \lim_{H \in \mathcal{H}^W(V; F)} \text{FH}_\ast(a, b)(H),
\]

and we claim that the two limits are equal. Recall that the space \(\mathcal{H}(V; F)\) consists of Hamiltonians \(H: \hat{V}_{F \cap W_{\text{bottom}}} \to \mathbb{R}\) which are linear outside a compact set and such that \(H = 0\) on \(V\). The claim is a consequence of the existence of a special cofinal family in \(\mathcal{H}^W(V; F)\), constructed as follows (see Figure 12): Consider a sequence \((\nu_k)\) for \(k \in \mathbb{Z}_-\) of positive real numbers such that \(\nu_k \notin \text{Spec}(\partial^+ V)\) and \(\nu_k \to \infty\) as \(k \to \infty\), and let \(H^V_k: \hat{V}_{F \cap W_{\text{bottom}}} \to \mathbb{R}\) be a cofinal family in \(\mathcal{H}(V; F)\) such that \(H^V_k(r, x) = \nu_k(r - 1)\) on \([1, \infty) \times \partial^+ V\). Consider, further, sequences

\[
(\eta_k), (R_k), (\tau_k), \quad k \in \mathbb{Z}_+.
\]
such that

- \( \eta_k > 0 \) is smaller than the distance from \( v_k \) to \( \text{Spec}(\partial^+ V) \), and \( \eta_k \to 0 \) as \( k \to \infty \);
- \( R_k > \max(1, (v_k - a) / \eta_k) \);
- \( \frac{1}{4} v_k < \tau_k < \frac{1}{2} v_k \) and \( \tau_k \notin \text{Spec}(\partial^+ W) \).

Let \( H_k : \hat{W}_F \to \mathbb{R} \) be a Hamiltonian that equals \( H_k^V \) on \( F \circ W_{\text{bottom}} \circ V \circ [1, R_k] \times \partial^+ V \), is constant equal to \( v_k(R_k - 1) \) on \( R_k W_{\text{top}} \), and equals \( v_k(R_k - 1) + \tau_k(r - R_k) \) on \([R_k, \infty) \times \partial^+ W\). Here \( R_k W_{\text{top}} \) stands for the image of \( W_{\text{top}} \) by the flow of the Liouville vector field at time \( \ln R_k \).

The Hamiltonian \( H_k \) has three more groups of 1–periodic orbits in addition to those of the Hamiltonian \( H_k^V \):

\( \text{(III}^-) \) Orbits corresponding to positively parametrized closed Reeb orbits on \( \partial^+ V = \partial^- W_{\text{top}} \) and located near \( R_k \partial^+ V \).

\( \text{(III}^0) \) Constants in \( R_k W_{\text{top}} \).

\( \text{(III}^+) \) Orbits corresponding to positively parametrized closed Reeb orbits on \( \partial^+ W = \partial^+ W_{\text{top}} \) and located near \( R_k \partial^+ W_{\text{top}} \).

The orbits in group \( \text{III}^0 \) have action \( -v_k(R_k - 1) \), the maximal action of an orbit in group \( \text{III}^- \) is smaller than \( -v_k(R_k - 1) + R_k(v_k - \eta_k) = v_k - R_k \eta_k \), and the maximal action of an orbit in group \( \text{III}^+ \) is smaller than \( -v_k(R_k - 1) + \frac{1}{2} R_k v_k = -v_k \left( \frac{1}{2} R_k - 1 \right) \).

The largest of these actions is the one in group \( \text{III}^- \), which however falls below the action window \( (a, b) \) due to the condition \( R_k > \max(1, (v_k - a) / \eta_k) \), so the orbits contributing to the Floer complex in the action window \( (a, b) \) are the same for \( H_k^V \) and for \( H_k \). Lemma 2.2 for \( s \)–dependent Hamiltonians (decreasing in \( s \) outside \( V_{\text{bottom}} \)) shows that the continuation Floer trajectories for the family \( H_k^V \) and for the family \( H_k \) stay within a neighbourhood of \( V_{F \circ W_{\text{bottom}}} \), where the two Hamiltonians coincide. These continuation Floer trajectories are therefore the same, and they define the same continuation maps in the two directed systems at hand. We obtain

\[
SH^*(a, b)(V) = \lim_{k \to \infty} \text{FH}^*(a, b)(H_k^V) = \lim_{k \to \infty} \text{FH}^*(a, b)(H_k).
\]

Since \( H_k \) for \( k \in \mathbb{Z}_- \) is a cofinal family in \( \mathcal{H}^W(V; F) \), the conclusion of the lemma follows. \( \square \)
We obviously have $\mathcal{H}(W; F) \subset \mathcal{H}^W(V; F)$, and for each Hamiltonian $K$ in $\mathcal{H}(W; F)$ there exists a Hamiltonian $H$ in $\mathcal{H}^W(V; F)$ such that $K \leq H$ (while the converse is not true). For any two such Hamiltonians we have continuation maps

$$f^{(a,b)}_{HK} : \text{FC}_*^{(a,b)}(K) \to \text{FC}_*^{(a,b)}(H)$$

induced by nonincreasing homotopies which are linear at infinity, and these continuation maps define a morphism between the directed systems determined by $\mathcal{H}(W; F)$ and $\mathcal{H}^W(V; F)$.

**Definition 5.2** The Viterbo transfer map in the action window $(a, b)$ is the limit continuation map

$$f^{(a,b)}_1 : \text{SH}_*^{(a,b)}(W) \to \text{SH}_*^{(a,b)}(V), \quad f^{(a,b)}_1 := \lim_{K \in \mathcal{H}(W; F), H \in \mathcal{H}^W(V; F)} f^{(a,b)}_{HK}.$$ 

By general properties of the continuation maps the Viterbo transfer maps $f^{(a,b)}_1$ fit into a doubly directed system, inverse on $a$ and direct on $b$.

**Definition 5.3** For $\bigcirc \in \{\emptyset, \geq 0, > 0, = 0, \leq 0, < 0\}$ the Viterbo transfer map

$$f^\bigcirc_1 : \text{SH}_*^\bigcirc(W) \to \text{SH}_*^\bigcirc(V)$$

is defined as

$$f^\bigcirc_1 = \lim_b \lim_a f^{(a,b)}_1,$$

where the limits are inverse or direct according to the value of $\bigcirc$, as in Definition 2.8.

**Proposition 5.4** (functoriality of the transfer map) Let $U \subset V \subset W$ be a triple of Liouville cobordisms with filling. Let $f^\bigcirc_{VW}, f^\bigcirc_{UW}$ and $f^\bigcirc_{UV}$ be the transfer maps for the pairs $(W, V), (W, U)$ and $(V, U)$, respectively, for $\bigcirc \in \{\emptyset, \geq 0, > 0, = 0, \leq 0, < 0\}$. Then

$$f^\bigcirc_{UV} = f^\bigcirc_{UW} \circ f^\bigcirc_{VW}.$$ 

**Proof** This is a direct consequence of the definition of the transfer map as a limit continuation map, together with functoriality of continuation maps. To see this, we recall the notation $W = W^\text{bottom} \circ V \circ W^\text{top}$ and $V = V^\text{bottom} \circ U \circ V^\text{top}$, and consider on $W$ the following three types of Hamiltonians (see Figures 12 and 13):

- Hamiltonians $K$ which are admissible for $W$, and thus vanish on $W$ and are linear increasing towards $\partial^+ W$. 

*Algebraic & Geometric Topology, Volume 18 (2018)*
• **One-step** Hamiltonians $H$ which vanish on $V$, take a positive constant value on $W^{\text{top}}$, and are linear increasing towards $\partial^+ V$ and $\partial^+ W$.

• **Two-step** Hamiltonians $G$ which vanish on $U$, take a constant value on $V^{\text{top}}$, take a constant value on $W^{\text{top}}$, and are linear increasing towards $\partial^+ U$, $\partial^+ V$ and $\partial^+ W$.

The transfer maps $f_{VW}^\heartsuit$ are defined above as limit continuation maps induced by monotone homotopies from $K$ (at $+\infty$) to $H$ (at $-\infty$). Similarly, the transfer maps $f_{UW}^\heartsuit$ can be obtained as limit continuation maps induced by monotone homotopies from $K$ (at $+\infty$) to $G$ (at $-\infty$), and the transfer maps $f_{UV}^\heartsuit$ can be obtained as limit continuation maps induced by monotone homotopies from $H$ (at $+\infty$) to $G$ (at $-\infty$). We can choose the homotopies from $K$ to $G$ to factor through $H$, so that they can be expressed as concatenation of homotopies from $K$ to $H$, and from $H$ to $G$. The composition of the continuation maps induced by each of these last two homotopies is equal to the continuation map induced by the concatenation of the two homotopies — this is what we call *functoriality of continuation maps* — and the same property holds in the limit. This proves $f_{UW}^\heartsuit = f_{UV}^\heartsuit \circ f_{VW}^\heartsuit$.

In the sequel we shall often drop the symbol $\heartsuit$ from the notation for the transfer map, and simply write $f_\circ$ instead of $f_\circ^\heartsuit$. 

*Algebraic & Geometric Topology, Volume 18 (2018)*
5.2 Homotopy invariance of the transfer map

Given a pair of Liouville cobordisms \((W, V)\) with filling, we denote the transfer map for a given Liouville structure \(\lambda\) by

\[
\text{SH}_\text{\textdagger}(W; \lambda) \xrightarrow{f_t, \lambda} \text{SH}_\text{\textdagger}(V; \lambda).
\]

**Proposition 5.5** (homotopy invariance of the transfer map) Let \((W, V)\) be a pair of Liouville cobordisms with filling. Given a homotopy of Liouville structures \(\lambda_t\) on \(W\) for \(t \in [0, 1]\), there are induced isomorphisms \(h_W: \text{SH}_\text{\textdagger}(W; \lambda_0) \to \text{SH}_\text{\textdagger}(W; \lambda_1)\) and \(h_V: \text{SH}_\text{\textdagger}(V; \lambda_0) \to \text{SH}_\text{\textdagger}(V; \lambda_1)\), and a commutative diagram

\[
\begin{array}{ccc}
\text{SH}_\text{\textdagger}(W; \lambda_0) & \xrightarrow{f_t, \lambda_0} & \text{SH}_\text{\textdagger}(V; \lambda_0) \\
\downarrow h_W & & \downarrow h_V \\
\text{SH}_\text{\textdagger}(W; \lambda_1) & \xrightarrow{f_t, \lambda_1} & \text{SH}_\text{\textdagger}(V; \lambda_1)
\end{array}
\]

The isomorphisms \(h_W\) and \(h_V\) do not depend on the choice of homotopy \(\lambda_t\) with fixed endpoints.
Proof The homotopy invariance of the transfer map under deformations of the Liouville structure which are constant along the boundaries of $W$ and $V$ is a consequence of its definition as a limit continuation map. In particular, given a Liouville cobordism $W$ with two Liouville structures $\lambda$ and $\lambda'$ which coincide along $\partial W$, the transfer map

$$SH^\otimes_*(W; \lambda) \to SH^\otimes_*(W; \lambda')$$

is an isomorphism.

The homotopy invariance in the general case is obtained using the functoriality of the transfer map, by a classical geometric construction which consists in attaching to $\partial W$ topologically trivial cobordisms with Liouville structures that interpolate between any two given Liouville structures on the boundary of $W$; see [24, Lemma 3.7]. A detailed argument is given in [47] in an $S^1$–equivariant setting.

That the isomorphisms $h_W$ and $h_V$ do not depend on the choice of homotopy $(\lambda_t)$ for $t \in [0, 1]$ is a consequence of the fact that any two such homotopies with the same endpoints are homotopic, together with the usual “homotopy of homotopies” argument in Floer theory (see also the discussion of Floer continuation maps at the end of Section 4).

6 Excision

Let $(W, V)$ be a pair of Liouville cobordisms and $F$ a filling of $W$, and define $W_F$ and $\hat{W}_F$ as in Section 2.4. Recall the class $\mathcal{H}(W, V; F)$ of admissible Hamiltonians defined in Section 2.5. For $0 < r_1 < r_2$ and a subset $A \subset \hat{W}_F$, we denote by $[r_1, r_2] \times A = \phi_{[\log r_1, \log r_2]}(A)$ the image of $A$ under the Liouville flow $\phi_t$ on the time interval $[\log r_1, \log r_2]$. For parameters

$$\mu, \nu, \tau > 0, \quad 0 < \delta, \varepsilon < 1$$

(which will be specified later), let $H \in \mathcal{H}(W, V; F)$ be a “staircase Hamiltonian” on $\hat{W}_F$, defined up to smooth approximation as follows (see Figure 14):

- $H \equiv (1 - \delta)\mu$ on $F \setminus (\delta, 1] \times \partial^- W$.
- $H$ is linear of slope $-\mu$ on $[\delta, 1] \times \partial^- W$.
- $H \equiv 0$ on $W_{\text{bottom}}$.
- $H$ is linear of slope $-\nu$ on $[1, 1 + \varepsilon] \times \partial^- V$.
- $H \equiv -\varepsilon \nu$ on $V \setminus ([1, 1 + \varepsilon] \times \partial^- V \cup [1 - \varepsilon, 1] \times \partial^+ V)$.
Symplectic homology and the Eilenberg–Steenrod axioms

- $H$ is linear of slope $\nu$ on $[1 - \varepsilon, 1] \times \partial^+ V$.
- $H \equiv 0$ on $W^{\text{top}}$.
- $H$ is linear of slope $\tau$ on $[1, \infty) \times \partial^+ W$.

A smooth approximation of $H$ will thus be of the form $H(r, \nu) = h(r)$ on $[0, \infty) \times \partial^+ W$ (and similarly near the other boundary components of $W$ and $V$). Hence, 1–periodic orbits of $X_H$ on $\{r\} \times \partial^+ W$ correspond to Reeb orbits on $\partial^+ W$ of period $h'(r)$, and their Hamiltonian action equals

$$rh'(r) - h(r).$$

We assume that $\mu$, $\nu$, $\nu$ and $\tau$ do not lie in the action spectrum of $\partial^- W$, $\partial^- V$, $\partial^+ V$ and $\partial^+ W$, respectively. We denote by $\eta_\nu > 0$ a positive real number smaller than the distance from $\nu$ to the union of the action spectra of $\partial^- V$ and $\partial^+ V$, and we define similarly $\eta_\mu, \eta_\tau > 0$. The 1–periodic orbits of $H$ fall into 11 classes:

- $(F^0)$ Constants in $F \setminus ([\delta, 1] \times \partial F)$.
- $(F^+)$ Orbits corresponding to negatively parametrized closed Reeb orbits on $\partial F = \partial^- W$ and located near $\delta \times \partial^- W$.
- $(I^-)$ Orbits corresponding to negatively parametrized closed Reeb orbits on $\partial^- W^{\text{bottom}} = \partial^- W$ and located near $\partial^- W$.
- $(I^0)$ Constants in $W^{\text{bottom}}$.

Figure 14: Hamiltonian in $\mathcal{H}(W, V; F)$
Orbits corresponding to negatively parametrized closed Reeb orbits on $\partial^+ W^{\text{bottom}} = \partial^- V$ and located near $\partial^- V$.

Orbits corresponding to negatively parametrized closed Reeb orbits on $\partial^- V$ and located near $(1 + \varepsilon) \times \partial^- V$.

Constants in $V \setminus ((1, 1 + \varepsilon] \times \partial^- V \cup [1 - \varepsilon, 1] \times \partial^+ V)$.

Orbits corresponding to positively parametrized closed Reeb orbits on $\partial^+ V$ and located near $(1 - \varepsilon) \times \partial^+ V$.

Orbits corresponding to positively parametrized closed Reeb orbits on $\partial^- W^{\text{top}} = \partial^+ V$ and located near $\partial^+ V$.

Constants in $W^{\text{top}}$.

Orbits corresponding to positively parametrized closed Reeb orbits on $\partial^+ W$ and located near $\partial^+ W^{\text{top}} = \partial^+ W$.

Notational convention For two classes of orbits $A$ and $B$ we write $A < B$ if the homological Floer boundary operator maps no orbit from $A$ to an orbit from $B$. A priori, this relation is not transitive. However, when we write $A < B < C$ we also mean that $A < C$. We write $A < B$ if all orbits in $A$ have smaller action than all orbits in $B$. Note that $A < B$ implies $A < B$, and $A < B < C$ implies $A < B < C$.

Lemma 6.1 Fix $a < b$. If the parameters $\mu$, $\nu$, $\tau$, $\delta$ and $\varepsilon$ above satisfy

$$
(1 - \delta)\mu > \min\{-a, \nu - \eta_\nu\} \quad \text{and} \quad \varepsilon \nu > \min\{b, \tau - \eta_\tau\},
$$

and if we use an almost complex structure that is cylindrical and has a long-enough neck near $(1 - 2\varepsilon) \times \partial^+ V$, then the four groups of orbits in the action interval $[a, b]$ satisfy

$$
F < I < III < II \quad \text{and} \quad III < I.
$$

Moreover, within each group of orbits we have the relations

$$
F^+ < F^0, \quad I^+ < I^- < I^0, \quad II^- < II^0 < II^+, \quad III^0 < III^- < III^+.
$$

Proof The combination of Lemmas 2.2 and 2.3 yields the relations

$$
F < I^-, \quad F, I < II^+, \quad F, I, II, III^0 < III^+, \quad I^+ < F, I^0, \quad III^- < F, I, II.
$$

For any choice of parameters, the actions satisfy

$$
F^+ < F^0, \quad F, I^- < I^0 = III^0 < II^0+, \quad III^- < F, I^- < II^0 < II^+.
$$
We see that $F < I^0, II, III$. The remaining relation $F < I^+$ follows if the actions satisfy $F^0 < I^+$, ie $-(1 - \delta)\mu < \max\{a, -(v - \eta_v)\}$, which is the first condition in (27). Next we see that $I < II, III$ and $III^- < I, II$. For the remaining relation $III^{0+} < I, II$ we arrange the actions to satisfy $III^+ < II^0$, ie $\min\{b, \tau - \eta_\tau\} < \varepsilon v$, which is the second condition in (27). Then we have $III^0 < III^+ < II^0 < II^+$. The relations $I^0 < III^0$ and $III^0 < I^0$ follow from monotonicity: there is an a priori strictly positive lower bound on the energy of trajectories traversing $V$, and this rules out trajectories running between $III^0$ and $I^0$ which after small Morse perturbation of $H$ have arbitrarily small energy. The remaining relation $III^{0+} < I, II^-$ now follows from Lemma 2.4, stretching the neck at the hypersurface $(1 - 2\varepsilon) \times \partial^+ V$ where $H \equiv -\varepsilon v$, and $\varepsilon v$ is bigger than all actions in the groups $III^0$ and $III^+$. This proves (28). The relations in (29) also follow from the preceding discussion. 

**Remark 6.2** Under the conditions of Lemma 6.1, the Floer boundary operator has upper triangular form if the periodic orbits are ordered by increasing action within each class and the classes are ordered (for example) as

$$F^+ < F^0 < I^+ < I^- < I^0 < III^0 < III^- < III^+ < II^- < II^0 < II^+.$$ 

Let us fix $a < 0 < b$ and $0 < \delta, \varepsilon < 1$ and consider $\mu, \nu, \tau > 0$ subject to the conditions

$$\mu > -\frac{a}{1 - \delta}, \quad \tau > b, \quad \nu > \max\{-a, \frac{b}{\varepsilon}\}.$$ 

Note that these conditions allow us to make $\mu, \nu$ and $\tau$ arbitrarily large, independently of each other. They ensure condition (27) in Lemma 6.1. Moreover, the actions of all orbits in the classes $F, II^0$ and $II^+$ lie outside the interval $[a, b]$. So the Floer chain complex can be written as

$$FC(a, b) = FC_{III}^{(a,b)} \oplus FC_I^{(a,b)} \oplus FC_{II^-}^{(a,b)}$$

and with respect to this decomposition the Floer boundary operator has the form

$$\begin{pmatrix} * & 0 & * \\ 0 & * & * \\ 0 & 0 & * \end{pmatrix}.$$ 

Let us fix $\mu$ and $\tau$ and consider $\nu < \nu'$ both satisfying (30). We denote the corresponding Hamiltonians by $H_{\nu'} \leq H_\nu$ and consider the continuation maps

$$\phi_{\nu\nu'}: FC(a, b)(H_{\nu'}) \to FC(a, b)(H_\nu)$$

*Algebraic & Geometric Topology, Volume 18 (2018)*
induced by convex interpolation between $H_v$ and $H_{v'}$. These continuation maps may not have the upper triangular form (31) since the combination of Lemmas 2.2 and 2.3 does not apply to the current homotopy situation. Therefore, we decompose the above chain complex instead as

$$
\text{FC}^{(a,b)} = \text{FC}^{(a,b)}_{\text{III}} \oplus \text{FC}^{(a,b)}_{\text{I,II}^-},
$$

with differential written in upper triangular form as $\begin{pmatrix} * & * \\ 0 & * \end{pmatrix}$. The continuation maps $\phi_{v,v'}$ have upper triangular form with respect to this decomposition and we obtain the commuting diagram with exact rows

$$
\begin{array}{cccc}
0 & \longrightarrow & \text{FC}^{(a,b)}_{\text{III}}(H_v) & \longrightarrow & \text{FC}^{(a,b)}(H_v) & \longrightarrow & \text{FC}^{(a,b)}_{\text{I,II}^-}(H_v) & \longrightarrow & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \\
0 & \longrightarrow & \text{FC}^{(a,b)}_{\text{III}}(H_{v'}) & \longrightarrow & \text{FC}^{(a,b)}(H_{v'}) & \longrightarrow & \text{FC}^{(a,b)}_{\text{I,II}^-}(H_{v'}) & \longrightarrow & 0 \\
\end{array}
$$

(32)

where $\text{FC}^{(a,b)}_{\text{I,II}^-}$ denotes the quotient complex $\text{FC}^{(a,b)}/\text{FC}^{(a,b)}_{\text{III}}$.

**Lemma 6.3** \[ \lim_{v \to \infty} \text{FH}^{(a,b)}_{\text{III}}(H_v) \cong \text{SH}^{(a,b)}(W^{\text{top}}, \partial^+ V). \]

**Proof** We consider a homotopy of Hamiltonians which on $V \cup W^{\text{top}} \cup [1, \infty) \times \partial^+ W$ is constant and which on $F \cup W^{\text{bottom}}$ is a convex interpolation between the Hamiltonian $H_v$ and the Hamiltonian $\overline{H}_v$ that is constant equal to $-\varepsilon v$. Since the homotopy is constant on the cobordism $V$, Lemma 2.4 applies and shows that there is no interaction between the orbits in $\text{III}$ and the orbits appearing in $F \cup W^{\text{bottom}}$. The usual continuation argument then shows that the homology $\text{FH}^{(a,b)}_{\text{III}}$ is invariant during this homotopy. Since $\lim_{v \to \infty} \text{FH}^{(a,b)}_{\text{III}}(\overline{H}_v) = \text{SH}^{(a,b)}(W^{\text{top}}, \partial^+ V)$ by definition, we obtain the desired isomorphism. \qed

**Lemma 6.4** \[ \lim_{v \to \infty} \text{FH}^{(a,b)}_{\text{I,II}^-}(H_v) \cong \text{SH}^{(a,b)}(W^{\text{bottom}}, \partial^- V). \]

**Proof** We consider a homotopy of Hamiltonians which on $F \cup W^{\text{bottom}} \cup V$ is constant and which on $W^{\text{top}} \cup [1, \infty) \times \partial^+ W$ is a convex interpolation between the Hamiltonian $H_v$ and the Hamiltonian $K_v$ that is constant equal to $-\varepsilon v$ on $V \cup W^{\text{top}}$ and is linear of slope $\tau$ (the same as the slope of $H_v$) on $[1, \infty) \times \partial^+ W$. See Figure 15.

We have $\text{FH}^{(a,b)}(K_v) = \text{FH}^{(a,b)}_{\text{I,II}^-}(K_v)$ and so we have a well-defined continuation map $\phi^H_{K} : \text{FH}^{(a,b)}_{\text{I,II}^-}(K_v) \to \text{FH}^{(a,b)}_{\text{I,II}^-}(H_v)$.
obtained by composing the continuation map $\text{FH}^{(a,b)}(K_\nu) \to \text{FH}^{(a,b)}(H_\nu)$ with the map induced by projection $\text{FH}^{(a,b)}(H_\nu) \to \text{FH}^{(a,b)}_{I,II-}(H_\nu)$. Since the homotopy is constant in the region $F \cup W_{\text{bottom}} \cup V$, which contains the orbits of types $I$ and $II^-$, it follows that this continuation map is an isomorphism. Indeed, the generators of the two chain complexes are canonically identified and upon arranging them in increasing order by the action the continuation map at chain level has upper triangular form with $+1$ on the diagonal. (Note that we do not use at this point Lemma 2.4.)

For $\nu \leq \nu'$ we get commutative diagrams, in which all maps are continuation morphisms,

$$\begin{array}{ccc}
\text{FH}_{I,II-}^{(a,b)}(H_\nu) & \xleftarrow{\phi_{\nu}^{HK}} & \text{FH}_{I,II-}^{(a,b)}(K_\nu) \\
\phi_{\nu \nu'} & \uparrow & \psi_{\nu \nu'} \\
\text{FH}_{I,II-}^{(a,b)}(H_{\nu'}) & \xleftarrow{\phi_{\nu'}^{HK}} & \text{FH}_{I,II-}^{(a,b)}(K_{\nu'})
\end{array}$$

Here $\psi_{\nu \nu'}: \text{FH}_{I,II-}^{(a,b)}(K_{\nu'}) \to \text{FH}_{I,II-}^{(a,b)}(K_\nu)$ is the continuation map induced by a convex interpolation between $K_\nu$ and $K_{\nu'}$. As a consequence we have a canonical isomorphism

$$\lim_{\nu \to \infty} \text{FH}_{I,II-}^{(a,b)}(H_\nu) \xleftarrow{\psi_{\nu \nu'}} \lim_{\nu \to \infty} \text{FH}_{I,II-}^{(a,b)}(K_\nu).$$

Figure 15: The Hamiltonians $H_\nu$ and $K_\nu$
The complex $\text{FC}_{I, II}^{(a,b)}(K_\nu)$ can be decomposed as

\begin{equation}
\text{FC}_{I, II}^{(a,b)}(K_\nu) = \text{FC}_I^{(a,b)}(K_\nu) \oplus \text{FC}_{II}^{(a,b)}(K_\nu),
\end{equation}

with differential of upper triangular form $(0 \ 0 \ 0)$. Lemma 6.5 below shows that this decomposition is preserved by the continuation maps $\psi_{\nu, \nu'}$, which also have upper triangular form. (That this precise property could a priori fail for the Hamiltonians $H_\nu$ was the reason to deform them to the Hamiltonians $K_\nu$.) In particular, there is a well-defined inverse system of quotient homologies $\text{FH}_{II}^{(a,b)}(K_\nu)$ for $\nu \rightarrow \infty$. Lemma 6.6 below shows that the inverse limit of this system vanishes, and we thus obtain a canonical isomorphism

\begin{equation}
\lim_{\nu \rightarrow \infty} \text{FH}_I^{(a,b)}(K_\nu) \cong \lim_{\nu \rightarrow \infty} \text{FH}_{I, II}^{(a,b)}(K_\nu),
\end{equation}

the map being induced in the limit by the inclusions $\text{FC}_I^{(a,b)}(K_\nu) \hookrightarrow \text{FC}_{I, II}^{(a,b)}(K_\nu)$.

We now prove the isomorphism

\begin{equation}
\lim_{\nu \rightarrow \infty} \text{FH}_I^{(a,b)}(K_\nu) = \text{SH}^{(a,b)}(W_{\text{bottom}}, \partial^{-} V).
\end{equation}

The Floer trajectories which are involved in the definition of the Floer differential for $\text{FC}_I^{(a,b)}(K_\nu)$ are contained in a neighbourhood of $F \cup W_{\text{bottom}}$ by Lemma 2.2. The key point is that the Floer trajectories involved in the definition of the continuation maps $\text{FC}_I^{(a,b)}(K_\nu) \rightarrow \text{FC}_I^{(a,b)}(K_\nu)$ are also contained in a neighbourhood of $F \cup W_{\text{bottom}}$. For this purpose we choose the Hamiltonians $K_\nu$ such that for $\nu' \geq \nu$ the Hamiltonian $K_{\nu'}$ coincides with $K_\nu$ on a neighbourhood of $F \cup W_{\text{bottom}}$ where the orbits in group $I$ for $K_\nu$ are located. This ensures that the assumptions in the last paragraph of Lemma 2.2 are satisfied for the homotopy obtained by convex interpolation between $K_\nu$ and $K_{\nu'}$. Denote by $\bar{K}_\nu$ the Hamiltonian defined on $F \cup W_{\text{bottom}} \cup [1, \infty) \times \partial^{-} V$ which is equal to $K_\nu$ on $F \cup W_{\text{bottom}}$ and linear of slope $-\nu$ (the same as the slope of $K_\nu$) on $[1, \infty) \times \partial^{-} V$. The previous argument then shows the equality

\begin{equation}
\lim_{\nu \rightarrow \infty} \text{FH}_I^{(a,b)}(K_\nu) = \lim_{\nu \rightarrow \infty} \text{FH}_I^{(a,b)}(\bar{K}_\nu),
\end{equation}

and the right-hand side is $\text{SH}^{(a,b)}(W_{\text{bottom}}, \partial^{-} V)$ by definition.

The conclusion of Lemma 6.4 now follows by combining the isomorphisms (33), (35) and (36). □
The next lemma was used in the previous proof. We recall that $K_v$ denotes a Hamiltonian which coincides with $H_v$ on $F \cup W_{\text{bottom}} \cup V$, is constant equal to $-\varepsilon v$ on $V \cup W_{\text{top}}$, and is linear of slope $\tau$ (the same as the slope of $H_v$) on $[1, \infty) \times \partial^+ W$. We choose the smoothings of the Hamiltonians $K_{v'}$ and $K_v$ to coincide up to a translation by $\varepsilon (v' - v)$ in the region $I^-$ but only for slopes in the interval $(-v + \eta v, 0)$. We recall the decomposition (34) of $\text{FC}_{I, I^-, K_v}$ with respect to which the differential has upper triangular form.

**Lemma 6.5** The Floer continuation map $\psi_{v,v'}: \text{FC}_{I, I^-, K_{v'}} \rightarrow \text{FC}_{I, I^-, K_v}$ induced by a nonincreasing $s$–dependent convex interpolation from $K_v$ at $-\infty$ to $K_{v'}$ at $+\infty$ has upper-triangular form with respect to the decompositions $\text{FC}_{I, I^-, K_v} = \text{FC}_{I, I^-, K_{v'}} \oplus \text{FC}_{I, I^-, K_v}$ for $K_v$ and $K_{v'}$.

**Proof** The only problematic relation is $I_{K_{v'}} < I^-_{K_v}$. To prove it we use the fact that in the region $I^-$ the two Hamiltonians coincide up to a translation, so in this region the homotopy is simply given by adding to the Hamiltonian $K_v$ some function $\varepsilon (v' - v)$ of $s$ with compactly supported derivative. As such, the constant trajectories at the orbits in $I^-_{K_v}$ solve the $s$–dependent continuation Floer equation.

Assume there exists a continuation Floer trajectory $u: \mathbb{R} \times S^1 \rightarrow \tilde{W}_F$ from some orbit $x_+ = \lim_{s \rightarrow +\infty} u(s, \cdot)$ in $I_{K_{v'}}$ to some orbit $x_- = \lim_{s \rightarrow -\infty} u(s, \cdot)$ in $I^-_{K_v}$. By Lemma 2.3, either $u$ is constant equal to $x_-$ for very negative values of the parameter $s$, or there exists $(s, t) \in \mathbb{R} \times S^1$ with $s$ very negative such that $r(u(s, t)) > r_- = r(x_-(t))$. In the first situation the Floer trajectory would need to be constant equal to $x_-$ for all values of $s$ because of unique continuation and the fact that the constant trajectory at $x_-$ solves the same equation. This is a contradiction since $x_+ \neq x_-$. In the second situation we reach a contradiction using Lemma 2.2, which we can apply in the $s$–independent case because the homotopy is just given by a shift by a function of $s$ on $V \cup W_{\text{top}} \cup [1, \infty) \times \partial^+ W$. \hfill $\square$

The next lemma was used in the proof of Lemma 6.4 as well. By Lemma 6.5 we have a well-defined inverse system $\text{FH}_{I^-, K_v}^{(a,b)}(v, v \rightarrow \infty).

**Lemma 6.6** $\lim_{v \rightarrow \infty} \text{FH}_{I^-, K_v}^{(a,b)}(v) = 0.$

**Proof** For $v' > v$, generators of $\text{FC}_{I^-, K_{v'}}^{(a,b)}(v)$ correspond to closed Reeb orbits $\gamma$ on $\partial^- V$ with Hamiltonian action satisfying

*Algebraic & Geometric Topology, Volume 18 (2018)*
\[ A_{K_{v'}}(\gamma) = -(1 + \varepsilon)\left( \int_{\gamma} \lambda \right) + \varepsilon v' \in (a, b). \]

Since this condition is equivalent to
\[ A_{K_{v}}(\gamma) = -(1 + \varepsilon)\left( \int_{\gamma} \lambda \right) + \varepsilon v \in (a + \varepsilon(v - v'), b + \varepsilon(v - v')) , \]

we see that the same Reeb orbits also correspond to generators of the Floer chain group \( FC_{\Pi^-}(a + \varepsilon(v - v'), b + \varepsilon(v - v'))(K_v) \). Varying the slope continuously from \( v' \) to \( v \), we obtain a continuation isomorphism between these two groups fitting into the commuting diagram
\[
\begin{array}{ccc}
\text{FH}_{\Pi^-}^{(a + \varepsilon(v - v'), b + \varepsilon(v - v'))}(K_v) & \cong & \text{FH}_{\Pi^-}^{(a, b)}(K_{v'}) \\
\downarrow & & \downarrow \psi_{v,v'} \\
\text{FH}_{\Pi^-}^{(a, b)}(K_v) & & \\
\end{array}
\]

That the horizontal map is an isomorphism follows from the fact that the Hamiltonian is deformed outside a compact set only by a global shift by a constant, and from the fact that there are no orbits that cross the boundary of the moving action window during the homotopy. The horizontal map can be expressed as a composition of small-time continuation maps induced by homotopies for fixed action windows, which are isomorphisms since each of these homotopies can be followed backwards, and of tautological isomorphisms given by shifting the action window by some small amount in the complement of the action spectrum.

Now if \( b + \varepsilon(v - v') < a \), then the intervals \([a + \varepsilon(v - v'), b + \varepsilon(v - v')]\) and \([a, b]\) do not overlap and thus the projection \( \pi \) vanishes in homology. Hence, the Floer chain map \( \psi_{v,v'} \) vanishes whenever \( v' - v > (b - a)/\varepsilon \), from which the lemma follows. \( \square \)

**Proposition 6.7** (excision for filtered symplectic homology) Let \((W, V)\) be a pair of Liouville cobordisms with filling and consider parameters \(-\infty < a < b < \infty \). There is a short exact sequence
\[
0 \to \text{SH}_*(a, b)(W_{\text{top}}, \partial^+ V) \to \text{SH}_*(a, b)(W, V) \to \text{SH}_*(a, b)(W_{\text{bottom}}, \partial^- V) \to 0.
\]
Moreover, this short exact sequence splits canonically, so that we have a canonical isomorphism
\[
\text{SH}_*(a, b)(W, V) \cong \text{SH}_*(a, b)(W_{\text{top}}, \partial^+ V) \oplus \text{SH}_*(a, b)(W_{\text{bottom}}, \partial^- V).
\]
Proof. We fix the parameters $0 < \delta, \varepsilon < 1$ and $\mu, \tau > 0$ so that the first two conditions in (30) hold, and we work with the family of Hamiltonians $H_v = H_{\mu, \nu, \tau}$ for $v \to \infty$ discussed above. Then

$$\lim_{v \to \infty} FH_{*, (a,b)}^*(H_v) \cong SH_{*, (a,b)}^*(W, V)$$

by definition. The short exact sequence of inverse systems (32) determines an inverse system of homology exact triangles in which each term is a finite-dimensional vector space. In this case the inverse limit preserves exactness and we obtain, using Lemmas 6.3 and 6.4, an exact triangle

$$\xymatrix{ SH_{*, (a,b)}^*(W_{\top}, \partial^+ V) \ar[rr] & & SH_{*, (a,b)}^*(W, V) \ar[dl] \ar[dd]_{[-1]} \ar[ll] \ar[dr] \ar[rr] \ar[dd] \ar[ll] & & \ar[ll] \ar[ll] \ar[ll] \ar[ll] \ar[ll] \ar[ll] \ar[ll] \ar[ll] \ar[ll] }$$

The proof of Lemma 6.4 shows that each class in $SH_{*, (a,b)}^*(W_{\text{bottom}}, \partial^- V)$ is represented by a sequence (indexed by $v$ and representing an element of the inverse limit) of classes in $FH_{I, II}^{(a,b)}(H_v)$ which are each represented by a cycle that is a linear combination of orbits in $I_{H_v}$. Indeed, the proof provides such a representative by a cycle in $FC_{I}^{(a,b)}(K_v)$, and we have $FC_{I}^{(a,b)}(K_v) = FC_{I}^{(a,b)}(H_v)$; on the other hand, since $I_{H_v} < I_{H_v}$ as already seen in (31), this continues to be a cycle in $FC_{I, II}^{(a,b)}(H_v)$.

