(Received 13 November 2017; published 16 January 2018)

We analyze the effects of electron-electron interactions and disorder on a Rashba double-nanowire setup coupled to an s-wave superconductor, which has been recently proposed as a versatile platform to generate Kramers pairs of Majorana bound states in the absence of magnetic fields. We identify the regime of parameters for which these Kramers pairs are stable against interaction and disorder effects. We use bosonization, perturbative renormalization group, and replica techniques to derive the flow equations for various parameters of the model and evaluate the corresponding phase diagram with topological and disorder-dominated phases. We confirm aforementioned results by considering a more microscopic approach, which starts from the tunneling Hamiltonian between the three-dimensional s-wave superconductor and the nanowires. We find again that the interaction drives the system into the topological phase and, as the strength of the source term coming from the tunneling Hamiltonian increases, strong electron-electron interactions are required to reach the topological phase.

I. INTRODUCTION

Over the past decade or so many studies on topological phases in condensed matter systems have been performed [1]. In particular, Majorana bound states (MBSs) in such systems have attracted a lot of attention because of their potential application in topological quantum computation based on their non-Abelian braiding statistics [2]. There have been many advancements both theoretically as well as experimentally on MBSs in semiconductor nanowires (NWs) with proximity gap and Rashba spin-orbit interaction and on their detection [3–30]. So far, most of the studies on MBSs have been focused on the generation of these exotic states in the presence of magnetic fields. However, recently, it has been shown that MBSs can also be generated in the absence of magnetic fields [31–41], having the advantage to avoid detrimental effects of the magnetic field on the host s-wave superconductor, which is needed to induce proximity gaps in the NWs. The resulting twofold degeneracy of these MBSs is protected by time-reversal symmetry and therefore gives rise to Kramers pairs of MBSs (KMBSs).

The key property of MBSs is their robustness against local perturbations. Therefore, for the low-energy physics, it becomes crucial to consider the effects of electron-electron interactions [42–51] and disorder [52–60], as these perturbations, taken independently, are able to affect the topological protection of the MBSs even if they preserve time-reversal symmetry. When both disorder and electron-electron interactions are taken into account, a perturbative treatment in disorder and pairing indicates that they indeed reinforce each other to destroy the topological gap [61], a result corroborated by a Gaussian variational ansatz [62] and further extended in the opposite strong disorder limit using the density matrix renormalization group approach [63], although some recent investigations indicate that in the moderate disorder regime both effects can cooperate to actually stabilize and even enhance the topological order [63,64].

In the present work, we consider a time-reversal invariant system, which supports KMBSs in the topological phase, and analyze the stability of this phase against bulk disorder and electron-electron interactions, using bosonization and Luttinger liquid (LL) techniques. In general, if we start from a gapped superconducting phase and switch on electron-electron interactions and/or disorder, their bulk effect is qualitatively not essential as long as their corresponding strengths are smaller than the effective gap in the system. Another approach is to start from a gapless phase and treat both the proximity effect and electron-electron interactions and/or disorder on equal footing by treating them as perturbations and determining which ones dominate [42,61,62]. Here we follow the latter approach, starting from a gapless phase, and analyze the competition between proximity, interaction, and disorder effects using a perturbative renormalization group (RG) approach.

As a model system we consider the double-NW setup proposed in Ref. [34], depicted in Fig. 1, which consists of two one-dimensional NWs labeled by $\tau = 1$ (I) for the upper (lower) NW, with Rashba spin-orbit interaction (SOI). The NWs are in proximity to an s-wave superconductor underneath. This geometry gives rise to two classes of proximity induced pairing terms, the first one is intrawire pairing due to tunneling of Cooper pairs as a whole to either of the NWs. The second class is the interwire pairing corresponding to crossed Andreev reflection [65–71]. It has been shown that this setup can support two MBSs at each end of the double-NW setup, which are time-reversal partners of each other, corresponding to KMBSs, provided the interwire crossed Andreev pairing gap exceeds the intrawire pairing gap. However, in the non-interacting system, it has been established that the value of the interwire pairing gap is always smaller than the intrawire one [72]. The goal of this work is to show that interactions can reverse the situation and enable the system to become topological.
II. MODEL

We consider a double-NW setup, depicted in Fig. 1, which consists of two Rashba NWs (of length $L$) labeled by an index $\tau = 1$ ($\tau = \bar{1}$) referring to the upper (lower) NW. The two NWs aligned along the $x$ direction are in the proximity of an $s$-wave superconductor. The Hamiltonian of the noninteracting and disorder-free system has the form

$$H = H_0 + H_{ac},$$

where $H_0$ describes the kinetic part of the Hamiltonian as $H_{ac}$ describes the superconducting pairing arising in the NWs due to the coupling to a bulk SC. The kinetic part is defined as

$$H_0 = \sum_{\tau} \int dx \left[ \sum_{\sigma} \Psi_{\tau,\sigma}^\dagger(x) \left( \frac{-\hbar^2 \partial_x^2}{2m} - \mu_\tau \right) \Psi_{\tau,\sigma}(x) \right] - i \sum_{\sigma,\sigma'} \alpha_{R\tau} \Psi_{\tau,\sigma}^\dagger(\Psi_{\tau,\sigma'} + \text{H.c.}),$$

where $\mu_\tau, \alpha_{R\tau} > 0$ are the chemical potential and Rashba SOI strength in the $\tau$-NW, respectively. Here, the operator $\Psi_{\tau,\sigma}(x)$ [$\Psi_{\tau,\sigma}^\dagger(x)$] creates (annihilates) an electron of band mass $m$ with spin $\sigma/2 = \pm 1/2$ at position $x$ of the $\tau$-NW. The Pauli matrices $\sigma_{1,2,3}$ act on the spin of the electron. In both NWs, the SOI vectors are aligned in the $z$ direction. The energy spectrum for electrons with spin component $\tau$ in the $\tau$-NW is given by

$$E_{\tau} = \hbar^2 (k - \Delta_{k_{so,\tau}}^2)/2m,$$

where $k_{so,\tau} = m \alpha_{R\tau}/\hbar^2$ is the SOI wave vector with $E_{so,\tau} = \hbar^2 k_{so,\tau}^2/2m$ being the SOI energy. For simplicity, we tune the chemical potentials in both NWs to the corresponding SOI energy, $\mu_\tau = E_{so,\tau}$.

The second term in the Hamiltonian $H$ is the proximity-induced superconducting pairing term $H_{ac}$ and has two contributions corresponding to intrawire ($H_s$) and interwire ($H_c$) pairings [34]. The intrawire pairing of strength $\Delta_c$ accounts for the tunneling of Cooper pairs as a whole from the superconductor to the $\tau$-NW. However, when the electrons from the same Cooper pair separate and each electron tunnels into a different NW, this gives rise to the interwire pairing gap of strength $\Delta_c$. This process is referred to as crossed-Andreev pairing and has been investigated in detail for the double-NW setup considered here [72] but in the absence of electron-electron interactions and for disorder-free NWs. The corresponding pairing terms in the Hamiltonian are written as

$$H_{ac} = H_s + H_c = \sum_{\tau,\sigma,\sigma'} \int dx \left[ \frac{\Delta_c}{2} \Psi_{\tau,\sigma}^\dagger (\sigma_2)_{\sigma\sigma'} \Psi_{\tau,\sigma'}^\dagger + \frac{\Delta_c}{2} \Psi_{\tau,\sigma}^\dagger (\sigma_2)_{\sigma\sigma'} \Psi_{\tau,\sigma'} + \text{H.c.} \right],$$

where $\bar{\tau} = -\tau$. The gap at $k = 0$ in the spectrum of the double-NW setup is given by $\Delta_k = \sqrt{\Delta_c^2 - \Delta_1 \Delta_\bar{1}}$ [34]. As a result, the topological phase hosting two MBSs at each end of the double-NW setup is defined by

$$\Delta_c^2 > \Delta_1 \Delta_{\bar{1}}.$$
and show that Eq. (5) can indeed be satisfied under certain conditions. In the following, we wish to study the proximity effect in current through setups similar to the one shown in Fig. 1 but where the NWs are replaced by quantum dots [66] or NWs [67,68] where also crossed Andreev processes get favored over direct ones by interaction effects. Such effects are expected to be well established for transport currents through setups similar to the one shown in Fig. 1 but where the NWs are replaced by quantum dots [69–71]. In the following, we wish to study the proximity effect in the presence of electron-electron interactions in the NWs and show that Eq. (5) can indeed be satisfied under certain conditions. For this, we have to treat the interaction effects in the one-dimensional NWs nonperturbatively, making use of bosonization, Luttinger liquid, and renormalization group techniques, as described in the following sections.

III. BOSONIZATION

In this section, we first linearize the spectrum around the Fermi points $k = 0$ and $k = \pm k_F$, $\equiv \pm k_{\text{ext}}$, (see Fig. 2) and subsequently bosonize the Hamiltonian to include the electron-electron interactions. We first decompose the Fermi fields in their right and left movers [74],

$$\begin{align*}
\Psi_1 &= R_{1\uparrow} e^{ik_{\text{ext}} x} + L_{1\downarrow}, \\
\Psi_\uparrow &= R_{\uparrow\downarrow} + L_{\downarrow\uparrow} e^{-ik_{\text{ext}} x}, \\
\Psi_\downarrow &= R_{\downarrow\uparrow} e^{ik_{\text{ext}} x} + L_{\uparrow\downarrow}, \\
\Psi_\downarrow &= R_{\downarrow\uparrow} + L_{\uparrow\downarrow} e^{-ik_{\text{ext}} x},
\end{align*}$$

(6)

where $R_{\tau\sigma}(x) [L_{\tau\sigma}(x)]$ is the slowly-varying right(left)-moving field of an electron at position $x$ in the $\tau$-NW with spin $\sigma$. The kinetic energy and SOI Hamiltonian $H_0$ [see Eq. (7)] reduces to

$$H_0 = \sum_{\tau,\sigma} i \hbar v_{F\tau} \int dx \left[ L_{\tau\sigma} \partial_x L_{\tau\sigma} - R_{\tau\sigma} \partial_x R_{\tau\sigma} \right].$$

(7)

where $v_{F\tau} = h k_{F\tau} / m$ is the Fermi velocity for $\tau$-NW. We note that the interwire pairing term $\Delta_k$ acts only on momenta close to zero, as described in Ref. [34]. We also divide the intrawire term into two parts, one ($\Delta_k^{\text{int}}$) term acts on states with momenta close to $k_F$ (exterior branches), while the other term ($\Delta_k^{\text{ext}}$) acts on states with momenta close to zero (interior branches). The intrawire and interwire proximity-induced pairing terms can then be rewritten as

$$\begin{align*}
H_c = \frac{\Delta_c}{2} \sum_{\tau} \Delta_{\text{ext}}^{\tau} &\int dx (R_{\tau\tau}^\dagger L_{\tau\tau}^\dagger - L_{\tau\tau}^\dagger R_{\tau\tau}^\dagger) \\
&+ \frac{\Delta_{\text{ext}}^{\tau}}{2} \int dx (L_{\tau\tau}^\dagger R_{\tau\tau}^\dagger - R_{\tau\tau}^\dagger L_{\tau\tau}^\dagger) + \text{H.c.}, \\
H_{\text{c}} = \frac{\Delta_c}{2} &\int dx (L_{\tau\tau}^\dagger R_{\tau\tau}^\dagger - R_{\tau\tau}^\dagger L_{\tau\tau}^\dagger) + \text{H.c.}
\end{align*}$$

(8)

Furthermore, we perform the standard bosonization of fermions by introducing the charge ($\phi_{\tau\tau}, \theta_{\tau\tau}$) and spin ($\phi_{\tau\tau}, \theta_{\tau\tau}$) bosonic fields [75]. These fields obey the bosonic commutation relations $[\phi_{\tau\tau}, \theta_{\tau\tau}(x')] = i \pi \delta_{\tau\tau} \text{sgn}(x' - x)/2$. We write the left and right moving fermions in terms of the charge-spin bosonic fields as

$$\begin{align*}
R_{\tau\sigma} &= \frac{1}{\sqrt{2\pi \alpha}} e^{-i/2[\phi_{\tau\tau}, \sigma \theta_{\tau\tau}],} \\
L_{\tau\sigma} &= \frac{1}{\sqrt{2\pi \alpha}} e^{-i/2[\theta_{\tau\tau}, \sigma \phi_{\tau\tau}],}
\end{align*}$$

(9)

where $\alpha$ is the ultraviolet (short-distance) cutoff of the continuum theory. In the following, we assume that $\alpha$ is given by the lattice constant of the NWs.

