Biomarker-based Prognostication of Adverse Cardiac Remodeling after STEMI: the Role of Single Nucleotide Polymorphism T786C in Endothelial NO-synthase gene

Olga V. Petyunina, Mykola P. Kopytsya, Alexander E. Berezin

BACKGROUND: Endothelial NO-synthase (eNOS) is constitutive enzyme, which expresses in mature endothelial cells and promotes direct vascular dilatation. Single nucleotide polymorphism (SNP) of T786C in eNOS gene may influence on adverse cardiac remodeling after ST-elevation myocardial infarction (STEMI). Purpose of the study was to investigate possible associations between SNP T786C in eNOS gene and adverse cardiac remodeling after STEMI.

METHODS: 177 acute STEMI patients treated with percutaneous coronary intervention and thrombolysis that were admitted to intensive care unit of GI “L.T. Malaya TNI NAMSU” were enrolled in the study. Anthropometry, cardiovascular risk assay, coronary angiography, echocardiography and biomarkers’ measurement were performed at baseline. The DNA extraction was performed with a commercial kit using real-time polymerase chain reaction PCR.

RESULTS: There were correlations between 786CC polymorphism in eNOS gene and adverse cardiac remodeling ($r = 0.48; p = 0.001$), LDL cholesterol ($r = 0.32; p = 0.012$), type 2 diabetes mellitus ($r = 0.30; p = 0.042$), diastolic BP ($r = -0.26; p = 0.048$), unstable angina prior to STEMI ($r = 0.25; p = 0.047$) and total quantity of complicated STEMI ($r = 0.23; p = 0.042$). Additionally, there were not significant relations between 786CC polymorphism in eNOS gene and multiple coronary vessel injury, STEMI localization, levels of circulating biomarkers of myocardial injury, and amount of damaged coronary arteries. Using univariate and multivariate regressive logistic analysis we found that 786CC genotype of eNOS was independent predictor for late adverse LV remodeling ($\beta$-coefficient = 1.57342; odds ration = 4.8231; 95% confidence interval = 1.5349-15.1552; $p = 0.0071$).

CONCLUSION: The polymorphism 786CC in eNOS gene was found as an independent predictor for late adverse cardiac remodeling after STEMI.

Key words: STEMI; Single nucleotide polymorphism T786C; Endothelial NO-synthase gene; Adverse cardiac remodeling

INTRODUCTION

Nitric oxide (NO) is well established fact that directly promotes vascular dilatation, regulates vascular smooth muscle cell proliferation and migration, endothelial permeability and has indirect antithrombotic effects\(^1\). NO is synthesized in vascular endothelium from its precursor L-arginine with endothelial NO synthase (eNOS)\(^2\). Endothelium-derived NO appears to be a constitutive enzyme, expression of which is dependent on appropriate eNOS gene\(^3\). Previous preclinical and clinical studies have been shown that genetic deletion of promoter region of eNOS gene – single nucleotide polymorphisms (SNP) T786C - frequently associated with lowered NO production\(^4\), SNP T786C in eNOS gene corresponded to lipid infiltration of vascular wall, apoptosis of mature and progenitor endothelial cells, oxidative stress-induced microvascular inflammation, mononuclear infiltration, proliferation of vascular smooth muscle cells (VSMCs), accumulation of extracellular matrix components, and platelet aggregation on the surface of endothelium\(^5\)\(^-\)\(^7\). Collectively, impaired eNOS bioavailability was found as main trigger for endothelial dysfunction, accelerating atherosclerosis, and thrombosis\(^8\). Additionally, deficiency of eNO through activating oxidant-sensitive pro-inflammatory cellular transcription factors, such as nuclear factor kB (NFxB) and FOXO-3, attenuate oxidative stress, and mitochondrial dysfunction that are considered as a main factor contributing in apoptosis and necrosis\(^9\). Indeed, altered suppressive effect due to eNO deficiency influence on proliferation of VSMCs, declined production of vascular endothelial growth factor-A and accumulation of inflammatory / immune cells, which exacerbate dysfunctional endothelium, persistence cell injury and modulate vessel stenosis and intravascular thrombus\(^10\). On the other hand, restored eNOS activity and improved NO production was able to inhibited cardiac myocyte apoptosis and promoted cardiac function after STEMI\(^11\). Because all these factors play a pivotal role in pathogenesis of adverse cardiac remodeling after successful opening of coronary artery with percutaneous coronary intervention (PCI) due to ST-elevation myocardial infarction (STEMI)\(^12\), and SNP N786C in eNOS gene, a G to T substitution at nucleotide 894 in exon 7 of eNOS, was found to be associated with STEMI\(^13\), we have been hypothesized that this polymorphism could be a predictor of adverse cardiac remodeling. Previous studies have shown that T-786C Glu298Asp polymorphism in eNOS gene has yielded conflicting associations with cardiovascular and renal diseases in numerous general populations\(^14\)\(^-\)\(^16\), but adverse cardiac remodeling was not being investigated in this conclusion. The aim of the study was to investigate possible associations between SNP T786C in eNOS gene and adverse cardiac remodeling after STEMI.