To prove the existence of the short exact sequence in the statement we use that the degree $-1$ connecting map $FH_{I, II}^{(a,b)}(H_v) \to FH_{III}^{(a,b)}(H_v)$ vanishes on elements of $I_{H_v}$ by (31). Thus the connecting map in the above exact triangle vanishes, and the latter becomes the short exact sequence

$$0 \to SH_{*, (a,b)}^*(W_{\top}, \partial^+ V) \to SH_{*, (a,b)}^*(W, V) \to SH_{*, (a,b)}^*(W_{\text{bottom}}, \partial^- V) \to 0.$$  

To prove the existence of a canonical splitting for this exact sequence we use again that $I < III$ for $H_v$. Thus a cycle in $FC_{I, II}^{(a,b)}(H_v)$ which is a linear combination of orbits in $I_{H_v}$ is canonically also a cycle in $FC^{(a,b)}(H_v)$. The splitting $SH_{*, (a,b)}^*(W_{\text{bottom}}, \partial^- V) \to SH_{*, (a,b)}^*(W, V)$ associates to each class, represented by a sequence of classes of cycles in $FC_{I, II}^{(a,b)}(H_v)$ which are linear combinations of orbits in $I_{H_v}$, the sequence of classes represented by the same cycles viewed in $FC^{(a,b)}(H_v)$. The latter indeed represents an element in the inverse limit of $FH_{I, II}^{(a,b)}(H_v)$, $v \to \infty$ because the continuation maps $\phi_{v, v'}$: $FC^{(a,b)}(H_{v'}) \to FC^{(a,b)}(H_v)$ preserve the relation $I < III$.  

\[\square\]
Taking limits over $a$ and $b$, Proposition 6.7 implies:

**Theorem 6.8** (excision) Let $(W, V)$ be a pair of Liouville cobordisms with filling. Then for each flavour $\diamondsuit$ we have canonical isomorphisms

$$\text{SH}_\diamondsuit^*(W, V) \cong \text{SH}_\diamondsuit^*(W^\text{bottom}, \partial^- V) \oplus \text{SH}_\diamondsuit^*(W^\text{top}, \partial^+ V).$$

In Proposition 6.7 and Theorem 6.8 we allow $W^\text{bottom}$ or $W^\text{top}$ to be empty, in which case the corresponding term is not present in the diagram. In particular, taking $V$ to be a collar neighbourhood of some boundary components we obtain:

**Corollary 6.9** Given a Liouville cobordism $W$ and an admissible union of connected components $A \subset \partial W$, we have

$$\text{SH}_\diamondsuit^*(W, A) \cong \text{SH}_\diamondsuit^*(W, I \times A),$$

where $I \times A$ is a collar neighbourhood of $A$ in $W$ which we view as a trivial cobordism, so that $(W, I \times A)$ is a Liouville pair.

This is the precise sense in which Definitions 2.13 and 2.15 are compatible.

In order to make the excision theorem resemble the one in algebraic topology, we introduce the following notion:

**Definition 6.10** A Liouville cobordism triple $(W, V, U)$ consists of three Liouville cobordisms $U \subset V \subset W$ such that $(W, V)$ and $(V, U)$ are Liouville cobordism pairs. A filling of a Liouville cobordism triple is a filling of $W$, which induces fillings of $V$ and $U$ in the obvious way.

Then we have:

**Theorem 6.11** (excision for triples) Let $(W, V, U)$ be a filled Liouville cobordism triple. Then for each flavour $\diamondsuit$ we have canonical isomorphisms

$$\text{SH}_\diamondsuit^*(W, V) \cong \text{SH}_\diamondsuit^*(\overline{W \setminus U}, \overline{V \setminus U}).$$

Here, if some boundary component $A$ of $V$ and $U$ coincides, then the homology on the right-hand side has to be understood relative to $A$. (Alternatively, one can use Proposition 9.3 below to move $U$ into the interior of $V$ and avoid this situation.) Also, if $\overline{W \setminus U}$ contains both a bottom and an upper part then the right-hand side has to be understood according to Section 2.6 as a direct sum, as in the statement of Theorem 6.8.
Proof Let us write
\[ W \setminus V = W_{\text{bottom}} \sqcup W_{\text{top}}, \quad V \setminus U = V_{\text{bottom}} \sqcup V_{\text{top}}. \]
Then
\[ W \setminus U = (W_{\text{bottom}} \sqcup V_{\text{bottom}}) \sqcup (W_{\text{top}} \sqcup V_{\text{top}}) \]
and we find
\[ \SH_*(W \setminus U, V \setminus U) = \SH_*(W_{\text{bottom}} \sqcup V_{\text{bottom}}, V_{\text{bottom}}) \oplus \SH_*(W_{\text{top}} \sqcup V_{\text{top}}, V_{\text{top}}) \]
\[ \cong \SH_*(W_{\text{bottom}}, \partial V) \oplus \SH_*(W_{\text{top}}, \partial^+ V) \]
\[ \cong \SH_*(W, V), \]
where the first equality is the definition and the other two isomorphisms follow from Theorem 6.8. \hfill \Box

7 The exact triangle of a pair of filled Liouville cobordisms

The main result of this section is:

**Theorem 7.1** (exact triangle of a pair) For each filled Liouville cobordism pair \((W, V)\) and \(\heartsuit \in \{\emptyset, \geq 0, > 0, = 0, \leq 0, < 0\}\), there exist exact triangles

\[ \SH_*(W, V) \xrightarrow{[-1]} \SH_*(V) \xrightarrow{[-1]} \SH_*(W) \]

\[ \SH_*(V) \xleftarrow{[+1]} \SH_*(W) \]

These triangles are functorial with respect to inclusions of Liouville pairs.

This theorem will be proved in Section 7.3.

7.1 Cofinal families of Hamiltonians

As a preparation, we now recast the definition of the symplectic homology groups \(\SH_*(W)\) and \(\SH_*(V)\) and of the transfer map \(f^\heartsuit_1\): \(\SH_*(W) \rightarrow \SH_*(V)\) at chain level in terms of some carefully chosen cofinal families of Hamiltonians. This will allow us to further express the relative symplectic homology groups \(\SH_*(W, V)\) in terms of the cone construction.

Let \((W, V)\) be a Liouville pair with filling \(F\).
Notational convention  Let $P$ and $Q$ denote sets of 1–periodic orbits of a given Hamiltonian $H$. Recall that we write $Q < P$ if all the orbits in group $Q$ have strictly smaller action than all the orbits in group $P$, and we write $Q < P$ if there is no Floer trajectory for $H$ asymptotic at the positive puncture to an orbit in $Q$ and asymptotic at the negative puncture to an orbit in $P$. This implies that the expression of the Floer boundary operator on any orbit in $Q$ does not contain any element in $P$. It is understood that the Floer equation involves some almost complex structure which is not specified in the notation.

Similarly, given two Hamiltonians $H_\pm$ and a homotopy $H_s$ for $s \in \mathbb{R}$ equal to $H_\pm$ near $\pm \infty$, and given sets of 1–periodic orbits $P_{H_\pm}$ for $H_\pm$, we write

$$P_{H_+} < P_{H_-}$$

if there is no Floer continuation trajectory for the homotopy $H_s$ asymptotic at the positive puncture to an orbit in $P_{H_+}$ and asymptotic at the negative puncture to an orbit in $P_{H_-}$. This implies that the expression of the Floer continuation map on any orbit in $P_{H_+}$ does not contain any element in $P_{H_-}$. Here it is again understood that the Floer continuation equation involves some almost complex structure which is not specified in the notation. In the previous context, we write

$$P_{H_+} < P_{H_-}$$

if the $H_+–$action of any orbit in $P_{H_+}$ is smaller than the $H_–$–action of any orbit in $P_{H_-}$. This implies $P_{H_+} < P_{H_-}$ if $H_+ \leq H_-$ and the homotopy $H_s$ is nonincreasing with respect to the $s$–variable.

Given $c \in \mathbb{R}$, we write

$$P_{H_+} < P_{H_-} - c$$

if the difference between the $H_+–$action of any orbit in $P_{H_+}$ and the $H_–$–action of any orbit in $P_{H_-}$ is smaller than $-c$.

**Lemma 7.2**  Consider Hamiltonians $H_+ \geq H_-$ and a homotopy $H_s$ which is a convex interpolation between $H_+$ and $H_-$ given by a nondecreasing $s$–dependent function, ie $H_s = H_- + f(s)(H_+ - H_-)$ with $f: \mathbb{R} \to [0, 1]$, $f' \geq 0$, $f = 0$ near $-\infty$ and $f = 1$ near $+\infty$. Then $P_{H_+} < P_{H_-} - \|H_+ - H_-\|_\infty$ implies $P_{H_+} < P_{H_-}$.

**Proof**  If there is a continuation Floer trajectory $u: \mathbb{R} \times S^1 \to \hat{W}_F$ solving

$$\partial_s u + J_{s,t}(u)(\partial_t u - X_{H_s}(u)) = 0$$

In *Algebraic & Geometric Topology, Volume 18 (2018)*
with \( \lim_{s \to \pm \infty} u(s, \cdot) = x_{\pm}(\cdot) \), where \( x_{\pm} \) are 1–periodic orbits of \( H_{\pm} \), then we have

\[
A_{H_{+}}(x_{+}) - A_{H_{-}}(x_{-})
\]

\[
= \int_{-\infty}^{\infty} \frac{d}{ds} A_{H_{s}}(u(s, \cdot)) \, ds
\]

\[
= \int_{-\infty}^{\infty} \int_{0}^{1} \|\partial_{s} u(s, t)\|^2 \, dt \, ds
\]

\[
- \int_{-\infty}^{\infty} \int_{0}^{1} f'(s)(H_{+}(t, u(s, t)) - H_{-}(t, u(s, t))) \, dt \, ds
\]

\[
\geq -\int_{-\infty}^{\infty} \int_{0}^{1} f'(s) \sup_{t, x} (H_{+}(t, x) - H_{-}(t, x)) \, dt \, ds
\]

\[
= -\|H_{+} - H_{-}\|_{\infty}.
\]

Since the domain of definition of the Hamiltonians that we use in this paper is a noncompact manifold, it is appropriate to discuss the degree of applicability of the previous principle: it holds for compactly supported homotopies, so that \( \|H_{+} - H_{-}\|_{\infty} \) is finite (and can be explicitly computed), but it also holds for noncompactly supported homotopies if one knows a priori that the continuation Floer trajectories are contained in a compact set, in which case it is enough to estimate \( \|H_{+} - H_{-}\|_{\infty} \) on that compact set.

### 7.1.1 Hamiltonians for \( \mathbf{SH}_{*}^{\mathcal{Q}}(W) \)

Let \( \mu, \tau > 0 \)

be such that \( \mu \notin \text{Spec}(\partial^{-} W) \) and \( \tau \notin \text{Spec}(\partial^{+} W) \). Denote by \( \eta_{\mu} > 0 \) the distance from \( \mu \) to \( \text{Spec}(\partial^{-} W) \) and let \( \delta > 0 \) be such that

\[
\delta \mu < \eta_{\mu}.
\]

We denote by

\[
K_{\mu, \tau} = K_{\mu, \tau, \delta} : \hat{W}_{F} \to \mathbb{R}
\]

the Hamiltonian which is defined up to smooth approximation as follows: it is constant equal to \( \mu(1 - \delta) \) on \( F \setminus [\delta, 1] \times \partial F \); it is linear equal to \( \mu(1 - r) \) on \( [\delta, 1] \times \partial F \), it is constant equal to 0 on \( W \), and it is linear equal to \( \tau(r - 1) \) on \( [1, \infty) \times \partial^{+} W \). See Figure 16.

A smooth approximation of \( K_{\mu, \tau} \) will thus be of the form \( K_{\mu, \tau}(r, y) = k(r) \) on \( [1, \infty) \times \partial^{+} W \) (and similarly near the negative boundary \( \partial^{-} W \)). The 1–periodic orbits
of $X_{K_{\mu,\tau}}$ on $\{r\} \times \partial^+ W$ correspond to Reeb orbits on $\partial^+ W$ of period $k'(r)$, and their Hamiltonian action equals

$$rk'(r) - k(r).$$

Since we assumed that $\mu$ and $\tau$ are not equal to the period of a closed Reeb orbit on the respective boundaries of $W$, it follows that $K_{\mu,\tau}$ has no 1–periodic orbits in the regions where it is linear.

The 1–periodic orbits of the Hamiltonian $K_{\mu,\tau}$ naturally fall into five classes as follows:

- $(F^0)$ Constants in $F \setminus [\delta, 1] \times \partial F$.
- $(F^+)$ Orbits corresponding to negatively parametrized closed Reeb orbits on $\partial F = \partial^- W$ and located near $\{\delta\} \times \partial^- W$.
- $(I^-)$ Orbits corresponding to negatively parametrized closed Reeb orbits on $\partial^- W$ and located near $\partial^- W$.
- $(I^0)$ Constants in $W$.
- $(I^+)$ Orbits corresponding to positively parametrized closed Reeb orbits on $\partial^+ W$ and located near $\partial^+ W$.

We denote by $F$ the group of orbits $F^{0+}$, and by $I$ the group of orbits $I^{-0+}$. The maximal action of an orbit in group $F$ is $-\mu(1 - \delta) = -\mu + \delta \mu$, while the minimal action of an orbit in group $I$ is $-\mu + \eta \mu$. Condition (37) implies $F < I$, and in particular

$$F < I.$$

This last relation actually holds regardless of the choice of parameters by combining Lemmas 2.2 and 2.3 in order to prohibit trajectories from $F$ to $I^-$ with the relation
$F < I^{0^+}$, which prohibits trajectories from $F$ to $I^{0^+}$. Alternatively, the relation $F < I^0$ is also a consequence of Lemma 2.5, while $F < I^+$ is also a consequence of Lemmas 2.2 and 2.3.

Now let $(\mu_i)$ for $i \in \mathbb{Z}_-$ and $(\tau_j)$ for $j \in \mathbb{Z}_+$ be two sequences which do not contain elements in $\text{Spec}(\partial^-W) \cup \text{Spec}(\partial^+W)$ and such that $\mu_{i'} > \mu_i$ for $i' < i$ and $\tau_{j'} < \tau_j$ for $j < j'$. We moreover require that $\mu_i \to \infty$ as $i \to -\infty$ and $\tau_j \to \infty$ as $j \to \infty$. Choose a sequence $(\delta_i)$ for $i \in \mathbb{Z}_-$ of positive numbers such that $\delta_{i'} < \delta_i$ for $i' < i$, such that $\delta_i \to 0$ as $i \to -\infty$, and such that condition (37) is satisfied:

$$\delta_i \mu_i < \eta \mu_i \quad \text{for all} \quad i \in \mathbb{Z}_-.$$

We let

$$K_{i,j} := K_{\mu_i, \tau_j, \delta_i}, \quad i \in \mathbb{Z}_-, \ j \in \mathbb{Z},$$

so that $K_{i',j} \geq K_{i,j}$ for $i' \leq i$, and $K_{i,j} \leq K_{i',j'}$ for $j \leq j'$. We consider $\text{FC}_*(K_{i,j})$ as a doubly directed system in $\text{Kom}$, inverse on $i \to -\infty$ and direct on $j \to \infty$, with maps

$$\text{FC}_*(K_{i',j}) \to \text{FC}_*(K_{i,j}), \quad i' \leq i,$$

induced by nondecreasing homotopies, and maps

$$\text{FC}_*(K_{i,j}) \to \text{FC}_*(K_{i,j'}), \quad j \leq j',$$

induced by nonincreasing homotopies. Denote by $\text{FC}_F(K_{i,j})$ the Floer subcomplex of $\text{FC}_*(K_{i,j})$ generated by orbits in the group $F$, and denote by $\text{FC}_I(K_{i,j})$ the Floer quotient complex generated by orbits in the group $I$. The groups of orbits $I^-$, $I^0$ and $I^+$ are ordered by action as $I^- < I^0 < I^+$ within the group of orbits $I$, so that we have corresponding subcomplexes and quotient complexes $\text{FC}_{I\diamond} (K_{i,j})$ for $\diamond \in \{\emptyset, \geq, 0, > 0, = 0, \leq 0, < 0\}$, where $I^0$ has the following meaning:

$$I^\emptyset = I, \quad I^\leq = I^0, \quad I^> = I^+, \quad I^< = I^-, \quad I^= = I^0, \quad I^\geq = I^{0^+}.$$

**Lemma 7.3** The homotopies that define the doubly directed system $\text{FC}_*(K_{i,j})$ for $i \in \mathbb{Z}_-$ and $j \in \mathbb{Z}_+$ induce doubly directed systems

$$\text{FC}_{I\diamond} (K_{i,j}), \quad i \in \mathbb{Z}_-, \ j \in \mathbb{Z}_+, \quad \text{for} \quad \diamond \in \{\emptyset, \geq, 0, > 0, = 0, \leq 0, < 0\}.$$

**Proof** Our choice of parameters ensures that

(38) \quad $F_{K_{i',j}} < I_{K_{i,j}}$, \quad $F_{K_{i,j}} < I_{K_{i,j'}}$. 

*Algebraic & Geometric Topology, Volume 18 (2018)*
for $i' \leq i$ and $j \leq j'$. To prove these relations let $\mu' = \mu_{i'}$, $\tau' = \tau_{j'}$ and $\delta' = \delta_{i'}$, and similarly $\mu$, $\tau$ and $\delta$ for the corresponding numbers not decorated with primes. The first relation follows from Lemma 7.2 and the relation $F_{K_{i',j}} < I_{K_{i',j}} - \|K_{i',j} - K_{i,j}\|_\infty$: the maximal action of an orbit in $F_{K_{i',j}}$ is $-\mu'(1-\delta')$, the minimal action of an orbit in $I_{K_{i',j}}$ is $-\mu + \eta \mu$, and the maximal oscillation of the homotopy is $\|K_{i',j} - K_{i,j}\|_\infty = \mu'(1-\delta') - \mu(1-\delta)$; the desired relation then follows from (37). The second relation in (38) follows from $F_{K_{i',j}} < I_{K_{i',j}}$ because in this case the homotopy is nonincreasing.

Now we have already seen that $F_{K_{i,j}} < I_{K_{i,j}}$, while the action of the orbits in $I_{K_{i,j}}$ is never smaller than the action of the orbits in $I_{K_{i,j}}$. This proves the relations (38). They imply that we have a doubly directed subsystem $FC_{F}(K_{i,j})$ and a doubly directed quotient system $FC_{I}(K_{i,j})$ for $i \in \mathbb{Z}_-$ and $j \in \mathbb{Z}_+$. To prove that we have doubly directed systems $FC_{I \bowtie}(K_{i,j})$ for $i \in \mathbb{Z}_-$ and $j \in \mathbb{Z}_+$ for all values of $\bowtie$ we need to show the relations

$$I_{K_{i',j}}^0 < I_{K_{i,j}}^{0+} \quad \text{and} \quad I_{K_{i,j}}^- < I_{K_{i,j}}^0 \quad \text{for} \quad i' \leq i,$$

$$I_{K_{i,j}}^- < I_{K_{i',j}}^{0+} \quad \text{and} \quad I_{K_{i,j}}^- < I_{K_{i,j}}^0 \quad \text{for} \quad j \leq j'.$$

The last two relations follow from the fact that the nonincreasing homotopies which induce maps $FC_{\bowtie}(K_{i,j}) \to FC_{\bowtie}(K_{i',j})$ for $j \leq j'$ preserve the filtration by the action. In contrast, this argument cannot be used to prove the first two relations since nondecreasing homotopies typically do not preserve the action filtration. Instead we argue using the confinement lemmas in Section 2.3: the first relation follows from Lemma 2.5, and the second relation follows from Lemmas 2.2 and 2.3.

Lemma 7.4  We have isomorphisms

$$SH_\bowtie(K_{i,j}) \cong \lim_{j} \lim_{i} FH_{I \bowtie}(K_{i,j})$$

for $\bowtie \in \{\emptyset, \geq, >, 0, =, 0, \leq, 0, <\}$.

Proof  Recall that the slopes of $K_{i,j}$ are $-\mu_i$ and $\tau_j$, with $-\mu_i < 0 < \tau_j$. We claim that

(39)  $$SH_\bowtie(-\mu_i, \tau_j)(W) \cong FH_{I}(K_{i,j}).$$

To prove (39) recall that $SH_{\bowtie}(a,b)(W) = \lim_{K} FH_{\bowtie}(a,b)(K)$, where $K$ ranges over the space $\mathcal{H}(W; F)$ of admissible Hamiltonians on $\hat{W}_F$ with respect to the filling $F$ and the direct limit is considered with respect to nonincreasing homotopies; see Section 2.4.

Algebraic & Geometric Topology, Volume 18 (2018)
Consider a decreasing sequence $i_k \to -\infty$ and an increasing sequence $j_k \to \infty$ as $k \to \infty$. The sequence of Hamiltonians $K_{i_k,j_k}$ for $k \in \mathbb{Z}_+$ is then cofinal in $\mathcal{H}(W; F)$ and we have

$$\text{SH}_*^{(a,b)}(W) = \lim_{k \to \infty} \text{FH}_*^{(a,b)}(K_{i_k,j_k}),$$

where the direct limit is considered with respect to continuation maps $\text{FH}_*^{(a,b)}(K_{i_k,j_k}) \to \text{FH}_*^{(a,b)}(K_{i_k',j_k'})$ induced by nonincreasing homotopies. We can assume without loss of generality that $-\mu_{i_k} \leq a$ and $\tau_{j_k} \geq b$. The smoothings of any such two Hamiltonians $K_{i_k,j_k}$ and $K_{i_k',j_k'}$ for $k \leq k'$ can be constructed so that they coincide in the neighbourhood of $W$ where the periodic orbits in group $I$ for $K_{i_k,j_k}$ appear. As such, the continuation map $\text{FC}_*^{(a,b)}(K_{i_k,j_k}) \to \text{FC}_*^{(a,b)}(K_{i_k',j_k'})$, which is upper triangular if we arrange the generators in increasing order of the action, has diagonal entries equal to $+1$ and is therefore an isomorphism. This proves that the canonical map $\text{FH}_*^{(a,b)}(K_{i_k,j_k}) \to \text{SH}_*^{(a,b)}(W)$ is an isomorphism for all $k$ (such that $-\mu_{i_k} \leq a$ and $\tau_{j_k} \geq b$).

The isomorphism \text{(39)} is proved by considering the following three isomorphisms: we have $\text{FH}_I(I_{i,j}) = \text{FH}_*^{- \mu_1 + \eta, \tau_1}(K_{i,j})$ for any $\eta > 0$ such that $\delta_i \mu_i < \eta < \eta \mu_i$; we have $\text{FH}_*^{- \mu_i + \eta, \tau_i}(K_{i,j}) \cong \text{SH}_*^{- \mu_i + \eta, \tau_i}(W)$ by the above; and $\text{SH}_*^{- \mu_i + \eta, \tau_i}(W) \cong \text{SH}_*^{- \mu_i, \tau_i}(W)$ since there is no periodic Reeb orbit on $\partial^- W$ with period in the interval $(\mu_i - \eta, \mu_i)$.

A variant of the same argument shows that, under the isomorphism \text{(39)}, the continuation maps $\text{FH}_I(K_{i',j}) \to \text{FH}_I(K_{i,j})$ for $i' \leq i$ and $\text{FH}_I(K_{i,j}) \to \text{FH}_I(K_{i,j'})$ for $j \leq j'$ induced by a nondecreasing homotopy and a by a nonincreasing homotopy, respectively, coincide with the canonical maps $\text{SH}_*^{- \mu_i', \tau_i'}(W) \to \text{SH}_*^{- \mu_i, \tau_i}(W)$ and $\text{SH}_*^{- \mu_i, \tau_i}(W) \to \text{SH}_*^{- \mu_i', \tau_i'}(W)$, respectively. From this the conclusion of the lemma follows in the case $\heartsuit \neq \emptyset$.

The proof in the case $\heartsuit \neq \emptyset$ is similar in view of the isomorphisms

$$\text{SH}_*^{0+, \tau_i}(W) \cong \text{FH}^{>0}_{I}(K_{i,j}), \quad \text{SH}_*^{(-\mu_i, 0+)}(W) \cong \text{FH}^{<0}_{I}(K_{i,j}),$$

$$\text{SH}_*^{0-, \tau_i}(W) \cong \text{FH}^{\geq 0}_{I}(K_{i,j}), \quad \text{SH}_*^{(-\mu_i, 0-)}(W) \cong \text{FH}^{<0}_{I}(K_{i,j}),$$

$$\text{SH}_*^{0-, 0+}(W) \cong \text{FH}^{=0}_{I}(K_{i,j}).$$

Here $0^-$ and $0^+$ denote a negative and a positive real number, respectively, which is close enough to zero (with absolute value smaller than the minimal period of a closed Reeb orbit on $\partial^- W$ and $\partial^+ W$, respectively). \hfill $\square$
7.1.2 Hamiltonians for $\text{SH}_*^\sigma(W, \partial^\pm W)$

We shall need in the sequel (Lemma 7.9) alternative descriptions of the homology groups $\text{SH}_*^\sigma(W, \partial^\pm W)$ in the spirit of the previous section, which we now explain. We refer freely to the notation of Section 7.1.1.

Given $\mu, \tau > 0$ such that $\mu \notin \text{Spec}(\partial^- W)$ and $\tau \notin \text{Spec}(\partial^+ W)$, and given $\delta \in (0, 1)$, we consider Hamiltonians $K^\pm = K^\pm_{\mu, \tau, \delta} : \hat{W}_F \to \mathbb{R}$ defined as follows:

- The Hamiltonian $K^-_{\mu, \tau, \delta}$ coincides with the Hamiltonian $K_{\mu, \tau, \delta}^-$ of Section 7.1.1 on $W \cup [1, \infty) \times \partial^+ W$ and is equal to $-K_{\mu, \tau, \delta}$ on $F$. See Figure 17.
- The Hamiltonian $K^+_{\mu, \tau, \delta}$ coincides with the Hamiltonian $K_{\mu, \tau, \delta}^+$ on $F \cup W$ and is equal to $-K_{\mu, \tau, \delta}$ on $[1, \infty) \times \partial^+ W$. See Figure 17.

The 1–periodic orbits of each of these Hamiltonians naturally fall into five groups, which we denote by $F^{0+}$ and $\text{III}^{-0+}$ for $K^-$, and by $F^{0+}$ and $I^{-0+}$ for $K^+$. We denote as usual by $\eta_\mu, \eta_\tau > 0$ positive numbers smaller than the distance from $\mu$ to $\text{Spec}(\partial^- W)$ and smaller than the distance from $\tau$ to $\text{Spec}(\partial^+ W)$, respectively. If the parameters are chosen so that

\begin{equation}
\delta \mu < \eta_\mu \quad \text{and} \quad \mu - \eta_\mu > \tau - \eta_\tau,
\end{equation}

then we have $F < I$ for $K^+$ and $\text{III} < F$ for $K^-$, respectively. We write $\text{III} = 0 = \text{III}^0$ and $\text{III} > 0 = \text{III}^{+0}$, and also $I = 0 = I^0$ and $I < 0 = I^{-+}$.

This construction is well-behaved in families, just like the construction in the previous section. Consider first an indexing parameter $j \in \mathbb{Z}_+$. We choose sequences $\mu_j \to \infty$. 

Figure 17: Hamiltonians $K^\pm$ for the definition of $\text{SH}_*^\sigma(W, \partial^\pm W)$
As a consequence, we obtain well-defined directed systems in \( \text{Kom} \). This proves the second relation. (Note that one could not argue here using the gap.)

To prove the second relation we observe that the map induced by the homotopy is the composition of the maps induced by each of the monotone homotopies which constitute it. For the first homotopy, supported in \( F \), there are no trajectories from \( \text{III}_{K_j^0}^- \) to \( \text{III}_{\mu_{j},\tau_{j},\delta_{j}}^- \) by Lemma 2.5, and there are no trajectories from \( \text{III}_{K_j^0}^- \) to \( \text{III}_{K_{\mu_{j},\tau_{j},\delta_{j}}^+}^+ \) by Lemmas 2.2 and 2.3. For the second homotopy, there are no trajectories from \( \text{III}_{K_{\mu_{j},\tau_{j},\delta_{j}}^-}^- \) to \( \text{III}_{K_j^0}^0 \) because the homotopy is nonincreasing and

\[
\text{III}_{K_{\mu_{j},\tau_{j},\delta_{j}}^-}^- < \text{III}_{K_j^0}^0.
\]

This proves the second relation. (Note that one could not argue here using the gap.)

As a consequence, we obtain well-defined directed systems in \( \text{Kom} \),

\[
\text{FC}_{\text{III}^\odot}(K_j^-), \quad j \to \infty, \quad \text{for } \odot \in \{ \emptyset, = 0, > 0 \}.
\]

Consider now an indexing parameter \( i \in \mathbb{Z}_- \). Given sequences \( \mu_i \to \infty, \tau_i \to \infty \) and \( \delta_i \to 0 \) as \( i \to -\infty \) such that \( \mu_i \notin \text{Spec}(\partial^-W) \) and \( \tau_i \notin \text{Spec}(\partial^+W) \), such that \( (\mu_i) \) and \( (\tau_i) \) are increasing and \( (\delta_i) \) is decreasing, and such that (40) is satisfied for each \( i \). We define \( K_i^+ = K_{\mu_i,\tau_i,\delta_i}^+ \). Given \( i' \leq i \) the homotopy from \( K_i^+ \)

\[\text{Symplectic homology and the Eilenberg–Steenrod axioms}
\]

\[2047\]

\[\text{Algebraic \& Geometric Topology, Volume 18 (2018)}\]
at $+\infty$ to $K_i^+$ at $-\infty$ defined as the concatenation of the two monotone homotopies from $K_i^+$ to $K_{i,\tau,\delta}$ and from $K_{i,\tau,\delta}$ to $K_i^+$ is such that
\[
F_{K_i^+} < I_{K_i^+}, \quad I_{K_i^+} < I = 0.
\]
The proof involves arguments entirely similar to the above ones for the Hamiltonians $K^-$, hence we omit the details. We obtain well-defined inverse systems in $\text{Kom}$
\[
\text{FC}_I\circ (K_i^+), \quad i \to -\infty, \quad \text{for } \varpi \in \{\varnothing, < 0, = 0\}.
\]

Lemma 7.5
(a) For $\varpi \in \{\varnothing, \geq 0, > 0, = 0, \leq 0, < 0\}$ we have isomorphisms
\[
\text{SH}_*(W, \partial^- W) \cong \lim_{j} \text{FH}_{III}\circ (K_j^-).
\]
(b) For $\varpi \in \{\varnothing, \geq 0, > 0, = 0, \leq 0, < 0\}$ we have isomorphisms
\[
\text{SH}_*(W, \partial^+ W) \cong \lim_{i} \text{FH}_{I}\circ (K_i^+).
\]

Proof The proof is similar to that of Lemma 7.4. For part (a) observe first that the right-hand side does not depend on the choice of the family $K_j^-$ subject to conditions (40). We pick $\mu_j = \tau_j$ outside the action spectra of $\partial^- W$ and $\partial^+ W$ such that $\eta_{\mu_j} < \eta_{\tau_j}$, and then $\delta_j$ sufficiently small that (40) holds for all $j$. Then a similar proof to that of (39) yields
\[
\text{SH}_*^{(-\infty, \tau_j)}(W, \partial^- W) \cong \text{FH}_*^{(-\infty, \tau_j)}(K_j^-) \cong \text{FH}_{III}(K_j^-).
\]
In the direct limit over $j$ we obtain part (a) for $\varpi$ is $\varnothing$. The cases $\varpi$ is $><0$ and $\varpi$ is $=0$ are proved similarly, and the remaining cases are a formal consequence of these three. The proof of part (b) is analogous, where now it suffices to treat the cases $\varpi \in \{\varnothing, = 0, < 0\}$. \qed

7.1.3 Hamiltonians for $\text{SH}_*(V)$ inside $\hat{W}_F$ Heuristically, the construction presented in this section can be viewed as the “gluing” of the three constructions presented in the two previous sections.

We consider a Liouville cobordism pair $(W, V)$ with filling $F$ and write $W = W_{\text{bottom}} \circ V \circ W_{\text{top}}$. Let
\[
\mu, \quad \nu, \quad \tau > 0
\]
be such that $\mu \notin \text{Spec}(\partial^- W)$, $\nu \notin \text{Spec}(\partial^\pm W)$ and $\tau \notin \text{Spec}(\partial^+ W)$. Let $\eta_\mu$, $\eta_\nu$, and $\eta_\tau$ be positive real numbers smaller than $\frac{1}{2}$ and smaller than the distances from $\mu$, $\nu$ and $\tau$.
\( \nu_{\pm} \) and \( \tau \) to the corresponding action spectra. Let
\[
\delta, \varepsilon \in (0, 1), \quad R \in (1, \infty)
\]
be such that
\[
(41) \quad \delta \mu < \eta_{\mu}, \quad \varepsilon \nu_- < \eta_{\nu_-}, \quad \nu_+ < R \eta_{\nu_+},
\]
and
\[
(42) \quad R(\tau - \eta_{\tau}) < R(\nu_+ - \eta_{\nu_+}) < \nu_+(R - 1) < \nu_- - \eta_{\nu_-} < \mu - \eta_{\mu}.
\]
Note that the second inequality in (42) is automatic in view of (41). Also note that the inequalities in (42) impose relations between \( \mu, \nu_+, \nu_- \) and \( \tau \). Typically, an ordering of the kind
\[
\tau \leq \nu_+, \quad \nu_+ R \leq \nu_-, \quad \nu_- \leq \mu
\]
is enough to ensure condition (42) if \( \eta_{\tau} > \eta_{\nu_+}, \eta_{\nu_-} > \eta_{\mu} \) and \( \nu_+ > 1 \). These last three conditions are not in the least restrictive, since the parameters \( \eta_{\tau}, \eta_{\nu_\pm} \) and \( \eta_{\mu} \) are to be thought of as arbitrarily small, and the slope \( \nu_+ \) is to be thought of as large. However, the previous three conditions on \( \tau, \nu_\pm \) and \( \mu \) are restrictive, and among these three the most restrictive one is \( \nu_+ R \leq \nu_- \): it forces \( \nu_- \) to be larger than \( \nu_+ \), and indeed much larger, in an uncontrolled way. This has implications for the kind of doubly directed systems that we will construct, namely systems for which we can consider first an inverse limit as the negative slopes go to \( -\infty \), then a direct limit as the positive slopes go to \( +\infty \), but not the other way around.

We denote by
\[
H_{\mu, \nu_{\pm}, \tau} = H_{\mu, \nu_{\pm}, \tau, \delta, \varepsilon, R}: \hat{W}_F \to \mathbb{R}
\]
the Hamiltonian which is defined up to smooth approximation as follows: it is constant equal to \( \varepsilon \mu(1 - \delta) + \nu_-(1 - \varepsilon) \) on \( F \setminus [\delta \varepsilon, 1] \times \partial F \), it is linear equal to \( \mu(\varepsilon - \delta \varepsilon) + \nu_-(1 - \varepsilon) + \mu(\delta \varepsilon - r) \) on \( [\delta \varepsilon, \varepsilon] \times \partial F \), it is constant equal to \( \nu_-(1 - \varepsilon) \) on \( \varepsilon W_{\text{bottom}} \), it is linear equal to \( \nu_-(1 - \varepsilon) + \nu_-(\varepsilon - r) \) on \( [\varepsilon, 1] \times \partial^{-} V \), it is constant equal to 0 on \( V \), it is linear equal to \( \nu_+(r - 1) \) on \( [1, R] \times \partial^{+} V \), it is constant equal to \( \nu_+(R - 1) \) on \( RW_{\text{top}} \), and it is linear equal to \( \nu_+(R - 1) + \tau(r - R) \) on \( [R, \infty) \times \partial^{+} W \).