To incorporate electron-electron interactions, we consider three types of low-energy excitations close to the Fermi surface: (a) $g_2$-type forward-scattering processes (with momentum transfer $q \sim 0$) coupling fermions only on the same side of the Fermi surface; (b) $g_2$-type forward-scattering processes (with $q \sim 0$) coupling left- and right-moving electrons, however, such that each scattering partner stays on the same side of the Fermi surface, and (c) $g_1$-type backscattering processes (with $q \sim 2 k_F$), where electrons are transferred from one side of the Fermi surface to the other [75,83]. These scattering processes (a)–(c) [involving two electrons with the same spin], can be incorporated in the kinetic part of the Hamiltonian, whereas the backscattering process (c) involving scattering between electrons with opposite spins should be considered separately [75].

The kinetic part of Hamiltonian takes the following form:

$$\begin{align*}
H_0 = \sum_{\tau} &\int \frac{dx}{2\pi} \left[ \frac{\partial_\tau \phi_{\tau\tau}}{K_{\tau\tau}} \left( \frac{\partial_\tau \phi_{\tau\tau}}{K_{\tau\tau}} + K_{\tau\tau} \partial_\tau \theta_{\tau\tau} \right)^2 \\
&+ \frac{\partial_\tau \theta_{\tau\tau}}{K_{\tau\tau}} \left( \frac{\partial_\tau \theta_{\tau\tau}}{K_{\tau\tau}} + K_{\tau\tau} \partial_\tau \phi_{\tau\tau} \right)^2 \right].
\end{align*}$$

(11)
where $u_{\tau,c/s}$ and $K_{\tau,c/s}$ are the charge-spin velocity and LL parameters for $\tau$-NW.

The simultaneous backscattering of spin-up and spin-down electrons in $\tau$-NWs [75], characterized by the coupling strength $g_\tau$, result in the following term in the total Hamiltonian [75,79]:

$$H_g = \sum \tau g_\tau \int dx \left(R_\tau^\dagger L_\tau L_\tau^\dagger R_\tau^\dagger + \text{H.c.}\right)$$

$$= \sum \tau \frac{g_\tau}{2\pi^2 \alpha^2} \int dx \cos(2\sqrt{2}\phi). \quad (12)$$

To simplify further calculations, we introduce the new bosonic field basis defined as

$$\phi_{1/2} = \frac{\theta_{1/1,c} - \theta_{1/1,s}}{\sqrt{2}}, \quad \phi_{1/2} = \frac{\theta_{1/1,c} - \theta_{1/1,s}}{\sqrt{2}}.$$  

$$\phi_{3/4} = \frac{\phi_{1/1,c} + \theta_{1/1,c}}{\sqrt{2}}, \quad \phi_{3/4} = \frac{\phi_{1/1,c} + \theta_{1/1,c}}{\sqrt{2}}. \quad (13)$$

Expressing the Hamiltonian $H_0$ in this basis, we assume that the off-diagonal terms can be neglected (they are marginally relevant, see below), thus we keep only the diagonal terms, yielding

$$H_0 = \sum_i u_i \int df \frac{(\partial f_i)^2}{2\pi K_i} + K_i(\partial f_i)^2. \quad (14)$$

where $u_i$ and $K_i$ are the new velocity and LL parameters of the NWs. In Appendix A, we derive these LL parameters in terms of original charge $(K_{\tau,c})$ and spin $(K_{\tau,s})$ LL parameters and Fermi velocity $v_{F,\tau}$ of the $\tau$-NW. Using the relation $u_{\tau,c/s} = v_{F,\tau}/K_{\tau,c/s}$ valid for ideal LLs, we arrive at

$$u_{1/2} = u_{3/4} = \frac{v_{F,1/1}\sqrt{(1 + K_{1/1}^2)}(1 + K_{1/1}^2)}{2K_{1/1}^2 K_{1/1}^2},$$

$$K_{1/2} = K_{3/4} = \frac{K_{1/1}^2}{K_{1/1}^2} \sqrt{(1 + K_{1/1}^2)/(1 + K_{1/1}^2)}. \quad (15)$$

The intrawire and interwire proximity-induced superconducting pairing terms of the Hamiltonian under bosonization reduce to the following form:

$$H_s = \frac{\Delta_s}{\alpha} \int dx \cos(2\phi_1) + \frac{\Delta_s}{\alpha} \int dx \cos(2\phi_2)$$

$$+ \frac{\Delta_s}{\alpha} \int dx \cos(2\phi_3) + \frac{\Delta_s}{\alpha} \int dx \cos(2\phi_4). \quad (17)$$

$$H_c = \frac{\Delta_c}{\alpha} \int dx \cos(\phi_3 + \phi_4) \cos(\theta_3 - \theta_4). \quad (18)$$

Notably, in the new basis of bosonic fields, the $\Delta_c$ part commutes with the $\Delta_c$ part and thus they do not compete with each other to form an ordered phase. However, the $\Delta_s$ part does not commute with the $\Delta_c$ part and thus they cannot be ordered simultaneously [75–77]. Finally, the assumption of considering $H_0$ diagonal is justified since the nondiagonal terms are marginal operators in the sense that they are negligible under the RG flow compared to the cosine terms which flow to their strong coupling regime much faster [78].

In the new basis, the Hamiltonian $H_g$ corresponding to the processes of simultaneous backscattering of spin-up and spin-down electrons in each NW converts to the following form:

$$H_g = \frac{1}{2\pi^2 \alpha^2} \int dx \left[ g_1 \cos(2\phi_1 - \phi_3) \right.$$  

$$+ g_1 \cos(2\phi_2 - \phi_4) \left]. \quad (19)$$

IV. TREATMENT OF DISORDER

In this section, we incorporate the effects of bulk nonmagnetic disorder [75,79] in each of the NWs by introducing the term

$$H_{\text{dis}} = \sum \tau \int dx V_\tau(x) \rho_\tau(x), \quad (20)$$

where $V_\tau(x)$ is a random potential produced by impurities or defects and $\rho_\tau(x)$ is the electron density in the $\tau$-NW. We consider the case of weak uncorrelated disorder following a Gaussian distribution

$$\langle V_\tau(x) V_\sigma(x') \rangle = D_\delta(x - x') \delta_{\tau\sigma}. \quad (21)$$

The Gaussian disorder corresponds to the limit of very dense impurities, where the effect of a single impurity is very weak. The parameter $D_\delta$ measures the strength of the disorder induced by the dense distribution of impurities in the $\tau$-NW. We assume that the disorder in each NW is independent of the other one and the disorder strength $V_\tau(x)$ in each NW is much smaller than the Fermi energy such that the disorder affects only the states close to the Fermi points. In this case, we can focus on Fourier harmonics of the disorder term $V_{q,\tau}$ corresponding to momentum values close to $q \sim 0$ and to $q \sim 2k_{\alpha,\tau}$, the so-called forward (backward) scattering contributions in each $\tau$-NW. As a result, the Hamiltonian describing disorder takes the following form:

$$H_{\text{dis}} = \frac{1}{L} \sum_{\tau,\sigma} \sum_{q = 0}^{2k_{\alpha,\tau}} V_{q,\tau} \int \frac{dk}{2\pi} \sum_k \psi^\dagger_{k+q,\tau} \psi_{k,\tau}$$

$$+ \frac{1}{L} \sum_{\tau,\sigma} \sum_{q = 2k_{\alpha,\tau}} V_{q,\tau} \int \frac{dk}{2\pi} \sum_k \psi^\dagger_{k+q,\tau} \psi_{k,\tau}, \quad (22)$$

which reduces in the continuum limit to

$$H_{\text{dis}} = \sum_{\tau,\sigma} \int dx \eta_\tau(x) \left[ R_\tau L_\tau^\dagger + L_\tau^\dagger R_\tau \right]$$

$$+ \sum_{\tau,\sigma} \int dx \left[ L_\tau^\dagger \rho_\tau + \text{H.c.} \right], \quad (23)$$

such that

$$\eta_\tau(x) = \frac{1}{L} \sum_{q = 0}^{2k_{\alpha,\tau}} V_{q,\tau} e^{iqx},$$

$$\xi_\tau(x) = \frac{1}{L} \sum_{q = 0}^{2k_{\alpha,\tau}} V_{q,\tau} e^{iqx} \quad (24)$$

Here, $\eta_\tau$ and $\xi_\tau$ correspond the to $q = 0$ and $q = 2k_{\alpha,\tau}$ Fourier components of the random potential $V_\tau(x)$, respectively. These are essentially independent fields.
and when averaging over disorder we can use the following relations:
\[
(\eta_\tau(x) \eta_\tau(x')|_{\text{avg}} = D_\tau \delta(x-x') \delta_{\tau,\tau'},
\]
\[
(\xi\tau_\tau(x) \xi\tau_\tau(x')|_{\text{avg}} = D_\tau \delta(x-x') \delta_{\tau,\tau'},
\]
\[
(\xi_\tau(x) \eta_\tau(x')|_{\text{avg}} = 0, \xi_\tau(x) \xi_\tau(x')|_{\text{avg}} = 0.
\]
In terms of the bosonized fields, Eq. (23) takes the form
\[
H_\text{dis} = \sum_\tau \int d\xi \frac{\sqrt{\gamma}}{\alpha} \xi\tau_\tau(x) \nabla \phi_\tau_\tau(x) \right] + \sum_\tau \int dx \left[ \frac{\xi\tau_\tau(x)}{\alpha} e^{i\sqrt{2} \phi_\tau_\tau} \cos(\sqrt{2} \phi_\tau_\tau) \right] + \text{H.c.}\right].
\]
We gauge away the forward scattering term by the following transformation:
\[
\tilde{\phi}_{\tau,\tau}(x) = \phi_{\tau,\tau}(x) - \frac{K_{\tau,\tau} \sqrt{\gamma}}{\gamma_{\tau,\tau}} \int dy \eta(y).
\]

The only effect of this transformation is to redefine the phase of the backscattering term. The backscattering term leads to pinning of the fields, which corresponds to localization in one-dimensional systems. Moreover, in order to deal with the disorder averaging, we use the replica method [75,79]. We introduce \( N \) copies of the fields \((\phi_i, \theta_i) \rightarrow (\phi_i^n, \theta_i^n)\) with \( n \in \{1, N\} \), average over the Gaussian disorder, and finally take the limit \( N \rightarrow 0 \).

At the end, we obtain a Gaussian action in the replica space which we use to derive the RG equations. The replica term in the action, obtained with help of Eq. (25), is given by
\[
S_{\text{dis},\tau} = -\frac{D_\tau}{2\pi^2 \alpha^2} \left[ \sum_{m,n} \int dx dt dt' e^{i\sqrt{2} \phi_\tau_\tau(x,t)} e^{-i\sqrt{2} \phi_\tau_\tau(x,t')} \times \cos \left( \sqrt{2} \phi_\tau_\tau(x,t) \right) \cos \left( \sqrt{2} \phi_\tau_\tau(x,t') \right) + \text{H.c.} \right],
\]
where \( m \) and \( n \) are replica indices, while \( t \) and \( t' \) are imaginary time coordinates. We rewrite the foregoing action for each NW in terms of the new fields given by Eq. (13) as
\[
S_{\text{dis},1/1} = -\frac{D_{1/1}}{2\pi^2 \alpha^2} \left[ \sum_{m,n} \int dx dt dt' e^{i\sqrt{2} \phi_\tau_\tau(x,t)+\theta_\tau_\tau(x,t)} \times e^{-i[\theta_\tau_\tau(x,t')]+\theta_\tau_\tau(x,t')} \cos \left( \phi_{1/2}^m(x,t) - \phi_{1/2}^n(x,t) \right) \times \cos \left( \phi_{1/2}^m(x,t') - \phi_{1/2}^n(x,t') \right) + \text{H.c.} \right].
\]
Below, we calculate the RG flow equations in first order in \( D_{1/1} \), therefore the perturbative expansion will be carried out without the replica indices [75,79].