METHODS

Patients’ population

A total of 268 patients with confirmed acute STEMI were analyzed for participation in the study. From entire population of STEMI (n = 268) according to inclusion and non-inclusion criteria it was enrolled 177 individuals that were admitted to intensive care unit of GI “L.T.Malaya TNI NAMSU” with acute STEMI during 2-12 hours of symptoms onset in a given period between August 2016 and July 2018. STEMI was diagnosed according to ECS Guidelines (2017)\(^17\). Inclusion criteria were: confirmed STEMI, age > 18 years old, and lack of contraindication to PCI. Non-inclusion criteria were previous myocardial infarction, established chronic heart failure, known malignancy, severe comorbidities (anemia, chronic obstructive lung disease, bronchial asthma, liver cirrhosis, chronic kidney disease, valvular heart disease, bleeding), inability to understand of written informed consent. Primary PCI with bare-metal stent (COMMANDER, “Alvimedica”, Turkey) implantation was performed in 133 patients and 44 patients were previously treated with primary thrombolysis (tenecteplase, alteplase) before admission with followed PCI during 6-12 hours after initial STEMI confirmation. Thrombolysis was done with tenecteplase (Metalise, Boehringer Ingelheim Pharma, Germany), depending on patients weight and was not more then 50 mg iv bolus. Alteplase (Actilyse, Boehringer Ingelheim Pharma, Germany) 100mg infused intravenous during 2 hours. All investigated patients received adjuvant treatment due to current ESC recommendations\(^17\).

Ethical declaration

All procedures performed in the study involving human participants were in accordance with the ethical standards and with the 1964 Helsinki declaration and its later amendments or comparable ethical standards and approved by the local ethics committee (Protocol No8, 29.08.2016). Inform consent was obtained from each patient.

Adverse LV remodeling determination

The study patients were followed through the outpatient clinic of our institution at 6-month observation. Adverse cardiac remodeling was defined as increased LVEDV (>10% from baseline)\(^18\).

Coronary angiography

Conventional coronary angiography was performed immediately after admission of the patients to the hospital using Digital X-Ray system “Integris Allura” (Philips Healthcare, Best, The Netherlands) and automatic contrast injector were used. The contrast amount used in coronary angiography in each injection was 8 - 10 mL at 4 mL/s for the left coronary artery and 6 mL at 3 mL/s for the right coronary artery (radiation exposure 20 to 35 mGy/cm). The number of views obtained was decided by the operator depending on coronary anatomy. The coronary arteries were divided into segments according to the American Heart Association classification\(^19\).

Determination of STEMI prognosis

TIMI score was used to validate prognostic capacity after STEMI\(^20\).