See Figure 18.

The 1–periodic orbits of the Hamiltonian \( H_{\mu, \nu_{\pm}, \tau} \) fall into 11 classes as follows:

\( (F^0) \) Constants in \( F \setminus ([\delta \varepsilon, 1] \times \partial F) \).

\( (F^+) \) Orbits corresponding to negatively parametrized closed Reeb orbits on \( \partial F = \partial^{-} W \) and located near \( \delta \varepsilon \partial^{-} W \).
Figure 18: Hamiltonian adapted to the construction of the transfer map $\text{SH}_*^{\infty}(W) \to \text{SH}_*^{\infty}(V)$

(I-) Orbits corresponding to negatively parametrized closed Reeb orbits on $\partial^- W^{\text{bottom}} = \partial^- W$ and located near $\varepsilon \partial^- W$.

(I0) Constants in $\varepsilon W^{\text{bottom}}$.

(I+) Orbits corresponding to negatively parametrized closed Reeb orbits on $\partial^+ W^{\text{bottom}} = \partial^- V$ and located near $\varepsilon \partial^- V$.

(II-) Orbits corresponding to negatively parametrized closed Reeb orbits on $\partial^- V$ and located near $\partial^- V$.

(II0) Constants in $V$.

(II+) Orbits corresponding to positively parametrized closed Reeb orbits on $\partial^+ V$ and located near $\partial^+ V$.

(III-) Orbits corresponding to positively parametrized closed Reeb orbits on $\partial^- W^{\text{top}} = \partial^+ V$ and located near $R \partial^+ V$.

(III0) Constants in $RW^{\text{top}}$.

(III+) Orbits corresponding to positively parametrized closed Reeb orbits on $\partial^+ W$ and located near $R \partial^+ W^{\text{top}} = R \partial^+ W$.

We denote by $F$ the group of orbits $F^{0+}$, and by $J$ the group of orbits $J^{-0+}$ for $J = I, II, III$. 
Lemma 7.6  For the previous choices of parameters the above groups of orbits for $H_{\mu, v_{\pm}, \tau}$ are ordered as

$$F < I < III < II$$

and

$$III < I,$$

provided the almost complex structure is cylindrical and stretched enough on a collar neighbourhood of $\partial^+ V$ in $V$.

Proof The relation $F < I$ holds because $F < I$. Indeed, the maximal action of an orbit in $F$ equals $-\epsilon \mu (1 - \delta) - v_-(1 - \epsilon)$ (and is attained on $F^0$). The minimal action of an orbit in $I$ is larger than $-v_- (1 - \epsilon) + \min(-\epsilon (\mu - \eta_\mu), -\epsilon (v_- - \eta v_-))$. The conclusion follows in view of $\delta \mu < \eta_\mu$ and $\mu (1 - \delta) > \mu - \eta_\mu > v_- - \eta v_-.$

The relation $I < III$ holds because $I < III$. Indeed, the maximal action of an orbit in $I$ equals $-v_- (1 - \epsilon)$ (and is attained on $I^0$). The minimal action of an orbit in $III$ is equal to $-v_+ (R - 1)$ (and is attained on $III^0$). The conclusion follows in view of $v_+ (R - 1) < v_- - \eta v_- < v_-(1 - \epsilon)$.

The relation $F < III$ holds because $F < I < III$ by the above.

The relation $I < II$ holds because $I < II$. Indeed, the maximal action of an orbit in $I$ equals $-v_- (1 - \epsilon)$. The minimal action of an orbit in $II$ is larger than $-v_- + \eta v_-$. The conclusion follows in view of $\epsilon v_- < \eta v_-.$

The relation $F < II$ holds because $F < I < II$ by the above.

The relation $III < II$ is seen as follows. On the one hand we have $III < II^{0+}$. Indeed, the maximal action of an orbit in $III$ is smaller than

$$-v_+ (R - 1) + \max(R(v_+ - \eta v_+), R(\tau - \eta \tau)).$$

The minimal action of an orbit in $II^{0+}$ equals 0, and the conclusion follows in view of $R(\tau - \eta \tau) < R(v_+ - \eta v_+) < v_+ (R - 1)$. On the other hand we have $III < II^-$ by Lemma 2.4 for an almost complex structure which is cylindrical and stretched enough within a collar neighbourhood of $\partial^+ V$ in $V$.

The relation $III < I$ (and actually also $III < F$) follows also from Lemma 2.4.

Remark Lemma 7.6 should be compared to Lemma 6.1, which asserts the same ordering of groups of orbits. The latter concerns the simpler Hamiltonians in Figure 14 and its proof crucially uses Lemmas 2.2 and 2.3. The former concerns the more complicated Hamiltonians in Figure 18 (with two additional parameters $\epsilon$ and $R$) and its proof uses only action estimates and Lemma 2.4. This has the advantage that the
ordering in Lemma 7.6 is preserved by continuation maps (see the proof of Lemma 7.7 below), whereas the one in Lemma 6.1 is not.

We now define a special cofinal family of Hamiltonians in $\mathcal{H}^W(V; F)$ of the form above. Besides conditions (41) and (42), we will also need a finer relation, stated as (45) below, which will be used in order to show that the continuation maps preserve the decomposition into groups of orbits given by Lemma 7.6. We will first choose the parameters $v_+, R$ and $\tau$ in the region with positive slopes, and then choose the parameters $v_-, \varepsilon, \mu$ and $\delta$ in the region with negative slopes.

(a) **Choice of the parameters in the region with positive slopes**  We start with a sequence $(v_{+,j})$ for $j \in \mathbb{Z}_+$ consisting of real numbers $v_{+,j} \geq 1$, which does not contain elements in $\text{Spec}(\partial^+ V)$, such that $v_{+,j} < v_{+,j'}$ for $j < j'$, and such that $v_{+,j} \to \infty$ as $j \to \infty$.

We further consider a sequence $(\tau_j)$ for $j \in \mathbb{Z}_+$ consisting of positive real numbers such that $\tau_j \in \left(\frac{1}{4} v_{+,j}, \frac{1}{2} v_{+,j}\right)$, which does not contain elements in $\text{Spec}(\partial^+ W)$, and such that $\tau_j < \tau_{j'}$ for $j < j'$.

We choose the parameters $\eta_{v_{+,j}}, \eta_{\tau_j} \in (0, \frac{1}{2})$ such that they form monotone sequences which converge to 0.

We then choose a sequence $(R_j)$ for $j \in \mathbb{Z}_+$ consisting of numbers $R_j \geq 1$, such that $R_j < R_{j'}$ for $j < j'$ and $R_j \to \infty$ for $j \to \infty$, and such that the last condition in (41) is satisfied under the stronger form

$$R_j \eta_{v_{+,j}} > 2v_{+,j} \quad \text{for all } j \in \mathbb{Z}_+.$$  

(This stronger form of (41) will be used in Lemma 7.8.) The first two inequalities in (42) are then satisfied.

(b) **Choice of the parameters in the region with negative slopes**  We start with a sequence $(v_{-,i})$ for $i \in \mathbb{Z}_-$ consisting of real numbers $v_{-,i} \geq 1$, which does not contain elements in $\text{Spec}(\partial^- V)$, such that

$$v_{-,i-1} \geq v_{-,i} + 2 \quad \text{for all } i \in \mathbb{Z}_-.$$  

This implies $v_{-,i'} \geq v_{-,i} + 2$ for $i' < i$ and $v_{-,i} \to \infty$ as $i \to -\infty$. We choose the parameters $\eta_{v_{-,i}} \in (0, \frac{1}{2})$ and such that they form a monotone sequence which converges to 0. We require that the third inequality in (42) is satisfied:

$$v_{+,j}(R_j - 1) < v_{-,i} - \eta_{v_{-,i}} \quad \text{for all } i \leq -j.$$
This last condition is implied by \( v_{-,i} > v_{+,-i}(R_{-i} - 1) + \frac{1}{2} \) for \( i \in \mathbb{Z}_- \), which provides an explicit recipe for the construction.

We choose a sequence \( (\varepsilon_i) \) for \( i \in \mathbb{Z}_- \) of numbers \( \varepsilon_i \in (0, \frac{1}{2}) \) such that \( \varepsilon_{i'} < \varepsilon_i \) for \( i' < i \), such that \( \varepsilon_i \to 0 \) as \( i \to -\infty \), and such that the second condition in (41) is satisfied:

\[
\varepsilon_i v_{-,i} < \eta v_{-,i} \quad \text{for all } i \in \mathbb{Z}_-.
\]

We also require that the sequence \( 1/\varepsilon_i \) does not contain any element in \( \text{Spec}(\partial^- W) \), which is a generic property.

We then consider two sequences \( (\mu_i) \) and \( (\delta_i) \) for \( i \in \mathbb{Z}_- \) such that

\[
\varepsilon_i \mu_i (1 - \delta_i) = 1 \quad \text{for all } i \in \mathbb{Z}_-
\]

and which moreover satisfy the following conditions: the sequence \( (\mu_i) \) consists of positive numbers and does not contain elements of \( \text{Spec}(\partial^- W) \), we have \( \mu_{i'} > \mu_i \) for \( i' < i \) and \( \mu_i \to \infty, i \to -\infty \); the sequence \( (\delta_i) \) is such that \( \delta_i \in (0, 1) \) for all \( i \in \mathbb{Z}_- \), we have \( \delta_{i'} < \delta_i \) for \( i' < i \) and \( \delta_i \to 0 \) as \( i \to -\infty \), and the first condition in (41) is satisfied:

\[
\delta_i \mu_i < \eta \mu_i \quad \text{for all } i \in \mathbb{Z}_-.
\]

Such sequences are easily constructed by choosing \( \mu_i \) slightly larger than \( 1/\varepsilon_i \) for all \( i \in \mathbb{Z}_- \).

These conditions imply \( \mu_i > 1/\varepsilon_i > v_{-,i}/\eta v_{-,i} \geq 2v_{-,i} \) for all \( i \in \mathbb{Z}_- \), so that the last inequality in (42) is also satisfied since \( v_{-,i} \geq 1 \).

Now let

\[
H_{i,j} := H_{\mu_i,v_{-,i},v_{+,-i},\varepsilon_i,\delta_i,\eta,\tau_j,\varepsilon_i,\beta_j}, \quad i \in \mathbb{Z}_-, \ j \in \mathbb{Z}, \ i \leq -j.
\]

Then we have \( H_{i',j} \geq H_{i,j} \) for \( i' \leq i \) and \( H_{i,j} \leq H_{i,j'} \) for \( j \leq j' \). Indeed, the first inequality follows from conditions (44) and (45), which imply that for \( i' < i \) the value of \( H_{i',j} \) on \( \varepsilon_i \partial_- V \) satisfies

\[
v_{-,i'}(1 - \varepsilon_i) \geq (v_{-,i} + 2)(1 - \varepsilon_i) \geq v_{-,i} - (1 - \varepsilon_i) + 1 = v_{-,i} - (1 - \varepsilon_i) + \varepsilon_i \mu_i (1 - \delta_i) = \max_{F} H_{i,j}.
\]

The second inequality follows from the conditions \( v_{+,j'} \geq v_{+,j} \geq \tau_j \) and \( R_{j'} \geq R_j \geq 1 \), which imply \( (v_{+,j'} - \tau_j)(R_{j'} - 1) \geq (v_{+,j} - \tau_j)(R_j - 1) \), or equivalently
\(v_{+,-}(R_{j'} - 1) \geq v_{+,-}(R_j - 1) + \tau_j(R_{j'} - R_j),\) so \(H_{i,j'} \geq H_{i,j}\) on \(R_{j'} \delta^+ W\) and therefore everywhere.

We consider \(\text{FC}_*(H_{i,j})\) as a doubly directed system in \(\text{Kom}\), inverse on \(i \to -\infty\) and direct on \(j \to \infty\), with maps

\[
\text{FC}_*(H_{i',j}) \to \text{FC}_*(H_{i,j}), \quad i' \leq i \leq -j,
\]
induced by nondecreasing homotopies, and maps

\[
\text{FC}_*(H_{i,j}) \to \text{FC}_*(H_{i,j'}), \quad j \leq j', \quad i \leq -j',
\]
induced by nonincreasing homotopies. (The nondecreasing homotopies will actually be chosen more specifically, as a composition of “small-distance” homotopies; see the proof of Lemma 7.7 below.) The choice of parameters ensures that for each \(H_{i,j}\) the groups of orbits are ordered as in Lemma 7.6. Denote by \(\text{FC}_I(H_{i,j})\) the Floer subcomplex of \(\text{FC}_*(H_{i,j})\) generated by orbits in the group \(F\), denote by \(\text{FC}_{I,II,III}(H_{i,j})\) the Floer quotient complex generated by orbits in the groups \(I, II\) and \(III\), and consider similarly \(\text{FC}_{II}(H_{i,j})\) and \(\text{FC}_{III}(H_{i,j})\). The groups of orbits \(II^-\), \(II^0\) and \(II^+\) are ordered by the action as \(II^- < II^0 < II^+\) within the group of orbits \(II\), so we have corresponding subcomplexes and quotient complexes \(\text{FC}_\odot(H_{i,j})\) for \(\odot \in \{\emptyset, \geq 0, > 0, = 0, \leq 0, < 0\}\), where \(II^\emptyset\) has the following meaning:

\[
II^\emptyset = II, \quad II^0 = II^-, \quad II^+ = II^+, \quad II^0 = II^- , \quad II^0 = II^- , \quad II^0 = II^- .
\]

Similarly, we have orderings by the action \(I^{++} < I^0 \) within the group \(I\), and \(III^0 < III^{-+} \) within the group \(III\), as well as orderings \(I < III\) and \(III < I\) from Lemma 7.6. We thus define \(\text{FC}_{(I,III)}(H_{i,j})\) for \(\odot \in \{\emptyset, \geq 0, > 0, = 0, \leq 0, < 0\}\) via

\[
(I, III)^\emptyset = (I, III), \quad (I, III)^0 = (I, III^0), \quad (I, III)^{++} = III^{-+},
(I, III)^0 = I^{++}, \quad (I, III)^{=0} = (I^0, III^0), \quad (I, III)^{\geq 0} = (I^0, III^0).
\]

Lemma 7.7 The homotopies that define the doubly directed system \(\text{FC}_*(H_{i,j})\) can be chosen so that they induce doubly directed systems

\[
\text{FC}_{II}(H_{i,j}), \quad \text{FC}_{I}(H_{i,j}), \quad \text{FC}_{III}(H_{i,j}) \quad \text{and} \quad \text{FC}_{(I,III)}(H_{i,j})
\]
for \(i \in \mathbb{Z}_-, \quad j \in \mathbb{Z}_+, \quad i \leq -j\) and \(\odot \in \{\emptyset, \geq 0, > 0, = 0, \leq 0, < 0\}\).

Proof (1) We consider first the continuation maps

\[
\text{FC}_*(H_{i',j}) \to \text{FC}_*(H_{i,j}), \quad i' \leq i \leq -j.
\]
induced by nondecreasing homotopies equal to \( H_{i,j} \) near \( +\infty \) and equal to \( H_{i,j} \) near \( -\infty \). The positive slopes \( v_{+,j} \) and \( \tau_j \) are fixed, as well as the parameter \( R_j \), and the homotopy is constant outside \( F \circ W_{\text{bottom}} \).

Write for simplicity \( H = H_{i,j} \), \( H' = H_{i',j} \), and \( v_- = v_{-,i} \), \( v'_- = v_{-,i'} \), \( \varepsilon = \varepsilon_i \), \( \varepsilon' = \varepsilon_{i'} \), \( \mu = \mu_i \) and \( \mu' = \mu_{i'} \). The gap \( \|H - H'\|_{\infty} \) between the two Hamiltonians is equal to the biggest value among \( (1 - \varepsilon')v'_- - (1 - \varepsilon)v_- \) (the difference of values in the region \( I^0 \)) and \( (1 - \varepsilon')v'_- + \varepsilon'\mu'(1 - \delta') - (1 - \varepsilon)v_- - \varepsilon\mu(1 - \delta) \) (the difference of values in the region \( F^0 \)). Condition (45) ensures that these two values are equal, hence

\[
\text{gap} := \|H - H'\|_{\infty} = (1 - \varepsilon')v'_- - (1 - \varepsilon)v_-.
\]

In the sequel we will repeatedly apply Lemma 7.2 (without further mentioning it), which asserts that, for two groups of orbits, \( P_{H_+} < P_{H_-} \) gap implies \( P_{H_+} < P_{H_-} \).

We first prove that

\[
F_{H'}, I_{H'} < II_{H},
\]

so that we have induced maps \( FC_{II}(H') \to FC_{II}(H) \). We have \( F^0_{H'} + \text{gap} < I^0_{H'} + \text{gap} < II_{H} \): the first inequality is obvious, and the second inequality is equivalent to \(- (1 - \varepsilon)v_- < - v_- + \eta v_- \), which is implied by \( \varepsilon v_- < \eta v_- \). This ensures \( F_{H'} < II_{H} \) and \( I_{H'} < II_{H} \).

We now prove

\[
III_{H'} < (F, I, II)_{H}.
\]

Note that \( H \) and \( H' \) coincide in the regions \( II^{0+} \) and \( III \), and from the proof of Lemma 7.6 we know that \( III_{H} < II_{H}^{0+} \). The conditions \( III_{H'} < (F, I, II)_{H} \) follow from Lemma 2.4. To prove the condition \( III_{H'} < II_{H}^{0+} \), we cannot argue directly by action considerations as in the proof of \( III_{H} < II_{H}^{0+} \) since the gap between \( H \) and \( H' \) could be arbitrarily large. Instead, we use again \( III_{H} < II_{H}^{0+} \), so we can find some \( \varepsilon > 0 \) such that \( III_{H} < II_{H}^{0+} - \varepsilon \). We specialize now to nondecreasing homotopies from \( H \) to \( H' \) which are compositions of “small-distance” homotopies with gap smaller than \( \varepsilon \). (This can always be achieved by cutting and reparametrizing a given homotopy.) Note that all the homotopies are fixed on \( II^{0+} \) and \( III \). For each of these small-distance homotopies, say running from \( H_- \) at \(-\infty \) to \( H_+ \) at \(+\infty \), we then have \( III_{H_+} < II_{H_-}^{0+} \) by Lemma 7.2, and we also have \( III_{H_+} < (F, I, II)_{H_-} \) by Lemma 2.4. In other words, \( III_{H_+} < (F, I, II)_{H_-} \) and the image through the continuation map of a generator in \( III_{H_+} \) lies in \( III_{H_-} \). As a result, the image of a generator in \( III_{H'} \).
through a composition of such “small-distance” homotopies lies in $III_H$ and we have $III_{H'} < (F, I, II)_H$. (This reproves in particular $III_{H'} < (F, I, II^-)_H$.)

We now prove that

$$F_{H'} < I_H, III_H,$$

wherefrom induced maps

$$FC_{I, II, III}(H') \to FC_{I, II, III}(H) \quad \text{and} \quad FC_{I, III}(H') \to FC_{I, III}(H).$$

The relation $F_{H'} < I_H$ follows from $F^0_{H'} + \text{gap} < \min(I^-_{H}, I^+_{H})$, which is

$$-\varepsilon'(1 - \delta')\mu' - (1 - \varepsilon)v_+ < -(1 - \varepsilon)v_- + \min(-\varepsilon(\mu - \eta_\mu), -\varepsilon(v_- - \eta v_-))$$

$$= -(1 - \varepsilon)v_- - \varepsilon(\mu - \eta_\mu).$$

This is equivalent to $-(1 - \delta)\mu < -(\mu - \eta_\mu)$ in view of (45), and holds in view of $\delta \mu < \eta_\mu$. The relation $F_{H'} < III_H$ follows from the previous one; indeed, $I_H < III_H$, hence $F^0_{H'} + \text{gap} < III_H$. We also have

$$I_{H'} < III_H.$$  

This follows from $I^0_{H'} + \text{gap} < III^0_H$, which is $-(1 - \varepsilon')v'_+ + (1 - \varepsilon')v'_- - (1 - \varepsilon)v_- < -v_+(R - 1)$, which is equivalent to $v_+(R - 1) < (1 - \varepsilon)v_-$ and is implied by (41) and (42). Since we already proved $III_{H'} < I_H$, we infer that the continuation maps therefore preserve the decomposition $FC_{I, III}(H) = FC_I(H) \oplus FC_{III}(H)$.

We now prove that

$$II^-_{H'} < II^0_H \quad \text{and} \quad II^0_{H'} < II^+_H,$$

so that we have induced maps $FC_{II^\bigcirc}(H') \to FC_{II^\bigcirc}(H)$ for all values of $\bigcirc$. The first relation follows from Lemmas 2.2, 2.3 and 2.5, while the last relation follows from Lemmas 2.2 and 2.3 (using $H' = H$ outside $F \circ W^{\text{bottom}}$). Note that in this situation we cannot argue using the action because the homotopy only preserves the action filtration up to an error given by the gap, and the latter can be arbitrarily large. We now prove that

$$I^-_{H'} < (I^0_{H'}, III_H) \quad \text{and} \quad (I_{H'}, III^0_{H'}) < III^-_{H'}.$$

which implies that we have induced maps $FC_{(I, III)^\bigcirc}(H') \to FC_{(I, III)^\bigcirc}(H)$ for all values of $\bigcirc$.  

*Algebraic & Geometric Topology*, Volume 18 (2018)
In view of $I_{H'} < III_{H}$, the first relation is a consequence of $I_{H'}^+ < I_H^0$, which is in turn implied by $I_{H'}^+ + \text{gap} < I_H^0$. The latter is seen to hold as follows. Denote by $T_{\delta-V}$ and $T_{\delta-W}$ the minimal period of a closed Reeb orbit on $\partial^- V$ and on $\partial^- W$, respectively, and set $T_- := \min(T_{\delta-V}, T_{\delta-W}) > 0$. The desired inequality is implied by $-(1-\varepsilon')v'_- - \varepsilon'T_- + (1-\varepsilon')v'_- - (1-\varepsilon)v_- < -(1-\varepsilon)v_-$, which holds because $-\varepsilon'T_- < 0$.

In view of $I_{H'} < III_{H}$, the second relation is a consequence of $III_{H'}^0 < III_{H}^-$. The relation $III_{H'}^0 < III_{H}^-$ is a consequence of Lemmas 2.2 and 2.3 in view of the fact that the homotopy is constant outside $F \circ W^{\text{bottom}}$. The relation $III_{H'}^0 < III_{H}^-$ is a consequence of Lemma 2.5. Note that in both situations we cannot argue using the action because the homotopy only preserves the action filtration up to an error given by the gap, and the latter can be arbitrarily large.

(2) We now consider the continuation maps

$$\text{FC}_*(H_{i,j}) \to \text{FC}_*(H_{i,j'})$$

induced by nonincreasing homotopies equal to $H_{i,j}$ near $+\infty$ and equal to $H_{i,j'}$ near $-\infty$. The negative slopes $v_{-j}$ and $\mu_i$ are fixed, as well as the parameters $\varepsilon_i$ and $\delta_i$, and the homotopy is constant on $F \circ W^{\text{bottom}} \circ V$. This situation is easier than the one in (1) because here the continuation maps preserve the action filtration.

Write again for simplicity $H = H_{i,j}$, $H' = H_{i,j'}$, and $v_+ = v_{+j}$, $v'_+ = v_{+j'}$, $R = R_j$, $R' = R'_j$, $\tau = \tau_j$ and $\tau' = \tau_{j'}$.

The relations

$$F_H < I_{H'}, II_{H'}, III_{H'} \quad \text{and} \quad I_H < II_{H'}$$

follow as in Lemma 7.6. On the one hand we have $I_{H'} = I_H$ and $II_{H'}^{-0} = II_{H}^{-0}$, so that $F_H < I_{H'}, II_{H'}^{-0}$ and $I_H < II_{H}^{-0}$. On the other hand we have $F_H^{0} < II_{H'}^{0} = II_{H}^{0}$, and $F_H^{0} = F_H^{0} < III_{H'}^{0} < III_{H}^{0}$ for $i \leq -j'$, which implies $F_H < II_{H'}^{+}, III_{H'}$. Finally, we also have $I_H = I_H' < II_{H'}^{0}, < II_{H'}^{+}$, which implies $I_H < II_{H'}$.

The relation

$$III_{H} < II_{H'}$$

is proved as follows. We have $III_{H} < II_{H}^{+}$, as in Lemma 7.6, using Lemma 2.4. We have $III_{H}^{0+} < II_{H}^{0+}$ by (42), namely $R(\tau - \eta_\tau) < v_+(R-1)$. Finally we have $III_{H}^{0} < II_{H}^{0+}$ by (41), namely $R \eta v_+ > v_+$. 

The relation
\[ \text{III}_H < I_{H'} \]
is proved as in Lemma 7.6, using Lemma 2.4.

The continuation map
\[ FC_H(H) \to FC_{H'}(H') \]
is induced by a nonincreasing homotopy, hence preserves the filtration by the action. As a consequence we obtain well-defined continuation maps
\[ FC_{H'}(H) \to FC_{H'}(H') \]
for all values of \( \varnothing \).

Let us now prove that the continuation map
\[ FC_{I,III}(H) \to FC_{I,III}(H') \]
duces maps
\[ FC_{(I,III)}(H) \to FC_{(I,III)}(H') \]
for all values of \( \varnothing \). We need to show the relations
\[ I_H^- < I_{H'}^0, \text{III}_{H'}^0 < \text{III}_{H'}^- \quad \text{and} \quad I_H, I_H^0 < \text{III}_{H'}^- . \]
The first relation follows from \( I_H^- < I_{H'}^0 = I_{H'}^0 < \text{III}_{H'}^0 < \text{III}_{H'}^- \), where the middle inequality is ensured by (41) and (42), namely \( v_+(R - 1) < v_+ - \eta v_- < v_-(1 - \varepsilon_i) \).

The second relation follows from \( I_H^0 < \text{III}_{H'}^0 < \text{III}_{H'}^- \).

The above shows that we actually have noninteracting doubly directed systems
\[ FC_{I}(H_{i,j}) \quad \text{and} \quad FC_{III}(H_{i,j}) \]
for all values of \( \varnothing \) and Lemma 7.7 is proved. \( \square \)

**Lemma 7.8** We have isomorphisms
\[ SH^\varnothing_*(V) \cong \lim_{j} \lim_{i} FH_{H'}(H_{i,j}) \]
for \( \varnothing \in \{ \varnothing, \geq 0, > 0, = 0, \leq 0, < 0 \} \).

**Proof** The proof is very much similar to that of Lemma 7.4. Recalling that the slopes near \( \partial V \) for \( H_{i,j} \) are \( -v_{-,i} \) and \( v_{+,j} \), the key identity is
\[ SH^\varnothing_{(v_{-,i},v_{+,j})}(V) \cong FH_{H}(H_{i,j}) . \]
To prove (46), recall from Lemma 5.1 that \( \text{SH}_*^{(a,b)}(V) \) can be expressed as a direct limit over Hamiltonians in \( H^W(V; F) \) of Floer homology groups truncated in the action window \((a, b)\). In particular, considering a decreasing sequence \( i_k \to -\infty \) and an increasing sequence \( j_k \to \infty \) as \( k \to \infty \) with \( i_k \leq -j_k \), we have \( \text{SH}_*^{(a,b)}(V) = \lim_{k \to \infty} \text{FH}_*^{(a,b)}(H_{i_k,j_k}) \). Here the direct limit is understood with respect to continuation maps \( \text{FH}_*^{(a,b)}(H_{i_k,j_k}) \to \text{FH}_*^{(a,b)}(H_{i_{k'},j_{k'}}) \) induced by nonincreasing homotopies. We claim that for \( k \) large enough such that \( v_{+,j_k} \geq -a \) we have \( \text{FC}_*^{(a,b)}(H_{i_k,j_k}) = \text{FC}_*^{(a,b)}(H_{i_k,j_k}) \). The proof is similar to the proof of Lemma 5.1: We need to show that the actions of orbits in groups \( F, I \) and \( III \) are below \( a \). For the groups \( F \) and \( I \) this is obvious. The actions within group \( III \) are ordered as \( III^0 < III^- \). The maximal action of the orbits in group \( III^- \) is bounded above by \( -v_+(R-1) + R(v_+-\eta_{v_+}) = v_+ - R\eta_{v_+} < -v_+ \leq a \), where we have dropped the index \( j_k \) and the first inequality follows from condition (43). Similarly, the maximal action of the orbits in group \( III^+ \) is bounded above by \( -v_+(R-1) + R(\tau-\eta_\tau) < -v_+(R-1) + R(v_+-\eta_{v_+}) < a \), where the first inequality follows from (42) and the second one from the one for group \( III^- \). Combining this with the previous paragraph we obtain

\[
\text{SH}_*^{(a,b)}(V) = \lim_{k \to \infty} \text{FH}_*^{(a,b)}(H_{i_k,j_k}).
\]

Assume now without loss of generality that \( -v_{-,i_k} \leq a \) and \( v_{+,j_k} \geq b \). The smoothings of any such two Hamiltonians \( H_{i_k,j_k} \) and \( H_{i_{k'},j_{k'}} \) for \( k \leq k' \) can be constructed so that they coincide in the neighbourhood of \( V \) where the periodic orbits in group \( II \) for \( H_{i_k,j_k} \) appear. As such, the continuation map \( \text{FC}_*^{(a,b)}(H_{i_k,j_k}) \to \text{FC}_*^{(a,b)}(H_{i_{k'},j_{k'}}) \), which is upper triangular if we arrange the generators in increasing order of the action, has diagonal entries equal to \(+1\) and is therefore an isomorphism. This proves that we have a canonical isomorphism \( \text{FH}_*^{(a,b)}(H_{i_k,j_k}) \cong \text{SH}_*^{(a,b)}(V) \) for all \( k \) (such that \( -v_{-,i_k} \leq a \) and \( v_{+,j_k} \geq b \)). This implies (46) by choosing \( a = -v_{-,i} \) and \( b = v_{+,j} \).

A variant of this argument shows that, under the isomorphism (46), the continuation maps \( \text{FH}_II(H_{i',j}) \to \text{FH}_II(H_{i,j}) \) for \( i' \leq i \) and \( \text{FH}_II(H_{i,j}) \to \text{FH}_II(H_{i,j'}) \) for \( j \leq j' \) induced by a nondecreasing homotopy, respectively by a nonincreasing homotopy, coincide with the canonical maps \( \text{SH}_*^{(-v_{-,i'},v_{+,j})}(V) \to \text{SH}_*^{(-v_{-,i},v_{+,j})}(V) \) and \( \text{SH}^{(-v_{-,i},v_{+,j'})}(V) \to \text{SH}_*^{(-v_{-,i'},v_{+,j})}(V) \), respectively. The conclusion of the lemma follows in the case \( \heartsuit \neq \emptyset \) is \( \emptyset \).

The proof in the case \( \heartsuit \neq \emptyset \) is similar, as in Lemma 7.4.  

\[\square\]
Lemma 7.9 We have isomorphisms
\[ \text{SH}_*(W_{\text{bottom}}, \partial^+ W_{\text{bottom}}) \cong \lim_{j} \lim_{i} \text{FH}_{J}(H_{i,j}) \]
and
\[ \text{SH}_*(W_{\text{top}}, \partial^- W_{\text{top}}) \cong \lim_{j} \lim_{i} \text{FH}_{III}(H_{i,j}) \]
for \( \varpi \in \{ \emptyset, \geq 0, > 0, = 0, \leq 0, < 0 \} \).

Proof (1) We prove the first isomorphism. Since the group of orbits \( I \) is located in the region where the Hamiltonians \( H_{i,j} \) have negative slope the direct limit over \( j \) plays no role and we can assume without loss of generality that \( j = j_0 \) is constant. The Floer trajectories involved in the differential for FC\(_I(H_{i,j})\) and also the relevant continuation Floer trajectories are confined to a neighbourhood of \( F \circ W_{\text{bottom}} \) by Lemma 2.2. We can thus replace the Hamiltonians \( H_i = H_{i,j_0} \) by Hamiltonians \( \tilde{H}_i \) which coincide with \( H_i \) in \( F \circ W_{\text{bottom}} \circ V \) and are constant equal to 0 on \( V \circ W_{\text{top}} \circ [1, \infty) \times \partial^+ W \).

We can further shift these Hamiltonians to \( \tilde{H}_i = \tilde{H}_i - v_{-i}(1 - \varepsilon_i) \) so that the orbits in group \( I \) lie on level 0, and further replace \( \tilde{H}_i \) by \( \mathcal{H}_i = \varepsilon_i \tilde{H}_i \circ \phi_{Z}^{1/\varepsilon_i} \), so that the orbits in group \( I \) for \( \mathcal{H}_i \) lie in a neighbourhood of \( W_{\text{bottom}} \), and the slopes of \( \mathcal{H}_i \) in the linear regions are the same as the slopes of \( \tilde{H}_i \). Finally, we can further replace the Hamiltonians \( \mathcal{H}_i \) by \( \bar{\mathcal{H}}_i \) defined on \( \bar{W}_{F} \) which coincide with \( \mathcal{H}_i \) on \( F \circ W_{\text{bottom}} \) and continue on \( [1, \infty) \times \partial^+ W_{\text{bottom}} \) linearly with the same slope \(-v_{-i} \). The resulting inverse system is cofinal and, by Lemma 7.5(b), it computes \( \text{SH}_*(W_{\text{bottom}}, \partial^+ W_{\text{bottom}}) \).

(2) We prove the second isomorphism. Since the group of orbits \( III \) is located in the region where the Hamiltonians \( H_{i,j} \) have positive slope, the inverse limit over \( i \) plays no role. Consider the Hamiltonian \( \tilde{H}_j \) which coincides with \( H_{i,j} \) on \( V \circ W_{\text{top}} \circ [1, \infty) \times \partial^+ W \), and is constant equal to 0 on \( F \circ W_{\text{bottom}} \circ V \). The complex FC\(_{III}(\tilde{H}_j)\) is well-defined by the same action considerations, which show that \( III H_{i,j} < II H_{i,j}^0 \). Consider a nonincreasing homotopy from \( H_{i,j} \) at \(-\infty\) to \( \tilde{H}_j \) at \(+\infty\), and also the reverse nondecreasing homotopy from \( \tilde{H}_j \) at \(-\infty\) to \( H_{i,j} \) at \(+\infty\). We claim that these homotopies induce chain maps between FC\(_{III}(H_{i,j})\) and FC\(_{III}(\tilde{H}_j)\) which are homotopy inverses to each other. We first prove that \( III \tilde{H}_j < (F, I, II) H_{i,j} \) and \( III H_{i,j} < (F, II) \tilde{H}_j \), where in the latter case \( F \) stands for critical points in \( F \circ W_{\text{bottom}} \) and \( II = II^0 \). The first relation follows from Lemma 2.4 for \((F, I, II) H_{i,j}\) and from action considerations for \( II^0_{H_{i,j}} \) since the homotopy is nonincreasing. The second relation follows from Lemmas 2.2 and 2.3 for \( II^0_{H_{i,j}} \), from Lemma 2.5 for \( III^0_{H_{i,j}} \), and it also follows for \( III^0_{H_{i,j}} \) by specializing.
to homotopies which are compositions of “small-distance” homotopies as in the proof of Lemma 7.7. As a result, the induced chain maps between $\text{FC}(H_{i,j})$ and $\text{FC}(\tilde{H}_j)$ preserve the subcomplexes generated by $\text{III}_{H_{i,j}}$ and $\text{III}_{\tilde{H}_j}$. These chain maps are homotopy inverses of each other, and a similar argument shows that the corresponding chain homotopies also preserve the subcomplexes generated by $\text{III}_{H_{i,j}}$ and $\text{III}_{\tilde{H}_j}$. This proves the claim.