V. RG EQUATIONS FOR EFFECTIVE HAMILTONIAN

In the following section, we investigate the RG flow equations for different parameters in the system. Collecting all terms described above, we define an effective Hamiltonian for a double-NW setup with electron-electron interaction as
\[
H_{\text{eff}} = H_0 + H_s + H_e + H_{e-e},
\]
where \( H_0, H_s, H_e, \) and \( H_{e-e} \) are given by Eqs. (14), (17), (18), and (19), respectively. To the action obtained from \( H_{\text{eff}} \) we add the nonlocal contribution coming from the disorder averaged part given in Eq. (25). The proximity induced pairing and disorder terms in the Hamiltonian are competing with each other since they do not commute, therefore we perform a standard RG analysis [73] to find out which terms are dominant as a function of the system parameters. In Ref. [80], it has been shown that in the presence of the interactions, velocities flow to the equal limit, thus we do not incorporate the renormalization of velocities while deriving the RG equations for the couplings. This amounts to assuming that \( u_i \equiv u \). In what follows, we use the dimensionless coupling constants defined as \( \bar{\Delta}_{\tau/c} = \Delta_{\tau/c}/u, \bar{\Delta}_{\bar{c}} = \Delta_{\bar{c}}/(2\pi u) \), and \( \gamma_1 = g_\tau/(2\pi u) \).

From the RG flow equations, we can deduce the conditions under which the interwire (crossed Andreev) pairing gap dominates over the intrawire one and over the disorder. In the RG interpretation, this means to find a parameter regime for which \( \bar{\Delta} \) becomes of order one, while \( \bar{\Delta}_c^{\text{int}} < \bar{\Delta}_c \), and \( \bar{D}_1, \gamma_1 \ll 1 \). When these conditions are satisfied, the spectrum is gapped [see Eq. (5)] and the system is in a topological phase supporting KMBs. We note that this bosonic system can be adiabatically connected to the noninteracting system as was done in Ref. [42] since the relevant LL parameter \( K_3 \) flows to the effectively noninteracting value, thus allowing a refermionization of the action to a quadratic Hamiltonian but with all gaps renormalized by interactions.

To derive the RG equations for the coupling constants and LL parameters present in the effective Hamiltonian given by Eq. (30), we use the operator product expansion (OPE) expressions [81–84] listed in Appendix B. As a result, we arrive at (see Appendix C for more details)
\[
\frac{d\bar{\Delta}_1}{dl} = -2 K_1 \bar{\Delta}_1^{\text{ext}}, \quad \frac{d\bar{\Delta}_1}{dl} = -2 K_2 \bar{\Delta}_1^{\text{int}},
\]
\[
\frac{d\bar{\Delta}_c}{dl} = -2 K_3 \bar{\Delta}_3, \quad \frac{d\bar{\Delta}_c}{dl} = -2 K_4 \bar{\Delta}_4,
\]
\[
\frac{dK_1}{dl} = \left[ 1 - \frac{1}{4} \left( K_3 + K_4 + \frac{1}{K_3} + \frac{1}{K_4} \right) \right] \bar{\Delta}_c,
\]
\[
\frac{dK_2}{dl} = -\left( \bar{\Delta}_1^{\text{int}} \right)^2 \frac{K_3 + \bar{D}_1 (1 - K_3^2)}{2},
\]
\[
\frac{dK_3}{dl} = -\left( \bar{\Delta}_1^{\text{int}} \right)^2 \frac{K_4 + \bar{D}_1 (1 - K_4^2)}{2},
\]
\[
\frac{dK_4}{dl} = -\left( \bar{\Delta}_1^{\text{int}} \right)^2 \frac{K_3 + \bar{D}_1 (1 - K_3^2)}{2},
\]
\[
\frac{d\bar{D}_1}{dl} = \left[ 3 - \frac{1}{2} \left( K_1 + K_3 + \frac{1}{K_1} + \frac{1}{K_3} \right) - y_1 \right] \bar{D}_1,
\]
\[
\frac{dy_1}{dl} = (2 K_1 - K_3) y_1 - \bar{D}_1,
\]
\[
\frac{dy_1}{dl} = (2 K_2 - K_4) y_1 - \bar{D}_1.
\]
where \( l = \ln(\alpha/\alpha_0) \) is the dimensionless RG flow parameter, \( \alpha_0 \) is the lattice constant of the NWs, and \( \alpha \) is the rescaled lattice constant that grows under the various perturbations.

To reduce the number of parameters, we assume that the electron-electron interactions are similar in both NWs so we set \( K_1 = K_2 \) and \( K_3 = K_4 \) such that there are only seven independent parameters in Eq. (31). Even with these assumptions, the system of coupled RG equations stays involved and below we comment on limiting cases.

For \( \Delta^\text{ext}_{\tau}, \Delta^\text{int}_{\tau}, \Delta \), to be relevant in the RG sense (terms grow with \( l \)), we should have \( K_1 < 2, K_3 < 2, \) and \( K_3 + K_3^{-1} < 4 \Rightarrow (2 - \sqrt{3}) < K_3 < (2 + \sqrt{3}) \), respectively. Thus, for \( (2 - \sqrt{3}) < K_3 < 2 \), both \( \Delta \) and \( \Delta^\text{int}_{\tau} \) are relevant. For the disorder coupling constant \( D \) to be a relevant parameter, the condition \( K_1 + K_3 + K_3^{-1} + y = 6 \) should be satisfied. Motivated by the initial condition of LL parameters (see Appendix A), \( K_1(0) = K_3(0) \), for our estimate we use \( K_1 = K_3 \) and \( y \rightarrow 0 \). Thus disorder is a relevant parameter in the range \( (3 - \sqrt{5})/2 < K_{1,3} < (3 + \sqrt{5})/2 \) of LL parameters. For the backscattering coupling constant \( y \) to be a relevant parameter in the absence of disorder (\( D \rightarrow 0 \)), one needs to work in the regime \( K_1 + K_3 < 2 \). Generally, in the most interesting topological regime, both disorder and backscattering terms can be relevant. Thus we consider an interplay between these and the superconducting terms taking into account also the initial values of the coupling constants and LL parameters, which determine the RG flow.

In what follows, we will focus on \( \Delta \) and find regimes in which it dominates over other coupling constants. First, we solve the system of coupled RG equations to find the parametric dependence of \( \Delta \) on \( K_3(l) \) for various initial conditions of LL parameters \( K_1(0) = K_3(0) \), see Fig. 3. We find that \( \Delta_c = 0 \) is the stable fixed point. Moreover, for the initial condition \( K_1(0) = K_3(0) < 1 \), the crossed Andreev pairing \( \Delta_\times \) flows to zero before reaching the strong coupling limit. In contrast to that, for \( K_1(0) = K_3(0) > 1 \), \( \Delta_\times \) reaches the strong coupling limit as long as the initial value of \( D \) is smaller than \( \Delta_c \). We note here that for \( K_{1,3} > 1 \), the backscattering coupling constant \( y \) is an irrelevant parameter and flows to negative values. We remind that the flow is stopped as soon as \( \Delta_c = 1 \).

The RG flow of all other coupling constants and LL parameters in the regime of interest \( K_1(0) = K_3(0) > 1 \) as a function of flow parameter \( l \) is shown in Fig. 4. Indeed, the crossed Andreev term grows most rapidly and reaches the strong coupling limit first for some range of parameters and thus drives the system into the topological phase (see below). We note that in spite of the fact that the RG flow equations for \( K_1 \) and \( K_3 \) are different, they stay almost the same during the flow, which justifies the estimates of scaling dimensions done above. The LL parameters \( K_{1,3} \) can be mapped back to more standard \( K_{\text{tc}} \) and \( K_{\text{tr}} \) by using Eq. (16). To enter the topological phase, we need \( K_{1,3}(0) > 1 \), which implies \( K_{\text{tc}} < K_{\text{tr}} \). If the interactions are such that the spin rotation symmetry is preserved (broken), \( K_{\text{tr}} = 1 \) \( (K_{\text{tc}} > 1) \). In any case, \( K_{\text{tr}} \) is always smaller than one, which corresponds to repulsive interactions. To analyze the stability of the obtained topological phase, we explore different initial values of coupling constants and obtain the phase diagram.

First, we focus on effects of disorder on the topological phase. The RG flow of the coupling constants and the LL parameters shown in Fig. 4 indicate that for the initial values \( K_{1,3}(0) > 1 \), though disorder grows fast under RG, as long as the starting value of \( D(0) \) is small enough, the crossed Andreev pairing amplitude \( \Delta \) reaches the strong coupling limit first before the disorder can grow to an appreciable value. However, it is expected that if disorder is strong initially, it will win over the superconducting gaps and drive the system into the disordered phase without MBSs. We solve numerically the coupled RG equations [see Eq. (31)] for different initial conditions of disorder strength \( D \) and of the topological gap \( \Delta_g = \sqrt{\Delta^2 - \Delta^\text{int} \Delta^\text{ext}} \) for \( K_{1,3} > 1 \), see Fig. 5. Here, we assume that the system is already in the topological phase with \( \Delta^\text{left}(0) = \Delta^\text{right}(0) \Delta^\text{int}(0) \). Under the RG, both \( \Delta_g \) and \( D \) flow to larger values. If \( D(\Delta_g) \) reaches the strong coupling limit first, the system is in the disordered (topological) phase. The critical line indicating the quantum phase transition separating the two
FIG. 5. The flow phase diagram consisting of topological and disorder phases obtained numerically from Eq. (31). Both disorder strength $D$ and the topological gap $\Delta_3 = \sqrt{\Delta_2^2 - \Delta_1^m \Delta_1^m}$ are increasing under the flow. By comparing $K_\text{solid}$ (green dotted) flow lines. The other initial parameters are fixed to weak (strong) disorder and initially large (small) topological gap, $\Delta_3(0)$, under the RG flow, see Figs. 4 and 5. However, one should keep in mind that for realistic systems only the physical values of the superconducting pairing $\Delta_{\tau, c}$ are of relevance. To extract these physical gaps, we use the relation $\Delta_{\tau,c} = \Delta_{\tau,c}(0)/2$. By plotting numerically the flow lines of $\Delta_{\tau,c}(l)$ versus the LL parameters $K_3(l)$ (see Fig. 6), we see that electron-electron interactions suppress the superconducting gaps, which is a generic behavior as discussed in Ref. [42]. Importantly, the intrawire superconducting pairing is suppressed stronger than the interwire (crossed Andreev) superconducting pairing. This reflects the physical expectation that interactions suppress the tunneling of two electrons in the same NW stronger than when the two electrons from the Cooper pair separate and tunnel each into a different NW. Following the reasoning of Ref. [42], we continue the flow until the special point $K_{1,3} = 1$ (effectively noninteracting limit) is reached. At this point we can refermionize our bosonic system to an effectively noninteracting system whose Hamiltonian is purely quadratic in the fermionic operators, and solve for the spectrum straightforwardly with renormalized pairing amplitudes given at $\Delta_{\tau,c}(K_3 = 1)$ and $\Delta_3(K_3 = 1)$. For these parameters, we find that the topological criterion (5), $\Delta_2^2 > \Delta_1^m \Delta_1^m$, is satisfied. Hence the system is in the topological phase and hosts one KMBS at each end of the double-NW system. We also explored the stability of the obtained topological phase towards initial conditions. In Fig. 7, we plot the phase diagram for different initial values of pairing amplitudes and LL parameters. Importantly, even if the system is initially in the trivial phase with $\Delta_1^m(0) > \Delta_2(0)$, under the RG flow, electron-electron interactions drive the system into the topological phase for which $\Delta_2^m < \Delta_3$. However, as the ratio between the initial values of superconducting pairings $\Delta_2^m(0)/\Delta_3(0)$ increases, we need increasingly stronger repulsive electron-electron interactions in the NWs to reach the topological phase.