Determination of risk factors and comorbidities

Hypercholesterolemia (HCE) was diagnosed if total cholesterol (TC) level was above 5.2 mmol/L, and/or low density lipoprotein cholesterol (LDL) level was above 3.0 mmol/L, and/or level of triglycerides (TG) was above 1.7 mmol/L according to with European Cardiology Society dyslipidemia guideline (2016)\(^21\). Hypertension was diagnosed if systolic blood pressure (SBP) was >140 mm Hg, and/or diastolic blood pressure (DBP) >90 mm Hg according to European guideline on diagnostics and treatment of arterial hypertension (2018)\(^22\). Type 2 diabetes mellitus determined according to new ADA statement (2017)\(^23\). Premature MI was verified if it appeared to be diagnosed in patients 55 years and younger.

Echo and Doppler examination

Echo-CG performed on “Aplo 500” (TUS-A500) TOSHIBA MEDICAL SYSTEMS CORPORATION with usage of 3.5 MHz phase probe at discharge and at 6-month observation period.
Left ventricular end diastolic volume (LV EDV), left ventricular end systolic volume (LV ESV), left ventricular ejection fraction (LVEF) measuring were done according to Simpson’s method per contemporary recommendation \(^{[34]}\). Left ventricular myocardial mass (LVMM) was calculated in automatic manner per protocol of echocardiograms evaluation \(^{[33]}\).

**Blood samples**

Blood samples were drawn immediately before PCI and at 6 month of investigation. Blood samples were centrifuged, serum was isolated within 30 min of sample acquisition and after then they were freezeed with -70°C and stored in plastic tubes until being shipped to the laboratory of immune-chemical and molecular-genetic researches of GI “LT.Malaya TNI NAMSU”.

Troponin I (Tn I) level measuring performed with chemoluminescent immunoassay (Humalyzer 2000, Mannheim, Germany). The TnI level average was 0.5-50 ng/mL.

Total cholesterol (TC), low density lipoprotein (LDL) cholesterol, high density lipoprotein (HDL) cholesterol and triglycerides (TG) were measured direct enzymatic method (Roche P800 analyzer, Basel, Switzerland). The intra-assay and inter-assay coefficients of variation were < 5%.

Fasting glucose level was measured by a double-antibody sandwich immunoassay (Elecsys 1010 analyzer, Hoffmann-La Roche Diagnostics, Mannheim, Germany). The intra-assay and inter-assay coefficients of variation were < 5%.

Total creatine kinase (CK) and CK MB-fraction (CK-MB) were analyzed using immunoinhibition method on quantitative immunoassay analyzer Humalyzer 2000 (HUMAN GmbH, Germany) according to the manufacturers’ recommendations.

N-terminal fragment of brain natriuretic peptide (NT-proBNP) was measured by commercially available standard kit (R&D Systems GmbH, Wiesbaden-Nordenstadt, Germany). The NT-proBNP level average was 10-12000 pg/mL.

**SNP T786C (rs2070744) in eNOS gene determination**

The DNA extraction was performed according to the protocol for a commercial set «DNA-Sorb-B» (Amplysens, Russia). The assessment of allelic states of SNP studied was performed using real-time polymerase chain reaction (PCR). For real-time PCR a commercial kit qPCR mix “SNP-Screen”, catalogue number NP-554-100 (Syntol, Russia) was used. PCR was performed on CFX96 thermocycler (BioRad, USA) using an allelic discrimination test. PCR conditions: 95°C – 3’, 40 cycles of 95°C – 15”, 65°C – 40”.