We can now further shift these Hamiltonians $\tilde{H}_j$ to $\bar{H}_j = \tilde{H}_j - v_{+,j}(R_j - 1)$ so that the orbits in group III lie on level 0, and further replace $\bar{H}_j$ by $\mathcal{H}_j = R_j \bar{H}_j \circ \phi_{Z}^{1/R_j}$, so that the orbits in group III for $\mathcal{H}_j$ lie in a neighbourhood of $W^{\text{top}}$. The resulting direct system is cofinal and, by Lemma 7.5(a), it computes $\text{SH}_{\bigodot}(W^{\text{top}}, \partial^{-} W^{\text{top}})$. □

Lemmas 7.8 and 7.9 imply that for all flavours $\bigodot$ we have isomorphisms

$$\text{SH}_{\bigodot}(W^{\text{top}}, \partial^{-} W^{\text{top}}) \oplus \text{SH}_{\bigodot}(W^{\text{bottom}}, \partial^{+} W^{\text{bottom}}) \cong \lim_{j} \lim_{i} \text{FH}_{(I,\text{III})\bigodot}(H_{i,j}).$$

On the other hand, by the excision theorem, Theorem 6.8, we have isomorphisms

$$\text{SH}_{\bigodot}(W, V) \cong \text{SH}_{\bigodot}(W^{\text{bottom}}, \partial^{-} V) \oplus \text{SH}_{\bigodot}(W^{\text{top}}, \partial^{+} V).$$

Combining these isomorphisms we obtain:

**Corollary 7.10** We have isomorphisms

$$\text{SH}_{\bigodot}(W, V) \cong \lim_{j} \lim_{i} \text{FH}_{(I,\text{III})\bigodot}(H_{i,j})$$

for $\bigodot \in \{\emptyset, \geq 0, > 0, = 0, \leq 0, < 0\}$. □

**7.1.4 The transfer map revisited** Consider again a Hamiltonian $H = H_{\mu, v_{\pm}, \tau}$ as in Figure 18. We associate to it a new Hamiltonian $L \leq H$ defined as follows: it is constant equal to $\mu(\varepsilon - \delta \varepsilon) + v_{-}(1 - \varepsilon)$ on $F \setminus [\delta \varepsilon, 1] \times \partial F$, it is linear of slope $-\mu$ on $[\delta \varepsilon, \xi] \times \partial F$, it is constant equal to 0 on $[\xi, 1] \times \partial F \cup W \cup [1, R] \times \partial^{+} W$, and it is linear of slope $\tau$ on $[R, \infty) \times \partial^{+} W$. See Figure 19.

Here the constant $\xi$ is determined by the construction and given by

$$\xi = \frac{v_{-}}{\mu}(1 - \varepsilon) + \varepsilon \in (\varepsilon, 1).$$

The orbits of the Hamiltonian $L$ fall as usual into five groups, $F^{0+}$ and $I^{-0+}$, and we have $F < I^{-} < I^{0} < I^{+}$. Indeed, the smallest action of an orbit in group $I^{-}$ is
Figure 19: Hamiltonian $L$ for the construction of the transfer map $-\xi (\mu - \eta_\mu)$, whereas the largest action of an orbit in group $F$ is $-\mu (\xi - \delta \varepsilon)$, and we have $-\mu (\xi - \delta \varepsilon) < -\xi (\mu - \eta_\mu)$, which is equivalent to $\mu \delta \varepsilon < \xi \eta_\mu$, in view of $\mu \delta < \eta_\mu$ and $\varepsilon < \xi$. Arguing differently, for the Hamiltonian $L$ we have $F < I$ regardless of the choice of parameters using Lemmas 2.2, 2.3 and 2.5, and the orbits within each of the groups $F$ and $I$ are naturally ordered by the action as $F < F^0$ and $I < I^0 < I^+$. Consider now a Hamiltonian $K := K_{\mu, \tau, \delta'}$ as in Figure 16, with $\delta' \in (0, 1)$ such that $\mu \delta' < \eta_\mu$ and $\mu (1 - \delta') > \mu (\xi - \delta \varepsilon)$, i.e. the maximal level of $K$ is larger than the maximal level of $L$. We then have $L \leq K$.

Lemma 7.11 The homotopy from $K$ to $L$ given by slow convex interpolation induces for all flavours $\bowtie$ homotopy equivalences

$$\text{FC}_{I \bowtie} (L) \xrightarrow{\sim} \text{FC}_{I \bowtie} (K).$$

Proof Although the homotopy is decreasing in the convex end, the Floer equation remains unchanged in the region $\{ r \geq R \}$ where the Hamiltonians $L$ and $K$ have the same slope. So the maximum principle applies and the continuation map $\text{FC}(L) \rightarrow \text{FC}(K)$ is well-defined. It is a homotopy equivalence with homotopy inverse given by the continuation map induced by the reverse homotopy from $L$ to $K$.

We assume without loss of generality that $L$ has no critical points in the region $[\xi, 1] \times \partial F \cup [1, R] \times \partial^+ W$ and that it coincides with $K$ on $W$. 

Algebraic & Geometric Topology, Volume 18 (2018)
It is useful to define the following Hamiltonians: $LK$ is equal to $L$ on $F$ and is equal to $K$ on $W \cup [1, \infty) \times \partial^+ W$, and $KL$ is equal to $K$ on $F \circ W$ and is equal to $L$ on $[1, \infty) \times \partial^+ W$. We accordingly have chain homotopy equivalences $\text{FC}(L) \to \text{FC}(KL) \to \text{FC}(K)$ and also $\text{FC}(L) \to \text{FC}(LK) \to \text{FC}(K)$ induced respectively by homotopies supported in the positive/negative end. We will show that we have corresponding chain homotopy equivalences $\text{FC}(L) \to \text{FC}(KL) \to \text{FC}(K)$ for all flavours $\varnothing$. The same statement holds if we replace $KL$ with $LK$, but we will not use it.

We first consider the homotopies connecting $L$ and $KL$, supported in the negative end, and show that they induce chain maps $\text{FC}(L) \to \text{FC}(KL)$ and $\text{FC}(KL) \to \text{FC}(L)$ which are homotopy inverses of each other for all flavours $\varnothing$. We first consider the nondecreasing homotopy from $L$ to $KL$, constant on $W \cup [1, \infty) \times \partial^+ W$. Each element in the homotopy is of the following form: outside $F$ it coincides with $L$, and inside $F$ it is linear of slope $-\mu$ in some region $[a, b] \times \partial F$ with $0 < a < b \leq 1$ depending continuously on the Hamiltonian; it is constant equal to $0$ on $\{b \leq r \leq 1\}$ and it is constant equal to $\mu(b-a)$ on $\{r \leq a\}$. Also, each element in the homotopy satisfies $F < I^- < I^0 < I^+$. We can decompose the homotopy into “small-distance” homotopies of gap $e > 0$ small enough that, at the endpoints $L_{\pm}$ of each such homotopy, we have $F_{L_+} < I_{L_-} - e$, $I_{L_+}^- < I_{L_-}^0 - e$ and $I_{L_+}^0 < I_{L_-}^+ - e$. This ensures that we have induced chain maps $\text{FC}(L) \to \text{FC}(KL) \to \text{FC}(L)$ for all flavours $\varnothing$, and the result of the composition is a continuation chain map $\text{FC}(KL) \to \text{FC}(L)$. By considering the reverse homotopy, the same argument produces a chain map $\text{FC}(L) \to \text{FC}(KL)$. The same argument applied in 1–parametric families shows that each of the small-distance chain maps $\text{FC}(L) \to \text{FC}(L)$ is a chain homotopy equivalence, and so is their composition.

The same arguments show that we have chain homotopy equivalences $\text{FC}(KL) \to \text{FC}(K)$ for all flavours $\varnothing$. By composition we obtain chain homotopy equivalences $\text{FC}(L) \to \text{FC}(K)$ for all flavours $\varnothing$.

Remark We have used an argument based on “small-distance” isomorphisms also in the proof of Lemma 7.7. It is likely that it can be used in order to simplify further the proof of Lemma 7.7.

Consider now a doubly directed system $H_{i,j}$ as in Section 7.1.3. Let $L_{i,j}$ and $K_{i,j}$ be the Hamiltonians associated to $H_{i,j}$ as in Lemma 7.11. We turn $L_{i,j}$ into a doubly...
directed system in \( \text{Kom} \) by composing the continuation maps \( \text{FC}(K_{i',j}) \to \text{FC}(K_{i,j}) \) and \( \text{FC}(K_{i,j}) \to \text{FC}(K_{i,j'}) \) with the canonical maps in Lemma 7.11 and their inverses. (Note that in general we do not have \( L_{i',j} \geq L_{i,j} \) for \( i' \leq i \leq -j \).) Then all the results for the system \( K_{i,j} \) in Section 7.1.1 carry over to the system \( L_{i,j} \).

Recall that \( L_{i,j} \leq H_{i,j} \) and the orbits in group \( F \) for \( L_{i,j} \) and \( H_{i,j} \) coincide. Therefore, by Lemma 7.6 the actions of the orbit groups satisfy \( F_{L_{i,j}} < (I, II, III)_{H_{i,j}} \). We thus obtain induced chain maps

\[
 f_{i,j} : \text{FC}_I(L_{i,j}) \to \text{FC}_{I,II,III}(H_{i,j}) \to \text{FC}_{II}(H_{i,j})
\]

which define a morphism of doubly directed systems in \( \text{Kom} \). Here the first map is the continuation map and the second one the projection onto the quotient complex in view of Lemma 7.6. Since these maps preserve the filtration by the action, we also have induced chain maps

\[
 f_{i,j}^\odot : \text{FC}_I^\odot(L_{i,j}) \to \text{FC}_{II}^\odot(H_{i,j})
\]

for \( \odot \in \{ \emptyset, \geq 0, >0, = 0, \leq 0, <0 \} \), which define morphisms of doubly directed systems in \( \text{Kom} \). We denote by \( (f_{i,j}^\odot)_* \) the maps induced in homology.

**Lemma 7.12** Under the isomorphisms of Lemmas 7.4, 7.8 and 7.11 we have

\[
 f_{i,j}^\odot = \lim_{j} \lim_{i} (f_{i,j}^\odot)_*,
\]

where \( f_{i,j}^\odot : \text{SH}_*^\odot(W) \to \text{SH}_*^\odot(V) \) is the transfer map from Definition 5.3.

**Proof** Recall from (39) and Lemma 7.11 the isomorphisms

\[
 \text{SH}_*^{(-\mu_i,\tau_j)}(W) \cong \text{FH}_I(K_{i,j}) \cong \text{FH}_I(L_{i,j}).
\]

Recall also from (46) the isomorphism

\[
 \text{SH}_*^{(-\nu_{-i},\nu_{+j})}(V) \cong \text{FH}_{II}(H_{i,j}).
\]

Recall that \( \mu_i \geq \nu_{-i} \) and \( \tau_j \leq \nu_{+j} \). It follows from the proofs of Lemmas 7.4 and 7.8 that the continuation map \( (f_{i,j})_* : \text{FH}_I(L_{i,j}) \to \text{FH}_{II}(H_{i,j}) \) coincides via the above isomorphisms with the composition of the transfer map

\[
 f_{i,j}^{(-\mu_i,\tau_j)} : \text{SH}_*^{(-\mu_i,\tau_j)}(W) \to \text{SH}_*^{(-\mu_i,\tau_j)}(V)
\]

with the canonical map given by enlarging/restricting the action window

\[
 \text{SH}_*^{(-\mu_i,\tau_j)}(V) \to \text{SH}_*^{(-\nu_{-i},\nu_{+j})}(V),
\]
Since $-v_{-i} \to -\infty$ as $i \to -\infty$ and $\tau_j \to +\infty$ as $j \to +\infty$, and since the continuation maps in the doubly directed systems for $L_{i,j}$ and $H_{i,j}$ correspond under the previous isomorphisms to enlarging/restricting the action windows (Lemmas 7.4 and 7.8), we obtain

$$f_1 = \lim_{j} \lim_{i} (f_{i,j})_*.$$ 

This proves the lemma when $\heartsuit$ is $\emptyset$. The proof for the other values of $\heartsuit$ is entirely analogous. $\square$

### 7.2 Symplectic homology of a pair as a homological mapping cone

Let $f_{i,j}^\heartsuit$ be the chain maps constructed in Section 7.1.4. The discussion in Section 4 shows that the cones $C(f_{i,j}^\heartsuit)$ form a doubly directed system, and we define (compare with Corollary 7.10)

$$\text{SH}^\heartsuit_{*, \text{cone}}(W, V) := \lim_{j} \lim_{i} H_*(C(f_{i,j}^\heartsuit)).$$

The goal of this section is to prove the following proposition:

**Proposition 7.13** Let $(W, V)$ be a cobordism pair. Then we have an isomorphism

$$\text{SH}^\heartsuit_{*, \text{cone}}(W, V) \cong \text{SH}^\heartsuit_{*}(W, V)[{-1}]$$

for $\heartsuit \in \{\emptyset, \geq 0, >0, =0, \leq 0, <0\}$.

**Proof** In view of Corollary 7.10 it will be enough to prove

$$(47) \quad \lim_{j} \lim_{i} H_*(C(f_{i,j}^\heartsuit)) = \lim_{j} \lim_{i} \text{FH}(I, \text{III})^\heartsuit(H_{i,j})[-1]$$

for all values of $\heartsuit$.

We recall the notation $W = W^\text{bottom} \circ V \circ W^\text{top}$. Recall the families of Hamiltonians $H_{i,j}$ and $L_{i,j}$ from Section 7.1.4. For a fixed value of the double index $(i, j)$ we write for readability $H = H_{i,j}$ and $L = L_{i,j}$. 

*Algebraic & Geometric Topology, Volume 18 (2018)*
Let $\heartsuit$ be $\emptyset$. We claim that any monotone homotopy from $L$ to $H$ induces a homotopy equivalence

$$FC_I(L) \cong FC_{I,III}(H).$$

To see this, consider for $t \in [0, 1]$ the nonincreasing homotopy of Hamiltonians $H^t$ as in Figure 19 from $H^0 = H$ to $H^1 = L$. Each $H^t$ has the shape considered in Section 7.1.3 with parameters

$$\mu^t = \mu, \quad v_\infty^t \in [0, v_\infty], \quad v_\infty^t \in [0, v_\infty], \quad \tau^t = \tau, \quad \delta^t > 0, \quad \epsilon^t \in [\epsilon, \xi], \quad R^t = R$$

satisfying

$$\delta^t \epsilon^t = \delta \epsilon, \quad v_\infty^t(1 - \epsilon^t) = \mu(\xi - \epsilon^t).$$

Thus $\epsilon^t$ increases with $t$, while $\delta^t$ and $v_\infty^t$ decrease with $t$. The actions of orbits in the regions $I$, $II$ and $III$ are bounded below by $-\mu(\xi - \epsilon^t) - \epsilon^t(\mu - \eta_{\mu}) = -\mu \xi + \epsilon^t \eta_{\mu}$, $-v_\infty^t$ and $-v_\infty^t(R - 1)$, respectively, all of which increase with $t$. Here $v_\infty^t$ denotes $v_\infty - \eta_{v_\infty}$ for $v_\infty^t \geq v_\infty - \eta_{v_\infty}$ and $v_\infty^t$ otherwise. Since the action of orbits in region $F$ is independent of $t$ and the actions satisfy $F < I, II, III$ for $t = 0$, it follows that $F < I, II, III$ holds for all $t \in [0, 1]$. Considering a moving action window separating the orbit group $F$ from the groups $I$, $II$ and $III$, we see that the continuation map $FH_I(L) \rightarrow FH_{I,II,III}(H)$ is a composition of small-distance homotopy equivalences and thus an isomorphism. This proves the claim.

Let us consider the commutative diagram

$$\begin{array}{ccc}
FC_I(L) & \xrightarrow{f} & FC_{II}(H) \\
\downarrow{\sim} & & \downarrow{p} \\
FC_{I,II,III}(H) & & 
\end{array}$$

in which $p$ is the projection induced by the ordering $I, III < II$. By Lemma 4.3(ii) we have an isomorphism in $Kom$,

$$C(f) \cong C(p) \cong FC_{I,III}(H)[-1].$$

This isomorphism is compatible with continuation maps, and hence with the structure of a doubly directed system. In the first-inverse-then-direct limit this yields (47) for $\heartsuit$ is $\emptyset$.

Let $\heartsuit$ be “$=$ 0”. The orbits of $L$ in the group $I^0$ are constants, and we separate them as $I^0 = I^0_{\text{bottom}} \sqcup I^0_{\text{top}} \sqcup I^0_{\text{top}}$, according to whether they lie in $W_{\text{bottom}}$, $W_{\text{top}}$ or $W_{\text{top}}$.
V or \( W^{\text{top}} \), respectively, with the orbits lying in \( W^{\text{bottom}} \cup W^{\text{top}} \) forming a subcomplex, and the orbits lying in \( V \) forming a quotient complex (this is achieved by perturbing \( L \) along \( W \) by a Morse function whose restriction to \( V \) is smaller than its restriction to \( W^{\text{bottom}} \cup W^{\text{top}} \)). The Floer complex reduces to the Morse complex by symplectic asphericity [65], and we therefore have canonical identifications \( \text{FC}_{I^{\text{bottom}}}(L) \equiv \text{FC}_{I^{\text{top}}}(H) \), \( \text{FC}_{I^{\text{top}}}(L) \equiv \text{FC}_{II^{\text{top}}}(H) \) and \( \text{FC}_{I^{\text{top}}}(L) \equiv \text{FC}_{III^{\text{top}}}(H) \).

The continuation map \( f^{=0}: \text{FC}_{I^{\text{bottom}}}(L) \to \text{FC}_{II^{\text{bottom}}}(H) \) is identified with the projection \( \text{FC}_{I^{\text{bottom}}}(L) \to \text{FC}_{I^{\text{top}}}(V) \), and by Lemma 4.3(ii) we have an isomorphism in \( \text{Kom} \),

\[
C(f^{=0}) \cong \text{FC}_{I^{\text{bottom}}}(V)[0] = \text{FC}_{II^{\text{bottom}}}(H)[0].
\]

This identification is compatible with continuation maps, and hence with the structure of a doubly directed system. In the first-inverse-then-direct limit this yields (47) for \( \heartsuit \) is “= 0”.

Let \( \heartsuit \) be “< 0”. We denote by \( \text{FC}_{I^{\text{bottom}}}(L) \) the complex generated by the critical points of \( L \) inside \( W^{\text{bottom}} \), and we recall the canonical identification \( \text{FC}_{I^{\text{bottom}}}(L) \simeq \text{FC}_{I^{\text{top}}}(H) \), which we already discussed in the case \( \heartsuit \) is “= 0” above. We claim that any monotone homotopy from \( L \) to \( H \) induces a homotopy equivalence

\[
\text{FC}_{I^{\text{bottom}}}(L) \xrightarrow{g} \text{FC}_{I^{\text{bottom}}}(H).
\]

To see this, consider the composition

\[
g: \text{FC}_{I^{\text{bottom}}}(L) \to \text{FC}_{I^{\text{bottom}}}(H) \to \text{FC}_{I^{\text{bottom}}}(H).
\]

where the first map is the continuation map and the second one is the quotient projection according to Lemma 7.6. Note that the subcomplexes \( \text{FC}_{I^{\text{bottom}}}(L) \) and \( \text{FC}_{I^{\text{bottom}}}(H) \) correspond to the negative action parts if we choose the perturbing Morse functions to be positive on \( W^{\text{bottom}} \) and negative on \( V \cup W^{\text{top}} \). Since the homotopy is constant on \( V \), Lemma 2.2 shows that the Floer cylinders counted by the map \( g \) lie entirely in \( F \cup W^{\text{bottom}} \). Therefore, the map \( g \) agrees with the continuation map \( \text{FC}^{<0}(\bar{L}) \to \text{FC}^{<0}(\bar{H}) \), where \( \bar{L} \) and \( \bar{H} \) are the Hamiltonians that agree with \( L \) and \( H \) on \( F \cup W^{\text{bottom}} \) and are equal to zero on \( V \cup W^{\text{top}} \). The argument in the case \( \heartsuit \) is \( \varnothing \), setting the Hamiltonians \( H^{l} \) also to zero on \( V \cup W^{\text{top}} \), shows that this map is a homotopy equivalence. This proves the claim.

Consider now the commutative diagram
in which \( p \) is the projection determined by the ordering \( I < II^- \). It follows from Lemma 4.3(ii) that we have an isomorphism in \( \text{Kom} \)

\[
C(\phi) \cong C(p) \cong FC_I(H)[-1].
\]

We then consider the diagram of short exact sequences of complexes

\[
\begin{array}{ccccccccc}
FC_I^- (L) & \rightarrow & FC_{I^-0} (L) & \rightarrow & FC_{I0} (L) & \rightarrow & 0 \\
| & & | & & | & & | \\
\downarrow f^{<0} & & \downarrow \phi & & \downarrow & & \downarrow \\
FC_{II^-} (H) & \rightarrow & FC_{II^-} (H) & \rightarrow & FC_{II0} (H) & \rightarrow & 0 \\
| & & | & & | & & | \\
\downarrow C(f^{<0}) & & \downarrow C(\phi) \cong FC_I(H)[-1] & \rightarrow & \cong\text{proj}[{-1}] & \rightarrow & C(0) \cong FC_{I0}(H)[-1] \\
\end{array}
\]

The top-right square commutes up to homotopy by Proposition 4.4 because the cone of the identity map on the second line is homotopic to zero. The cone of \( \phi \) has been identified above, and the bottom-right map induced between the cones is homotopic to the projection \( FC_I(H)[-1] \overset{\text{proj}[{-1}]}{\rightarrow} FC_{I0}(H)[-1] \). It then follows from Proposition 4.4 and Lemma 4.3(ii) that we have isomorphisms in \( \text{Kom} \),

\[
C(f^{<0}) \cong C(\text{proj}[{-1}])[1] \cong C(\text{proj}) \cong FC_{I^+}(H)[-1].
\]

For the middle isomorphism see (23). The identification \( C(f^{<0}) \cong FC_{I^+}(H)[-1] \) is compatible with continuation maps, and hence with the structure of a doubly directed system. In the first-inverse-then-direct limit this yields (47) for \( \heartsuit \) is “\( < 0 \)”. Let \( \heartsuit \) be “\( \geq 0 \)”. This is a consequence of the cases \( \heartsuit \) is \( \emptyset \) and \( \heartsuit \) is “\( < 0 \)”. For this, we consider the diagram

\[
\begin{array}{ccccccccc}
FC_I^- (L) & \rightarrow & FC_I (L) & \rightarrow & FC_{I0+} (L) & \rightarrow & 0 \\
| & & | & & | & & | \\
\downarrow f^{<0} & & \downarrow f & & \downarrow f^{\geq0} & & \downarrow \\
FC_{II^-} (H) & \rightarrow & FC_{II} (H) & \rightarrow & FC_{II0+} (H) & \rightarrow & 0 \\
| & & | & & | & & | \\
\downarrow C(f^{<0}) & & \cong FC_{I^-+}(H)[-1] & \rightarrow & \cong\text{incl}[{-1}] & \rightarrow & C(f) \cong FC_{I,III}(H)[-1] \\
\end{array}
\]
The cones of $f < 0$ and $f$ have been identified above, and the map induced between the cones is homotopic to the inclusion $\text{FC}_{I} \rightarrow \text{FC}_{I, III}(H)[-1]$. It then follows from Proposition 4.4 and Lemma 4.3(ii) that we have isomorphisms in $\text{Kom}$,

$$C(f_{\geq 0}) \cong C(\text{incl}[-1]) \cong C(\text{incl})[-1] \cong \text{FC}_{I, III}(H)[-1].$$

For the middle isomorphism see (23). The identification $C(f_{\geq 0}) \cong \text{FC}_{I, III}(H)[-1]$ is compatible with continuation maps, and hence with the structure of a doubly directed system. In the first-inverse-then-direct limit this yields (47) for $\heartsuit$ is $\geq 0$.

Let $\heartsuit$ be $> 0$. This is a consequence of the cases $\heartsuit$ is $= 0$ and $\heartsuit$ is $\geq 0$. The proof is similar to that of the case $\heartsuit$ is $\geq 0$.

Let $\heartsuit$ be $\leq 0$. This is a consequence of the cases $\heartsuit$ is $> 0$ and $\heartsuit$ is $\emptyset$. The proof is similar to that of the case $\heartsuit$ is $\geq 0$.

Remarks on the proof of Proposition 7.13  It is worth noting that we really needed to consider only three cases: $\heartsuit$ is $\emptyset$, $\heartsuit$ is $= 0$ and $\heartsuit$ is $< 0$, the other three cases being in a sense formal consequences. As a matter of fact, given the cases $\heartsuit$ is $\emptyset$ and $\heartsuit$ is $= 0$, any of the four remaining cases suffices in order to deal with the other remaining three. A strategy that would have worked is to have considered the case $\heartsuit$ is $> 0$, i.e. work our way from the convex end throughout the cobordism (instead of starting from the concave end as in the proof). Should one wish to start with one of the cases $\heartsuit$ is $\leq 0$ or $\heartsuit$ is $\geq 0$, an additional argument would be needed, related to excision, that would allow one to decouple $I$ from $III$ and $I^0$ from $III$, respectively.

We can see a posteriori that the proof consists in a suitable iterative application of the following two elementary steps:

(i) Identify suitable complexes for $L$ and $H$ which are homotopy equivalent via the continuation map.

(ii) Embed the maps $f^{\heartsuit}$ whose cone we wish to compute inside grid diagrams of the type considered in Proposition 4.4, in which the other maps are either some of the homotopy equivalences of step (i), or maps $f^{\heartsuit}$ whose cones have been already computed, or natural projections/inclusions for which the cones are known via Lemma 4.3.

7.3 The exact triangle of a pair

The homotopy invariance of the transfer map, together with the identification between the dynamical definition of the relative symplectic homology groups and the definition
using cones given by Proposition 7.13 implies that for any exact inclusion of pairs \((W, V) \xrightarrow{f} (W', V')\) and for any \(\varnothing \in \{\varnothing, \geq 0, > 0, = 0, \leq 0, < 0\}\) we have an induced transfer map

\[
\text{SH}_*^{\varnothing}(W', V') \xrightarrow{f_!} \text{SH}_*^{\varnothing}(W, V).
\]

The following proposition establishes Theorem 7.1 (the case of symplectic cohomology is completely analogous to that of symplectic homology).

**Proposition 7.14**  Let \((W, V)\) be a cobordism pair, for which we denote the inclusions by \(V \xrightarrow{i} W \xrightarrow{j} (W, V)\). Given \(\varnothing \in \{\varnothing, \geq 0, > 0, = 0, \leq 0, < 0\}\) the following hold:

(i) For any Liouville structure \(\lambda\) there exists an exact triangle

\[
\begin{array}{ccc}
\text{SH}_*^{\varnothing}(W, V; \lambda) & \xrightarrow{j_!} & \text{SH}_*^{\varnothing}(W; \lambda) \\
\downarrow \partial & & \downarrow i_! \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace \negthinspace
\end{array}
\]

where the various symplectic homology groups are understood to be computed with respect to the Liouville structure \(\lambda\).

(ii) Given a homotopy of Liouville structures \(\lambda_t\) for \(t \in [0, 1]\), there are induced isomorphisms \(h_W: \text{SH}_*^{\varnothing}(W; \lambda_0) \rightarrow \text{SH}_*^{\varnothing}(W; \lambda_1)\), \(h_V: \text{SH}_*^{\varnothing}(V; \lambda_0) \rightarrow \text{SH}_*^{\varnothing}(V; \lambda_1)\) and \(h_{W,V}: \text{SH}_*^{\varnothing}(W, V; \lambda_0) \rightarrow \text{SH}_*^{\varnothing}(W, V; \lambda_1)\) which define a morphism between the exact triangles in (i) corresponding to \(\lambda_0\) and \(\lambda_1\).

(iii) Given an exact inclusion of pairs

\[(W, V) \xrightarrow{f} (W', V'),\]

the transfer maps \(f_!: \text{SH}_*^{\varnothing}(V') \rightarrow \text{SH}_*^{\varnothing}(V), \ f_!: \text{SH}_*^{\varnothing}(W') \rightarrow \text{SH}_*^{\varnothing}(W)\) and \(f_!: \text{SH}_*^{\varnothing}(W', V') \rightarrow \text{SH}_*^{\varnothing}(W, V)\) define a morphism between the exact triangles of the pairs \((W', V')\) and \((W, V)\).

**Proof**  The existence of the exact triangle in (i) is a consequence of the tautological homology exact triangle of a cone (20) and of the identification between \(\text{SH}_*^{\varnothing}(W, V)[−1]\) and \(\text{SH}_*^{\varnothing, \text{cone}}(W, V)\) proved in Proposition 7.13.

Part (ii) follows from the naturality of the homology exact triangle of a cone with respect to chain maps, and from the naturality of the absolute transfer map \(\text{SH}_*^{\varnothing}(W; \lambda) \rightarrow \text{SH}_*^{\varnothing}(V; \lambda)\) with respect to homotopies of Liouville structures.
Part (iii) follows from the naturality of the homology exact triangle of a cone and from the functoriality of transfer maps (Proposition 5.4).

The excision theorem, Theorem 6.11, can also be reinterpreted using transfer maps. The proof uses the same kinds of arguments as above and we shall omit it.

**Proposition 7.15** Given a Liouville cobordism triple \((W, V, U)\), denote the inclusion by
\[
(W \setminus \overline{U}, V \setminus \overline{U}) \hookrightarrow (W, V).
\]
The excision isomorphism in Theorem 6.11 is induced by the transfer map \(i_1\).

### 7.4 Exact triangle of a triple and Mayer–Vietoris exact triangle

**Proposition 7.16** (exact triangle of a triple) Let \(U \subset V \subset W\) be a triple of Liouville cobordisms with filling, meaning that \((V, U)\) and \((W, V)\) are pairs of Liouville cobordisms with filling, and denote the inclusions by \((V, U) \hookrightarrow (W, U) \hookrightarrow (W, V)\). For \(\heartsuit \in \{\emptyset, \geq 0, > 0, = 0, \leq 0, < 0\}\) there exists an exact triangle
\[
\xymatrix{ \text{SH}^\heartsuit_*(W, V) \ar[r]^{j_1} & \text{SH}^\heartsuit_*(W, U) \ar[d]^{\partial} & \text{SH}^\heartsuit_*(V, U) \ar[l]^{i_1} \ar[l]_{[-1]} } \]
which is functorial with respect to inclusions of triples, and which is invariant under homotopies of the Liouville structure that preserve the triple.

**Proof** The proof is a formal consequence of the functorial properties of the long exact sequence of a pair. The proof of Theorem I.10.2 in [34] holds verbatim.

**Theorem 7.17** (Mayer–Vietoris exact triangle) Let \(U, V \subset W\) be Liouville cobordisms such that \(W = U \cup V\) and \(Z := U \cap V\) is a Liouville cobordism such that
\[
U = U^{\text{bottom}} \circ Z, \quad V = Z \circ V^{\text{top}}, \quad W = U^{\text{bottom}} \circ Z \circ V^{\text{top}},
\]
with \(U^{\text{bottom}} = \overline{U \setminus Z}, \quad V^{\text{top}} = \overline{V \setminus Z}\). We denote the inclusion maps by
\[
\xymatrix{ Z \ar[rr]^{i_U} & & U \ar[rr]^{f_U} & & W \ar[ll]^{j_U} \\
\ar[rr]_{i_V} & & V \ar[ll]_{j_V} }
\]
There is a functorial Mayer–Vietoris exact triangle

\[
\begin{array}{ccc}
\text{SH}^\diamondsuit_*(W) & \xrightarrow{(j_U^*, j_V^*)} & \text{SH}^\diamondsuit_*(U) \oplus \text{SH}^\diamondsuit_*(V) \\
\delta & & \downarrow i_{U*}-i_{V*} \\
\text{SH}^\diamondsuit_*(Z) & & \\
\end{array}
\]

For \(\text{SH}^{=0}\) this exact triangle is isomorphic to the Mayer–Vietoris exact triangle in singular cohomology.

**Proof** The Mayer–Vietoris exact triangle follows by a purely algebraic argument from the exact triangle of a pair and its naturality, and from the excision theorem, Theorem 6.11. The idea is to consider the following commutative diagram:

\[
\begin{array}{ccc}
\text{SH}^\diamondsuit_{*-1}(W) & & \\
\delta' & & \\
\text{SH}^\diamondsuit_{*-1}(V, Z) & \xleftarrow{\text{exc}} & \text{SH}^\diamondsuit_{*-1}(W, U) \\
\text{SH}^\diamondsuit_{*-1}(U, Z) & \xrightarrow{\text{exc}} & \text{SH}^\diamondsuit_{*-1}(Z) & \xrightarrow{\delta''} & \text{SH}^\diamondsuit_{*-1}(W, V) & \xleftarrow{\text{exc}} & \\
\text{SH}^\diamondsuit_{*-1}(W, V) & \xleftarrow{\text{exc}} & \\
\text{SH}^\diamondsuit_{*}(V) & \xrightarrow{\text{exc}} & \\
\text{SH}^\diamondsuit_{*}(W) & \xleftarrow{\text{exc}} & \\
\text{SH}^\diamondsuit_{*}(V, Z) & \xleftarrow{\text{exc}} & \text{SH}^\diamondsuit_{*}(W, U) & \xrightarrow{\delta''} & \\
\text{SH}^\diamondsuit_{*+1}(Z) & & \\
\end{array}
\]

The isomorphism \(\text{SH}^\diamondsuit_*(W, V) \xrightarrow{\sim} \text{SH}^\diamondsuit_*(U, Z)\) follows from the excision theorem, Theorem 6.11, for the exact triple \((W, V, V^{\text{top}})\). Similarly, we have an isomorphism \(\text{SH}^\diamondsuit_*(W, U) \xrightarrow{\sim} \text{SH}^\diamondsuit_*(V, Z)\). The maps \(\delta'\) and \(\delta''\) are obtained by inverting the corresponding excision isomorphisms, and we actually have \(\delta'' = -\delta'\) by the “hexagonal lemma” of Eilenberg and Steenrod [34, Lemma I.15.1], which we recall below. We define the map \(\delta\) in the statement of Theorem 7.17 to be equal to \(\delta''\), and a direct check by diagram chasing shows that the Mayer–Vietoris triangle is exact; see [34, Section I.15] for details.

\[\square\]
Lemma 7.18 \cite[hexagonal lemma I.15.1]{34} Consider the diagram of groups and homomorphisms

![Diagram]

Assume that each triangle is commutative, that $k_1$ and $k_2$ are isomorphisms, that the two diagonal sequences are exact at $G$, and that $j_0i_0 = 0$. Then the two homomorphisms from $G_0$ to $G_0'$ obtained by skirting the sides of the hexagon differ in sign only. □

The hexagonal lemma of Eilenberg and Steenrod is applied in the proof of Theorem 7.17 to the following configuration:

![Diagram]
The vertical isomorphisms $k_1$ and $k_2$ are the excision isomorphisms. The connecting homomorphism $\delta$ in the Mayer–Vietoris exact sequence, or the homomorphism $\delta''$ in the notation of the proof of Theorem 7.17, is defined to be $h_2k_2^{-1}l_2$.

### 7.5 Compatibility between exact triangles

In this section we use the notation $(\heartsuit, \heartsuit', \heartsuit'/\heartsuit)$ for any one of the triples $(<0, \varnothing, \geq 0), (\leq 0, \varnothing, > 0), (<0, \leq 0, = 0), \text{or } (= 0, \geq 0, > 0)$. To any such triple there corresponds a tautological exact triangle (see Propositions 2.12 and 2.18)

\[
\begin{array}{ccc}
\text{SH}_*^{\heartsuit} & \longrightarrow & \text{SH}_*^{\heartsuit'} \\
\downarrow \rightarrow & & \downarrow \rightarrow \\
\text{SH}_*^{\heartsuit'/\heartsuit} & \longrightarrow & \text{SH}_*^{\heartsuit'}/\heartsuit
\end{array}
\]

**Proposition 7.19** Let $(W, V)$ be a Liouville pair of cobordisms with filling. Let $(\heartsuit, \heartsuit', \heartsuit'/\heartsuit)$ be a triple as above.

(i) The transfer maps $f_{WV}^{\heartsuit'}, f_{WV}^{\heartsuit'/\heartsuit}$ and $f_{WV}^{\heartsuit'/\heartsuit'}$ induce a morphism between the tautological exact triangles corresponding to $(\heartsuit, \heartsuit', \heartsuit'/\heartsuit)$ for $W$ and $V$.