FIG. 6. The RG flows for the physical (dimensionful) pairing terms $\Delta_1/\Delta_0$ (blue solid curves) and $\Delta_2^m/\Delta_0$ (red dashed curves) as a function of $K_3$ obtained from Eq. (31) with three different initial conditions: $K_3(0) = K_3(0) = 1.2, 1.4, and 1.6$ (from left to right flow lines), which corresponds to $K_1 = 0.73, 0.59, and 0.49$, respectively, for $K_3 = 1$, see Eq. (16). The vertical black arrow corresponds to the point where $\Delta_3 = 1$ is reached. The vertical green dotted line at $K_3 = 1$ corresponds to the noninteracting limit, where the bosonic system can be refermionized to a noninteracting system with renormalized pairing gaps [42]. For $K_3 > 1$, the value of intrawire pairing gap is always greater than the respective intrawire pairing gap, hence, the system hosts KMBSs at each end of the NWs. The other initial conditions are fixed to $\Delta_0 = \Delta_3^m(0) = \Delta_1^m(0) = \Delta_3(0) = 0.01 u/a_0$, $D(0) = y(0) = 0.001$.

FIG. 7. Phase diagram determined numerically from the RG flow for different initial values of $\Delta_2^m(0)/\Delta_1(0)$ and $K_3(0)$. At the end of the RG flow (when one of the coupling constants reaches one), the pairing amplitudes satisfy $\Delta_1(l) > \Delta_2^m(l)$ in the topological phase (blue area). In the trivial phase (red area), $\Delta_1(l) < \Delta_2^m(l)$. Remaining initial conditions are $D(0) = y(0) = 0.001$ and $K_3(0) = K_3(0)$.

VI. RG TREATMENT OF THE TUNNELING HAMILTONIAN IN THE SOURCE TERM APPROACH

In the previous section, we worked with the effective Hamiltonian. In particular, we included intra- and interwire superconducting pairing terms in the Hamiltonian as model parameters [see Eqs. (8) and (9)]. Afterwards, we computed the RG flow by using Eq. (31). In a more microscopic approach, one should begin with the tunneling Hamiltonian between the superconductor and NWs, and derive the intrawire (direct) and interwire (crossed Andreev) pairing amplitudes explicitly. Such an approach has been developed, for example, in Ref. [72] for the same double-NW setup without electron-electron interactions or disorder. Here, we derive the RG flow equations for the superconducting pairing amplitudes in the presence of electron-electron interactions with the tunneling equations for the superconducting pairing amplitudes in the presence of proximity-induced superconductivity in strongly interacting interfaces of topological insulators. In this section, we do not consider the disorder and backscattering terms explicitly as was done in Sec. V. However, we have checked disorder effects numerically as discussed below.

We model the coupling between the three-dimensional bulk s-wave superconductor (SC) and the NWs by the following tunneling Hamiltonian:

\[ H_T = \sum_\tau \int dx \, dr \left[ |r^\dagger_\tau (x, r)| e^{-ik_{sc} x} R^\dagger_\tau (x) + H.c. \right] \]

where the operator \( \Psi_\sigma (r) \) is an annihilation operator acting on electrons with spin \( \sigma \) located at point \( r \) of the SC. The SC is characterized by the anomalous Green function

\[ F(r, r', \omega) = \int \frac{dk}{(2\pi)^3} e^{i(k-r')} \frac{\Delta}{\omega^2 + E_k^2 + \Delta^2}. \]

where \( \Delta \) is the superconducting pairing amplitude. The energy dispersion of the SC in the normal phase is given by \( E_k = hv_F \sqrt{k^2 - k_{sc}^2}/2m_e \), where \( m_e \) and \( k_{sc} \) are the mass of the electron and the Fermi wave vector of the SC, respectively. We again separate the tunneling amplitudes into two parts, \( t'_\text{int} \) and \( t'_\text{ext} \), that act at momenta close to \( \pm k_F \), and zero, respectively, which is important for the correct treatment of \( \Delta^{\text{int/ext}}_\tau \). Hence \( t'_\text{int} \) results in the source terms for generating the intrawire superconducting pairing for the interior branches, \( \Delta^{\text{int}}_\tau \), and the interwire (crossed Andreev) superconducting pairing, \( \Delta_\tau \), while \( t'_\text{ext} \) results in the source term for generating the interwire superconducting pairing for the exterior branches, \( \Delta^{\text{ext}}_\tau \). Note that for simplicity we set the tunneling strengths equal for both NWs and assume the pointlike tunneling

\[ t_\text{int/ext,}^\tau (x, r) = t_{\text{int/ext}}^\tau \delta (r_x - x) \delta (r_y - d_y) \delta (r_z). \]

Similarly to the previous section, before deriving the RG flow equations, we should introduce dimensionless parameters also for the tunneling terms, which will allow us later to define the strong coupling regime. From dimensional analysis of Eqs. (32) and (34) and noting that \( \Psi_\tau^\dagger / \psi \) is normalized to the volume of the bulk SC, we see that \( t_{\text{int/ext}}^{\text{int/ext}} \) depends on \( (\text{volume})^{1/2} \). We also recall that the system is translationally invariant along the \( x \) direction, apart from boundary effects, which, however, we ignore for the present RG analysis by assuming that \( L \), the length of the NWs in \( x \) direction, is much larger than any other length scales. Furthermore, the tunnel contributions of Cooper pairs from the SC to the NWs (responsible for the proximity gaps in the NWs) in the transverse \( y \) and \( z \) directions can only come from distances up to the coherence length \( \xi = hv_F / \Delta \) within the SC, where \( \Delta (v_F, \text{sc}) \) is the gap (Fermi velocity) of the bulk SC. In addition, obviously, the proximity-induced superconducting gaps should not depend on the size of the system in \( y/z \) direction as long as it exceeds \( \xi \). Thus the natural length scales for dividing out the volume dependence of \( t_{\text{int/ext}}^{\text{int/ext}} \) is given by \( \sqrt{\xi^2 L} \). As a result, applying dimensional analysis and using Eq. (10), we confirm that \( t_{\text{int/ext}}^{\text{int/ext}} \) has the dimension of energy. Thus we define the dimensionless coupling constants as

\[ \tilde{t}_{\text{int/ext}} = t_{\text{int/ext}} \sqrt{\frac{\alpha}{\xi^2 L}}. \]
The source term \( S^{2}_{\text{int/ext}} \) governs the intrawire direct pairing processes, while the source term \( S^{3}_{\text{int}} \) governs the interwire crossed Andreev pairing processes. Here, \( S \) and \( S_{c} \) are given by (see Appendix D)

\[
S = \frac{m_{e} v_{F,sc}^{2} L}{2 \pi \Delta \alpha} K_{0} \left( \frac{\alpha \Delta}{h u} \right),
\]

\[
S_{c} = \frac{m_{e} v_{F,sc}^{2} L |\sin(k_{F,sc} d)| e^{-\frac{\alpha}{\Delta}}}{\pi^{2} \alpha^{2}} \int_{0}^{\pi/2} d\theta K_{0} \left( \frac{\alpha|\sin(\theta)|\Delta}{h u} \right).
\]

where \( K_{0}(p) = \int_{0}^{\infty} dx \frac{\cos(px)}{\sqrt{x^{2}+p^{2}}} \) is the modified Bessel function of the second kind. We remark that for noninteracting systems with \( K_{1,3}(0) = 1 \), the derivatives of \( \tilde{t}_{\text{int}} \) and \( \tilde{t}_{\text{ext}} \) are finite rather than zero as these dimensionless quantities depend explicitly on the cutoff \( \alpha \) as \( \tilde{t}_{\text{int}}, \tilde{t}_{\text{ext}} \propto \alpha^{-3/2} \). However, the noninteracting case is reproduced correctly for physical quantities, \( dt_{\text{int}}/dl = dt_{\text{ext}}/dl = 0 \).

The source terms \( S \) and \( S_{c} \) are monotonically decreasing functions of the flow parameter \( l \), see Fig. 8. We further note that the crossed Andreev source term \( S_{c} \) gets exponentially suppressed with increasing distance \( d \) between the NWs on the scale of the coherence length \( \xi \) of the SC (with power-law correction \( 1/d \)), and, moreover, oscillates on the scale of the Fermi wavelength of SC. Since this source term generates the crossed Andreev pairing in the RG flow, the same parameter dependence holds for \( \Delta_{c} \) (possibly renormalized by interactions), which, again, is consistent with the noninteracting case obtained before [72].

Next, we solve the set of coupled RG equations [see Eq. (36)] numerically and plot the coupling constants and LL parameters as a function of flow parameter \( l \), see Fig. 9. First, we explore how the flow depends on the initial values of the LL parameters as a function of flow parameter \( l \), see Fig. 9. Initially, the intrawire direct pairing \( \tilde{t}_{\text{int}}(0) = \tilde{t}_{\text{int}}(0) = 3.8 \times 10^{-5} \), \( \Delta = 0.35 \) meV, \( u = 10^{6} \) m/s, \( v_{F,sc} = 10^{6} \) m/s, \( \alpha_{0} = 1 \) nm, \( d = 15 \alpha_{0} \), \( L = 1 \) \( \mu \)m, and \( \alpha_{sc} = 1/k_{F,sc} = 1 \) Å.

FIG. 8. The source terms, \( S^{2}_{\text{int}}/S_{\text{ext}} \) and \( S^{3}_{\text{int}}/S_{\text{ext}} \), as a function of the RG flow parameter \( l \), see Eqs. (37) and (38). Initially, the interwire source term \( S^{3}_{\text{int}} \) (red dashed), however, both vanish rapidly for large \( l \). The used parameter values are \( \tilde{t}_{\text{int}} = \tilde{t}_{\text{int}}(0) = \tilde{t}_{\text{ext}}(0) = 3.8 \times 10^{-5} \), \( \Delta = 0.35 \) meV, \( u = 10^{6} \) m/s, \( v_{F,sc} = 10^{6} \) m/s, \( \alpha_{0} = 1 \) nm, \( d = 15 \alpha_{0} \), \( L = 1 \) \( \mu \)m, and \( \alpha_{sc} = 1/k_{F,sc} = 1 \) Å.

The RG flow of dimensionless coupling constants and LL parameters as a function of flow parameter \( l \) obtained numerically in the source term approach from Eq. (36). The initial values of LL parameters are chosen as (a) \( K_{1,3}(0) = 1 \), (b) 1.6, and (c) 2. (a) For noninteracting systems, the intrawire pairing always dominates over the interwire pairing, \( \tilde{\Delta}_{\text{int}} > \tilde{\Delta}_{c} \), resulting in the system being in a trivial phase. (b) Due to strong repulsive interactions, there is a crossover between intrawire pairing amplitude (\( \tilde{\Delta}_{c} \)) and interwire pairing amplitude (\( \Delta_{c} \)) at the end of the RG flow. (c) As the interaction strength is increased, \( \Delta_{c} \) reaches the strong coupling limit much faster, which indicates that the RG flow brings the system into the topological phase. In addition, we calculate numerically the proximity-induced gaps in physical units: for (a), (b), and (c), the final flow values of these gaps are \( \Delta /\Delta = 0.33, 0.81, \) and \( 0.66, \) and \( \Delta_{\text{int/ext}} /\Delta = 1, 0.68, \) and 0.33, respectively. We note that we also stop the RG flow when a proximity gap reaches \( \tilde{\Delta}_{c} \) [86]. The other parameter values are fixed to \( \Delta = 0.35 \) meV, \( u = 10^{6} \) m/s, \( v_{F,sc} = 10^{6} \) m/s, \( \alpha_{0} = 1 \) nm, \( d = 15 \alpha_{0} \), \( L = 1 \) \( \mu \)m, and \( \alpha_{sc} = 1/k_{F,sc} = 1 \) Å. We use the initial conditions \( \tilde{t}_{\text{int}}(0) = 3.8 \times 10^{-5} \) and \( \tilde{\Delta}_{\text{int/ext}}(0) = \tilde{\Delta}_{c}(0) = 0 \).