**Statistics**

Statistical analyses were performed using SPSS for Windows v.23 (USA). Continuous variables are presented as mean ± standard deviation (SD) when normally distributed, or median and interquartile range (IQR) if otherwise. Categorical variables are presented as frequencies (n) and percentages (%). Mann-Whitney and Wald-Wolfowitz criteria were used for intergroup differences and quantitative values. The qualitative variables are expressed as percentages, and were analyzed by the \( \chi^2 \) and exact Fisher tests. The genotypic data were checked for Mendelian pedigree. Allele frequencies were estimated, and all polymorphisms were tested for Hardy–Weinberg Equilibrium. We performed univariate and multiple variate log-regression analysis to determine the factors that could predict late adverse cardiac remodeling at 6 month and combined end point. We calculated beta coefficient, standard errors (SE), odds ratio (OR), 95% confidence interval (CI) for each factor. Factor, for which \( P \) values were calculated as > 0.5 were not included in the multiple variate log-regression analysis. All differences were considered statistically significant with 2-tailed \( p < 0.05 \).

### Table 1 Characteristics of STEMI patients included in the study depending on major / minor alleles

|                      | Entire population \((n = 177)\) | TT genotype \((n = 73)\) | TC genotype \((n = 64)\) | CC genotype \((n = 40)\) | \( P \) value |
|----------------------|---------------------------------|--------------------------|--------------------------|--------------------------|--------------|
| Age, years (SD)      | 61.73 ± 9.44                    | 59.00 ± 10.10            | 59.27 ± 9.92             | 58.53 ± 8.29             | NS           |

RESULTS

Table 1 is reported characteristic of the STEMI patients included in the study. It turned out that T and C alleles were presented about 60% and 40% of entire cohort patients. Sorting of STEMI patients according to genotypes of T786C eNOs gene appeared to be shown following, such as TT genotype was found in 37 patients (42%), TC genotypes was identified in 64 patients (36%) and CC genotypes was determined in 40 patients (22%) respectively. All STEMI patients were completely matched each other to age, sex, hypertension, stable CAD prior to STEMI, hypercholesterolemia, and obesity. Consequently, T2DM smoking unstable angina prior to STEMI, premature MI and previously reported MI were determined frequently in patients with 786CC genotype than in other individuals. Therefore, all cohorts were comparable in serum concentrations of troponin T, CK-MB, NT-proBNP, total cholesterol and high-density lipoprotein cholesterol. Additionally, serum levels of low-density lipoprotein cholesterol in patients with CC-genotype were significantly higher to those who had other genotypes of eNOs gene.

Table 2 is presented STEMI risk according to TIMI score, STEMI localization and number of damaged coronary arteries in patients included in the study depending on major / minor alleles. There were not significant differences between three cohorts in TIMI risk, STEMI localization, number of damaged coronary arteries, and complication of MI, while damages in left anterior descending artery were found not significant differences between three cohorts in TIMI risk, STEMI localization, number of damaged coronary arteries in patients included in the study depending on major / minor alleles. There were correlations between STEMI localization and number of damaged coronary arteries in patients included in the study depending on major / minor alleles.

There were significant differences between patients’ cohorts in complications of MI apart from adverse LV remodeling at 6 month. In fact, total amount of STEMI patients with adverse LV remodeling was identified in 46 individuals. eNOs gene polymorphism was dispensed as following: 19.2% - TT genotype, 26.6% - TC genotype and 37.5% - CC genotype (p = 0.033). Hemodynamics in STEMI patients enrolled in the study is reported in Table 3. Apart from HR and LV end-diastolic volume other hemodynamic performances did not distinguished between patients’ cohorts.

There were correlations between T786CC polymorphism in eNOs gene and adverse LF remodeling (r = 0.48, p = 0.001), LDL cholesterol (r = 0.32, p = 0.012), T2DM (r = 0.30; p = 0.042), DBP (r = -0.26; p = 0.048), unstable angina prior to STEMI (r = 0.25, ...
p = 0.047) and total quantity of complicated STEMI (r = 0.23; p = 0.042). Additionally, there were not significant relations between 786CC polymorphism in eNOS gene and multiple coronary vessel injury, STEMI localization, levels of circulating biomarkers of myocardial injury, and amount of damaged coronary arteries.