(ii) The exact triangles of the pair $(W, V)$ for $(\heartsuit, \heartsuit', \heartsuit'/\heartsuit)$ determine “triangles of triangles” together with the corresponding tautological exact triangles. More precisely, upon expanding the exact triangles of a pair and the tautological ones into long exact sequences, we obtain the following diagram, in which all squares are commutative, except the bottom-right one, which is anticommutative:

\[
\begin{array}{ccc}
\text{SH}_*^{\heartsuit}(W, V) & \longrightarrow & \text{SH}_*^{\heartsuit}(W) \\
\downarrow & & \downarrow \\
\text{SH}_*^{\heartsuit'}(W, V) & \longrightarrow & \text{SH}_*^{\heartsuit'}(W) \\
\downarrow & & \downarrow \\
\text{SH}_*^{\heartsuit'/\heartsuit}(W, V) & \longrightarrow & \text{SH}_*^{\heartsuit'/\heartsuit}(W) \\
\downarrow & & \downarrow \\
\text{SH}_*^{\heartsuit}_{-1}(W, V) & \longrightarrow & \text{SH}_*^{\heartsuit}_{-1}(W) \\
\downarrow & & \downarrow \\
\text{SH}_*^{\heartsuit'}_{-1}(W, V) & \longrightarrow & \text{SH}_*^{\heartsuit'}_{-1}(W) \\
\downarrow & & \downarrow \\
\text{SH}_*^{\heartsuit'}_{-2}(W, V)
\end{array}
\]
(iii) The exact triangle of a pair \((W, V)\) for \(\text{SH}_{*}^{=0}\) is isomorphic to the exact triangle of the pair \((W, V)\) in singular cohomology \(H^{n-*}\).

**Proof** Assertion (i) follows from the fact that continuation maps induced by increasing homotopies respect the action filtration.

Assertion (ii) follows from Lemma 4.6, and from our identification of the relative symplectic homology groups with limit homology groups of mapping cones corresponding to chain level continuation maps (Proposition 7.13).

Lemma 4.6 is applied to the following morphism between action-filtration short exact sequences given by the chain-level continuation maps:

\begin{align*}
0 & \longrightarrow FC_{I^O}(K_{i,j}) \longrightarrow FC_{I^O}(K_{i,j}) \longrightarrow FC_{I^O/\sigma}(K_{i,j}) \longrightarrow 0 \\
0 & \longrightarrow FC_{H^O}(K_{i,j}) \longrightarrow FC_{H^O}(H_{i,j}) \longrightarrow FC_{H^O/\sigma}(H_{i,j}) \longrightarrow 0
\end{align*}

Assertion (iii) is proved mutatis mutandis like [29, Proposition 1.4]. We omit the details. \(\square\)

Finally, we prove the following compatibility between the tautological exact triangles:

**Proposition 7.20** For every filled Liouville pair \((W, V)\) the four tautological exact triangles fit into the commuting diagram

\begin{equation}
\begin{array}{c}
\text{SH}_{*+1}^{=0}(W, V) \\
\downarrow \\
\text{SH}_{*+1}^{0}(W, V)
\end{array}
\longrightarrow
\begin{array}{c}
\text{SH}_{*}^{=0}(W, V) \\
\downarrow \\
\text{SH}_{*}^{0}(W, V)
\end{array}
\longrightarrow
\begin{array}{c}
\text{SH}_{*}^{0}(W, V) \\
\downarrow \\
\text{SH}_{*}^{<0}(W, V)
\end{array}
\longrightarrow
\begin{array}{c}
\text{SH}_{*}^{<0}(W, V) \\
\downarrow \\
\text{SH}_{*}^{>0}(W, V)
\end{array}
\end{equation}

**Proof** Fix \(\varepsilon > 0\) small enough. For any choice of real numbers \(a\) and \(b\) such that \(-\infty < a < -\varepsilon < \varepsilon < b < \infty\), and for any choice of admissible Hamiltonian and almost
complex structure, we have a commutative diagram of short exact sequences

$$
\begin{array}{cccc}
0 & \rightarrow & FC_{\star}^{(a,-\varepsilon)} & \rightarrow & FC_{\star}^{(a,\varepsilon)} & \rightarrow & FC_{\star}^{(-\varepsilon,\varepsilon)} & \rightarrow & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \\
0 & \rightarrow & FC_{\star}^{(a,-\varepsilon)} & \rightarrow & FC_{\star}^{(a,b)} & \rightarrow & FC_{\star}^{(-\varepsilon,b)} & \rightarrow & 0
\end{array}
$$

in which the various maps are inclusions or projections. This induces a commutative diagram between the corresponding long exact sequences in homology, and by passing to the limit on the Hamiltonian and then on $a \to -\infty$ and $b \to \infty$ as in Section 2.5, we obtain the commutativity of the diagram formed by the two horizontal lines in the statement.

The commutativity of the diagram formed by the two vertical lines in the statement is proved analogously.

We conclude this subsection with a compatibility result between the exact triangle of a triple and Poincaré duality.

**Proposition 7.21** (Poincaré duality and long exact sequence of a triple) For every triple $(W, V, U)$ of filled Liouville cobordisms and $\heartsuit \in \{\emptyset, > 0, \geq 0, = 0, \leq 0, < 0\}$, there exists a commuting diagram

$$
\begin{array}{cccc}
\text{SH}_{\heartsuit}(W, V) & \rightarrow & \text{SH}_{\heartsuit}(W, U) & \rightarrow & \text{SH}_{\heartsuit}(V, U) & \rightarrow & \text{SH}_{\heartsuit-1}(W, V) \\
\text{exc} & \rightarrow & \text{exc} & \rightarrow & \text{exc} & \rightarrow & \text{exc} \\
\text{SH}_{\heartsuit}(W \setminus V, \partial V) & \rightarrow & \text{SH}_{\heartsuit}(W \setminus U, \partial U) & \rightarrow & \text{SH}_{\heartsuit}(V \setminus U, \partial U) & \rightarrow & \text{SH}_{\heartsuit-1}(W \setminus V, \partial V) \\
\text{PD} & \rightarrow & \text{PD} & \rightarrow & \text{PD} & \rightarrow & \text{PD} \\
\text{SH}_{\heartsuit-1}(W \setminus V, \partial V) & \rightarrow & \text{SH}_{\heartsuit-1}(W \setminus U, \partial W) & \rightarrow & \text{SH}_{\heartsuit}(V \setminus U, \partial V) & \rightarrow & \text{SH}_{\heartsuit-1}(W \setminus V, \partial W) \\
\text{exc} & \rightarrow & \text{exc} & \rightarrow & \text{exc} & & \rightarrow \\
\text{SH}_{\heartsuit-1}(W \setminus V, \partial W) & \rightarrow & \text{SH}_{\heartsuit-1}(W \setminus U, \partial W) & \rightarrow & \text{SH}_{\heartsuit-1}(W \setminus U, \partial W) & \rightarrow & \text{SH}_{\heartsuit-1}(W \setminus V, \partial W)
\end{array}
$$

where the first and last rows are the long exact sequences of the triples $(W, V, U)$ and $(W \setminus U, W \setminus V, \partial W)$, respectively, and the vertical arrows are the Poincaré duality and excision isomorphisms from Theorems 3.4 and 6.8. (The remaining horizontal maps are defined by this diagram.)

**Proof** The conclusion follows directly from the definition of the Poincaré duality isomorphism in Theorem 3.4 and the observation that for a Hamiltonian $G$ as in
Figure 13 adapted to the triple \((W, V, U)\), the Hamiltonian \(-G\) is adapted to the triple \((W \setminus U, W \setminus V, \partial W)\).

Alternatively, one can reduce the general case by a purely algebraic argument to the case \(U = \emptyset\), as in the proof of Proposition 7.16. The case \(U = \emptyset\) is in turn treated by noting that for a Hamiltonian \(H\) as in Figures 12 or 18 adapted to the pair \((W, V)\), the Hamiltonian \(-H\) is adapted to the triple \((W, W \setminus V, \partial W)\).

## 7.6 The exact triangle of a pair of Liouville domains revisited

The exact triangle

\[
\begin{array}{ccc}
\text{SH}_*(W, V) & \rightarrow & \text{SH}_*(W) \\
\downarrow [-1] & & \downarrow \partial \\
\text{SH}_*(V) & \rightarrow & \text{SH}_*(W) \\
\end{array}
\]

can be established in a more direct way for a pair \((W, V)\) of Liouville domains since there is no need to first identify the symplectic homology of the pair with a homological mapping cone. Instead, one can argue directly on the chain complexes using truncation by the action. We find it instructive to spell out the argument. This proof is only apparently simpler: since the transfer maps induced by the inclusions \(V \hookrightarrow W\) and \(W \hookrightarrow (W, V)\) are only implicitly constructed, this proof would require additional arguments in order to incorporate it into the larger framework that we discuss in this paper, and these additional arguments would essentially amount to reinterpreting this diagram in terms of transfer maps.

For a pair of Liouville domains we only need to consider three flavours \(\heartsuit \in \{\emptyset, = 0, > 0\}\). We prove below the compatibility of the exact triangle of the pair with the tautological exact triangle relating these three flavours.

Let \(V \subseteq W\) be an inclusion of Liouville domains and denote by \(\hat{W}\) the symplectic completion of \(W\). Let \(H = H_{v, \tau}\) for \(v > 0\) and \(\tau > 0\) be a one-step Hamiltonian on \(\hat{W}\), defined up to smooth approximation as follows (Figure 21):

- \(H = 0\) on \(W \setminus V\).
- \(H\) is linear of slope \(\tau\) on \(\hat{W} \setminus W\).
- \(H\) is linear of slope \(v\) on a collar \([\delta, 1] \times \partial V \subseteq V\) for some \(0 < \delta < 1\).
- \(H\) is constant equal to \(-v(1 - \delta)\) on the complement of this collar in \(V\).
For $\nu$ and $\tau$ not lying in the action spectrum of $\partial V$ and $\partial W$, respectively, the 1–periodic orbits of $H$ fall into five classes:

- $(II^0)$ Constants in the complement of the collar in $V$.
- $(II^+)$ Orbits corresponding to characteristics on $\partial V$ and located in the region $\{\delta\} \times \partial V$.
- $(III^-)$ Orbits corresponding to characteristics on $\partial V$ and located in the region $\partial V$.
- $(III^0)$ Constants in $W \setminus V$.
- $(III^+)$ Orbits corresponding to characteristics on $\partial W$ and located in the region $\partial W$.

Suitable choices of the parameters $\tau$ and $\delta$ as a function of $\nu$ ensure that the various classes of orbits are ordered according to the action as follows:

$$III^0 < III^\pm < II^0 < II^+.$$  

As $\nu \to \infty$ we can allow $\tau \to \infty$. In general we need to let $\delta \to 0$ if we wish to acquire $III^- < II^0$. However, by Lemmas 2.3 and 2.2 we have

$$III^- < II^0, II^+$$

for any fixed choice of $\delta > 0$, independently of the choice of $\nu$. Also, by Lemma 2.3 we have

$$III^- < III^+, II^0, II^+ < III^+.$$  

The outcome is that for suitable choices of the parameters we have

$$III^0 < III^- < II^0 < II^+ < III^+$$  

and

$$III^0 < III^- < III^+ < II^0 < II^+.$$
Let $F\!C_{\text{tot}}$ be the total Floer complex for the Hamiltonian $H$. For a subset $I \subset \{I^0, I^+, III^-, III^0, III^+\}$ denote by $F\!C_I$ the complex generated by the orbits in the classes belonging to $I$. For example, $F\!C_{III^-, III^0, III^+}$ stands for the subcomplex generated by the orbits in the classes $III^-, III^0$ and $III^+$, and $F\!C_{III^-, III^+}$ stands for its quotient complex modulo $F\!C_{III^0}$. We will also abbreviate $F\!C_H = F\!C_{H^0, H^+}$ and $F\!C_{III} = F\!C_{III^-, III^0, III^+}$.

Let us consider the following diagram, whose first two rows and first two columns are exact:

$$
\begin{array}{ccccccccc}
0 & \to & F\!C_{III^0} & \to & F\!C_{H, III^-, III^0} & \to & F\!C_{II, III^-} & \to & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \\
0 & \to & F\!C_{III} & \to & F\!C_{\text{tot}} & \to & F\!C_{II} & \to & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \\
F\!C_{III^-, III^+, III^+, III^+} & \to & F\!C_{III^+, III^+} & \to & F\!C_{III^-[-1]} & & & & \\
\downarrow & & \downarrow & & \downarrow & & & & \\
0 & & 0 & & 0 & & & & \\
\end{array}
$$

Here the chain maps $f: F\!C_H \to F\!C_{III^-[-1]}$ and $g: F\!C_{III^+} \to F\!C_{III^-[-1]}$ are uniquely determined, so we have natural identifications

$$F\!C_{II, III^-} = C(f)[1], \quad p = \beta(f), \quad F\!C_{III^-, III^+} = C(g)[1], \quad q = \beta(g).$$

Proposition 4.4 and its proof ensure that the bottom-right square in the above diagram is commutative in $\text{Kom}$, and moreover the diagram can be completed to a diagram in $\text{Kom}$ whose lines and columns are distinguished triangles, and all of whose squares are commutative except the bottom-right one, which is anticommutative:

$$
\begin{array}{ccccccccc}
F\!C_{III^0} & \to & F\!C_{H, III^-, III^0} & \to & F\!C_{II, III^-} & \to & F\!C_{III^0][-1] \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
F\!C_{III} & \to & F\!C_{\text{tot}} & \to & F\!C_{II} & \to & F\!C_{III}[-1] \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
F\!C_{III^-, III^+, III^+, III^+} & \to & F\!C_{III^+, III^+} & \to & F\!C_{III^-[-1]} & \to & F\!C_{III^-, III^+[-1]} \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
F\!C_{III^0[-1]} & \to & F\!C_{H, III^-, III^0[-1]} & \to & F\!C_{II, III^-[-1]} & \to & F\!C_{III^0[-2]} \\
\end{array}
$$
Indeed, the term $FC_{III}[-1]$ is isomorphic in $Kom$ to $C(p)[-1]$ on the one hand, and to $C(-q)[-1]$ on the other hand, and these two complexes are isomorphic as seen in the proof of Proposition 4.4.

We now remark that we have a homotopy equivalence that is well-defined up to homotopy

$$FC_{III}[-1] \cong FC_{II}^+.$$ 

This follows again from Proposition 4.4. For the proof we consider a homotopy from a Hamiltonian $K = K_\tau$ which is zero on $W$ and coincides with $H_{v,\tau}$ outside $W$ to the Hamiltonian $H$. We denote by $FC_V(K)$ the subcomplex of $FC(K)$ generated by critical points inside the domain $V$, so the continuation map induces a homotopy equivalence $FC_V(K) \cong FC_{II,III}^-$. On the other hand, we have a canonical identification $FC_V(K) \equiv FC_{II^0}$, and a commutative diagram up to homotopy

$$
\begin{array}{ccc}
FC_V(K) & \cong & FC_{II^0} \\
\downarrow^{h.e.} & & \downarrow^{incl} \\
FC_{II,III}^- & \rightarrow & FC_{II} \\
\end{array}
$$

Then Proposition 4.4 yields the desired homotopy equivalence $FC_{III}[-1] \cong FC_{II}^+$.

**Remark 7.22** This chain homotopy equivalence provides one point of view on the vanishing of $SH_\ast(I \times \partial V, \partial^-(I \times \partial V))$ proved in Proposition 9.3.

Diagram (48) can now be used as a building block to prove the existence of a diagram with exact lines and columns and in which all squares are commutative except the one marked “−”, which is anticommutative:

$$
\begin{array}{ccccccc}
H^{n-*}(W, V) & \rightarrow & H^{n-*}(W) & \rightarrow & H^{n-*}(V) & \rightarrow & H^{n-*+1}(W, V) \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
SH_\ast(W, V) & \rightarrow & SH_\ast(W) & \rightarrow & SH_\ast(V) & \rightarrow & SH_\ast-1(W, V) \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
SH^0_\ast(W, V) & \rightarrow & SH^0_\ast(W) & \rightarrow & SH^0_\ast(V) & \rightarrow & SH^0_\ast-1(W, V) \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
H^{n-*+1}(W, V) & \rightarrow & H^{n-*+1}(W) & \rightarrow & H^{n-*+1}(V) & \rightarrow & H^{n-*+2}(W, V) \\
\end{array}
$$

*Algebraic & Geometric Topology, Volume 18 (2018)*
This grid diagram expresses the compatibility between the exact triangle of a pair of Liouville domains \((W, V)\) and the tautological exact triangle involving singular cohomology, symplectic homology and positive symplectic homology. One relevant ingredient here is the chain homotopy equivalence \(C^{III} [-1] \cong C^{II}\). The other ingredient is that all the above homological constructions are compatible with continuation maps and with direct limits.

8 Variants of symplectic homology groups

8.1 Rabinowitz–Floer homology

Given a pair of Liouville domains \((W, V)\), Rabinowitz–Floer homology \(RFH_* (\partial V, W)\) was defined in [27] as a Floer-type theory associated to the Rabinowitz action functional

\[
\bar{A}_H : \mathcal{L} \hat{W} \times \mathbb{R} \to \mathbb{R}, \quad \bar{A}_H (\gamma, \eta) = A_{\eta H} (\gamma),
\]

where \(H : \hat{W} \to \mathbb{R}\) is a Hamiltonian such that \(\partial V = H^{-1} (0)\) is a regular level, \(H |_{V} \leq 0\), and \(H |_{\hat{W} \setminus V} \geq 0\). The dynamical significance of Rabinowitz–Floer homology is that it counts leafwise intersection points of \(\partial V\) under Hamiltonian motions [5], and one of its most useful properties is that Hamiltonian displaceability of \(\partial V\) (and hence of \(V\)) implies vanishing.

It was proved in [29] that \(RFH_* (\partial V, W)\) does not depend on \(W\), so we will denote it by \(RFH (\partial V)\) (it does however depend on the filling \(V\) of \(\partial V\)). The main result of [29] is that, with our current notation, we have an isomorphism

\[
(50) \quad RFH_* (\partial V) \cong SH_* (\partial V),
\]

ie Rabinowitz–Floer homology is the symplectic homology of the trivial cobordism over \(\partial V\). As such, Rabinowitz–Floer homology is naturally incorporated within the setup that we develop in this paper.

8.2 \(S^1\)–equivariant symplectic homologies

The circle \(S^1 = \mathbb{R} / \mathbb{Z}\) acts on the free loop space by shifting the parametrization. As such, one can define \(S^1\)–equivariant flavours of symplectic homology groups. In the case of Liouville domains relevant instances have been defined in [68; 66; 18; 71; 4]. Following Seidel [66] and [18; 71], the relevant structure is that of an \(S^1\)–complex,
meaning a $\mathbb{Z}$–graded chain complex $(C_*, \partial)$ together with a sequence of maps $\partial_i : C_* \to C_{*+2i-1}$ for $i \geq 0$ such that $\partial_0 = \partial$ and

$$\sum_{i+j=k} \partial_i \partial_j = 0$$

(51)

for all $k \geq 0$. An $S^1$–complex for which $\partial_i = 0$ for $i \geq 2$ is called a mixed complex in the literature on cyclic homology. One should view $S^1$–complexes as being $\infty$–mixed complexes, or mixed complexes up to homotopy; see [18]. Given a Hamiltonian $H$ one can endow $FC^{(a,b)}_*(H)$ with the structure of an $S^1$–complex that is canonical up to homotopy equivalence. Moreover, a homotopy of Hamiltonians induces a morphism between the $S^1$–complexes defined on the Floer chain groups at the endpoints.

Recall that we work with coefficients in a field $\mathbb{K}$. Denote by $u$ a formal variable of degree $-2$. Given an $S^1$–complex $\mathcal{C} = (C_*, \{\partial_i\}_{i \geq 0})$ we define, following Jones [51] and Zhao [71], the periodic cyclic chain complex

$$C_*[u, u^{-1}], \quad \partial_u = \sum_{i \geq 0} u^i \partial_i, \quad |u| = -2.$$

Here elements in $C_*[u, u^{-1}]$ of degree $k$ are by definition Laurent polynomials $\sum_{j=-N}^{N} x_j u^j$ with $x_j \in C_{k+2j}$. Then $\partial_u^2 = 0$ as a consequence of (51) and the map $\partial_u$ is $\mathbb{K}[u]$–linear. We consider the subcomplex and quotient complex

$$C_*[u], \quad C_*[u^{-1}] = C_*[u, u^{-1}]/uC_*[u]$$

with differential induced by $\partial_u$ and the induced $\mathbb{K}[u]$–module structure. The homologies

$$HC_*^u(\mathcal{C}) := H_*(C_*[u]), \quad HC_*^{[u,u^{-1}]}(\mathcal{C}) := H_*(C_*[u, u^{-1}]),$$

$$HC_*^{[u^{-1}]}(\mathcal{C}) := HC_*^{[u^{-1}]}(\mathcal{C}) := H_*(C_*[u^{-1}])$$

correspond to certain versions of the negative cyclic homology, periodic (or Tate) cyclic homology and cyclic homology, respectively, of the $S^1$–complex $\mathcal{C}$ in the literature. We will not use these names but rather indicate in the notation which version of (Laurent) polynomials we are using. Due to the short exact sequence of complexes of $\mathbb{K}[u]$–modules

$$0 \to C_*[u] \to C_*[u, u^{-1}] \to C_*[u, u^{-1}]/C_*[u] \cong C_*[u^{-1}][-2] \to 0,$$
these homology groups fit into the fundamental exact triangle

\[
\begin{array}{ccc}
\text{HC}^{[u]}(C) & \to & \text{HC}^{[u,u-1]}(C) \\
\downarrow^{[+1]} & & \downarrow^{[-2]} \\
\text{HC}(C) & & 
\end{array}
\]

Example 8.1  Given an $S^1$–space $X$, its singular chain complex with arbitrary coefficients $C_*(X)$ carries the structure of a mixed complex $C = (C_*, \partial, \partial_1)$ such that [49] (also Hingston, private communication, 2012) we have

\[
\text{HC}_*(C) \cong H_*^{S^1}(X).
\]

Here $H_*^{S^1}(X) = H_*(X \times S^1 E S^1)$ is the usual $S^1$–equivariant homology group of $X$ defined by the Borel construction. The map $\partial_1: C_* \to C_*+1$ is defined by inserting a suitable representative of the fundamental class of the oriented circle $S^1$ into the first argument of the composite map $C_*(S^1) \otimes C_*(X) \xrightarrow{\text{EZ}} C_*(S^1 \times X) \xrightarrow{\mu_*} C_*(X)$, where $\mu: S^1 \times X \to X$ is the $S^1$–action and EZ is the Eilenberg–Zilber equivalence, explicitly described by the Eilenberg–Mac Lane shuffle map [33, page 64]. Define the homology groups

\[
H_*^{[u,u-1]}(X) = \text{HC}^{[u,u-1]}(C), \quad H_*^{[u]}(X) = \text{HC}^{[u]}(C).
\]

While these groups cannot be described as homology groups of a topological space in the manner of $H_*^{S^1}(X)$ — they typically have infinite support in the negative range — they are nevertheless unavoidable should one wish to formulate duality. More precisely, let us assume that $X$ is an oriented manifold of dimension $n$ with boundary preserved by the $S^1$–action. Denoting by $H_{S^1}^*(X) = H^*(X \times S^1 E S^1)$ the usual $S^1$–equivariant cohomology groups, Poincaré duality in the $S^1$–equivariant setting takes the form

\[
H_{S^1}^i(X) \cong H_{n-i}^{[u]}(X, \partial X).
\]

More generally, dualizing the mixed complex structure on $C_*(X)$ and changing the degree of $u$ to $+2$, one can define two other versions $H_{[u,u-1]}^*(X)$ and $H_{[u-1]}^*(X)$ of $S^1$–equivariant cohomology, with Poincaré duality isomorphisms

\[
H_{[u,u-1]}^i(X) \cong H_{n-i}^{[u,u-1]}(X, \partial X), \quad H_{[u-1]}^i(X) \cong H_{n-i}^{[u-1]}(X, \partial X) = H_{n-i}^{S^1}(X).
\]

See [50; 23] for proofs of related statements. We shall use below the following simple instance of duality: Consider an oriented manifold $X$ of dimension $n$ with boundary,
viewed as an $S^1$–space with trivial action. Then
\[ H^i_{S^1}(X) = \bigoplus_{j \geq 0} H^{i-2j}_i(X) \]
and
\[ H^i_{[u^{-1}]}(X, \partial X) = \prod_{j \geq 0} H^{i+2j}_i(X, \partial X) = \bigoplus_{j \geq 0} H^{i+2j}_i(X, \partial X), \]
so that we indeed have $H^i_{S^1}(X) \cong H^i_{[u^{-1}]}(X, \partial X)$ as a consequence of classical Poincaré duality.

In order to define $S^1$–equivariant symplectic homology and cohomology groups, we use the structure of an $S^1$–complex on each truncated Floer chain complex $C := FC_{(a,b)}^*(H)$ and cochain complex $C^\vee := FC_{(a,b)}^*(H)$ constructed in [18; 71]. We set
\[
\begin{align*}
FH^*(a,b), S^1(H) &= HC_*(C), \quad FH^*(a,b), [u,u^{-1}](H) = HC_*^{[u,u^{-1}]}(C), \\
FH^*(a,b), [u](H) &= HC_*^[[u]](C)
\end{align*}
\]
and
\[
\begin{align*}
FH^*(a,b), S^1(H) &= HC^*(C^\vee), \quad FH^*(a,b), [u,u^{-1}](H) = HC^*_{[u,u^{-1}]}(C^\vee), \\
FH^*(a,b), [u^{-1}](H) &= HC^*_{[u^{-1}]}(C^\vee)
\end{align*}
\]
and use these groups in formulas (5), (8), (9), (11) and (12), as well as in Definitions 2.8, 2.13, 2.15, 3.1 and 3.2. The outcome for a pair $(W, V)$ of Liouville cobordisms with filling is $S^1$–equivariant symplectic homology groups
\[
SH^*_{S^1, \bigcirc}(W, V), \quad SH^*_{[u,u^{-1}], \bigcirc}(W, V), \quad SH^*_{[u], \bigcirc}(W, V),
\]
and $S^1$–equivariant symplectic cohomology groups
\[
SH^*_{S^1, \bigtriangledown}(W, V), \quad SH^*_{[u,u^{-1}], \bigtriangledown}(W, V), \quad SH^*_{[u], \bigtriangledown}(W, V), \quad S^*_{[u^{-1}], \bigtriangledown}(W, V),
\]
with $\bigcirc \in \{\emptyset, > 0, \geq 0, = 0, \leq 0, < 0\}$ as usual.

**Remark 8.2** The notation $[[u]]$ and $[[u, u^{-1}]]$ in the equivariant symplectic cohomology groups is a reminder that, in the case of a Liouville domain, the inverse limit in the definition leads in general to formal power series rather than polynomials. It also indicates the analogy to the $S^1$–equivariant cohomology groups defined by Jones and Petrack [52]. Indeed, it is proved in [71; 4] that for a Liouville domain $W$ and with rational coefficients the second group satisfies fixed-point localization:
\[
SH^*_{[[u,u^{-1}]]}(W; \mathbb{Q}) \cong H_{n+*}(W, \partial W; \mathbb{Q}) \otimes_{\mathbb{Q}} \mathbb{Q}[u, u^{-1}].
\]
One can define several other potentially interesting versions of $S^1$–equivariant symplectic homology by applying the direct/inverse limit over the bounds of the action window $(a, b)$, the homology functor and the completions with respect to $u$ and $u^{-1}$ in different orders [4]. In particular, this gives rise to a version of periodic/Tate symplectic cohomology of a Liouville domain that equals the localization of $S^1$–equivariant cohomology and obeys Goodwillie’s theorem [45]. This can also serve as a motivation to phrase the theory of symplectic homology at chain level; see also the discussion of coefficients in the introduction regarding this point.

The equivariant symplectic (co)homology groups are connected to each other by fundamental exact triangles similar to the one for cyclic homology above, namely

\[
\begin{align*}
\text{SH}_{[u]} & \quad \rightarrow \quad \text{SH}_{[u, u^{-1}]} \\
\text{SH}_{S^1} & \quad \rightarrow \quad \text{SH}_{[[u, u^{-1}]]} \\
\text{SH} & \quad \rightarrow \quad \text{SH}_{[u]} \\
\end{align*}
\]

The nonequivariant and equivariant theories are connected by Gysin exact triangles

\[
\begin{align*}
\text{SH}_* & \quad \rightarrow \quad \text{SH}^{S^1}_* \\
\text{SH}^{S^1}_* & \quad \rightarrow \quad \text{SH}_* \\
\text{SH} & \quad \rightarrow \quad \text{SH}^{S^1}_* \\
\end{align*}
\]

and

\[
\begin{align*}
\text{SH}_{[u]} & \quad \rightarrow \quad \text{SH}_* \\
\text{SH}_* & \quad \rightarrow \quad \text{SH}_{[u^{-1}]} \\
\text{SH} & \quad \rightarrow \quad \text{SH}_{[u]} \\
\end{align*}
\]

respectively. By construction, all $S^1$–equivariant symplectic homology and cohomology groups are modules over $\mathbb{K}[u]$. Moreover, the periodic versions are actually modules over the larger ring $\mathbb{K}[u, u^{-1}]$. In particular, this module structure induces periodicity isomorphisms

\[
\begin{align*}
\text{SH}_{[u, u^{-1}]} & \cong \text{SH}_*^{[u, u^{-1}]} \\
\text{SH} & \cong \text{SH}^{[u, u^{-1}]} \\
\end{align*}
\]

All the exact triangles above are obtained at the level of truncated Floer homology by writing the complex that computes $HC_{[u, u^{-1}]}(C)$ as the product total complex of a multicomplex of the form

\[
\text{Algebraic & Geometric Topology, Volume 18 (2018)}
\]
and considering natural subcomplexes and quotient complexes; see [51; 18]. The \([u^{-1}]\)–complex sits on the right half-plane with respect to the 0th column, the \([u]\)–complex sits on the left half-plane, and the nonequivariant theory sits on the 0th column. For cohomology the arrows need to be reversed. The resulting exact triangles for truncated Floer (co)homology pass to the limit in symplectic (co)homology due to our choice of order in the first-inverse-then-direct limit. Note that, since for a given Hamiltonian \(H\) and finite action window \((a, b)\) the complex \(FC^{(a, b)}(H)\) has finite rank, it actually does not matter whether we consider the product total complex or the direct sum total complex to compute \(HC^{[u, u^{-1}]}(C)\).

Here are some further properties of these symplectic (co)homology groups:

1. At action level zero we have

\[
SH_*^{S^1,0}(W, V) \cong H_{[u-1]}^{n-\ast}(W, V), \quad SH_*^{[u]=0}(W, V) \cong H_{S^1}^{n-\ast}(W, V)
\]

and

\[
SH_*^{[u, u^{-1}]=0}(W, V) \cong H_{[u, u^{-1}]}^{n-\ast}(W, V).
\]

In particular, for a Liouville domain \(W\) of dimension \(2n\) we have

\[
SH_*^{S^1,0}(W) \cong H_{[u]}^{n-\ast}(W) \cong H_{S^1}^{n+1}(W, \partial W).
\]

This formula appears already in [68]. We interpret in the introduction this formula as a motivation for viewing the transfer maps as shriek maps.
(2) For a Liouville domain $W$, it is proved in [18] that $\text{SH}^{S^1, >0}_{\ast}(W)$ is isomorphic over $\mathbb{Q}$ to linearized contact homology of $\partial W$ whenever the latter is defined; see also [47; 48; 55] for applications.

(3) The arguments in [18] carry over to the setting of pairs of Liouville cobordisms with filling in order to show that there is a spectral sequence converging to $\text{SH}^{S^1, \ast}_{\ast}(W, V)$ with second page given by $E^2 = \text{SH}^\partial_{\ast}(W, V) \otimes \mathbb{K}[u^{-1}]$. In combination with the Gysin exact triangle this yields the fact that the nonequivariant symplectic homology of a pair $(W, V)$ vanishes if and only if its $S^1$–equivariant symplectic homology vanishes. The fixed-point localization (53) shows that this is not true anymore for $\text{SH}^{[u, u^{-1}]}_{\ast}$.

(4) The above flavours of $S^1$–equivariant symplectic homology satisfy Poincaré duality in the following general form: given a Liouville cobordism $W$ and an admissible union of boundary components $A \subset \partial W$, for any $\heartsuit \in \{\varnothing, > 0, \geq 0, = 0, \leq 0, < 0\}$ we have isomorphisms

$$\text{SH}^{S^1, \heartsuit}_{\ast}(W, A) \cong \text{SH}^{\partial\heartsuit}_{\ast[u^{-1}]}(W, A^c), \quad \text{SH}^{[u, u^{-1}], \heartsuit}_{\ast}(W, A) \cong \text{SH}^{\partial\heartsuit}_{S^1, \heartsuit}(W, A^c),$$

$$\text{SH}^{[u, u^{-1}], \heartsuit}_{\ast}(W, A) \cong \text{SH}^{\partial\heartsuit}_{[u, u^{-1}]}(W, A^c),$$

where the notation $\partial\heartsuit$ has the same meaning as in Section 3.2. There are also algebraic dualities over the ring $\mathbb{K}[u]$ analogous to those in [50] which pair $\text{SH}^{S^1, \heartsuit}_{\ast}$ with $\text{SH}^{[u, u^{-1}], \heartsuit}_{\ast}$, $\text{SH}^{[u, u^{-1}], \heartsuit}_{\ast}$ with $\text{SH}^{S^1, \heartsuit}_{\ast}$ and $\text{SH}^{[u, u^{-1}], \heartsuit}_{\ast}$ with $\text{SH}^{[u, u^{-1}], \heartsuit}_{\ast}$.

Each of the flavours of $S^1$–equivariant symplectic homology groups obeys the same set of Eilenberg–Steenrod-type axioms as their nonequivariant counterparts. Transfer maps and invariance for the case of Liouville domains were previously discussed in [68; 71; 47]. Moreover, it follows from the construction that the Gysin and fundamental exact triangles are functorial with respect to the tautological exact triangles and also with respect to the exact triangles of pairs; see also [17; 18] for a basic instance of this phenomenon.

### 8.3 Lagrangian symplectic homology, or wrapped Floer homology

Let $W$ be a Liouville cobordism. An exact Lagrangian cobordism in $W$ or, for short, a Lagrangian cobordism, is an exact Lagrangian $L \subset W$ which intersects the boundary $\partial W$ transversally along a Legendrian submanifold $\partial L = L \cap \partial W$. This means that $\lambda|_L$ is an exact 1–form which vanishes when restricted to $\partial L$. We write $\varphi^\pm L = L \cap \varphi^\pm W$.

Up to applying a Hamiltonian isotopy that fixes $\partial W$, one can assume without loss of generality that $L$ is invariant under the Liouville flow near the boundary [3, Section 3a].
This means that near its negative or positive boundary we can identify $L$ via the Liouville flow with $[1, 1 + \varepsilon] \times \partial^- L$ and with $[1 - \varepsilon, 1] \times \partial^+ L$, respectively. We interpret $L$ as a cobordism from $\partial^+ L$ to $\partial^- L$. We refer to $\partial^- L$ and $\partial^+ L$ as being the positive and negative (Legendrian) boundary of $L$, respectively.

Let $F$ be a Liouville filling of $\partial^- W$. An exact Lagrangian filling of $\partial^- L$ or, for short, a filling of $\partial^- L$, is a Lagrangian cobordism $F_L \subset F$ whose positive Legendrian boundary is $\partial^- L$ (and which has empty negative boundary).

One can associate to a Lagrangian cobordism $L$ with filling $F_L$ Lagrangian symplectic homology groups

$$SH^\varnothing_*(L), \quad \varnothing \in \{\emptyset, > 0, \geq 0, = 0, \leq 0, < 0\}.$$

Similarly, given a pair of Lagrangian cobordisms $K \subset L$ inside a pair of Liouville cobordisms $V \subset W$, with Lagrangian filling $F_L$ inside a Liouville filling $F$, we define Lagrangian symplectic homology groups of the pair $(L, K)$:

$$SH^\varnothing_*(L, K), \quad \varnothing \in \{\emptyset, > 0, \geq 0, = 0, \leq 0, < 0\}.$$

These are “open string analogues” of the symplectic homology groups defined for the filled Liouville cobordism $W$ and for the pair of Liouville cobordisms $(W, V)$ with filling. They are defined using exactly the same shape of Hamiltonian as in the “closed string” case. Given such a Hamiltonian, the generators of the corresponding chain complexes are Hamiltonian chords with endpoints on $L$

$$\gamma: [0, 1] \to W, \quad \gamma(\{0, 1\}) \subset L, \quad \dot{\gamma} = X_H \circ \gamma,$$

and the Floer differential counts strips with Lagrangian boundary condition on $L$ which are finite-energy solutions of the Floer equation

$$u: \mathbb{R} \times [0, 1] \to W, \quad u(\mathbb{R} \times \{0, 1\}) \subset L, \quad \partial_s u + J(u)(\partial_t u - X_H \circ u) = 0.$$

The theory is naturally defined over $\mathbb{Z}/2$, and an additional assumption on the Lagrangian is needed (eg relatively spin) in order to define the theory with more general coefficients.