FIG. 9. The RG flow of dimensionless coupling constants and LL parameters as a function of flow parameter \( l \) obtained numerically in the source term approach from Eq. (36). The initial values of LL parameters are chosen as (a) \( K_{1,3}(0) = 1 \), (b) 1.6, and (c) 2. (a) For noninteracting systems, the intrawire pairing always dominates over the interwire pairing, \( \tilde{\Delta}_{\text{int}} > \tilde{\Delta}_{c} \), resulting in the system being in a trivial phase. (b) Due to strong repulsive interactions, there is a crossover between intrawire pairing amplitude (\( \Delta_{c} \)) and interwire pairing amplitude (\( \tilde{\Delta}_{c} \)) at the end of the RG flow. (c) As the interaction strength is increased, \( \Delta_{c} \) reaches the strong coupling limit much faster, which indicates that the RG flow brings the system into the topological phase. In addition, we calculate numerically the proximity-induced gaps in physical units: for (a), (b), and (c), the final flow values of these gaps are \( \Delta_{c}/\Delta = 0.33, 0.81, \) and \( 0.66, \) and \( \Delta_{\text{int/ext}}/\Delta = 1, 0.68, \) and 0.33, respectively. We note that we also stop the RG flow when a proximity gap reaches \( \Delta \) [86]. The other parameter values are fixed to \( \Delta = 0.35 \) meV, \( u = 10^{6} \) m/s, \( v_{F,sc} = 10^{6} \) m/s, \( \alpha_{0} = 1 \) nm, \( d = 15 \alpha_{0} \), \( L = 1 \) \( \mu \)m, and \( \alpha_{sc} = 1/k_{F,sc} = 1 \) Å. We use the initial conditions \( \tilde{t}_{\text{int}}(0) = 3.8 \times 10^{-5} \) and \( \tilde{\Delta}_{\text{int/ext}}(0) = \tilde{\Delta}_{c}(0) = 0 \).
FIG. 10. The phase diagram as a function of initial values of the source term $\Delta_\alpha(0)/\Delta$ and LL parameter $K_3(0)$ obtained numerically by solving the RG equations with source terms, see Eq. (36). Here, $\Delta$ is the gap of the bulk SC and $\Delta_\alpha(0) = S(0)\tilde{\tau}^{\text{int/ext}}_{\alpha}(0)\tilde{a}_{\alpha}$ is the source term where we put back the $\hbar$ factor for proper energy units. Again, whenever one of the coupling constants reaches unity, we stop the flow. If the crossed Andreev pairing amplitude $\Delta_\alpha(t) > \Delta_{\text{int}}(0)$ dominates, the system is in the topological phase (blue area). If the direct pairing amplitude wins, the system is in the trivial phase (red area). For small initial values of the tunneling amplitude, the system tends to be always in the topological phase. If the tunneling is increased or the distance $d$ between the NW grows, stronger and stronger interactions are required to bring the system into the topological phase. The initial conditions are $\Delta_{\text{int}}(0) = \Delta_{\text{ext}}(0) = 0$ and $K_3(0) = K_2(0)$, and the parameter values are $\Delta = 0.35 \text{ meV}$, $u = 10^4 \text{ m/s}$, $v_F,sc = 10^9 \text{ m/s}$, $\alpha_0 = 1 \text{ nm}$, $d = 15\alpha_0$, $L = 1 \mu\text{m}$, and $\alpha_{sc} = 1/k_{F,sc} = 1 \text{ Å}$.

In the later part of the flow, the interwire pairing will dominate over the intrawire one. In other words, the crossed Andreev pairing ($\Delta_\alpha$) should reach the strong coupling limit much faster than the direct pairings ($\Delta_{\text{int}}$ and $\Delta_{\text{ext}}$). This eventually drives the system into the topological phase [see Figs. 9(b) and 9(c)]. As in previous sections, we stop the RG flow whenever one of the coupling constants reaches unity.

In addition, we explore how the phase diagram depends on different initial conditions. In particular, on the tunneling strengths, $\tilde{\tau}^{\text{int/ext}}_{\text{int/ext}}(0)$, and LL parameters, $K_1$ and $K_3$, see Fig. 10. The energy scale for the tunneling terms is defined via the source term as $\Delta_\alpha = S(0)\tilde{\tau}^{\text{int/ext}}_{\text{int/ext}}(0)\tilde{a}_{\alpha}$. Similarly, to the previous section, as the ratio between the initial value of source term and superconducting gap increases, we need stronger and stronger interactions to reach the topological phase in the system. This can be understood in the following sense. The initial values of source term always favor the intrawire pairing as $S > S_\alpha$, see Fig. 8. Only at large $I$, the crossed Andreev pairing grows and begins to dominate. However, if the intrawire pairing was large from the beginning, the intrawire pairing has already reached the strong coupling regime and the flow must be stopped [86], see Fig. 9. As a result, the crossed Andreev term does not have a chance to develop.

To conclude, we note that the two phase diagrams obtained by solving the RG equations for the effective Hamiltonian (see Fig. 4) and by using the source term approach (see Fig. 9) qualitatively look similar. However, quantitatively, they are different in the following way: (1) the crossed Andreev pairing amplitude $\Delta_\alpha$ reaches the strong coupling limit faster in Fig. 9(c) compared to Fig. 4. (2) As shown in Fig. 9, at the beginning of the RG flow, the contribution coming from the intrawire source term $S$ is always greater than the one from the interwire term, $S_\alpha$ (see Fig. 8), which results in $\Delta_{\text{int/ext}}(0)$ being greater than $\Delta_\alpha$. In contrast to that, for larger values of flow parameter $I$ and due to strong repulsive electron-electron interactions in the NWs, there is a crossover between $\Delta_{\text{int/ext}}(0)$ and $\Delta_\alpha$. However, as seen from Fig. 4, if $\Delta_{\text{int/ext}}(0) = \Delta_\alpha(0)$, $\Delta_\alpha$ is always greater than $\Delta_{\text{int/ext}}(0)$ for repulsive interactions in the NWs, while for initial values $\Delta_{\text{int/ext}}(0) > \Delta_\alpha(0)$, there is also a crossover between $\Delta_{\text{int/ext}}(0)$ and $\Delta_\alpha$, and the topological phase can be reached. Thus the results obtained in Sec. V also hold if we start from a more microscopic approach in terms of a tunneling Hamiltonian between superconductor and NWs. Finally, we note that we have also checked numerically the RG flows for disordered NWs in the source term approach, and we got essentially the same qualitative results as already presented in Sec. V. Thus we do not consider the RG flow equation of disorder and backscattering terms in this section.

However, there is a qualitative difference between the two approaches in that stronger electron-electron interactions (larger $K_3$) are needed in the tunneling approach in order to reach the topological phase. This can be understood by the following qualitative reasoning (see also Refs. [66,67]). In the tunneling approach, the suppression of the direct pairing is less pronounced than in the phenomenological approach. This is so because the two electrons from a Cooper pair enter the NW in a second-order tunneling process, which implies that the electrons of the NW interact with each tunneling electron (more or less) one by one since they hop from the SC on the NW one after the other in a co-tunneling fashion, with some virtual delay time between them. This delay time is roughly inversely proportional to the SC gap $\Delta$—the energy cost of the virtual excitation on the SC (ignoring correlation effects in the NW). Thus the smaller $\Delta$ the more the electrons are separated in time, and the less difference we get between direct and crossed Andreev processes. In contrast, in the phenomenological model, the electrons are added as a whole Cooper pair (with twice the electron charge) to the NWs, which gives rise to stronger repulsive interactions with the electrons in the NWs. As a consequence, the direct and the crossed Andreev processes are less distinguishable by the interactions in the tunneling than in the phenomenological approach and it takes stronger interactions in the former case to make the crossed Andreev process to dominate over the direct one.

To summarize, in the microscopic source-term approach, the interactions are taken into account at a more fundamental level than in the effective Hamiltonian approach. In particular, interactions modify already the tunneling process that generates the superconducting pairing terms in the NWs, while in the effective Hamiltonian approach we add interactions only at a later stage after the pairing gap is already formed. However, very similar conclusions are reached in both approaches.

VII. CONCLUSIONS AND OUTLOOK

In this work, we studied a setup consisting of two Rashba NWs coupled to a bulk three-dimensional $s$-wave supercon-
ductor. We focused on the interplay between direct (intrawire) and crossed Andreev (interwire) superconducting pairing processes. Standard bosonization techniques were used to treat strong electron-electron interactions and weak uncorrelated Gaussian disorder. For the latter, we employed the replica trick of disorder averaging. We performed an RG analysis to determine which terms dominate and identified the parameter regime for which the system is in the topological phase, with a KMBS at each end of the double-NW system. In particular, the crossed Andreev pairing amplitude \( \Delta_c \) reaches the strong coupling limit for \( K_{1,3} > 1 \), while for \( K_{1,3} < 1 \) it flows to zero as \( \Delta_c = 0 \) is a stable fixed point. The value of spin and charge LL constants in the NWs should satisfy the condition \( K_{\tau s} > K_{\tau c} \), which is possible only for repulsive electron-electron interactions in the NWs. By evaluating numerically the phase diagram, we have confirmed that the topological phase is stable against weak disorder. Generally, electron-electron interactions lower the value of all types of gaps in the NWs [42], however, the interwire (crossed Andreev) pairing amplitude gets reduced less than the intrawire (direct) pairing amplitude, enabling eventually the topological phase hosting KMBSs. Importantly, the topological phase is achieved even if the system is initially in the trivial phase with dominant magnetic effects properly into account. For such a treatment, the coupled-wire model seems to be a most suitable starting point as it will allow one to describe both integer and fractional superconducting pairings induced in helical edge states can be mapped to our model by retaining only terms acting on the interior branches of the spectrum. Again, one would expect that the crossed Andreev pairing dominates in the regime of strong electron-electron interactions and is stable against weak disorder treated as in Ref. [88].

Alternatively, crossed Andreev pairing also plays an important role in many proposals for parafermions in quantum Hall systems coupled to bulk \( s-wave \) superconductors. Based on our analysis, we can expect that strong electron-electron interactions will suppress the proximity-induced pairing gap in the chiral edge channels. However, in this case, the RG analysis should be carefully redone by including time-reversal symmetry breaking terms to take Zeeman splittings and orbital magnetic effects properly into account. For such a treatment, the coupled-wire model seems to be a most suitable starting point as it will allow one to describe both integer and fractional filling factors [89–100]. The source term approach also opens up the possibility to obtain the dependence of crossed-Andreev pairings on the distance between two NWs. In our calculations, we worked with an effectively infinite bulk \( s-wave \) superconductor. As a consequence, proximity-induced pairing terms are independent of the size of the SC. However, it would be interesting to consider SCs of finite geometry such as thin films, as done for noninteracting systems [101]. In this case, one needs to use appropriate Green functions which account for the finite-size effects of the SC. We believe that similar progress can be made along the lines shown here.