Using univariate and multivariate regressive logistic analysis (Table 4) we found that 786CC genotype of eNOS gene was independent predictor for late adverse LV remodeling (β-coefficient = 1.57342; odds ration = 4.8231; 95% confidence interval = 1.5349 - 15.1552; p = 0.0071).

**DISCUSSION**

The results of the study have revealed first that the 786CC genotype of eNOS gene was able to independently predict a late adverse cardiac remodeling in STEMI after primary or facilitate PCI. Consequently, we yielded unexpectedly result because other risk factors of poor clinical outcomes, such as T2DM, left main damage, did not correspond to adverse cardiac remodeling at 6 month after successful PCI. Recent clinical studies have shown a pivotal role of DNA variants in the eNOS gene in vascular nitric oxide production and consequently vascular tone modulating.[25-27] Yet, SNP in promoter region of eNOS gene was strongly associated with a risk of cardiovascular and renal disease in several populations.[28,29] Moreover, meta-analysis provided by Kong XZ et al (2017)[30] is reported that 786CC polymorphism in eNOS gene corresponded well with increased risk of primary MI. Therefore, negative impact of the 786CC polymorphism in eNOS gene on a risk of death after MI was determined in manyflore populations.[31-34] However, previous clinical studies were tackled SNP in eNOS gene with endogenous NO production and vascular endothelial growth factor (VEGF), which is reported as key regulator of angiogenesis, coagulation and tissue reparation.[35,36] We have hypothesized that 786CC polymorphism in eNOS gene suppressing endogenous production of NO and VEGF may worsen myocardial perfusion and impair LV function due to persistent ischemia leading to late adverse cardiac remodeling. Although complete opening of large MI-relating artery is discussed as main factor contributing to improve survival in STEMI patients, metabolic regulation of effective myocardial perfusion through small collateral branches could be sufficient trigger to prevent post-MI remodeling and improving survival rate. Indeed, adverse cardiac remodeling strongly associated with short-term as well as long-term mortality regardless of initial TIMI status of STEMI patients after PCI[37].

Taken together, altered production of NO and VEGF in patients with 786CC polymorphism in eNOS gene may potentially contribute to adverse cardiac remodeling that requires to be validated in future investigations. Finally, it can suggest that there is linkage between several polymorphisms affecting not just eNOS gene, but other genes corresponding to VEGF, collagen, matrix metalloproteinases, apoptotic-related and heat-shock proteins, which are involved into post-MI cardiac remodeling and play a protective role from ischemia preventing necrosis. Hens, our results clearly indicate that the 786CC polymorphism in eNOS gene has turn out to be core element of the molecular mechanisms underlying cardiac remodeling that pre-specified a factor for poor clinical outcomes in STEMI patients. We suggest that the risk stratification in the STEMI population based on 786CC polymorphism in eNOS gene identification could be useful for aggressive medical care after PCI and probably pre-treatment procedure implementation.

In conclusion, polymorphism 786CC in eNOS gene was found as an independent predictor for late adverse cardiac remodeling after STEMI.

**ACKNOWLEDGEMENTS**

There are no previous presentations of the information reported in the article. We thank Nataliia Tytarenko and Igor Polivenok for performing ultrasound examination and cardiac interventions respectively. Additionally, we thank, Galina Bugrimenko for her excellent technical assistance. Permission to acknowledge has been obtained.

**AUTHOR CONTRIBUTION**

Conception and design: Olga V. Petyunina; writing of the article Olga V Petyunina, Mykola P. Kopytsya, Alexander E. Berezin; critical revision of the article for intellectual content Alexander E Berezin.

**FOUNDING**

The study is a fragment of the research project: “To study the biochemical, genetic mechanisms of reperfusion damage of the myocardium and to assess the cardioprotective effect of antiplatelet therapy in acute myocardial infarction”, State Registration No. 0117U003028 / Ukraine