**Example 8.3** Let $L$ be a Lagrangian cobordism inside a Liouville domain $W$, so that $L$ has empty negative boundary and empty filling. The Lagrangian symplectic homology group $SH^\varnothing_*(L)$ coincides with the wrapped Floer homology group of $L$ introduced

\[2\text{Not to be confused with the (wrapped) Lagrangian intersection Floer homology of a pair of Lagrangians.}\]
The Lagrangian symplectic homology group $\text{SH}_{>0}(L)$ is isomorphic to the linearized Legendrian contact homology group of $\partial^\pm L$ [35; 38]. The Lagrangian symplectic homology group $\text{SH}^=0(L)$ is isomorphic to the singular cohomology group $H^{n-*}(L)$ of $L$. The Lagrangian symplectic homology group of the trivial cobordism $I \times \partial^+ L \subset I \times \partial^+ W$, with $I$ a closed interval in $(0, \infty)$ is isomorphic to the Lagrangian Rabinowitz–Floer homology group of $\partial^+ W$ [59; 11].

The Lagrangian symplectic homology groups obey the same formal properties as their closed counterparts, reminiscent of the Eilenberg–Steenrod axioms: functoriality, homotopy invariance, exact triangle of a pair and excision. Also, the various flavours $\text{SH}_{\bowtie}(L, K)$ fit into tautological exact triangles, which are compatible with the exact triangles of pairs. The proofs of all these properties are word-for-word the same as for Liouville cobordisms, using Lagrangian analogues of our confinement lemmas, Lemmas 2.2, 2.3 and 2.4; see also [39].

**Open–closed theory**  Let $(W, V)$ be a pair of Liouville cobordisms with filling $F$, and $(L, K) \subset (W, V)$ be a pair of Lagrangian cobordisms with filling $F_L$. One can define open–closed symplectic homology groups

$$\text{SH}_{\bowtie}(\langle W, V \rangle, (L, K)), \quad \bowtie \in \{\varnothing, > 0, \geq 0, = 0, \leq 0, < 0\},$$

by simultaneously taking into account closed Hamiltonian orbits in $W$ and Hamiltonian chords with endpoints on $L$, using the same shape of Hamiltonians as in the closed or open setting (see also [39]). These homology groups fit into exact triangles

$$\text{SH}_{\bowtie}(W, V) \rightarrow \text{SH}_{\bowtie}(\langle W, V \rangle, (L, K)) \leftarrow \text{SH}_{\bowtie}(L, K)$$

and can be thought of as the homology groups of the cone of the open–closed map, defined by the count of solutions of a Hamiltonian Floer equation on a disk with one interior negative puncture and one boundary positive puncture. The Eilenberg–Steenrod package holds in this extended setup as well.

**9 Applications**

**9.1 Ubiquity of the exact triangle of a pair**

A certain number of previous computations in the literature can be reinterpreted from a unified point of view and generalized from our perspective.
One of our original motivations for the definition of the symplectic homology groups of a Liouville cobordism was the exact triangle relating symplectic homology and Rabinowitz–Floer homology [29]

\[ \text{RFH}_*(\partial V) \rightarrow \text{SH}_*(V) \rightarrow \text{SH}^{*-1}(V) \rightarrow \text{RFH}_*(\partial V) \]

In view of Poincaré duality \( \text{SH}^{-*}(V) \cong \text{SH}_*(V, \partial V) \) and the isomorphism (50), this is just the exact triangle of the pair \((V, \partial V)\). See Theorem 9.1 for a more detailed discussion of this triangle.

The subcritical and critical handle attaching exact triangles from [24; 13] are special instances of the exact triangle of a pair; see Sections 9.6 and 9.7. Moreover, the surgery exact triangles for linearized contact homology appear as formal consequences of the corresponding triangles for symplectic homology, via the relations between equivariant and nonequivariant symplectic homologies; see Section 9.8.

Let \( L \subset V \) be an exact Lagrangian in a Liouville domain \( V \) satisfying \( \text{SH}_*(L) = 0 \). For example, by a straightforward adaptation of the vanishing results in [27; 53], this is the case if the completion \( \hat{L} \) is displaceable from \( V \) in the completion \( \hat{V} \). Then the tautological sequence yields the isomorphism

\[ \text{SH}^{*-1}_*(L) \cong \text{SH}^{*}_*(L) \cong H^{*-1}_nC(L), \]

which was previously conjectured by Seidel (see [35, Conjecture 1.2]) and proved from a Legendrian contact homology perspective by Dimitroglou Rizell [31, Theorem 2.5]. This isomorphism implies the refinement of Arnold’s chord conjecture given in [36]; see Corollary 9.14. A combination of the tautological sequence with the exact sequence of the pair \((L, \partial L)\) and Poincaré duality yields the \textbf{Poincaré duality long exact sequence for Legendrian contact homology} in [36]

\[ H^{*-1}(\partial L) \rightarrow \text{SH}^{-*}_0(\partial L) \rightarrow \text{SH}^{*-1}_0(\partial L) \rightarrow H^{*}_n(\partial L) \]

as well as its refinement in [35, Corollary 1.3; 31, Corollary 2.6]; see Proposition 9.15.
(4) The results of Chantraine, Dimitroglou Rizell, Ghiggini and Golovko [22; 44] can also be reinterpreted from the perspective of the exact triangle of a pair. As an example, consider the following setup: \( L \) is an exact Lagrangian cobordism, \( \partial^{-}L \) has an exact Lagrangian filling \( F_L \), and we assume that \( F_L \circ L \) is displaceable from the Liouville domain which contains \( F_L \circ L \) in the symplectic completion of the ambient exact symplectic manifold. Then \( \text{SH}_*(F_L \circ L) = 0 \) and \( \text{SH}_*(F_L) = 0 \) (see Theorems 9.11 and 9.13), hence also \( \text{SH}_*(L, \partial^{-}L) = 0 \). The second long exact sequence in [44, Theorem 1.2] is the exact triangle of the pair \((F_L \circ L, F_L)\) for \( \text{SH}^*_{>0} \). The setup considered in [22] is that in which \( L \) is a Lagrangian concordance, so that the transfer map \( \text{SH}^{=0}_*(F_L \circ L) \xrightarrow{\cong} \text{SH}^{=0}_*(F_L) \) is an isomorphism. In view of the commutative diagram given by the compatibility of tautological exact triangles with the exact triangle of the pair \((F_L \circ L, F_L)\)

\[
\begin{array}{ccc}
\text{SH}^{=0}_*(F_L \circ L) & \xrightarrow{\cong} & \text{SH}^{=0}_*(F_L) \\
\downarrow & & \downarrow \\
\text{SH}^{=0}_{*-1}(F_L \circ L) & \xrightarrow{\cong} & \text{SH}^{=0}_{*-1}(F_L)
\end{array}
\]

the vertical arrows being isomorphisms since \( \text{SH}_*(F_L \circ L) \) and \( \text{SH}_*(F_L) \) vanish, we obtain that the top transfer map is an isomorphism. This is the content of the main result of [22] in the case of linearized Legendrian contact homology; see also [44]. The more general bilinearized setup in [22] can be reinterpreted in a similar way.

This circle of ideas should be compared with the results of Biran and Cornea [9], and also with the results of Dimitroglou Rizell and Golovko [32].

### 9.2 Duality results

The following consequence of the long exact sequence of a pair and Poincaré duality is proved in [29]. For convenience, we provide the short proof in our framework.

**Theorem 9.1** (duality sequence [29]) For a Liouville domain \( V \) there is a commuting diagram with exact upper row

\[
\begin{array}{ccc}
\cdots & \xrightarrow{\phi} & \text{SH}^{-*}(V) \\
\downarrow & & \downarrow \\
H_{n+*}(V) & \xrightarrow{\psi} & H^{n-*}(V)
\end{array}
\]

This circle of ideas should be compared with the results of Biran and Cornea [9], and also with the results of Dimitroglou Rizell and Golovko [32].
Here the horizontal maps come from the long exact sequences of the pair \((V, \partial V)\) in view of the Poincaré duality isomorphisms \(\text{SH}_*(V, \partial V) \cong \text{SH}^{-*}(V)\) and \(H_{n-*}(V) \cong H_{n-*}(V, \partial V)\), and the vertical maps are given by the compositions:

\[
\begin{align*}
\text{SH}^{-*}(V) &\to \text{SH}_{\leq 0}^{-*}(V) = \text{SH}_{\leq 0}^{-*}(V) \cong H_{n-*}(V), \\
H_{n-*}(V) &\cong \text{SH}_{\leq 0}^{-*}(V) = \text{SH}_{\leq 0}^{-*}(V) \to \text{SH}_*(V).
\end{align*}
\]

**Proof** Commutativity of the diagram (54) follows from commutativity of the diagram:

\[
\begin{array}{ccc}
\text{SH}^{-*}(V) & \xrightarrow{=} & \text{SH}_*(V, \partial V) \\
\downarrow & & \downarrow \\
\text{SH}_{\leq 0}^{-*}(V) & \xrightarrow{=} & \text{SH}_{\leq 0}^{-*}(V) \\
\downarrow & & \downarrow \\
H_{n-*}(V) & \xrightarrow{=} & H_{n-*}(V, \partial V) \\
\end{array}
\]

Here the left horizontal maps are Poincaré duality isomorphisms and the lower-right square commutes by Proposition 7.19. The commutativity of the upper-right square can be interpreted as follows: by definition of the symplectic homology groups, the composition of the three maps around the upper square is obtained by considering a Hamiltonian vanishing on \(V\) and increasing its slope near \(\partial V\) from large negative to small negative to small positive to large positive, which yields the upper horizontal map.

Here is a computational application of the Poincaré duality result, Theorem 3.4, which will be needed for the discussion of products in Section 10.

**Proposition 9.2** Let \(W\) be a Liouville cobordism with Liouville filling \(F\). Then we have a canonical isomorphism

\[
\text{SH}^{<0}_* (W) \cong \text{SH}^{-*}_{>0} (F).
\]

**Proof** We successively have

\[
\text{SH}^{<0}_* (W) \cong \text{SH}^{<0}_{*-1} (F \cup W, W) \cong \text{SH}^{<0}_{*-1} (F, \partial F) \cong \text{SH}^{-*+1}_{>0} (F).
\]

The first isomorphism follows from the exact triangle of the pair \((F \cup W, W)\) for \(\text{SH}^{<0}_*\) (see Section 7) taking into account that \(\text{SH}^{<0}_* (F \cup W) = 0\) because \(F \cup W\) has empty negative boundary. The second isomorphism is the excision theorem, Theorem 6.8. The third isomorphism is Poincaré duality.

For further duality results we will need the following vanishing result:
Proposition 9.3  Let $V$ be a Liouville domain. Then

$$\text{SH}^\bigcap_{\varnothing}([0, 1] \times \partial V, 0 \times \partial V) = 0.$$  

for $\bigcap \in \{\emptyset, > 0, \geq 0, = 0, \leq 0, < 0\}$. 

Proof  We are computing the symplectic homology group of a cobordism relative to the concave part of the boundary and therefore the relevant Floer complexes do not involve orbits with negative action. Thus,

$$\text{SH}^{(a, b)}_{*}([0, 1] \times \partial V, 0 \times \partial V) = \text{SH}^{(-\varepsilon, b)}_{*}([0, 1] \times \partial V, 0 \times \partial V)$$

for all $a < 0$, $b > 0$ and $\varepsilon > 0$ smaller than the period of a closed Reeb orbit on $\partial V$. In the definition of symplectic homology the inverse limit over $a \to -\infty$ therefore stabilizes and we have $\text{SH}_{*}([0, 1] \times \partial V, 0 \times \partial V) = \lim_{b \to \infty} \text{SH}_{*}^{(-\varepsilon, b)}([0, 1] \times \partial V, 0 \times \partial V)$.

The point now is that $\text{SH}^{(-\varepsilon, b)}_{*}([0, 1] \times \partial V, 0 \times \partial V) = 0$ for all $b > 0$. Indeed, for $b > 0$ not lying in the action spectrum of $\partial V$, this homology group is computed using the Floer complex generated by closed orbits near $[0, 1] \times \partial V$ for a Hamiltonian which vanishes on $[0, 1] \times \partial V$, which has positive slope $b$ near $\{0, 1\} \times \partial V$, and which is constant in $V$ away from $[0, 1] \times \partial V$. But such a Hamiltonian can be deformed to one which has constant slope equal to $b$ all over $[0, 1] \times \partial V$ and for which the corresponding chain complex is zero. See Figure 22, in which the deformed Hamiltonian is drawn with a dashed line. The conclusion follows using the homotopy invariance of the homology under compactly supported deformations.

This proves $\text{SH}^{\geq 0}_{*}([0, 1] \times \partial V, 0 \times \partial V) = 0$. The vanishing of $\text{SH}^{= 0}_{*}([0, 1] \times \partial V, 0 \times \partial V)$ follows from the vanishing of relative singular cohomology, and the vanishing of $\text{SH}^{> 0}_{*}([0, 1] \times \partial V, 0 \times \partial V)$ then follows from the truncation exact triangle. Since there are no other versions to consider, this proves the proposition.  

Figure 22: Symplectic homology relative to the negative boundary for a trivial cobordism
**Theorem 9.4** (Poincaré duality for a trivial cobordism) For every Liouville domain $V$ there exist canonical isomorphisms between the symplectic homology and cohomology groups of the trivial cobordism over $\partial V$,

\[ \text{PD: } \SH^\heartsuit (\partial V) \cong \SH_\heartsuit^{-1}(\partial V) \]

for $\heartsuit \in \{\varnothing, > 0, \geq 0, = 0, \leq 0, < 0\}$.

**Proof** We consider the trivial cobordism $W = I \times \partial V$ and apply Proposition 7.21 to the triple $(W, \partial W, \partial_+ W)$ to obtain the commuting diagram

\[
\begin{array}{cccccc}
SH_\heartsuit^\heartsuit(W, \partial_+ W) & \longrightarrow & SH_\heartsuit^\heartsuit(W, \partial_+ W) & \cong & SH_{\heartsuit-1}(W, \partial W) & \longrightarrow & SH_{\heartsuit-1}(W, \partial_+ W) \\
\downarrow & & \text{exc} & \cong & \text{PD} & \cong & \downarrow \\
0 & \longrightarrow & SH_\heartsuit(W) & \cong & SH_1^{-\heartsuit}(W) & \longrightarrow & 0 \\
\downarrow & & \text{PD} & \cong & \text{exc} & \cong & \downarrow \\
SH_{\heartsuit-1}(W, \partial_-. W) & \longrightarrow & SH_{1-\heartsuit}^{-\heartsuit}(W, \partial W) & \cong & SH_{1-\heartsuit}^{-\heartsuit}(\partial W, \partial_- W) & \longrightarrow & \SH_{\heartsuit}^{-\heartsuit}(W, \partial_- W)
\end{array}
\]

where the first and last row are the long exact sequences of the triples $(W, \partial W, \partial_+ W)$ and $(W, \partial W, \partial_- W)$, respectively, and the vertical arrows are the Poincaré duality and excision isomorphisms. The groups $\SH_{\heartsuit}^\heartsuit(W, \partial_+ W)$ and $\SH_{\heartsuit}^{-\heartsuit}(W, \partial_- W)$ vanish by Proposition 9.3. The middle horizontal map defined by this diagram is the desired Poincaré duality isomorphism from $\SH_{\heartsuit}^\heartsuit(\partial V) = \SH_{\heartsuit}^\heartsuit(W)$ to $\SH_{1-\heartsuit}^{-\heartsuit}(W, \partial_- W)$.

\[ \square \]

**Theorem 9.5** (Poincaré duality and exact triangle of $(V, \partial V)$) For every Liouville domain $V$ and $\heartsuit \in \{\varnothing, > 0, \geq 0, = 0, \leq 0, < 0\}$, there exists a commuting diagram

\[
\begin{array}{cccccc}
\SH_\heartsuit^\heartsuit(V, \partial V) & \longrightarrow & SH_\heartsuit^\heartsuit(V) & \longrightarrow & SH_\heartsuit^\heartsuit(\partial V) & \longrightarrow & SH_{\heartsuit-1}(V, \partial V) \\
\downarrow & \cong & \downarrow & \cong & \downarrow & \cong & \downarrow \\
\SH_{\heartsuit-1}(V) & \longrightarrow & SH_{\heartsuit-1}(V, \partial V) & \longrightarrow & SH_{1-\heartsuit}(\partial V) & \longrightarrow & \SH_{\heartsuit}^{-\heartsuit}(V)
\end{array}
\]

where the rows are the long exact sequences of the pair $(V, \partial V)$ and the vertical arrows are the Poincaré duality isomorphisms from Theorem 9.4 (the third one) and Theorem 3.4 (the other ones). Moreover, the Poincaré duality isomorphisms are compatible with filtration exact sequences.
Proof Denote by $W$ the trivial cobordism given by a collar neighbourhood of the boundary $\partial V$ in $V$. Write $U = \overline{V \setminus W}$, so that $\partial_+ W = \partial V$ and $\partial_- W = \partial U \simeq \partial V$. Consider the following diagram:

$$
\begin{array}{ccccccc}
\text{SH}^*_\partial(V, \partial V) & \longrightarrow & \text{SH}^*_\partial(V) & \longrightarrow & \text{SH}^*_\partial(\partial V) & \longrightarrow & \text{SH}^*_{-1}(V, \partial V) \\
\downarrow \text{PD} \cong & & \downarrow \text{PD} \cong & & \downarrow \text{PD} \cong & & \downarrow \text{PD} \cong \\
\text{SH}^-_{-\partial}(V) & \longrightarrow & \text{SH}^-_{-\partial}(V, \partial V) & \longrightarrow & \text{SH}^-_{-\partial}(V, U \cup \partial V) & \longrightarrow & \text{SH}^1_{-\partial}(V) \\
\downarrow \text{exc} \cong & & \downarrow \text{exc} \cong & & \downarrow \text{exc} \cong & & \\
\text{SH}^-_{-\partial}(U \cup \partial V, \partial V) & \longrightarrow & \text{SH}^-_{-\partial}(V, \partial V) & \longrightarrow & \text{SH}^-_{-\partial}(V, U \cup \partial V) & \longrightarrow & \text{SH}^1_{-\partial}(U \cup \partial V, \partial V) \\
\end{array}
$$

The diagram is commutative. The first three rows with their vertical maps correspond to the commutative diagram in Proposition 7.21 applied to the triple $(V, W, \varnothing)$, so the first and third rows are the long exact sequences of the triples $(V, W, \varnothing) \cong (V, \partial V, \varnothing)$ and $(V, U \cup \partial V, \partial V)$, respectively. The right bottom-most square is commutative because the maps are induced by the inclusion of triples $(W, \partial W, \partial_+ W) \hookrightarrow (V, U \cup \partial V, \partial V)$. The bottom-right triangle is commutative by definition.

The third column vertical downward composition

$$
\text{SH}^*_{-\partial}(V, \partial V) \rightarrow \text{SH}^-_{-\partial}(V, U \cup \partial V) \rightarrow \text{SH}^-_{-\partial}(W, \partial W) \\
\rightarrow \text{SH}^*_{-\partial}(\partial W, \partial_+ W) \cong \text{SH}^-_{-\partial}(W, \partial W) \cong \text{SH}^*_{-\partial}(\partial_+ W) \cong \text{SH}^{-*}_{-\partial}(V)
$$

is the Poincaré duality isomorphism of Theorem 9.4 (by inspection of the diagram in its proof).

The bottom arrow composition

$$
\text{SH}^-_{-\partial}(V, \partial V) \rightarrow \text{SH}^-_{-\partial}(V, U \cup \partial V) \rightarrow \text{SH}^-_{-\partial}(W, \partial W) \\
\rightarrow \text{SH}^*_{-\partial}(\partial W, \partial_+ W) \cong \text{SH}^-_{-\partial}(W, \partial W) \cong \text{SH}^*_{-\partial}(\partial_+ W) \cong \text{SH}^-_{-\partial}(V)
$$

is the connecting homomorphism in the cohomology long exact sequence of the pair $(V, \partial V)$.
Finally, the fourth column vertical upward composition
\[ \text{SH}_1^-(\partial V) \simeq \text{SH}_1^-(\partial W) \rightarrow \text{SH}_1^-(\partial W, \partial_+ W) \rightarrow \text{SH}_1^-(U \cup \partial V, \partial V) \rightarrow \text{SH}_1^-(V) \]
is the cohomology transfer map for the inclusion \( \partial V \hookrightarrow V \).

Remark 9.6 Upon considering the triple \((W, \partial W, \partial_+ W)\) in the proof of Theorem 9.4 and the triple \((V, U \cup \partial V, \partial V)\) in the proof of Theorem 9.5, we formally enter the setup of multilevel cobordisms discussed in Section 2.6. While we have not explicitly provided proofs for the excision theorem and for the existence of the homology long exact sequences of pairs/triples in that setup, the particular situations that we consider in Theorems 9.4 and 9.5 are the simplest possible and the proofs of those results clearly follow from the corresponding theorems for cobordisms with one level. See also the discussion at the end of Section 2.6.

Recall that at action zero symplectic homology specializes to singular cohomology, \( \text{SH}_n^0(V) \cong H^{n-*}(V) \), and similarly for the other versions. Therefore, we obtain:

**Corollary 9.7** The commuting diagram in Theorem 9.5 specializes at action zero to
\[
\begin{array}{ccccccc}
H^{n-*}(V, \partial V) & \rightarrow & H^{n-*}(V) & \rightarrow & H^{n-*}(\partial V) & \rightarrow & H^{n-*+1}(V, \partial V) \\
\text{PD} \downarrow \cong & & \text{PD} \downarrow \cong & & \text{PD} \downarrow \cong & & \text{PD} \downarrow \cong \\
H_{n+*}(V) & \rightarrow & H_{n+*}(V, \partial V) & \rightarrow & H_{n+*+1}(\partial V) & \rightarrow & H_{n+*+1}(V) \\
\end{array}
\]
where the rows are the long exact sequences of the pair \((V, \partial V)\) and the vertical arrows are the Poincaré duality isomorphisms for the closed manifold \( \partial V \) (the third one) and the manifold with boundary \( V \) (the other ones).

We conclude this subsection with an example illustrating that full symplectic homology and cohomology do not obey any kind of algebraic duality for general Liouville cobordisms.

**Example 9.8** Let \( V \) be the canonical Liouville filling of a Brieskorn manifold
\[
\left\{ z \in \mathbb{C}^{n+1} \left| \sum_{j=0}^{n} z^{a_j} = 0, |z| = 1 \right. \right\}
\]
with \( n \geq 3 \) and integers \( a_j \geq 2 \) satisfying \( \sum_{j=0}^{n} 1/a_j = 1 \). P Uebele (private communication, 2015) has shown that with \( \mathbb{Z}_2 \)-coefficients its symplectic homology in

*Algebraic & Geometric Topology, Volume 18 (2018)*
degrees \( n \) and \( 1 - n \) is an infinite direct sum

\[
SH_k(V; \mathbb{Z}_2) \cong \bigoplus_{\mathbb{N}} \mathbb{Z}_2 \quad \text{for } k = n \text{ and } k = 1 - n.
\]

By algebraic duality, it follows that its symplectic cohomology in these degrees is an infinite direct product

\[
SH^k(V; \mathbb{Z}_2) \cong SH_k(V; \mathbb{Z}_2)^\vee \cong \prod_{\mathbb{N}} \mathbb{Z}_2 \quad \text{for } k = n \text{ and } k = 1 - n.
\]

In view of the exact sequence (54) with the map \( \phi \) of finite rank, \( SH_k(\partial V; \mathbb{Z}_2) \) agrees with \( SH_k(V) \oplus SH^{1-k}(V) \) up to an error of finite dimension, hence

\[
SH_k(\partial V; \mathbb{Z}_2) \cong \bigoplus_{\mathbb{N}} \mathbb{Z}_2 \oplus \prod_{\mathbb{N}} \mathbb{Z}_2 \quad \text{for } k = n \text{ and } k = 1 - n.
\]

By Theorem 9.4, the symplectic cohomology groups in these degrees are the same:

\[
SH^k(\partial V; \mathbb{Z}_2) \cong \bigoplus_{\mathbb{N}} \mathbb{Z}_2 \oplus \prod_{\mathbb{N}} \mathbb{Z}_2 \quad \text{for } k = n \text{ and } k = 1 - n.
\]

Since the dual of the infinite direct product is not the infinite direct sum, this shows that for \( k = n, 1 - n \) neither \( SH^k(\partial V; \mathbb{Z}_2) = SH_k(\partial V; \mathbb{Z}_2)^\vee \) nor \( SH_k(\partial V; \mathbb{Z}_2) = SH^k(\partial V; \mathbb{Z}_2)^\vee \).

### 9.3 Vanishing and finite-dimensionality

In this subsection we give some conditions under which symplectic homology groups are zero or finite-dimensional. We begin with a simple consequence of the duality sequence (54).

**Corollary 9.9** For a Liouville domain \( V \) the following hold using field coefficients:

(a) If one among \( SH_n(V), SH^{-n}(V), SH_n(\partial V) \) or \( SH_n(V, \partial V) \) vanishes, then all of \( SH_*(V), SH^*(V), SH_*(\partial V) \) and \( SH_*(V, \partial V) \) vanish.

(b) If one among \( SH_*(V), SH^*(V), SH_*(\partial V) \) or \( SH_*(V, \partial V) \) is finite-dimensional, then so are the other three.

**Proof** Part (a) is [64, Theorem 13.3], except for the statement involving \( SH_*(V, \partial V) \), which is a consequence of Poincaré duality. For part (b), in view of the Poincaré duality \( SH_*(V, \partial V) \cong SH^{*-}(V) \) we only need to deal with \( SH_*(V), SH^*(V) \) and
Since $\text{SH}^k(V) \cong \text{Hom}(\text{SH}_k(V), \mathbb{K})$ in each degree, $\text{SH}^*(V)$ is finite-dimensional if and only if $\text{SH}_*(V)$ is. If both are finite-dimensional, then two out of three terms in the exact sequence (54) are finite-dimensional, so the third term $\text{SH}_*(\partial V)$ is finite-dimensional as well. Conversely, suppose that $\dim \text{SH}(\partial V) < \infty$. Then the map $\psi$ in (54) has finite rank, as does the map $\phi$ (because it factors through singular homology), and thus $\dim \text{SH}_*(V) < \infty$. Alternatively, one could argue by contradiction: if $\dim \text{SH}(\partial V) < \infty$ and $\text{SH}_*(V)$, $\text{SH}^*(V)$ were infinite-dimensional, then the long exact sequence (54) would imply $\dim \text{SH}_*(V) = \dim \text{SH}^*(V)$, which is impossible by Remark 9.10 below.

**Remark 9.10**  A $\mathbb{K}$–vector space is isomorphic to its dual space if and only if it is finite-dimensional (see [60] for a nice proof—we thank I Blechschmidt for pointing this out). Hence, for a pair of Liouville cobordisms with filling $(W, V)$ and using field coefficients we obtain that $\text{SH}^k(W, V)$ is isomorphic to $\text{SH}^k(W, V)$ for $\bigodot \in \{<0, \leq 0, = 0, \geq 0, > 0\}$ if and only if both vector spaces are finite-dimensional.

We say that a subset of a symplectic manifold is *displaceable* if it can be displaced from itself by a compactly supported Hamiltonian isotopy. It has been known for a while that displaceability implies vanishing of Rabinowitz–Floer homology [27] and symplectic homology [53] of a Liouville domain. In the context of this paper, these appear as special cases of the following general vanishing result, whose proof is a straightforward adaptation of the ones in [27; 53].

**Theorem 9.11**  (displaceability implies vanishing)  
(a) Let $(W, V)$ be a Liouville cobordism pair with filling $F$ such that $V$ is displaceable in the completion of $F \circ W$. Then $\text{SH}_*(V) = 0$.

(b) Let $L \subset V$ be an exact Lagrangian in a Liouville domain $V$ whose completion $\hat{L}$ is displaceable from $V$ in the completion $\hat{V}$. Then $\text{SH}_*(L) = 0$. 

For example, the displaceability hypothesis in (a) is always satisfied if the completion of $F \circ W$ is a subcritical Stein manifold, or more generally the product of a Liouville manifold with $\mathbb{C}$.

**Remarks 9.12**  
(i) If in Theorem 9.11(a) the cobordism $V$ as well as its filling $E = F \cup W^{\text{bottom}}$ are connected, then displaceability of $V$ implies displaceability of $E \cup V$ and the vanishing of $\text{SH}_*(V)$ follows from the vanishing of symplectic homology of the Liouville domains $E$ and $E \cup V$. 

Algebraic & Geometric Topology, Volume 18 (2018)
(ii) In the situation of Theorem 9.11(a), displaceability of \( V \) implies that of \( \partial V \), so we also have \( SH_\ast(\partial V) = SH_\ast(\partial V) = 0 \) and (via exact sequences of triples) \( SH_\ast(V, \partial V) = SH_\ast(V, \partial V) = 0 \).

Another condition that ensures the vanishing of \( SH_\ast(V) \) is the vanishing of \( SH_\ast(W) \) for a pair \((W, V)\). This was observed for Liouville domains by Ritter [64] as a consequence of the product structure: vanishing of \( SH_\ast(W) \) implies that its unit \( 1_W \) vanishes, hence so does its image \( 1_V \) under the transfer map \( SH_\ast(W) \rightarrow SH_\ast(V) \), which implies \( SH_\ast(V) = 0 \). In view of Theorem 10.2, the same argument proves:

**Theorem 9.13** (vanishing is inherited) *Let \((W, V)\) be a Liouville cobordism pair. Then \( SH_\ast(W) = 0 \) implies \( SH_\ast(V) = 0 \).* \( \square \)

Again, the hypothesis \( SH_\ast(W) = 0 \) is satisfied if the completion of \( F \circ W \) is a subcritical Stein manifold, or more generally the product of a Liouville manifold with \( \mathbb{C} \). However, there exist Liouville domains \( W \) that are not of this type and still have vanishing symplectic homology, eg flexible Stein domains [25] as well as certain nonflexible Stein domains [58; 2; 61; 63]. Conversely, there exist many examples of Liouville pairs \((W, V)\) with \( V \) displaceable and \( SH_\ast(W) \neq 0 \). So neither of the two vanishing theorems, Theorems 9.11 and 9.13, implies the other.

### 9.4 Consequences of vanishing of symplectic homology

Suppose that \( V \) is a Liouville domain with \( SH_\ast(V) = 0 \). Then the tautological sequence yields

\[
SH_\ast > 0(V) \cong SH_\ast \leq 0(V) \cong H^{n-*+1}(V) \neq 0.
\]

Similarly, if \( L \subset V \) is an exact Lagrangian with \( SH_\ast(L) = 0 \), then

\[
SH_\ast > 0(L) \cong SH_\ast \leq 0(L) \cong H^{n-*+1}(L) \neq 0.
\]

This has the following dynamical consequences [68; 64]:

**Corollary 9.14**

(a) *Let \( V \) be a Liouville domain with \( SH_\ast(V) = 0 \) (eg this is the case if \( \partial V \) is displaceable in \( \hat{V} \)). Then there exists at least one closed Reeb orbit.*

(b) *Let \( L \) be an exact Lagrangian \( L \subset V \) with \( SH_\ast(L) = 0 \) (eg this is the case if \( \hat{L} \) is displaceable from \( V \) in \( \hat{V} \)). Then there exists at least one Reeb chord with boundary on \( \partial L \). If all the Reeb chords are nondegenerate, their number is bounded from below by \( \text{rk} H_\ast(L) \geq \frac{1}{2} \text{rk} H_\ast(\partial L) \).*
Proof The assertion in (a) follows immediately from (57) because $\text{SH}_{*}^{>0}(V)$ is generated by closed Reeb orbits. Similarly, the first assertion in (b) follows from (58).

The second assertion in (b) follows from (58) because, if all Reeb chords are non-degenerate, their number is bounded from below by $\text{rk} \text{SH}_{*}^{>0}(L) = \text{rk} H^{*}(L)$. The estimate $\text{rk} H_{*}(L) \geq \frac{1}{2} \text{rk} H_{*}(\partial L)$ follows readily from the long exact sequence of the pair $(L, \partial L)$ in singular homology and Poincaré duality.

Vanishing of symplectic homology also implies the following refinement of the duality sequence (54).

Proposition 9.15  (duality sequence for positive symplectic homology)  (a) Let $V$ be a Liouville domain with $\text{SH}_{*}(V) = 0$ (eg this is the case if $\partial V$ is displaceable in $\hat{V}$). Then there exists a commuting diagram with exact rows

\[
\begin{array}{ccccccc}
H^{n-*}(\partial V) & \xrightarrow{\sigma} & \text{SH}_{>0}^{2-*}(\partial V) & \xrightarrow{\tau} & \text{SH}_{*}^{0}(\partial V) & \xrightarrow{\rho} & H^{n-*+1}(\partial V) \\
\Downarrow & \simeq & \Downarrow & \simeq & \Downarrow & \simeq & \Downarrow \\
H^{n-*}(\partial V) & \xrightarrow{\sigma_{0}} & H^{n-*+1}(V, \partial V) & \xrightarrow{\tau_{0}} & H^{n-*+1}(V) & \xrightarrow{\rho_{0}} & H^{n-*+1}(\partial V) \\
\end{array}
\]

(b) Let $L \subset V$ be an exact Lagrangian in a Liouville domain with $\text{SH}_{*}(L) = 0$ (eg this is the case if $\hat{L}$ is displaceable from $V$ in $\hat{V}$). Then there exists a commuting diagram with exact rows

\[
\begin{array}{ccccccc}
H^{n-*}(\partial L) & \xrightarrow{\sigma} & \text{SH}_{>0}^{2-*}(\partial L) & \xrightarrow{\tau} & \text{SH}_{*}^{0}(\partial L) & \xrightarrow{\rho} & H^{n-*+1}(\partial L) \\
\Downarrow & \simeq & \Downarrow & \simeq & \Downarrow & \simeq & \Downarrow \\
H^{n-*}(\partial L) & \xrightarrow{\sigma_{0}} & H^{n-*+1}(L, \partial L) & \xrightarrow{\tau_{0}} & H^{n-*+1}(L) & \xrightarrow{\rho_{0}} & H^{n-*+1}(\partial L) \\
\end{array}
\]

Proof For part (a) consider the commuting diagram, whose columns are the exact sequences of the pair $(V, \partial V)$ and whose rows are the tautological sequences,

\[
\begin{array}{ccccccc}
\text{SH}_{*}^{=0}(V) & \longrightarrow & \text{SH}_{*}^{=0}(V) & \longrightarrow & \text{SH}_{*}^{=0}(V) & \longrightarrow & \text{SH}_{*}^{=0}(V) \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
\text{SH}_{*}^{=0}(\partial V) & \longrightarrow & \text{SH}_{*}^{=0}(\partial V) & \longrightarrow & \text{SH}_{*}^{=0}(\partial V) & \longrightarrow & \text{SH}_{*}^{=0}(\partial V) \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
\text{SH}_{*}^{=0}(V, \partial V) & \longrightarrow & \text{SH}_{*}^{=0}(V, \partial V) & \longrightarrow & \text{SH}_{*}^{=0}(V, \partial V) & \longrightarrow & \text{SH}_{*}^{=0}(V, \partial V) \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
\text{SH}_{*}^{=0}(V) \\
\end{array}
\]

\[\text{Algebraic \\& Geometric Topology, Volume 18 (2018)}\]
We replace the groups $\text{SH}_*^{=0}$ by the corresponding singular cohomology groups, and insert $\text{SH}_*^{=0}(V) = \text{SH}_*(V) = 0$ (which holds by hypothesis) and $\text{SH}_*^{=0}(V, \partial V) = 0$ (which always holds). Moreover, we replace $\text{SH}_*^{\geq 0}(V, \partial V)$ by the isomorphic group  
$\text{SH}_*^{\leq 0-2}(V, \partial V) \cong \text{SH}_*^{\geq 0-2}(V) = \text{SH}_*^{\geq 0-2}(\partial V)$, where the first isomorphism comes from the tautological sequence in view of $\text{SH}_*(V, \partial V) = 0$ (which follows from the hypothesis $\text{SH}_*(V) = 0$ via Corollary 9.9) and the second one is Poincaré duality. Then the diagram becomes

$$
\begin{array}{cccccc}
H^{n-*}(V) & \rightarrow & 0 & \rightarrow & \text{SH}_*^{>0}(V) & \cong \rightarrow & H^{n-*+1}(V) \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
H^{n-*}(\partial V) & \rightarrow & \text{SH}_*^{\leq 0}(\partial V) & \rightarrow & \text{SH}_*^{>0}(\partial V) & \cong \rightarrow & H^{n-*+1}(\partial V) \\
\downarrow \sigma_0 & & \downarrow \sigma & & \downarrow \tau & & \downarrow \\
H^{n-*+1}(V, \partial V) & \cong \rightarrow & \text{SH}_*^{\leq 0}(\partial V) & \rightarrow & 0 & \rightarrow & H^{n-*+2}(V, \partial V) \\
\downarrow \tau_0 & & \downarrow & & \downarrow & & \\
H^{n-*+1}(V) & & & & & & \\
\end{array}
$$

From this we read off the commuting diagram in Proposition 9.15(a). Part (b) is proved analogously.