**APPENDIX A: TRANSFORMATION RELATIONS OF LL PARAMETERS**

In this appendix, we compute relations between the new bosonic field velocities \( u_i \) and LL parameters \( K_i \) \((i = 1, 2, 3, 4)\) and the charge-spin velocities \( u_{\tau c}, u_{\tau s} \) and LL parameters \( K_{\tau c}, K_{\tau s} \) for each \( \tau \)-NW. First, we define the charge-spin bosonic fields as \( (\phi_{\tau c}, \phi_{\tau s}) \) and their conjugate fields as \( (\theta_{\tau c}, \theta_{\tau s}) \). These fields obey the commutation relation \( [\phi_{\tau c,j}(x), \theta_{\tau c,j}(x')] = i\pi \delta_{\tau c, s}\text{sgn}(x' - x)/2 \). Using Eq. (10), the Hamiltonian \( H_0 \) given by Eq. (7) in the main text takes the following form:

\[
H_0 = \sum_\tau \int \frac{dx}{2\pi} \left\{ u_{\tau c} \left[ \frac{(\partial_x \phi_{\tau c})^2}{K_{\tau c}} + K_{\tau c} (\partial_x \phi_{\tau s})^2 \right] + u_{\tau s} \left[ \frac{(\partial_x \phi_{\tau s})^2}{K_{\tau s}} + K_{\tau s} (\partial_x \theta_{\tau s})^2 \right] \right\}.
\]

Next, we change to the new bosonic field basis \( (\phi_j, \theta_j) \), where \( j = 1, 2, 3, 4 \) introduced in Eq. (13) of the main text with commutation relations defined as \( [\phi_j(x), \theta_j(x')] = i\pi \delta_{j, s}\text{sgn}(x' - x)/2 \). As a result, Eq. (A1) takes the form

\[
H_0 = \int \frac{dx}{2\pi} \left\{ u_{1,c} \frac{1}{2} \left[ \frac{(\partial_x (\phi_1 + \phi_2))^2}{K_{1,c}} + K_{1,c} (\partial_x (\phi_1 + \phi_3))^2 \right] + u_{1,s} \frac{1}{2} \left[ \frac{(\partial_x (\phi_3 - \phi_1))^2}{K_{1,s}} + K_{1,s} (\partial_x (\theta_3 - \theta_1))^2 \right] \right. \]

\[
+ \left. u_{1,c} \frac{1}{2} \left[ \frac{(\partial_x (\phi_2 + \phi_4))^2}{K_{1,c}} + K_{1,c} (\partial_x (\phi_2 + \phi_4))^2 \right] + u_{1,s} \frac{1}{2} \left[ \frac{(\partial_x (\phi_4 - \phi_2))^2}{K_{1,s}} + K_{1,s} (\partial_x (\theta_4 - \theta_2))^2 \right] \right\}.
\]
We recall that $u_i$ and $K_i$ are the new velocities and LL parameters, respectively. We consider only the diagonal terms in Eq. (A2) as the nondiagonal terms are marginal operators which are negligible under the RG flow [78]. The Hamiltonian $H_0$ in Eq. (A2) takes the form

$$H_0 = \sum_{i=1,2,3,4} u_i \int \frac{dx}{2\pi} \left[ \frac{(\partial_x \phi_i)^2}{K_i} + K_i (\partial_x \theta_i)^2 \right],$$

(A3)

with the following constraints:

$$\frac{u_1}{K_1} = \frac{u_3}{K_3} = \frac{u_{1,\zeta}}{2K_{1,\zeta}} + \frac{K_{1,\zeta}u_{1,\zeta}}{2}, \quad \frac{u_2}{K_2} = \frac{u_{4,\zeta}}{2K_{1,\zeta}} + \frac{K_{1,\zeta}u_{1,\zeta}}{2},$$

$$u_1K_1 = u_3K_3 = \frac{u_{1,\zeta}}{2K_{1,\zeta}} + \frac{K_{1,\zeta}u_{1,\zeta}}{2}, \quad u_2K_2 = u_{4,\zeta}K_{1,\zeta} + \frac{K_{1,\zeta}u_{1,\zeta}}{2}.$$  

(A4)

This allows us to determine $u_i$ and $K_i$,

$$u_{1/2} = u_{3/4} = \frac{1}{2} \sqrt{\left(\frac{u_{1,\zeta}}{K_{1,\zeta}} + K_{1,\zeta}u_{1,\zeta}\right)\left(\frac{u_{2,\zeta}}{K_{1,\zeta}} + K_{1,\zeta}u_{2,\zeta}\right)},$$

(K_1/2 = K_{3/4} = \sqrt{\frac{u_{1,\zeta}}{K_{1,\zeta}} + K_{1,\zeta}u_{1,\zeta}} - \sqrt{\frac{u_{2,\zeta}}{K_{1,\zeta}} + K_{1,\zeta}u_{2,\zeta}).$$

(A5)

(A6)

For an ideal LL (Galilean invariant continuum model) we have $u_{\tau,c/s} = \frac{u_{\tau,c/s}}{K_{\tau,c/s}}$. This leads us to the expressions given in Eqs. (15) and (16) of the main text.

**APPENDIX B: OPERATOR PRODUCT EXPANSION (OPE)**

In this appendix, we write the expressions for OPE [81–84] used later in Appendix C to derive the RG equations. The kinetic part of the Hamiltonian is given by

$$H_{0a} = u \int \frac{dx}{2\pi} \left[ \frac{(\partial_x \phi)^2}{K} + K (\partial_x \theta)^2 \right],$$

(B1)

where $K$ is the LL parameter and $\phi$ and its conjugate field $\theta$ are bosonic fields with the only nonzero commutation relation given by $[\phi(x), \bar{\phi}(x')] = i\pi \frac{\text{sgn}(x'-x)}{2}$. We define the complex coordinates $(z, \bar{z})$ as $z = -i x + u t$ and $\bar{z} = i x + u t$, where $x$ and $t$ are position and imaginary time coordinates, respectively. The corresponding derivatives are given by $\partial_c = -\frac{i}{2}(\partial_x - i \partial_t)$ and $\partial_{\bar{c}} = -\frac{i}{2}(\partial_x + i \partial_t)$ [75,83]. In the OPE expressions, we use the following relations for bosonic operators $A$ and $B$ [75,102]:

$$e^A e^B = e^{A+B + \frac{\lambda^2}{4\pi^2} K}.$$  

(B2)

where $: C :$ denotes normal ordering of the operator $C$. In what follows, we will be also using the following expressions:

$$\langle (\phi(z), \bar{\phi}(0,0)) \rangle_0 = K \ln \left| \frac{1}{\alpha} \right|, \quad \langle (\phi(0,0), \bar{\phi}(0)) \rangle_0 \sim -\frac{K}{2} \ln \alpha,$$

$$\langle (\theta(z), \bar{\theta}(0,0)) \rangle_0 = \frac{1}{K} \ln \left| \frac{1}{\alpha} \right|, \quad \langle (\theta(0,0), \bar{\theta}(0)) \rangle_0 \sim -\frac{1}{2K} \ln \alpha,$$

(B3)

where the expectation value $\langle \cdots \rangle_0$ is taken with respect to the LL Hamiltonian $H_{0a}$ defined in Eq. (B1), and where “$\sim$” indicates omission of constant units.

Further, we write the OPEs [81–85] for the conjugate $\phi$ and $\theta$ fields,

$$e^{i\lambda \phi(z)} e^{-i\lambda \phi(0,0)} = \frac{1}{(|z|/\alpha)^{2K/2}} + \frac{\lambda}{(|z|/\alpha)^{2K/2}} (z J_\phi - \z J_\phi) + \frac{i \lambda \alpha^2}{2(|z|/\alpha)^{2K/2}} (\partial_x \phi) + \frac{i \lambda}{2(|z|/\alpha)^{2K/2}} \left[z^2 (\bar{z}^2 \phi) + \bar{z}^2 (\bar{z}^2 \phi) \right]$$

$$+ \frac{\lambda^2}{2(|z|/\alpha)^{2K/2}} \left[z^2 : J_\phi^2 : + \bar{z}^2 : J_\phi^2 : \right] - \frac{\lambda^2 \alpha^2}{2(|z|/\alpha)^{2K/2}} (\partial_x \phi) + \frac{i \lambda \alpha^2}{2(|z|/\alpha)^{2K/2}} (\partial_x \phi),$$

$$e^{i\lambda \phi(z)} e^{-i\lambda \phi(0,0)} = \frac{1}{(|z|/\alpha)^{2K/2}} + \frac{\lambda}{(|z|/\alpha)^{2K/2}} (z J_\theta - \z J_\theta) + \frac{i \lambda \alpha^2}{2(|z|/\alpha)^{2K/2}} (\partial_x \theta) + \frac{i \lambda}{2(|z|/\alpha)^{2K/2}} \left[z^2 (\bar{z}^2 \theta) + \bar{z}^2 (\bar{z}^2 \theta) \right]$$

$$+ \frac{\lambda^2}{2(|z|/\alpha)^{2K/2}} \left[z^2 : J_\theta^2 : + \bar{z}^2 : J_\theta^2 : \right] - \frac{\lambda^2 \alpha^2}{2(|z|/\alpha)^{2K/2}} (\partial_x \theta) + \frac{i \lambda \alpha^2}{2(|z|/\alpha)^{2K/2}} (\partial_x \theta),$$

(B4)

(B5)
\[ e^{i \lambda \phi(z_2, z_1)} e^{-i \frac{\lambda}{2} \phi(0, 0) + \theta(0, 0)} = \frac{1}{(z_1/|z_1|)^{\lambda} (z_2/|z_2|)^{\lambda}} \left[ \frac{\lambda}{(z_1/|z_1|)^{\lambda} (z_2/|z_2|)^{\lambda}} (z(J_\phi + J_\theta) - \bar{z}(\bar{J}_\phi + \bar{J}_\theta)) \right] + \frac{i \lambda \alpha^2}{(z_1/|z_1|)^{\lambda} (z_2/|z_2|)^{\lambda}} (\partial_\phi \phi + \theta) + \frac{i \lambda}{2 (z_1/|z_1|)^{\lambda} (z_2/|z_2|)^{\lambda}} \left( z^2 \partial^2_\phi + \bar{z}^2 \partial^2_\phi \right) + \frac{\lambda}{2 (z_1/|z_1|)^{\lambda} (z_2/|z_2|)^{\lambda}} \left[ \left( J_\phi^2 + J_\theta^2 \right) + \left( \bar{J}_\phi^2 + \bar{J}_\theta^2 \right) \right] + \cdots \right] e^{i \frac{\lambda}{2} \phi(0, 0) + \theta(0, 0)}, \] (B6)

where \( \lambda \) is a real constant and \( J_\phi = [i \partial_\phi \phi(z, \bar{z})]_{(z, \bar{z})=(0,0)} \), \( J_\theta = [-i \partial_\theta \theta(z, \bar{z})]_{(z, \bar{z})=(0,0)} \), \( J_\phi(\bar{z}) = [i \partial_\phi \theta(z, \bar{z})]_{(z, \bar{z})=(0,0)} \), and \( J_\theta(\bar{z}) = [-i \partial_\theta \theta(z, \bar{z})]_{(z, \bar{z})=(0,0)} \). In the above OPEs, the terms that renormalize the kinetic energy terms are given by

\[ J_\phi \bar{J}_\phi = \frac{(\partial_\phi \phi)^2 + (\partial_\theta \phi)^2}{4}, \]
\[ J_\theta \bar{J}_\theta = \frac{(\partial_\theta \theta)^2 + (\partial_\bar{\theta} \theta)^2}{4}. \] (B7)

**APPENDIX C: DERIVATION OF RG EQUATIONS IN THE EFFECTIVE HAMILTONIAN APPROACH**

In this appendix, we derive the RG flow equations for coupling constants and LL parameters in the effective Hamiltonian approach. The effective Hamiltonian is defined in Eq. (30) of the main text. Before calculating the RG flow equations for our involved Hamiltonian, we show the basic steps how to perform the RG analysis for the simple Hamiltonian, \( H = H_{0a} + \frac{\Lambda}{\pi} \int dx \cos(\lambda \phi) = H_{0a} + \frac{\Lambda}{\pi \alpha} \int dx \cos(\lambda \phi) \), where \( H_{0a} \) is defined in Eq. (B1). Here, the following symbols were introduced: \( \Lambda \) (coupling constant with dimension of energy), \( \bar{\Lambda} = \Lambda \alpha / u \) (dimensionless coupling constant), \( \alpha \) (lattice constant), \( \lambda \) (real constant), and \( u \) (Fermi velocity in the NWs). Before obtaining the RG flow equations for \( \Lambda \) and \( K \), we write down the OPE for \( \cos(\lambda \phi) \) for \( (z_1/z_2, z_1 \bar{z}_2) \to (\bar{z}_c, z_c) \), where \( z_c = (z_1 + z_2)/2 \) is the center-of-mass coordinate. In what follows, we will keep only singular terms, which leads to

\[ \cos(\lambda \phi(z_1, \bar{z}_1)) \cos(\lambda \phi(z_2, \bar{z}_2)) = [e^{i \lambda \phi(z_1, \bar{z}_1)} e^{-i \lambda \phi(z_2, \bar{z}_2)} + e^{-i \lambda \phi(z_1, \bar{z}_1)} e^{i \lambda \phi(z_2, \bar{z}_2)}] / 4, \]
\[ = \frac{1}{2 (z_1 - \bar{z}_2/|z_2|)^{\lambda} K/2} - \frac{\lambda^2 \alpha^2}{2 (z_1 - \bar{z}_2/|z_2|)^{\lambda} K/2} \left[ J_\phi \bar{J}_\phi \right]_{(z, \bar{z})} + \cdots, \quad (C1) \]