Corollary 9.14(b) and the upper long exact sequence in Proposition 9.15(b) were proved in [36] in the context of contact manifolds of the form $P \times \mathbb{R}$ (compare also with [64]). The commuting diagram in Proposition 9.15(b) appears in [35, Corollary 1.3] and [31, Corollary 2.6].

### 9.5 Invariants of contact manifolds

We describe in this subsection how to obtain invariants of contact manifolds from the various symplectic homology groups that we defined in this paper. Recall that a contact manifold with chosen contact form $(M^{2n-1}, \alpha)$ is called hypertight if it has no contractible closed Reeb orbits. Following [67] we call $(M, \alpha)$ index-positive if either

(i) $\xi = \ker \alpha$ satisfies $c_1(\xi)|_{\pi_2(M)} = 0$ and the Conley–Zehnder index of every contractible closed Reeb orbit $\gamma$ in $M$ satisfies $\text{CZ}(\gamma) + n - 3 > 1$, or

(ii) the space $(M, \alpha)$ admits a Liouville filling $F$ with $c_1(F)|_{\pi_2(F)} = 0$ such that $\text{CZ}(\gamma) + n - 3 > 0$ for every closed Reeb orbit $\gamma$ in $M$ which is contractible in $F$. 

*Algebraic & Geometric Topology, Volume 18 (2018)*
We will call a (cooriented, as always) contact manifold \((M, \xi)\) hypertight or index-positive if it admits a defining contact form with this property.

**Remark 9.16** Condition (ii) is in particular satisfied if \((M, \alpha)\) admits a subcritical Stein filling \(F\) of dimension \(2n \geq 4\) with \(c_1(F)|_{\pi_2(F)} = 0\). Indeed, \(M = \partial F\) then admits a contact form such that all Conley–Zehnder indices of closed Reeb orbits which are contractible in \(\partial F\) are \(> 1\) \[70\], and therefore \(> 3 - n\) provided that \(n \geq 2\). Since \(F\) is Stein subcritical, the map \(\pi_1(\partial F) \to \pi_1(F)\) induced by the inclusion is injective. Indeed, the subcritical skeleton has codimension \(\geq n + 1 \geq 3\) and a generic homotopy of paths will avoid it, so that it can afterwards be pushed by the Liouville flow to the boundary. Thus any loop in \(\partial F\) which is contractible in \(F\) is also contractible in \(\partial F\) and the condition on the indices therefore holds for all loops which are contractible in \(F\).

The following result follows in the index-positive case (ii) from the arguments of \[15\], as remarked in \[29; 18\]. For the hypertight case or the index-positive case (i) see \[67; 18\]. For another instance in the \(S^1\)-equivariant case see \[47\]. We sketch below a short unified proof.

**Proposition 9.17** Given a Liouville cobordism \(W\) whose negative boundary \(\partial^- W\) is hypertight or index-positive, the symplectic homology groups

\[
\text{SH}^\emptyset_\ast(W) \quad \text{and} \quad \text{SH}^\diamondsuit^1_\ast(W),
\]

are defined, independent of the contact form \(\alpha\) on \(\partial^- W\) in the given class, and independent of the filling in case (ii).

**Proof** We will discuss the case \(\text{SH}^\emptyset_\ast(W)\), the equivariant case being analogous.

In case (ii) we define \(\text{SH}^\emptyset_\ast(W)\) as the usual symplectic homology group with respect to a filling \(F\) in the given class. To show independence of the filling, fix a finite action window \((a, b)\) and consider a Hamiltonian \(H\) on the completion \(\hat{W}_F\) as in Figure 8. We perform neck-stretching as described in the proof of Lemma 2.4, inserting cylindrical pieces \([-R_k, R_k] \times M\) with \(R_k \to \infty\), at the hypersurface \(M := \{\delta\} \times \partial^- W\) where \(H \equiv c\) for a constant \(c > -a\). We claim that for \(k\) sufficiently large, Floer cylinders appearing in the differential between 1-periodic orbits \(x_{\pm}\) of \(H\) of types \(I^-\), \(I^0\) and \(I^+\) with action in \((a, b)\) do not enter the region \(F \setminus [\delta, 1] \times \partial F\). Then it follows that all these Floer cylinders can be viewed as lying in the 2-sided completion \(\hat{W}\), so
$\text{FH}^{(a,b)}_\ast(H)$ is independent of the filling. By the same claim applied to continuation morphisms, we deduce independence of the filling for the filtered symplectic homology groups $\text{SH}^{(a,b)}_\ast(W)$ and the groups $\text{SH}^{\triangledown}_\ast(W)$.

To prove the claim, we argue by contradiction and suppose that for all $k$ there exist Floer cylinders $u_k$ as above entering $F \setminus [\delta, 1] \times \partial F$. In the limit $k \to \infty$ they converge in the SFT sense [14; 30] to a broken holomorphic curve $C$ with punctures asymptotic to closed Reeb orbits on $M$. Here it is understood that the almost complex structure is chosen to be cylindrical and time-independent in the neck $[-R_k, R_k] \times M$ that is inserted near the hypersurface $M = \{\delta\} \times \partial^{-} W$. We first observe that $C$ can have only one component in $\hat{W}$. This follows by the argument in the proof of Lemma 2.4: otherwise, there would exist for large $k$ a separating loop $\delta_k$ on the domain $\mathbb{R} \times S^1$, winding around in the negative $S^1$–direction, such that $u_k(\delta_k)$ is $C^1$–close to a (positively parametrized) closed Reeb orbit $\gamma$ on $M$, and the resulting estimate $A_H(x_-) \leq -c < a$ would contradict the condition $A_H(x_-) > a$. It follows that $C$ consists of a Floer cylinder $C_+$ in $\hat{W}$ with $p \geq 1$ negative punctures asymptotic to closed Reeb orbits $\gamma_i$ and holomorphic planes $C_i$ in $\hat{F}$ asymptotic to $\gamma_i$. In particular, the orbits $\gamma_i$ are contractible, and this already leads to a contradiction in the hypertight case. To reach a contradiction in the index-positive case, we remark that the component $C_+$ belongs to a moduli space which is transversely cut out. Indeed, the equation is perturbed by an $S^1$–dependent Hamiltonian term near the punctures where $C_+$ converges to Hamiltonian periodic orbits, and the almost complex structure is chosen to be generic and time-dependent in the region where all the Hamiltonian orbits are located, hence transversality follows as in Hamiltonian Floer theory; see eg [65]. If nonempty, the moduli space to which $C_+$ belongs has dimension at least 1 (due to $\mathbb{R}$–translations in the domain), so the Fredholm index of $C_+$ satisfies $\text{ind}(C_+) \geq 1$. On the other hand, the index of $C_+$ is given by

$$\text{ind}(C_+) = \text{CZ}(x_+) - \text{CZ}(x_-) - \sum_{i=1}^{p} (\text{CZ}(\gamma_i) + n - 3),$$

which in view of $\text{CZ}(x_+) - \text{CZ}(x_-) = 1$ for contributions to the Floer differential yields

$$\sum_{i=1}^{p} (\text{CZ}(\gamma_i) + n - 3) \leq 0.$$

Now the assumption of index-positivity and the fact that the orbits $\gamma_i$ are contractible implies $\text{CZ}(\gamma_i) + n - 3 > 0$. This contradicts the fact that $p \geq 1$, and proves case (ii).
The proof in case (i) is very similar. We again consider \((a, b)\) and \(H\) as above, where \(H\) is now defined on the 2–sided completion \(\hat{W}\) rather than \(\hat{W}_F\). We define the Floer differential for \(H\) by counting Floer cylinders between orbits \(x_\pm\) in \(\hat{W}\). This is well-defined because SFT-type breaking of Floer cylinders at the negative end of \(\hat{W}\) is ruled out by exactly the same argument as in case (ii). In contrast to case (ii), where this was automatic, we now must also show that the Floer differential squares to zero. For this, we must rule out SFT-type breaking of Floer cylinders connecting orbits \(x_\pm\) of index difference 2. If such breaking occurs, the argument in case (ii) directly leads to a contradiction in the hypertight case, while in the index-positive case it leads to \(p \geq 1\) contractible orbits \(\gamma_i\) satisfying

\[
\sum_{i=1}^{p} (\text{CZ}(\gamma_i) + n - 3) \leq 1.
\]

Under the stronger hypothesis \(\text{CZ}(\gamma_i) + n - 3 > 1\) this is again a contradiction and case (i) is proved. \(\square\)

This proposition leads to the definition of homological invariants of hypertight or index-positive contact manifolds,

\[
\text{SH}_{*}^{[S^1,\varnothing]}(M, \xi) = \text{SH}_{*}^{[S^1,\varnothing]}(I \times M), \quad \varnothing \in \{\varnothing, > 0, \geq 0, = 0, \leq 0, < 0\},
\]

where \(I = [0, 1]\) and \(I \times M\) is the trivial Liouville cobordism. Here the notation \(\text{SH}_{*}^{[S^1,\varnothing]}\) means that the symbol \(S^1\) is optional.

**Example 9.18** In view of [29], the group \(\text{SH}_{*}(M, \xi)\) can be interpreted as the Rabinowitz–Floer homology group of \((M, \xi)\). A construction of Rabinowitz–Floer homology for hypertight contact manifolds has recently been carried out in [6].

These contact invariants satisfy various functoriality relations, as dictated by our functoriality relations for Liouville cobordisms. The general picture is the following: Given a Liouville cobordism \(W\) whose negative boundary is hypertight or index-positive, we have maps

\[
\text{SH}_{*}^{[S^1,\varnothing]}(\partial^{-}W) \leftarrow \text{SH}_{*}^{[S^1,\varnothing]}(W) \rightarrow \text{SH}_{*}^{[S^1,\varnothing]}(\partial^{+}W)
\]

determined by the embedding of trivial cobordisms

\[
I \times \partial^{-}W \subset W \supset I \times \partial^{+}W.
\]
Since $I \times \partial^- W$ and $W$ share the same negative boundary, we have an isomorphism

$$\text{SH}^{[S^1,] < 0}_{\ast}(\partial^- W) \cong \text{SH}^{[S^1,] < 0}_{\ast}(W),$$

and since $W$ and $I \times \partial^+ W$ share the same positive boundary we have an isomorphism

$$\text{SH}^{[S^1,] > 0}_{\ast}(W) \cong \text{SH}^{[S^1,] > 0}_{\ast}(\partial^+ W).$$

In particular we obtain maps

$$\text{SH}^{[S^1,] > 0}_{\ast}(\partial^- W) \leftarrow \text{SH}^{[S^1,] > 0}_{\ast}(\partial^+ W) \quad \text{and} \quad \text{SH}^{[S^1,] < 0}_{\ast}(\partial^- W) \rightarrow \text{SH}^{[S^1,] < 0}_{\ast}(\partial^+ W).$$

In the equivariant case and under slightly different assumptions the first of these two maps was previously constructed by Jean Gutt [47]. Such direct maps do not exist for the other versions $\otimes \in \{\emptyset, \geq 0, = 0, \leq 0\}$. In general the cobordism $W$ has to be interpreted as providing a correspondence, and this holds in particular for the case of Rabinowitz–Floer homology.

**Invariants of Legendrian submanifolds** Let $(M^{2n-1}, \alpha)$ be a manifold with chosen contact form and $\Lambda^{n-1} \subset M$ a Legendrian submanifold. Extending the earlier definitions to the open case, we call $\Lambda$ hypertight if $(M, \alpha)$ is hypertight and $\Lambda$ has no contractible Reeb chords. We call $\Lambda$ index-positive if $(M, \alpha)$ is index-positive and in addition:

(i) In case (i), the Maslov class of $\Lambda$ vanishes on $\pi_2(M, \Lambda)$ and every Reeb chord $c$ that is trivial in $\pi_1(M, \Lambda)$ satisfies $\text{CZ}(c) > 1$.

(ii) In case (ii), $\Lambda$ admits an exact Lagrangian filling $L \subset F$ in the filling $F$ whose Maslov class vanishes on $\pi_2(F, L)$ such that $\text{CZ}(c) > 0$ for every Reeb chord $c$ for $\Lambda$ that is trivial in $\pi_1(F, L)$.

We call a Legendrian submanifold in a contact manifold $(M, \xi)$ hypertight or index-positive if it admits a defining contact form with this property.

The arguments given in the closed case adapt in a straightforward way in order to define invariants of hypertight or index-positive Legendrian submanifolds by

$$\text{SH}^{\otimes}_{\ast}(\Lambda) = \text{SH}^{\otimes}_{\ast}(I \times \Lambda), \quad \otimes \in \{\emptyset, \geq 0, = 0, \leq 0, < 0\}.$$

**9.6 Subcritical handle attaching**

In this subsection we compute the symplectic homology groups corresponding to a subcritical handle in the sense of [24], with coefficients in a field $\mathbb{K}$. 

*Algebraic & Geometric Topology, Volume 18 (2018)*
Proposition 9.19  Let $W^{2n}$ be a filled Liouville cobordism corresponding to a subcritical handle of index $k < n$. Then

$$SH_{\ast}(W, \partial^{-} W) = 0, \quad SH_{\ast}(W, \partial^{+} W) = 0,$$

$$SH^{0}_{\ast}(W, \partial^{-} W) \cong SH^{-0}_{\ast}(W, \partial^{+} W) = \begin{cases} \mathbb{K} & \text{if } \ast = n - k, \\ 0 & \text{otherwise}, \end{cases}$$

and the restriction maps induce isomorphisms

$$SH_{\ast}((\partial^{-} W) \leftarrow SH_{\ast}(W) \rightarrow SH_{\ast}(\partial^{+} W)).$$

Proof  The vanishing of $SH_{\ast}(W, \partial^{-} W)$ is proved in [24] with arbitrary coefficients as a consequence of the following fact: for each degree $i$ there exists $b_i > 0$ such that $SH^{(a, b)}_{i}(W, \partial^{-} W) = 0$ for any $a < 0$ and $b \geq b_i$. Since $SH_{\ast}(W, \partial^{-} W) = SH^{0}_{\ast}(W, \partial^{-} W)$, we can apply the algebraic duality result, Proposition 3.5, to obtain $SH^{\ast}(W, \partial^{-} W) = SH^{0}_{\ast}(W, \partial^{-} W) = 0$, which implies, by Poincaré duality, $SH_{-\ast}(W, \partial^{+} W) = 0$.

Since $H^{\ast}(W, \partial^{-} W)$ equals $\mathbb{K}$ in degree $k$ and vanishes in all the other degrees, we obtain

$$SH^{\ast=0}_{\ast}(W, \partial^{-} W) \cong H^{n-\ast}(W, \partial^{-} W) = \begin{cases} \mathbb{K} & \text{if } \ast = n - k, \\ 0 & \text{otherwise}. \end{cases}$$

The remaining two isomorphisms follow from the long exact sequences

$$0 = SH_{\ast}(W, \partial^{-} W) \rightarrow SH_{\ast}(W) \rightarrow SH_{\ast}(\partial^{-} W) \rightarrow SH_{\ast-1}(W, \partial^{-} W) = 0,$$

$$0 = SH_{\ast}(W, \partial^{+} W) \rightarrow SH_{\ast}(W) \rightarrow SH_{\ast}(\partial^{+} W) \rightarrow SH_{\ast-1}(W, \partial^{+} W) = 0. \quad \Box$$

Remarks 9.20  (a) From Proposition 9.19 and the tautological sequence we can compute the remaining relevant symplectic homology groups of the pair $(W, \partial_{\pm} W)$, namely

$$SH^{\ast \geq 0}_{\ast}(W, \partial^{-} W) \cong SH^{\ast \leq 0}_{\ast}(W, \partial^{+} W) = \begin{cases} \mathbb{K} & \text{if } \ast = n - k + 1, \\ 0 & \text{otherwise}. \end{cases}$$

Note that the symplectic homology groups relative to one boundary component only depend on the index $k$, whereas the group $SH_{\ast}(W)$ depends on the whole hypersurface $\partial^{-} W$ and its filling.

(b) In view of (50), the last statement in Proposition 9.19 gives in particular the isomorphism of Rabinowitz Floer homology groups

$$RFH(\partial^{+} W) \cong RFH(\partial^{-} W).$$
Suppose that \((W, V, U)\) is a Liouville cobordism triple such that \(W \setminus V\) is sub-critical. Then Proposition 9.19 implies \(\text{SH}_*(W, V) = 0\), which together with the exact sequence of the triple (Proposition 7.16) yields the isomorphism

\[
\text{SH}_*(W, U) \cong \text{SH}_*(V, U).
\]

In particular, for \(U = \emptyset\) we recover by induction the vanishing of symplectic homology for subcritical Stein domains.

The computation of Proposition 9.19 is valid more generally with coefficients in an abelian group, but the proof uses filtered symplectic homology and a more general universal coefficients theorem.

Together with the exact triangle of a pair, these computations provide a complete understanding of the behaviour of all the flavours of nonequivariant symplectic homology groups under subcritical handle attachment, as a consequence of the exact triangle of the pair \((V \circ W, V)\), where \(V\) is a Liouville domain. The equivariant case is discussed in Section 9.8.

### 9.7 Critical handle attaching

Recall that we use coefficients in a field \(\mathbb{K}\). In the previous section we saw that the key computation was that of \(\text{SH}_*(W, \partial^- W)\), and the key exact triangle was the exact triangle of the pair \((V', V)\), where \(V\) is the filling of \(\partial^- W\) and \(V' = V \circ W\) is the Liouville domain obtained after attaching the handle. These same objects form the relevant structure in the case of a critical handle attachment.

Let \(V\) be a Liouville domain, let \(\Lambda = \Lambda_1 \sqcup \cdots \sqcup \Lambda_I\) be a collection of disjoint Legendrian spheres in \(\partial V\), denote by \(W\) the cobordism obtained by attaching \(l\) critical handles (of index \(n\)) along these spheres, and let \(V' = V \circ W\). Bourgeois, Ekholm and Eliashberg [13] assert the existence of surgery exact triangles

\[
\begin{array}{ccc}
L\mathbb{H}^0(\Lambda)_* & \rightarrow & \text{SH}_*(V') \\
[-1] & & \text{SH}_*(V) \\
\downarrow & & \downarrow \\
L\mathbb{H}^{0+}(\Lambda)_* & \rightarrow & \text{SH}^{>0}_*(V') \\
[-1] & & \text{SH}^{>0}_*(V)
\end{array}
\]

Since at the time of writing this article the proof of this result is not yet completed, we formulate its consequences below as conjectures.
in which $LH^* Ho(\Lambda)$ and $LH^{Ho+}(\Lambda)_*$ are homology groups of Legendrian contact homology flavour; see also [40, Section 2.8; 37]. More precisely, $LH^{Ho+}(\Lambda)_*$ is defined as the homology of a complex $LH^{Ho+}(\Lambda)_*$ whose generators are words in Reeb chords on $\partial V$ with endpoints on $\Lambda$, and whose differential counts certain pseudoholomorphic curves in the symplectization of $\partial V$ with boundary on the conical Lagrangian $SA$ determined by $\Lambda$, with a certain number of interior and boundary punctures at which rigid pseudoholomorphic planes in $\hat{V}$ or rigid pseudoholomorphic half-planes in $\hat{V}$ with boundary on $SA$ are attached (following the terminology of [13], we call such curves anchored in $V$). The homology group $LH^* Ho(\Lambda)$ is defined as the cone of a map $LC^{Ho+}(\Lambda)_* \to C^{n-*+1}$, where $C^{n-*+1}$ is the cohomological Morse complex for the pair $(W, \partial^- W)$, which has rank $l$ in degree $n-*+1 = n$ and vanishes otherwise, and with zero differential. This map counts curves of the type taken into account in $LH^{Ho+}(\Lambda)_*$, rigidified by imposing an intersection with an unstable manifold of a critical point in $W$. The exact sequence of the cone of a map reads in this case

\begin{equation}
H^{n-*}(W, \partial^- W) \xrightarrow{[-1]} LH^* Ho(\Lambda)_* \xrightarrow{} \end{equation}

The surgery exact triangles of Bourgeois, Ekholm and Eliashberg can be reinterpreted in our language as follows:

**Conjecture 9.21** Let $W$ be a filled Liouville cobordism corresponding to attaching $l \geq 1$ critical handles of index $k = n$ along a collection $\Lambda$ of disjoint Legendrian spheres. With field coefficients we have isomorphisms

\[ SH^* >0(W, \partial^- W) \cong LH^{Ho+}(\Lambda)_*, \quad SH_*(W, \partial^- W) \cong LH^{Ho}(\Lambda)_* \]

such that the following hold:

(i) The tautological exact triangle involving $SH^* >0, SH_*$ and $SH^* >0$ for the pair $(W, \partial^- W)$ is isomorphic to (60).

(ii) The exact triangles (59) are isomorphic to the exact triangles of the pair $(V', V)$ for $SH_*$ and $SH^* >0$, respectively.

Let us explain how this conjecture would follow from the surgery exact triangle in [13]. To establish the first two isomorphisms, the first step is to give a description of $SH_*(W, \partial^- W)$ and $SH^* >0(W, \partial^- W)$ in terms of pseudoholomorphic curves in a
symplectization; this is similar to the description of $\text{SH}^{>0}_*(V)$ as a nonequivariant linearized contact homology group given in [15] and used in [13] as a definition of $\text{SH}^{>0}_*(V)$. The second step is to apply to this formulation of $\text{SH}^{\heartsuit}_*(W, \partial^- W)$ with $\heartsuit \in \{\varnothing, > 0\}$ the methods of [13]. The proof of (i) is then straightforward, since $\text{SH}_*$ can naturally be expressed as the homology of a cone using the action filtration.

To prove (ii), the main step is to establish an isomorphism between the transfer map $\text{SH}^{\heartsuit}_0(V') \to \text{SH}^{\heartsuit}_0(V)$ and the map with the same source and target that appears in (59) for $\heartsuit \in \{\varnothing, > 0\}$. The latter map is described in terms of anchored pseudoholomorphic curves in the symplectization of the cobordism $W$, and the proof of the isomorphism between these maps follows the same ideas as those in [15], applied to the monotone homotopies which induce in the limit the transfer map. The claim in (ii) then follows from the results of [13] because, up to rotating a triangle, the groups $L\mathbb{H}^{Ho+}(\Lambda)_*$ and $L\mathbb{H}^{Ho}(\Lambda)_*$ can be expressed as homology groups of cones of such maps induced by cobordisms.

Remark 9.22 Following [15; 18], all the constructions that we describe in the setup of symplectic homology can be replicated in the language of symplectic field theory, or SFT (with the usual caveat regarding the analytical foundations of the latter). One outcome of this parallel is that our six flavours of symplectic homology provide some new linear SFT-type invariants (the group $\text{SH}_*(\partial V)$ for $V$ a Liouville domain is the most prominent of these). It is a general fact that the Viterbo transfer maps for symplectic homology correspond to the well-known SFT cobordism maps.

As in the proof of Proposition 9.19, Conjecture 9.21 would imply:

Conjecture 9.23 With coefficients in a field $\mathbb{K}$ the following isomorphisms hold:

(i) $\text{SH}^{-*}(W, \partial^+ W) \cong L\mathbb{H}^{Ho}(\Lambda)_*$ and

\[
\text{SH}^{-*}(W, \partial^+ W) \cong \text{SH}^*(W, \partial^- W) \cong (L\mathbb{H}^{Ho}(\Lambda)_*)^\vee.
\]

(ii) $\text{SH}^{-0}_*(W, \partial^+ W) \cong L\mathbb{H}^{Ho+}(\Lambda)_*$ and

\[
\text{SH}^{-0}_*(W, \partial^+ W) \cong \text{SH}^*_0(W, \partial^- W) \cong (L\mathbb{H}^{Ho+}(\Lambda)_*)^\vee.
\]

We also have the obvious

\[
\text{SH}^{=0}_*(W, \partial^- W) \cong \text{SH}^{=0}_*(W, \partial^+ W) = \begin{cases} \mathbb{K} & \text{if } * = 0, \\ 0 & \text{otherwise.} \end{cases}
\]
Together with the long exact sequence of a pair, these computations provide a theoretically complete understanding of the behaviour of all the flavours of symplectic homology groups under critical handle attachment.

A particular case of interest is that of comparing $\text{SH}_\ast(\partial^-W)$ and $\text{SH}_\ast(\partial^+W)$. The answer does not take the form of a long exact sequence because these groups do not sit naturally in a long exact sequence of a pair. The best answer that one can give in such a generality is that we have a correspondence

$$\text{SH}_\ast(\partial^-W) \leftarrow \text{SH}_\ast(W) \rightarrow \text{SH}_\ast(\partial^+W),$$

in which the kernel and cokernel of each arrow can be described in terms of the groups $\text{SH}_\ast(W, \partial^-W)$ and $\text{SH}_\ast(W, \partial^+W)$, respectively, which in turn are described in terms of the groups $L^\text{H}H_0(\Lambda)$ as above, using the long exact sequences of the pairs $(W, \partial^-W)$ and $(W, \partial^+W)$. This situation parallels the one encountered when comparing the singular cohomology groups of a manifold before and after surgery (in this case $\partial^+W$ is obtained by surgery of index $n$ on $\partial^-W$).

### 9.8 Handle attaching and $S^1$–equivariant symplectic homologies

The discussion in Sections 9.6 and 9.7 has $S^1$–equivariant analogues. We treat here only $S^1$–equivariant symplectic homology, since negative $S^1$–equivariant symplectic homology and also (negative) $S^1$–equivariant symplectic cohomology can be reduced to the former using Poincaré and algebraic duality.

#### Subcritical handle attaching

**Proposition 9.24** Let $W$ be a Liouville cobordism corresponding to a subcritical handle of index $k < n$. Then with $\mathbb{K}$–coefficients we have

$$\text{SH}^{S^1}_\ast(W, \partial_{\pm}W) = 0,$$

$$\text{SH}^{S^1}_\ast(0)(W, \partial^-W) = \begin{cases} \mathbb{K} & \text{if } * = n - k + 2\mathbb{N}, \\ 0 & \text{otherwise,} \end{cases}$$

$$\text{SH}^{S^1}_\ast(0)(W, \partial^+W) = \begin{cases} \mathbb{K} & \text{if } * = k - n + 2\mathbb{N}, \\ 0 & \text{otherwise,} \end{cases}$$

$$\text{SH}^{S^1}_{\ast > 0}(W, \partial^-W) = \begin{cases} \mathbb{K} & \text{if } * = n - k + 1 + 2\mathbb{N}, \\ 0 & \text{otherwise,} \end{cases}$$

$$\text{SH}^{S^1}_{\ast < 0}(W, \partial^+W) = \begin{cases} \mathbb{K} & \text{if } * = k - n - 1 + 2\mathbb{N}, \\ 0 & \text{otherwise,} \end{cases}$$
and the restriction maps induce isomorphisms
\[ \text{SH}^S_1(\partial^- W) \cong \text{SH}^S_1(W) \cong \text{SH}^S_1(\partial^+ W). \]

**Proof** The vanishing of \( \text{SH}^S_1(W, \partial \pm W) \) follows from that of \( \text{SH}_*(W, \partial \pm W) \) using the spectral sequence from nonequivariant to equivariant symplectic homology. The statement concerning \( \text{SH}^S_1(0, \partial \pm W) \) is a direct computation, using the fact that the Floer complex reduces in low energy to the Morse complex (see also [68; 18]):
\[ \text{SH}^S_1(0, \partial \pm W) \cong H^{n-*}(W, \partial \pm W) \cong H^{n-*}(W, \partial \pm W) \otimes \mathbb{K}[u^{-1}]. \]

The statement concerning \( \text{SH}^S_1(>0, \partial^- W) \) and \( \text{SH}^S_1(<0, \partial^+ W) \) follows from tautological exact triangles in view of the fact that, by definition, \( \text{SH}^S_1(0, \partial^- W) = \text{SH}^S_{1,>0}(W, \partial^- W) \) and \( \text{SH}^S_1(W, \partial^+ W) = \text{SH}^S_{1,<0}(W, \partial^+ W) \). The last statement follows from the exact triangles of the pairs \( (W, \partial \pm W) \).

**Remark 9.25** Let \( D^{2n} \) be the unit ball in \( \mathbb{R}^{2n} \). Then \( \text{SH}^S_1(D^{2n}) = 0 \) and a direct computation, together with the tautological exact triangle, shows that
\[ \text{SH}^S_{1,=0}(W, \partial^- W) \cong \text{SH}^S_{1,=0}(D^{2(n-k)}) \]
and
\[ \text{SH}^S_{1,>0}(W, \partial^- W) \cong \text{SH}^S_{1,>0}(D^{2(n-k)}). \]

These isomorphisms are not just algebraic or formal, but have the following geometric interpretation [24]: for any given finite action window there exists a Liouville structure on \( W \) for which the periodic Reeb orbits on \( \partial^- W \) in the given action window survive to \( \partial^+ W \), and the new periodic Reeb orbits which are created after handle attachment are in one-to-one bijective correspondence with the periodic Reeb orbits on the boundary of the symplectic reduction of the coisotropic cocore disk in the handle, which is a symplectic ball \( D^{2(n-k)} \).

**Corollary 9.26** Let \( V \) be a Liouville domain of dimension \( 2n \) and \( V' \) be obtained from \( V \) by attaching a subcritical handle of index \( k < n \). We then have an exact triangle
\[ \text{SH}^S_{1,>0}(D^{2(n-k)}) \to \text{SH}^S_{1,>0}(V') \leftarrow \text{SH}^S_{1,>0}(V) \]
in which the map \( \text{SH}^S_{1,>0}(V') \to \text{SH}^S_{1,>0}(V) \) is the transfer map.
Proof This is simply a reformulation of the exact triangle of the pair $(V', V)$, using excision and the computation of $\text{SH}^*_S;>0(W, \partial^- W)$ above, with $W = V' \setminus V$. □

This statement can be interpreted as a subcritical surgery exact triangle for linearized contact homology in view of [18]. In that formulation, the case $k = 1$ of contact connected sums was proved using different methods by Bourgeois and van Koert [19]. Also in that formulation, the exact triangle implies Espina’s formula [41, Corollary 6.3.3] for the behaviour of the mean Euler characteristic of linearized contact homology under subcritical surgery. By induction over the handles, it yields M-L Yau’s formula for the linearized contact homology of subcritical Stein manifolds [70].

Critical handle attaching

We restrict to rational coefficients, and recall the geometric setup of Section 9.7: $V \subset V'$ is a pair of Liouville domains of dimension $2n$ such that $V'$ is obtained by attaching $l \geq 1$ handles of index $n$ to $\partial V$ along a collection $\Lambda$ of $l$ disjoint embedded Legendrian spheres. Following [13] we denote by $C\mathbb{H}(V)$ the linearized contact homology of $\partial V$. One of the main statements in [13] is the existence of a surgery exact triangle

\[
L\mathbb{H}^{\text{cyc}}(\Lambda)_* \rightarrow C\mathbb{H}(V') \rightarrow C\mathbb{H}(V) \rightarrow L\mathbb{H}^{\text{cyc}}(\Lambda)_* \quad \text{(-1)}
\]

where $L\mathbb{H}^{\text{cyc}}(\Lambda)_*$ is a homology group of Legendrian contact homology flavour. More precisely, $L\mathbb{H}^{\text{cyc}}(\Lambda)_*$ is defined as the homology of a complex $LH^{\text{cyc}}(\Lambda)_*$ whose generators are cyclic words in Reeb chords on $\partial V$ with endpoints on $\Lambda$, and whose differential counts certain pseudoholomorphic curves in the symplectization of $\partial V$, anchored in $V$, with boundary on the conical Lagrangian $S\Lambda$ determined by $\Lambda$. This exact triangle can be reinterpreted in our language as follows:

Conjecture 9.27 Let $W$ be a Liouville cobordism corresponding to attaching $l \geq 1$ critical handles of index $k = n$ along a collection $\Lambda$ of disjoint Legendrian spheres. With rational coefficients we have an isomorphism

\[
\text{SH}^*_S;>0(W, \partial^- W) \cong L\mathbb{H}^{\text{cyc}}(\Lambda)_*
\]

such that the exact triangle (61) is isomorphic to the exact triangle of the pair $(V', V)$ for $\text{SH}^*_S;>0$.  

Algebraic & Geometric Topology, Volume 18 (2018)
The proof should go along the same lines as the one of Conjecture 9.21, adding on top the isomorphism between $\text{SH}_{S^1,>0}(V)$ and $C\mathbb{H}(V)$ whenever the latter is defined [18]. There is also an $S^1$–equivariant counterpart of Conjecture 9.23(ii), which involves duality and hence the groups $\text{SH}_{[u].>0}$.

**Remark 9.28** One can also give a Legendrian interpretation of $\text{SH}_{S^1}^{S^1}(W, \partial^- W)$. This can be obtained either formally algebraically by computing ranks from the $S^1$–equivariant tautological exact triangle of the pair $(W, \partial^- W)$ using the fact that $\text{SH}_{S^1}^{S^1}(W, \partial^- W)$ is supported in positive degrees, or geometrically along the lines of [18], where a linearized contact homology counterpart of $\text{SH}_{S^1}^{S^1}(V)$ is defined.

## 10 Product structures

### 10.1 TQFT operations on symplectic homology

As before, we use coefficients in a field $\mathbb{K}$. Recall from [66; 64] the definition of TQFT operations on the Floer homology of a Hamiltonian $H$ on a completed Liouville domain $V$. We freely use in this section the terminology therein, namely “negative punctures”, “positive punctures”, “cylindrical ends” and “weights”; see also [39]. Consider a punctured Riemann surface $S$ with $p$ negative and $q$ positive punctures. Pick positive weights $A_i, B_j > 0$ and a 1–form $\beta$ on $S$ with the following properties:

(i) $H d\beta \leq 0$.

(ii) $\beta = A_i dt$ in cylindrical coordinates $(s, t) \in \mathbb{R}_- \times S^1$ near the $i$th negative puncture.

(iii) $\beta = B_j dt$ in cylindrical coordinates $(s, t) \in \mathbb{R}_+ \times S^1$ near the $j$th positive puncture.

Note that $\beta$ and the weights are related by Stokes’ theorem

$$\sum_{i=1}^p A_i - \sum_{j=1}^q B_j = -\int_S d\beta.$$ 

Conversely, if the quantity on the left-hand side is nonnegative (resp. zero, nonpositive), then we find a 1–form $\beta$ with properties (ii) and (iii) such that $d\beta \leq 0$ (resp. $= 0$, $\geq 0$). Thus, we can arrange conditions (i)–(iii) in the following situations:

(a) $H$ arbitrary, $d\beta \equiv 0$, $p, q \geq 1$.

(b) $H \geq 0$, $d\beta \leq 0$, $p \geq 1$.

(c) $H \leq 0$, $d\beta \geq 0$, $q \geq 1$. 

_Algebraic & Geometric Topology, Volume 18 (2018)_.

Note that the condition $H \geq 0$ is satisfied for admissible Hamiltonians on a Liouville cobordism.

We consider maps $u : S \to \hat{V}$ that are holomorphic in the sense that $(du - X_H \otimes \beta)^{0,1} = 0$ and have finite energy $E(u) = \frac{1}{2} \int_S |du - X_H \otimes \beta|^2 \text{vol}_S$. They converge at the negative/positive punctures to 1–periodic orbits $x_i$ and $y_j$ and satisfy the energy estimate

\begin{equation}
0 \leq E(u) \leq \sum_{j=1}^{q} A_{B_j H}(y_j) - \sum_{i=1}^{p} A_{A_i H}(x_i)
\end{equation}

(beware that our action is minus that in [64]). The signed count of such holomorphic maps yields an operation

\[
\psi_S : \bigotimes_{j=1}^{q} \text{FH}_*(B_j H) \to \bigotimes_{i=1}^{p} \text{FH}_*(A_i H)
\]

of degree $n(2 - 2g - p - q)$ which does not increase action. These operations are graded commutative if degrees are shifted by $-n$ and satisfy the usual TQFT composition rules. Let us pick real numbers $a_j < b_j$ for $j = 1, \ldots, q$ and $a'_i < b'_i$ for $i = 1, \ldots, p$ satisfying

\begin{equation}
\sum_i a'_i = \max \left(a_j + \sum_{j' \neq j} b_{j'}\right), \quad b'_i = \sum_j b_j - \sum_{i' \neq i} a'_{i'}.
\end{equation}

Consider a term $x_1 \otimes \cdots \otimes x_p$ appearing in $\psi_S(y_1 \otimes \cdots \otimes y_q)$. If $A_{B_j H}(y_j) \leq a_j$ for some $j$ and $A_{B_{j'} H}(y_{j'}) \leq b_{j'}$ for all $j' \neq j$, then the energy estimate and the first condition in (63) yield

\[
\sum_{i=1}^{p} A_{A_i H}(x_i) \leq a_j + \sum_{j' \neq j} b_{j'} \leq \sum_i a'_i,
\]

thus $A_{A_i H}(x_i) \leq a'_i$ for at least one $i$. This shows that $\psi_S$ is well-defined as an operation

\[
\psi_S : \bigotimes_{j=1}^{q} \text{FH}_*^{(a_j, b_j)}(B_j H) \to \bigotimes_{i=1}^{p} \text{FH}_*^{(a'_i, \infty)}(A_i H).
\]

Similarly, if $A_{B_j H}(y_j) \leq b_j$ for all $j$ and $A_{A_i H}(x_i) > a'_i$ for all $i$ (so $a_1 \otimes \cdots \otimes a_p \neq 0$ in the quotient space), then for each $i$ the energy estimate yields

\[
A_{A_i H}(x_i) + \sum_{i' \neq i} a'_{i'} \leq A_{A_i H}(x_i) + \sum_{i' \neq i} A_{A_i H}(x_{i'}) \leq \sum_j b_j.
\]
thus $A_i H(x_i) \leq b'_i$ by the second condition in (63). It follows that $\psi_S$ induces an operation on filtered Floer homology,

$$
\psi_S : \bigotimes_{j=1}^q \text{FH}^\infty_{a_j, b_j}(A_j H) \rightarrow \bigotimes_{i=1}^p \text{FH}^\infty_{a'_i, b'_i}(A_i H).
$$

To proceed further, let us first assume $p, q \geq 1$, so we are in case (a) above. We specialize the choice of actions to $a_j = a$ and $b_j = b$ for all $j$ and $a'_i = a'$ and $b'_i = b'$ for all $i$. Then (63) becomes

$$
(64) \quad pa' = a + (q - 1)b, \quad b' = qb - (p - 1)a',
$$

and, under these conditions, $\psi_S$ induces an operation

$$
\psi_S : \bigotimes_{j=1}^q \text{FH}^\infty_{a, b}(A_j H) \rightarrow \bigotimes_{i=1}^p \text{FH}^\infty_{a', b'}(A_i H).
$$

We now apply this to admissible Hamiltonians for a Liouville cobordism $W$ relative to some admissible union $A$ of boundary components as in Section 2.4. The map $\psi_S$ is compatible with continuation maps for $H \leq H'$ in the obvious way, and therefore passes through the inverse and direct limit to define a map on filtered symplectic homology

$$
\psi_S : \bigotimes_{j=1}^q \text{SH}^\infty_{a, b}(W, A) \rightarrow \bigotimes_{i=1}^p \text{SH}^\infty_{a', b'}(W, A).
$$

Let us first consider the case $p = 1$. Then $a' \rightarrow -\infty$ and $b' = qb$ remains constant as $a \rightarrow -\infty$, so we can pass to the inverse limits to obtain an operation

$$
\psi_S : \bigotimes_{j=1}^q \text{SH}^{(-\infty, b]}_{a, b}(W, A) \rightarrow \text{SH}^{(-\infty, qb]}_{a', b'}(W, A).
$$

In the direct limit as $b \rightarrow \infty$ this yields an operation

$$
\psi_S : \bigotimes_{j=1}^q \text{SH}_{a, b}(W, A) \rightarrow \text{SH}_{a', b'}(W, A).
$$

Taking instead limits as $b \searrow 0$ and $b \nearrow 0$, respectively, we see that this operation restricts to operations

$$
\psi_S : \bigotimes_{j=1}^q \text{SH}_{a, b}^0(W, A) \rightarrow \text{SH}_{a', b'}^0(W, A), \quad \psi_S : \bigotimes_{j=1}^q \text{SH}_{a, b}^{\leq 0}(W, A) \rightarrow \text{SH}_{a', b'}^{\leq 0}(W, A).
$$
In the case $p > 1$ this procedure fails because $b' \to \infty$ as $a \to -\infty$, so we cannot take the inverse limits $a, a' \to -\infty$ keeping $b$ and $b'$ fixed. If all actions are nonnegative, as in the case of a Liouville domain or a pair $(W, \partial^- W)$, then there is no need to take the inverse limit $a, a' \to -\infty$, but we can simply fix $a, a' < 0$ and take the direct limits $b, b' \to \infty$ to obtain operations $\psi_S$ on all symplectic homology groups.

Next consider the case $q = 0$ and $p \geq 1$, which is possible for $H \geq 0$ (and thus $A = \emptyset$) according to case (b) above. Pick $a' \leq 0$ and consider the associated map

$$
\psi_S: \mathbb{K} \to \bigotimes_{i=1}^p \text{SH}_*^{(a', \infty)}(W),
$$

with $\mathbb{K}$ the ground field. For a nonzero term $x_1 \otimes \cdots \otimes x_p$ appearing in $\psi_S(1)$ we have $A_{A_i H}(x_i) > a'$ for all $i$, so the energy estimate yields

$$
A_{A_i H}(x_i) + (p - 1)a' \leq A_{A_i H}(x_i) + \sum_{i' \neq i} A_{A_i H}(x_{i'}) \leq 0,
$$

thus $A_{A_i H}(x_i) \leq -(p - 1)a'$. So we obtain a map

$$
\psi_S: \mathbb{K} \to \bigotimes_{i=1}^p \text{SH}_*^{(a', -(p-1)a')}(W).
$$

If $p = 1$, then we take the inverse limit as $a' \to -\infty$ to obtain the unit

$$
\psi_S: \mathbb{K} \to \text{SH}_*^{\leq 0}(W).
$$

If $p > 1$, then we set $a' = 0$ to obtain the operation

$$
\psi_S: \mathbb{K} \to \bigotimes_{i=1}^p \text{SH}_*^{\geq 0}(W).
$$

So we have proved:

**Proposition 10.1** For a filled Liouville cobordism $W$ and an admissible union $A$ of boundary components, there exist operations

$$
\psi_S: \bigotimes_{j=1}^q \text{SH}_*^{\prec}(W, A) \to \bigotimes_{i=1}^p \text{SH}_*^{\succ}(W, A), \quad \bigotimes \in \{\emptyset, \leq 0, < 0\},
$$

of degree $n(2 - 2g - p - q)$ associated to punctured Riemann surfaces $S$ with $p$ negative and $q$ positive punctures, graded commutative if degrees are shifted by $-n$ and satisfying the usual TQFT composition rules, in each of the following situations:

(i) $\partial^- W = A = \emptyset$, $p \geq 1$, $q \geq 0$. 

*Algebraic & Geometric Topology, Volume 18 (2018)*
(ii) $A = \partial^+ W$, $p \geq 1$, $q \geq 1$.

(iii) $A = \emptyset$, $p = 1$, $q \geq 0$.

(iv) $A$ arbitrary, $p = 1$, $q \geq 1$.

As a consequence, we have:

**Theorem 10.2**

(a) For a filled Liouville cobordism $W$ and an admissible union $A$ of boundary components, the pair-of-pants product on Floer homology induces a product on $\text{SH}_*(W, A)$. The product has degree $-n$, and it is associative and graded commutative when degrees are shifted by $-n$.

(b) The symplectic homology groups $\text{SH}^0_*(W, A)$ and $\text{SH}^0_*(W, A)$ also carry induced products which are compatible with the tautological maps $\text{SH}^0_*(W, A) \to \text{SH}^0_*(W, A) \to \text{SH}_*(W, A)$. The image of the map $\text{SH}^0_*(W, A) \to \text{SH}^0_*(W, A)$ is an ideal in $\text{SH}^0_*(W, A)$.

(c) The symplectic homology group $\text{SH}^0_*(W, A)$ carries a product, which coincides with the cup product in cohomology via the isomorphism $\text{SH}^0_*(W, A) \cong H^{n-*}(W, A)$. The map $\text{SH}^0_*(W, A) \to \text{SH}^0_*(W, A)$ is compatible with the product structures.

(d) In the case $A = \emptyset$, the products on $\text{SH}^0_*(W)$, $\text{SH}_*(W)$ and $\text{SH}^0_*(W)$ have units, and the tautological maps $\text{SH}^0_*(W) \to \text{SH}_*(W)$ and $\text{SH}^0_*(W) \to \text{SH}^0_*(W)$ are morphisms of rings with unit.

(e) For a filled Liouville cobordism pair $(W, V)$, the transfer map $\text{SH}^0_*(W) \to \text{SH}^0_*(V)$ is a morphism of rings for $\varnothing \in \{< 0, \leq 0, \emptyset\}$, and a morphism of rings with unit for $\varnothing \in \{\leq 0, \emptyset\}$.

**Proof** Parts (a)–(d) follow directly from the preceding discussion, so it remains to prove part (e). For this, fix a finite action interval $(a, b)$ and consider two Hamiltonians $K \leq H$ for the Liouville cobordism pair $(W, V)$ as in Figure 12.

Let us first describe more explicitly the transfer map from Section 5.1. For this, let $\chi : \mathbb{R} \to [0, 1]$ be a smooth nondecreasing function with $\chi(s) = 0$ for $s \leq 0$ and $\chi(s) = 1$ for $s \geq 1$ and define the $s$–dependent Hamiltonian

$$\hat{H} := (1 - \chi(s))H + \chi(s)K,$$

where $(s, t)$ are coordinates on the cylinder $\mathbb{R} \times S^1$. Then $\partial_s \hat{H} \leq 0$ and the count of Floer cylinders for $\hat{H}$ defines a chain map $f : \text{FC}^{(a,b)}(K) \to \text{FC}^{(a,b)}(H)$. 

*Algebraic & Geometric Topology, Volume 18 (2018)*
Now we describe the products. Let $S$ be the Riemann sphere with two positive punctures and one negative puncture. Let $\tau: S \to \mathbb{R} \times S^1$ be a degree 2 branched cover with $\tau(s, t) = (s, t)$ in cylindrical coordinates $(s, t) \in [1, \infty) \times S^1$ near the positive punctures and $\tau(s, t) = (s, t)$ in cylindrical coordinates $(s, t) \in (-\infty, -1] \times S^1$ near the negative puncture. We use the 1–form $\beta := \tau^* dt$ on $S$ (with $d\beta = 0$) and weights $B_1 = B_2 = 1$ and $A_1 = 2$ at the positive/negative punctures to define the pair-of-pants product

$$\mu_K: FC^{(a, b]}(K) \otimes FC^{(a, b]}(K) \to FC^{(a+b, 2b]}(2K),$$

and similarly $\mu_H$. Next, consider for $\sigma \in \mathbb{R}$ the function $\chi_\sigma(s, t) := \chi(s - \sigma)$ and the Hamiltonian

$$\hat{H}_\sigma := (1 - \chi_\sigma \circ \tau) H + \chi_\sigma K$$

depending on points $z \in S$. Since $H \ d\beta = 0$ and $d_z H \wedge \beta \leq 0$ as 2–forms on $S$, the maximum principle holds for the Floer equation of $\hat{H}_\sigma$ (see eg [3; 39; 64]). It follows that the moduli spaces $M_\sigma(y_1, y_2; x_1)$ of pairs of pants for $\hat{H}_\sigma$ are compact modulo breaking, where $y_1, y_2$ and $x_1$ are 1–periodic orbits of $K$ and $2H$, respectively. Considering for index $CZ(y_1) + CZ(y_2) - CZ(x_1) - n = 0$ the natural compactifications of the 1–dimensional moduli spaces $\bigcup_{\sigma \in \mathbb{R}} \{\sigma\} \times M_\sigma(y_1, y_2; x_1)$, we obtain the relation

$$(65) \quad \mu_H(f \otimes f) - f \mu_K = \partial_2 H \theta - \theta \partial_K.$$ 

Here $\partial_K$ and $\partial_2 H$ are the Floer boundary operators for $K$ and $2H$, respectively, $f_2: FC^{(a, b]}(2K) \to FC^{(a, b]}(2H)$ is the chain map defined by $2\hat{H}$, and

$$\theta: FC^{(a, b]}(K) \otimes FC^{(a, b]}(K) \to FC^{(a+b, 2b]}(2H)$$

counts index $-1$ pairs of pants for $\hat{H}_\sigma$ occurring at isolated values of $\sigma$.

Let us now choose $K$ and $H$ such that the orbits in group $F$ for $K$ and in groups $F$, $I$ and $III^{0+}$ for $H$ have actions below $a$, so that $FC^{(a, b]}(K) = FH^{(a, b]}_I(K)$ and $FC^{(a, b]}(H) = FH^{(a, b]}_{II, III}(H)$. By Lemmas 2.2 and 2.3, $FH^{(a, b]}_{III}(H)$ is a 2–sided ideal for the product $\mu_H$, so the latter passes to the quotient as a product

$$\mu_H: FC^{(a, b]}_{II}(H) \otimes FC^{(a, b]}_{II}(H) \to FC^{(a+b, 2b]}_{II}(2H).$$

It follows that relation (65) persists when we compose the maps $f$, and $f_2$ and $\theta$, with their projections to $FC^{(a, b]}_{II}(H)$ and $FC^{(a, b]}_{II}(2H)$, respectively (keeping the same notation for the new maps). Passing to homology and the direct limit over $K$ and $H$,
we obtain the commuting diagram on filtered symplectic homology

\[
\begin{array}{ccc}
\text{SH}^{(a,b)}(W) \otimes \text{SH}^{(a,b)}(W) & \xrightarrow{\mu_W} & \text{SH}^{(a+b,2b)}(W) \\
\downarrow f \otimes f & & \downarrow f \\
\text{SH}^{(a,b)}(V) \otimes \text{SH}^{(a,b)}(V) & \xrightarrow{\mu_V} & \text{SH}^{(a+b,2b)}(V).
\end{array}
\]

Passing to the limits \(a \to -\infty\) and \(b \not\to 0, b \not\to 0\) or \(b \to \infty\), we conclude that the transfer map \(\text{SH}^\varhexagon(W) \to \text{SH}^\varhexagon(V)\) preserves the product for \(\varhexagon \in \{< 0, \leq 0, \varnothing\}\). A similar argument shows that the transfer map preserves the unit for \(\varhexagon \in \{\leq 0, \varnothing\}\) and Theorem 10.2 is proved.

In particular, Theorem 10.2 provides a product of degree \(-n\) with unit and a coproduct of degree \(-n\) (without counit) on \(\text{SH}_*(W)\) for every filled Liouville cobordism \(W\). Applied to the trivial cobordism, this yields, via the isomorphism (50), a corresponding product and coproduct on Rabinowitz–Floer homology. We refer to Uebele [67] and the appendix for a discussion of conditions under which the product is defined in the absence of a filling if the negative boundary is index-positive.

If \(W\) is a Liouville cobordism with filling and \(L \subset W\) is an exact Lagrangian cobordism with filling, then the preceding discussion shows that Lagrangian symplectic homology \(\text{SH}^\varhexagon_*(L)\) is a module over \(\text{SH}^\varhexagon_*(W)\) for \(\varhexagon \in \{< 0, \leq 0, \varnothing\}\); see also [64].

### 10.2 Dual operations

Combining Proposition 10.1 with the Poincaré duality isomorphism \(S^*_\varhexagon(W,A) \cong \text{SH}^\varhexagon_*(W,A^c)\), we obtain:

**Proposition 10.3** Consider a filled Liouville cobordism \(W\) and an admissible union \(A\) of boundary components. Then there exist operations

\[
\psi_S: \bigotimes_{j=1}^q \text{SH}^\varhexagon_*(W,A) \to \bigotimes_{i=1}^p \text{SH}^\varhexagon_*(W,A), \quad \varhexagon \in \{\varnothing, \geq 0, > 0\},
\]

of degree \(-n(2-2g-p-q)\), graded commutative if degrees are shifted by \(n\) and satisfying the usual TQFT composition rules, in the following situations:

(i) \(\partial^-W = \varnothing, A = \partial^+W, p \geq 1, q \geq 0\).

(ii) \(A = \partial^+W, p \geq 1, q \geq 1\).
(iii) \( A = \partial W, \ p = 1, \ q \geq 0. \)

(iv) \( A \) arbitrary, \( p = 1, \ q \geq 1. \)

Note that in Propositions 10.1 and 10.3 the conditions on \( p \) and \( q \) are the same, whereas \( \heartsuit \) is replaced by \(-\heartsuit\) and \( A \) by \( A^c.\)

Suppose now that the filled Liouville cobordism \( W \) has vanishing first Chern class and that \( \partial W \) carries only finitely many closed Reeb orbits of any given Conley–Zehnder index. Using field coefficients, Corollary 3.6 yields canonical isomorphisms \( SH_k^\heartsuit(W, A) \cong SH_k^{\heartsuit}(W, A)^\heartsuit \) for all \( A \) and all flavours \( \heartsuit. \) The dualization of the operations in Proposition 10.3 then yields:

**Corollary 10.4** Consider a filled Liouville cobordism \( W \) with vanishing first Chern class and an admissible union \( A \) of boundary components. Suppose that \( \partial W \) carries only finitely many closed Reeb orbits of any given Conley–Zehnder index. Then with field coefficients there exist operations (note the reversed roles of \( p \) and \( q \))

\[
\psi^\heartsuit_S: \bigotimes_{i=1}^p SH_i^\heartsuit(W, A) \to \bigotimes_{j=1}^q SH_j^\heartsuit(W, A), \ \heartsuit \in \{\varnothing, \geq 0, > 0\},
\]

of degree \( n(2 - 2g - p - q), \) graded commutative if degrees are shifted by \(-n\) and satisfying the usual TQFT composition rules, in the following situations:

(i) \( \partial^- W = \varnothing, \ A = \partial^+ W, \ p \geq 1, \ q \geq 0. \)

(ii) \( A = \partial^+ W, \ p \geq 1, \ q \geq 1. \)

(iii) \( A = \partial W, \ p = 1, \ q \geq 0. \)

(iv) \( A \) arbitrary, \( p = 1, \ q \geq 1. \)

\[\square\]

**10.3 A coproduct on positive symplectic homology**

Consider a Liouville cobordism \( W \) filled by a Liouville domain \( V. \) The choice of \( W \) will be irrelevant, so we can take eg \( W = I \times \partial V. \) Proposition 10.1(iii) provides a product of degree \(-n\) on \( SH_{*-0}(W). \) In view of the isomorphism \( SH_{*-0}(W) \cong SH_{*-0}^*(V) \) from Proposition 9.2, this gives a product of degree \( n - 1 \) on the symplectic cohomology group \( SH_{*-0}^*(V). \) Note that this cannot be the product arising from Proposition 10.3(iv) (with \( V \) in place of \( W \) and \( A = \varnothing \)) because the latter has degree \( n. \) Under the finiteness hypothesis in Corollary 10.4, this gives a coproduct of degree \( 1 - n \) on the symplectic homology group \( SH_{*-0}^*(V). \)
Remark 10.5 Following Seidel, there is another coproduct of degree $1 - n$ on $\text{SH}^n(V)$ obtained as a secondary operation in view of the fact that the natural coproduct given by counting pairs of pants with one input and two outputs vanishes; see also [39] for a generalization and [46] for a topological version of it. These two coproducts of degree $1 - n$ agree. The isomorphism between them is part of a larger picture related to Poincaré duality and will be the topic of another paper.

Appendix: An obstruction to symplectic cobordisms
by P Albers, K Cieliebak and A Oancea

In this joint appendix we use the results of this paper to define an obstruction to Liouville cobordisms between contact manifolds.

Consider a Liouville cobordism $W$ whose negative end $\partial_- W$ is hypertight, index-positive or Liouville fillable. As explained in Section 9.5, in these cases one can define symplectic homology groups $\text{SH}^\varnothing(W)$ for $\varnothing \in \{\emptyset, \leq 0, < 0, = 0, \geq 0, > 0\}$, which will be independent of a filling in the first two cases but may depend on the filling in the Liouville fillable case. We would like to show that vanishing of $\text{SH}^\varnothing(\partial_+ W)$ implies vanishing of $\text{SH}^\varnothing(\partial_- W)$. However, it is unclear how to deduce this from the functoriality under cobordisms, which only gives correspondences

\[
\begin{align*}
\text{SH}^\varnothing(W) \quad \text{SH}^\varnothing(\partial_- W) \quad \text{SH}^\varnothing(\partial_+ W)
\end{align*}
\]

Instead, we will consider the following property (using coefficients in a field $\mathbb{K}$):

Definition A.1 A Liouville cobordism $W$ is called SAWC if $1_W$ is mapped to zero under the map $H^0(W) \cong \text{SH}_{n=0}^\varnothing(W) \to \text{SH}_{n}^{\geq 0}(W)$, where $1_W$ is the unit in $H^0(W)$.

For a connected Liouville domain $W$, this agrees with the “strong algebraic Weinstein conjecture” property of Viterbo [68]. As usual, we define the SAWC property for $\partial_\pm W$ via the trivial cobordism $[0,1] \times \partial_\pm W$, where $\text{SH}_\pm(\partial_+ W)$ is defined with respect to the partial filling $W$. Then this property is inherited under cobordisms:

Proposition A.2 Let $W$ be a Liouville cobordism with vanishing first Chern class whose negative end $\partial_- W$ is hypertight, index-positive or Liouville fillable. If $\partial_+ W$ is SAWC, then so are $W$ and $\partial_- W$. 

Algebraic & Geometric Topology, Volume 18 (2018)
Appendix by Peter Albers, Kai Cieliebak and Alexandru Oancea

**Proof** If the first Chern class of $W$ vanishes the symplectic homology groups $\text{SH}_*^\sim$ are canonically graded in the component of constant loops. Consider thus the diagram with commutative squares and exact rows

$$
\begin{array}{c}
\text{SH}_{n+1}(\partial - W) \rightarrow \text{SH}_n(\partial - W) \simeq H^0(\partial - W) \rightarrow \text{SH}_n(\partial + W) \rightarrow \text{SH}_n(\partial + W) \\
\text{SH}_{n+1}(W) \rightarrow \text{SH}_n(W) \simeq H^0(W) \rightarrow \text{SH}_n(W) \rightarrow \text{SH}_n(W) \\
\text{SH}_n(\partial + W) \rightarrow \text{SH}_n(\partial + W) \simeq H^0(\partial + W) \rightarrow \text{SH}_n(\partial + W) \rightarrow \text{SH}_n(\partial + W)
\end{array}
$$

The lower vertical arrows at the extremities are isomorphisms since $W$ and $I \times \partial W$ share the same positive boundary. The map $H^0(W) \rightarrow H^0(\partial W)$ is injective because every component of $W$ has a positive boundary component. Injectivity of the vertical map $\text{SH}_n(\partial W) \rightarrow \text{SH}_n(\partial W)$ then follows from the five lemma as in [69, Exercise 1.3.3].

Suppose now that $1_{\partial - W}$ is sent to zero by the map $H^0(\partial - W) \rightarrow \text{SH}_n(\partial - W)$. Then commutativity of the lower-middle square implies that $1_W$ goes to zero under the map $H^0(W) \rightarrow \text{SH}_n(W)$, and commutativity of the upper-middle square implies that $1_{\partial + W}$ goes to zero under the map $H^0(\partial + W) \rightarrow \text{SH}_n(\partial + W)$. $\square$

Note that Proposition A.2 uses the product structure on singular cohomology but not on symplectic homology. Using the latter, we will now reformulate the SAWC condition. As observed by Uebele [67], the pair-of-pants product $\cdot$ in Section 10 makes $\text{SH}_*(W)$, $\text{SH}_0^*(W)$ and $\text{SH}_0^*(W)$ unital graded commutative rings for $W$ as in Proposition A.2, provided that in the index-positive case we require the following stronger condition (called “product index-positivity” in [67]):

1. $c_2(W)|_{\pi_2(\partial - W)} = 0$ and $\pi_1(\partial - W) = 1$, and

$$
\text{CZ}(\gamma) > 3 \quad \text{for every closed Reeb orbit } \gamma \text{ in } \partial - W;
$$

or

2. denoting by $\xi_-$ the contact distribution on $\partial - W$, there exists a trivialization of the square of the canonical bundle $\Lambda^\text{max}_C \xi_- \otimes \xi_-^2$ such that, with respect to that trivialization, all closed Reeb orbits $\gamma$ in $\partial - W$ satisfy (66); in addition, we
require that the trivialization of $\Lambda^{max} C_{TW} \otimes \mathbb{Z}$ determined by the trivialization of $\Lambda^{max} C \otimes \mathbb{Z}$ extends over $W$.

**Remark** Since the homotopy classes of trivializations of a line bundle are classified by the first integral cohomology group, the extension property in (ii) above is automatic if the map $H^1(W; \mathbb{Z}) \to H^1(\partial W; \mathbb{Z})$ is surjective.

**Remark** Examples in which (i) is satisfied are unit cotangent bundles of spheres $S^n$ of dimension $n \geq 5$, and more generally Milnor fibres of $A_k$–singularities

$$\{z_0^k + z_1^2 + \cdots + z_n^2 = 0\}$$

for $n \geq 5$; see [55, Appendix A] and also [67].

The proof of this observation is similar to that of Proposition 9.17. The new feature is that a pair of pants with inputs $x_1$ and $x_2$ and output $x_-$ might break into a Floer cylinder $C_1$ connecting $x_1$ and $x_-$ with a negative puncture asymptotic to a closed Reeb orbit $\gamma_1$, a Floer plane $C_2$ with input $x_2$ and a negative puncture at a closed Reeb orbit $\gamma_2$, and a holomorphic cylinder with two positive punctures asymptotic to $\gamma_1$ and $\gamma_2$. The first two components are regular, so their indices satisfy

$$\text{ind}(C_1) = CZ(x_1) - CZ(x_-) - (CZ(\gamma_1) + n - 3) \geq 0,$$

$$\text{ind}(C_2) = CZ(x_2) + n - (CZ(\gamma_2) + n - 3) \geq 0.$$ 

When showing well-definedness of the product (resp. commutativity with the boundary operator) we consider orbits satisfying

$$CZ(x_1) + CZ(x_2) - CZ(x_-) - n = 0 \quad (\text{resp. } = 1).$$

Adding the two inequalities and inserting this relation yields

$$(CZ(\gamma_1) - 3) + (CZ(\gamma_2) - 3) \leq 0 \quad (\text{resp. } \leq 1),$$

contradicting condition (66).

Let us fix a Liouville form $\lambda$ on $W$ and consider for $b \in \mathbb{R}$ the filtered symplectic homology groups $SH^*_b(W)$ defined in Section 2 (which also exist under the above assumptions on $W$). We define the *spectral value* of a class $\alpha \in SH_*(W)$ by

$$c(\alpha) := \inf\{b \in \mathbb{R} | \alpha \in \text{im}(SH^{(-\infty,b)}_*(W) \to SH_*(W))\} \in [-\infty, \infty).$$
Here $c(\alpha) < \infty$ follows from the definition of $SH_\ast(W) = \varprojlim_{b \to \infty} SH_\ast^{(-\infty,b)}(W)$. The fundamental inequality satisfied by spectral values is

$$c(\alpha \cdot \beta) \leq c(\alpha) + c(\beta),$$

as a consequence of the fact that the pair-of-pants product decreases action (see inequality (62) with $A_1 = 2$ and $B_1 = B_2 = 1$).

The unit $1_W \in SH_n(W)$ plays a particular role. Indeed, we have $c(1_W) \leq 0$ since $SH^{\geq 0}_\ast(W) \to SH_\ast(W)$ is a map of rings with unit, but also

$$c(1_W) = c(1_W \cdot 1_W) \leq 2c(1_W).$$

Thus, either $c(1_W) = 0$ or $c(1_W) = -\infty$ (note that these conditions are independent of the Liouville form $\lambda$). The condition $c(1_W) = -\infty$ is equivalent to the fact that the unit belongs to the image of the map $SH^{< 0}_\ast(W) \to SH_\ast(W)$. In the latter case we also obtain $c(\alpha) = -\infty$ for all $\alpha \in SH_\ast(W)$ since $c(\alpha) \leq c(1_W) + c(\alpha)$. This is in particular the case if $SH_\ast(W) = 0$, and the converse is also true. Indeed, assume $c(1_W) = -\infty$ and represent $1_W$ as the image of an element $\alpha^b \in SH_\ast^{-\infty,b}(W)$ for some $b < 0$. By definition of the inverse limit, such an element is the equivalence class of a sequence $\alpha^b_n \in SH_\ast^{-n,b}(W)$ for $n > |b|$. We claim that each such element $\alpha^b_n$ is zero, hence $1_W = 0$. Indeed, for any given $n$ we can choose $b' < -n$ and represent by assumption $1_W$ by an element $\beta^{b'} \in SH_\ast^{-\infty,b'}(W)$, given by a sequence $\beta^{b'}_n \in SH_\ast^{-n',b'}(W)$ for $n' > |b'|$. But then $\alpha^b_n$ must be the image of $\beta^{b'}_n$ under the map $SH_\ast^{-n',b'}(W) \to SH_\ast^{-n,b}(W)$, which is zero for $b' < -n$.

We thus obtain:

**Lemma A.3** Let $W$ be a Liouville cobordism whose negative end $\partial_- W$ is hypertight, Liouville fillable or index-positive with the stronger index condition (66). Then $W$ is SAWC if and only if $SH_\ast(W) = 0$.

**Proof** Proposition 7.20 yields the commuting diagram with exact rows and columns

$$
\begin{array}{ccc}
SH_{n+1}^{> 0}(W) & \to & SH_{n+1}^{> 0}(W) \\
\downarrow f & & \downarrow g \\
SH_n^{\leq 0}(W) & \xrightarrow{h} & SH_n^{\leq 0}(W) \xrightarrow{i} SH_n^{= 0}(W) \\
\downarrow j & & \downarrow k \\
SH_n^{\leq 0}(W) & \xrightarrow{l} & SH_n(W) \xrightarrow{m} SH_n^{\geq 0}(W)
\end{array}
$$
where $i$ and $j$ are maps of unital rings. We will denote all units by $1_W$. We prove that $W$ is SAWC if and only if $c(1_W) = -\infty$, which by the discussion above is equivalent to $\text{SH}_*(W) = 0$. Suppose first that $c(1_W) = -\infty$, ie $1_W = l\alpha$ for some $\alpha \in \text{SH}_n^0(W)$. Then $1_W - h\alpha = f\beta$ for some $\beta \in \text{SH}_{n+1}^0(W)$, hence $1_W = i(1_W - h\alpha) = g\beta$ is mapped to zero under $k$, which means that $W$ is SAWC. The converse implication is proved similarly.

**Corollary A.4** There is no Liouville cobordism $W$ with $\partial_- W$ hypertight and such that $\text{SH}_*(\partial_+ W) = 0$ (where $\text{SH}_*(\partial_+ W)$ is defined with respect to the partial filling $W$).

**Proof** If $\partial_- W$ is hypertight then the map $\text{SH}_n^0(\partial_- W) \rightarrow \text{SH}_n^0(\partial_- W)$ is an isomorphism, so $\partial_- W$ is not SAWC. On the other hand, $\text{SH}_*(\partial_+ W) = 0$ implies by Lemma A.3 that $\partial_+ W$ is SAWC. This is impossible by Proposition A.2.

**Corollary A.5** There is no Liouville cobordism $W$ of dimension $2n \geq 4$ with vanishing first Chern class such that $\partial_- W$ is hypertight, $\partial_+ W$ is fillable by a subcritical Stein manifold with vanishing first Chern class, and the map $\pi_1(\partial_+ W) \rightarrow \pi_1(W)$ induced by inclusion is injective.

**Proof** Let $F$ be such a subcritical Stein filling of $\partial_+ W$. Denote by $F \text{SH}_*(\partial_+ W)$ the symplectic homology computed with respect to the filling $F$, and $W \text{SH}_*(\partial_+ W)$ the symplectic homology computed with respect to the partial filling $W$. Since $\text{SH}_*(F) = 0$, we also have $F \text{SH}_*(\partial_+ W) = 0$ by Corollary 9.9. By Remark 9.16, one can choose on $\partial_+ W$ a contact form so that all Conley–Zehnder indices of closed Reeb orbits which are contractible in $\partial_+ W$ are $> 3 - n$. The injectivity of the map $\pi_1(\partial_+ W) \rightarrow \pi_1(W)$ implies that the same condition on the indices holds for all closed Reeb orbits which are contractible in $W$. Hence, by Proposition 9.17, we have $W \text{SH}_*(\partial_+ W) = F \text{SH}_*(\partial_+ W) = 0$, and the conclusion follows from Corollary A.4.

**Corollary A.6** There is no Weinstein cobordism $W$ of dimension $2n \geq 6$ with vanishing first Chern class such that $\partial_- W$ is hypertight and $\partial_+ W$ is fillable by a subcritical Stein manifold with vanishing first Chern class.

**Proof** Indeed, in this situation the skeleton of $W$ has codimension $\geq n \geq 3$ and a generic homotopy of paths will avoid it and can be subsequently pushed by the Liouville flow to $\partial_+ W$. Thus any loop in $\partial_+ W$ which is contractible in $W$ is also contractible in $\partial_+ W$, ie the map $\pi_1(\partial_+ W) \rightarrow \pi_1(W)$ induced by the inclusion is injective. We then conclude via Corollary A.5.
Examples  (1) Many examples of contact manifolds $M$ with $\text{SH}_*(M) = 0$ arise as boundaries of Liouville domains with vanishing symplectic homology, eg subcritical or flexible Stein manifolds [25].

(2) Examples of hypertight contact manifolds are the unit cotangent bundles of Riemannian manifolds of nonpositive curvature. Other examples are the $3$–torus $T^3$ with a Giroux contact structure $\xi_k = \text{ker}(\cos(ks)\, d\theta + \sin(ks)\, dt)$ and its higher-dimensional generalizations $(T^2 \times N, \xi_k)$ by Massot, Niederkrüger and Wendl [56]. The latter are not strongly symplectically fillable (so in particular not Liouville fillable) for $k \geq 2$. Therefore, it appears that Corollary A.4 with $\partial_- W$ being one of these manifolds cannot be obtained by more classical tools such as symplectic homology of Liouville domains.

(3) Let us mention in the same vein the fact that there is no Liouville cobordism $W$ with $\partial_- W$ hypertight and $\partial_+ W$ overtwisted. This is proved in the same way as nonfillability of overtwisted contact manifolds [10; 21], using filling by holomorphic discs in the symplectic manifold $(0,1) \times \partial_- W \cup W$. However, this seems to fall outside the scope of our methods, while at the same time the case that we address in Corollary A.4 seems to fall outside the scope of the method of filling by holomorphic discs.

(4) A contact manifold $(M, \xi)$ fails to satisfy the Weinstein conjecture if there exists a contact form whose Reeb vector field has no periodic orbit. In the simply connected case this is equivalent to the fact that $(M, \xi)$ is cobordant via a trivial cobordism to a hypertight contact manifold. Turning this around, $(M, \xi)$ satisfies the Weinstein conjecture if and only if it is not cobordant by a trivial Liouville cobordism to a hypertight manifold. From this perspective, obstructing the existence of Liouville cobordisms with hypertight negative end can be seen as a geometric generalization of the Weinstein conjecture.