To obtain the RG flow equations, the partition function is expanded in powers of the cosine term, which gives up to second order

\[ Z_\alpha = Z_{0a} \left[ 1 - \frac{\Lambda u}{\pi \alpha^2} \int dx dt \cos(\lambda \phi(x, t)) + \frac{\Lambda^2 u^2}{2 \pi \alpha^2} \int dx_1 dx_2 dt_1 dt_2 \cos(\lambda \phi(x_1, t_1)) \cos(\lambda \phi(x_2, t_2)) + \cdots \right]. \quad (C2) \]

where \( Z_{0a} \) is the partition function for fixed point Hamiltonian \( H_{0a} \). To implement the RG procedure, we change the cutoff from \( \alpha \) to \( \alpha + d \alpha \) and calculate the corresponding change in \( \Lambda \) in such a way that the partition function is preserved [81]. First, we consider the second term in Eq. (C2) and calculate the change in \( \Lambda \). From Eq. (C1), the scaling dimension of \( \cos(\lambda \phi) \) is half the power of \( 1/|z| \), i.e., \( \lambda^2 K / 4 \). Thus we obtain the RG flow equation for \( \Lambda \) as

\[ \frac{d \Lambda}{d l} = \left( 2 - \frac{\lambda^2 K}{4} \right) \Lambda, \quad \text{where} \quad d l = \frac{d \alpha}{\alpha}. \quad (C3) \]

Next, we consider the third term in Eq. (C2) and again change the cutoff from \( \alpha \) to \( \alpha + d \alpha \). For obtaining the contribution from this term to the quadratic part of the Hamiltonian, we change to the center-of-mass coordinates, \( X = (x_1 + x_2)/2, T = (t_1 + t_2)/2, x = x_1 - x_2 \) and \( t = t_1 - t_2 \), which in terms of the complex coordinates are defined as \( z_1/2 = -i x_1/2 + u t_1/2 \), and take the form \( z_c = (z_1 + z_2)/2 \). We then change to polar coordinates \((r, \theta')\) with \( \int dx(X, t) = \int dr dt d\theta' = 2\pi \int r dr \) and split the integral over \( r \) into two parts such that \( \int_{(r,u+d\alpha)} f_{(r,u)} = \int_{r} f_{r} - \int_{(r,u+d\alpha)} \). The first integral contributes towards the original integral in the partition function and we only need to compute the integral within \( \alpha < r < \alpha + d \alpha \). We use the OPE given by Eq. (C1), where we focus on the second term, which gives the renormalization of the LL parameter \( K \). Thus the contribution from the third term in the partition function which renormalizes \( K \) is given by

\[ I^{\alpha} = -\int dx dt dX dT \frac{\Lambda^2 u^2}{2 \pi \alpha^2} \left[ J_\phi \bar{J}_\phi \right]_{(X,T)} \]
\[ = -\frac{1}{16} \int dx dt dX dT \frac{\Lambda^2 u^2}{\pi \alpha^2} \left[ \frac{\lambda^2}{|z_1/\alpha|^{\lambda} K/2} \right] \left( \partial_\phi^2 + \frac{(\partial_\phi \theta)^2}{u^2} \right). \quad (C4) \]
We change the \((x,t)\) to \((r,\theta')\) as described above and compose the integral within \(\alpha < r < \alpha + d\alpha\). Thus, using \(f^{\alpha}_{\alpha + d\alpha} f(r) dr = f(\alpha) d\alpha\), Eq. (C4) takes the form

\[
I^{d\alpha} = \frac{\lambda^2 \bar{\Lambda}^2}{4} \frac{d\alpha}{\alpha} \int \frac{dX dT}{2\pi} \left[ u (\partial_x \phi)^2 + \frac{(\partial_r \phi)^2}{u} \right]. \tag{C5}
\]

Hence we get from Eq. (C5) that, in order to preserve the partition function \((Z_\alpha)\), the LL parameter \(K\) has to change in the following way:

\[
\frac{dK_{\alpha}}{dl} = \frac{\lambda^2 \bar{\Lambda}^2}{4} \Rightarrow \frac{dK}{dl} = -\left(\frac{\lambda}{2} - \frac{K}{\bar{\Lambda}}\right)^2. \tag{C6}
\]

Based on the discussion above, we explicitly derive the RG flow equations for the two terms from the Hamiltonian defined in Eq. (30) of the main text: for the superconducting pairing for exterior branches with the coupling amplitude \(\Delta_{\text{ext}}^s\) and for crossed Andreev superconducting pairing with the coupling amplitude \(\Delta_{\text{ext}}^a\). Note that we do not consider any crossterm between different coupling constants as they are less relevant compared to the original cosine terms [75]. The RG equations for the remaining coupling constants and LL parameters are determined by following the same procedure from Eqs. (C1)–(C6).

First, we consider the term \(\Delta_{\text{ext}}^s\) to calculate the contribution from the tunneling Hamiltonian given by Eq. (32) to the flow equation (31) of the text. We change the \((x,t)\) to \((r,\theta')\) as described above and compose the integral within \(\alpha < r < \alpha + d\alpha\). Thus, using \(f^{\alpha}_{\alpha + d\alpha} f(r) dr = f(\alpha) d\alpha\), Eq. (C4) takes the form

\[\int dX dT = \frac{\lambda^2 \bar{\Lambda}^2}{4} \frac{d\alpha}{\alpha} \Rightarrow dK_{\alpha} = -\left(\frac{\lambda}{2} - \frac{K}{\bar{\Lambda}}\right)^2.\]

To calculate the OPE for the \(\Delta_{\text{ext}}^s\) term, \(\lambda^2 \bar{\Lambda}^2 \int \frac{dX dT}{2\pi} \left[ u (\partial_x \phi)^2 + \frac{(\partial_r \phi)^2}{u} \right]\), Eq. (C5) we need to generalize the previous procedure. The only nonzero commutation relation between the fields \(\phi_1, \phi_2, \phi_3, \phi_4\) and \(B_1, B_2, B_3, B_4\) is given by \(\left[i \phi_1(x), B_2(x')\right] = i \lambda \alpha \cos(x - x')/2\). We again consider only the most singular terms in the limit \((z_1/\sqrt{v_1}) \rightarrow (z_2/\sqrt{v_2})\) and write down the OPEs relevant for the \(\Delta_{\text{ext}}^s\) term,

\[\cos[\phi_3(z_1, z_1) + \phi_4(z_2, z_2) - \theta_3(z_1, z_1) - \theta_4(z_2, z_2)] = \left[ e^{i\phi_3(z_1, z_1)} + e^{i\phi_4(z_2, z_2)} - e^{i\phi_3(z_1, z_2)} - e^{i\phi_4(z_2, z_1)} \right] \tag{C7}\]

\[= \left[ \frac{1}{2z/|\alpha|(|K_1 + K_2 + 1/K_3 + 1/K_4)/2)} \left[ J_{\alpha_1} J_{\alpha_2} + J_{\alpha_2} J_{\alpha_1} \right] \right] + \cdots \]

\[= \left[ \frac{1}{2z/|\alpha|(|K_1 + K_2 + 1/K_3 + 1/K_4)/2)} \left[ J_{\alpha_1} J_{\alpha_2} + J_{\alpha_2} J_{\alpha_1} \right] \right] + \cdots \tag{C8}\]

Hence the scaling dimension of the involved cosines in the \(\Delta_{\text{ext}}^s\) term is given by \((K_1 + K_2 + 1/K_3 + 1/K_4)/4\), and thus, the corresponding RG flow equations are written as \(\frac{dK_{\alpha}}{dl} = (2 - (K_1 + K_2 + 1/K_3 + 1/K_4)/4)\). The sum of the second terms in Eqs. (C7) and (C8) gives the renormalization of the LL parameters \(K_3\) and \(K_4\) and we follow the procedure defined in Eqs. (C4)–(C6) and compute the contributions to the \(K_3\) flow from the term \(J_{\alpha_1} J_{\alpha_2}\) as \(dK_{\alpha} = 2\lambda \Delta_{\text{ext}}^a \frac{d\alpha}{dl}\) and from the term \(J_{\alpha_1} J_{\alpha_2}\) as \(dK_{\alpha} = 2\lambda \Delta_{\text{ext}}^a \frac{d\alpha}{dl}\).

Summing up these two contributions, we arrive at \(dK_{\alpha} = \frac{(1-K_3)^2\lambda^2}{2}\). Similarly, we find the flow for the LL parameter \(K_4\), \(dK_{\alpha} = \frac{(1-K_4)^2\lambda^2}{2}\). In the same way, we calculate the OPE coefficient for the remaining terms in the Hamiltonian and get the RG flow equations displayed in Eq. (31) of the main text.

**APPENDIX D: DERIVATION OF RG EQUATIONS IN THE MICROSCOPIC SOURCE TERM APPROACH**

In this appendix, we compute the RG flow equations starting from the tunneling Hamiltonian given by Eq. (32). It describes the tunneling between each of two NWs and the three-dimensional s-wave superconductor. For simplicity, we assume that the strength of electron-electron interactions is the same in the two NWs such that \(K_1 = K_2\) and \(K_3 = K_4\). In the following section, we explicitly start from the partition function containing both NWs and SC degrees of freedom. By integrating out the SC part, we calculate the contribution to the pairing terms induced in the NWs by the tunneling terms.

**Terms associated with tunneling \(\text{tun} \) to interior branches of the spectrum**

\(a. \) **Contribution to the direct superconducting pairing \(\Delta_{\text{int}}^s \) induced at interior branches of the spectrum**

In the following section, we calculate the contribution from the tunneling Hamiltonian given by Eq. (32) to the flow equation of \(\Delta_{\text{int}}^s\). In the partition function \(Z\), we expand the action up to second order in the tunneling term, which results in a first-order
contribution to the proximity-induced superconducting pairing of the type $\sum_{i} \frac{\Delta^\mu u}{\alpha} \int dx (R_{i1}L_{i1} + L_{i1}R_{i1}^\dagger)$. Here, $\Delta^\text{int}$ is a dimensionless coupling constant, like in Eq. (8), which is initially zero but then assumes a finite value during the RG procedure as shown below. Without loss of generality, we focus on the first term in the first NW, i.e., on $R_{11}L_{11}$, which in terms of the bosonic operator has the form $\frac{\Delta^\mu u}{\pi \alpha^2} \int dx \, e^{2i\phi(x,t)}$. The partition function $[75, 81]$ (dimensionless) can be written as

$$Z = Z_0 \left[ 1 - \frac{\Delta^\text{int} u}{2 \pi \alpha^2} \int dx \, dt \, [e^{2i\phi(x,t)} + \text{H.c.}] + I + I + \cdots \right], \quad (D1)$$

where $Z_0$ is the partition function corresponding to the fixed point Hamiltonian $H_0$ written in Eq. (A3), and $(\cdots)_0$ denotes the expectation value over the NWs with respect to $H_0$. The second-order term $I$ in the partition function, coming from the tunneling Hamiltonian given by Eq. (32), is rewritten as

$$I = \frac{1}{2} \int dx \, dt \, dx_2 \, dt_2 \, d\tau \, d\tau' \, u^2 \left( \frac{\xi^2 L}{\alpha^3} \right) \int_0^\infty T[R_{11}(x_1,t_1)L_{11}(x_2,t_2)] \, [T[\Psi^\dagger_1(r,t_1)\Psi^\dagger_1(r',t_2)]] \times \delta(x_2-x_1) \delta(r_2 \delta(r_2) \delta(r_2') \delta(r_2') \delta(r_2'), \quad (D2)$$

where $R_{1\sigma}(x)$ and $L_{1\sigma}(x)$ are slowly varying right and left moving fields with spin $\sigma/2$ in the $\tau$-NW at position $x$ and $(\cdots)$ denotes the equilibrium expectation value over the degrees of freedom of the SC. We write $R_{11}(x_1,t_1)$ and $L_{11}(x_2,t_2)$ in bosonic language as $e^{i[\phi(x_1,t_1) - \phi(x_1,t_2)]} / \sqrt{2 \pi \alpha}$ and $e^{i[\phi(x_2,t_2) + \phi(x_2,t_1)]} / \sqrt{2 \pi \alpha}$. Thus $I$ can be written as

$$I = \frac{1}{4 \pi} \int dx \, dt \, dx_2 \, dt_2 \, d\tau \, d\tau' \, u^2 \left( \frac{\xi^2 L}{\alpha^3} \right) \int_0^\infty T[e^{i[\phi(x_1,t_1) - \phi(x_1,t_2)]} e^{i[\phi(x_2,t_2) + \phi(x_2,t_1)]}] \times \langle T[\Psi^\dagger_1(r,t_1)\Psi^\dagger_1(r',t_2)] \rangle \delta(x_2-x_1) \delta(r_2 \delta(r_2) \delta(r_2') \delta(r_2'), \quad (D3)$$

The anomalous Green function for our $s$-wave superconductor is given by $\langle T[\Psi^\dagger_{\sigma_1}(r,t_1)\Psi^\dagger_{\sigma_2}(r',t_2)] \rangle = \sigma \delta_{\sigma_1, \sigma_2} F(r, r', t_1, t_2)$ $[85]$, where the $F$ function can be calculated from its inverse Fourier transform function:

$$F(r, r', t_1, t_2) = \int \int \frac{d\omega \, dk}{(2\pi)^4} e^{i(r-r') \cdot k} e^{i(\omega t_1-\omega t_2)} \frac{\Delta}{\omega^2 + E_k^2 + \Delta^2}. \quad (D4)$$

Therefore the anomalous Green function becomes

$$\langle T[\Psi^\dagger_{\sigma_1}(r,t_1)\Psi^\dagger_{\sigma_2}(r',t_2)] \rangle = \int \int \frac{d\omega \, dk}{(2\pi)^4} \frac{\Delta e^{i(r-r') \cdot k + i(\omega t_1-\omega t_2)}}{\omega^2 + \Delta^2 + \left[\left(k^2 - k_{F,SC}^2\right)/2m_e\right]^2}$$

$$\quad = \int \int \frac{d\omega \, m_e \Delta e^{-\frac{\sqrt{\omega^2 + \Delta^2} \frac{\Delta}{\sqrt{\omega^2} + \frac{\Delta}{\omega}}}{2 \pi^2 |r-r'| \sqrt{\Delta^2 + \omega^2}} \sin(k_{F,SC} |r-r|), \quad (D5)$$

where $m_e, v_{F,SC}$, and $k_{F,SC}$ are the electron mass, Fermi velocity, and Fermi wave vector of the bulk SC, respectively. Hence Eq. (D3) can be rewritten as

$$I = -\frac{1}{4 \pi} u^2 \left( \frac{\xi^2 L}{\alpha^3} \right) \int dx \, dt \, dx_2 \, dt_2 \, T [e^{i[\phi(x_1,t_1) - \phi(x_1,t_2)]} e^{i[\phi(x_2,t_2) + \phi(x_2,t_1)]}] \times \int \int \frac{d\omega \, dm_e \Delta e^{-\frac{\sqrt{\omega^2 + \Delta^2} \frac{\Delta}{\sqrt{\omega^2} + \frac{\Delta}{\omega}}}{2 \pi^2 |x_1-x_2| \sqrt{\Delta^2 + \omega^2}} \sin(k_{F,SC} |x_1-x_2|), \quad (D6)$$

For low energy modes, we can approximate $e^{-\frac{\sqrt{\omega^2 + \Delta^2} \frac{\Delta}{\sqrt{\omega^2} + \frac{\Delta}{\omega}}}{2 \pi^2 |x_1-x_2| \sqrt{\Delta^2 + \omega^2}}} \approx e^{-\frac{\omega^2 + \Delta^2}{2 \pi^2 |x_1-x_2|^2 \Delta}},$ thus

$$I = -\frac{m_e \Delta u^2 \xi^2 L}{16 \pi^3 \alpha^4} \int dx \, dt \, dx_2 \, dt_2 \, T [e^{i[\phi(x_1,t_1) - \phi(x_1,t_2)]} e^{i[\phi(x_2,t_2) + \phi(x_2,t_1)]}] \sin(k_{F,SC} |x_1-x_2|) e^{-\frac{\omega^2 + \Delta^2}{2 \pi^2 |x_1-x_2|^2 \Delta}} \int d\omega \, \frac{e^{i(\omega t_1-\omega t_2)}}{\sqrt{\Delta^2 + \omega^2}}, \quad (D7)$$

$$= -\frac{m_e \Delta u^2 \xi^2 L}{16 \pi^3 \alpha^4} \int dx \, dt \, dx_2 \, dt_2 \, T [e^{i[\phi(x_1,t_1) - \phi(x_1,t_2)]} e^{i[\phi(x_2,t_2) + \phi(x_2,t_1)]}] \sin(k_{F,SC} |x_1-x_2|) e^{-\frac{\omega^2 + \Delta^2}{2 \pi^2 |x_1-x_2|^2 \Delta}} 2 K_0(|t_1-t_2| \Delta), \quad (D8)$$

where $K_0(p) = \int_0^\infty dx \frac{\sin(p x)}{x}$ is the modified Bessel function of the second kind. Furthermore, $\Delta$ is assumed to be $\omega$-independent. At the next step, we change to the center-of-mass coordinates $(X, T, x, t)$, where $X = (x_1 + x_2)/2$, $T = (t_1 + t_2)/2$, $x = x_1 - x_2$, $t = t_1 - t_2$. 

and \( t = t_1 - t_2 \). We also define complex coordinates \( z_{1/2} = -ix_{1/2} + u \), \( z_{c} = (z_1 + z_2)/2 \), and \( z = z_1 - z_2 \). As a result, we get

\[
I = -m_v \Delta u^2 \frac{\xi^2 L}{8 \pi^3 \alpha^4} \int dX dT dx dt T[e^{i[\phi_1(z_1) - \phi_2(z_2) + \theta(z_1, z_2)]}] \frac{\sin(k_{F,sc} |x|)}{|x|} e^{-\frac{\mid x \mid}{r_{sc}}} K_0(|r| \Delta). \tag{D9}
\]

To begin with the RG analysis, we again change the cutoff from \( \alpha \rightarrow \alpha + da \) (where \( da = adl \)). The integral over \((x, t)\) is converted to an integral over polar coordinates \((r, \theta)\). Next, we split the integral over \( r \) into two parts \( \int_{\alpha}^{\alpha + da} \rightarrow \int_{\alpha}^{\alpha + da/2} + \int_{\alpha + da/2}^{\alpha + da} \). The first one gives the original integral in the partition function and we only need to compute the integral \( I \) within \( \alpha < r < \alpha + da \). Again, we make use of following OPEs \cite{81} written in terms of the complex coordinates \((z_1, z_1)\) and \((z_2, z_2)\) with \( z_c = (z_1 + z_2)/2 \) and \( z = z_1 - z_2 \),

\[
T[e^{i[\phi_1(z_1, z_1) - \phi_2(z_1, z_1)]}] e^{i[\phi_1(z_2, z_2) + \theta(z_1, z_2)]}] \frac{1}{|z/|/\alpha|^{\pi \sin(\Delta)} + \ldots}, \tag{D10}
\]

where \( s_l = s_l = (K_3 + 1)/K_3 \) and \( s = K_3 \) are the scaling dimensions of \( e^{i[\phi_1(z_2, z_2) - \phi_2(z_1, z_2)]} \), \( e^{i[\phi_1(z_2, z_2) + \theta(z_1, z_2)]} \), and \( e^{2i\phi_1(z_2, z_2)} \), respectively. As a result, Eq. (D9) can be rewritten as

\[
I^{da} = \frac{m_v \Delta u^2 \xi^2 L}{8 \pi^3 \alpha^4} \int dX dT dx dt \frac{1}{|z/|/\alpha|^{\pi \sin(\Delta)}} e^{-\frac{|x|}{r_{sc}}} K_0(|r| \Delta). \tag{D11}
\]

For simplicity, we define \( I_1 \) such that

\[
I^{da} = \int dX dT e^{2i\phi(X,T)} I_1, \tag{D12}
\]

\[
I_1 = \frac{m_v \Delta u^2 \xi^2 L}{2 \pi^3 \alpha^4} \int_0^{\pi/2} d\theta' \sin(k_{F,sc} |\alpha \cos(\theta')|) e^{-\frac{|\alpha \sin(\theta')|}{r_{sc}}} K_0 \left( \frac{|\alpha \sin(\theta')|}{u} \right). \tag{D14}
\]

Therefore Eq. (D12) takes the form

\[
I^{da} = \left[ \frac{m_v \Delta^2 \xi^2 L}{2 \pi^3 \alpha^4} \int_0^{\pi/2} d\theta' \sin(k_{F,sc} |\alpha \cos(\theta')|) e^{-\frac{|\alpha \sin(\theta')|}{r_{sc}}} K_0 \left( \frac{|\alpha \sin(\theta')|}{u} \right) \right] \int_0^{1/2} \frac{u}{2 \pi^2 \alpha^2} dX dT e^{2i\phi(X,T)} \frac{d\alpha}{\alpha}. \tag{D15}
\]

This term allows us to find the contribution to the direct superconducting pairing \( S_{int} \) in the first order, see Eq. (D1). Since \( dl = \frac{dx}{\alpha} \) and \( \xi = v_{F,sc} / \Delta \), this leads us to

\[
\frac{d\Delta_{int}^2}{dl} = S_{int} \bar{\xi}^2, \tag{16}
\]

\[
S_{int} = \frac{m_v v_{F,sc} L}{\pi^2 \Delta \alpha} \int_0^{\pi/2} d\theta' \sin(k_{F,sc} |\alpha \cos(\theta')|) e^{-\frac{|\alpha \sin(\theta')|}{r_{sc}}} K_0 \left( \frac{|\alpha \sin(\theta')|}{u} \right) \times K_0 \left( \frac{|\alpha \sin(\theta')|}{u} \right). \tag{D17}
\]

Next, we estimate the integral over the polar angle by noting that the main contribution comes from angles close to \( \pi/2 \). We consider \( \theta' = \pi/2 \) and small contribution, where \( \theta' = \cos^{-1} \left( \frac{x}{2 \pi r_{sc}} \right) = \pi/2 - \sin^{-1} \left( \frac{\pi}{2 \pi r_{sc}} \right) = \pi/2 \left[ 1 - \right) \]

At the last step, we restore \( \hbar \) factors and arrive at \( S = \frac{m_v v_{F,sc} L}{\pi^2 \Delta \alpha} K_0 (\beta \Delta / \hbar u) \). In Fig. 11, we demonstrate that the approximate value \( S t_0^2 \) of the contribution coming from the tunneling term matches nicely with its exact value \( S_{int} \).
and Eq. (D18), respectively. Disregarding small oscillations, the electron mass, \( m_e \), is a good approximation for our low-energy theory. We change the coordinates to center-of-mass coordinates (1
2) \( T_{x,t} \times \bar{\rho} \), \( r, \theta \)

\[
I_c = -\frac{1}{4\pi} \int dx_1 dt_1 dx_2 dt_2 \int d\epsilon_x d\epsilon_t \left( \frac{\epsilon_x^2 L}{\alpha^4} \right) T_{x,t}^2 \left[ e^{i[\Phi(x_1,t_1) - \Phi(x_2,t_2)]} e^{i[\Phi(x_1,t_1) + \Phi(x_2,t_2)]} \right]
\]

\[
\times \sqrt{\Delta^2 + \omega^2}\int d\omega e^{-\frac{\omega^2}{2 \epsilon_x^2 L}} \left[ \frac{\sin(k_{F,sc} \sqrt{|x_1 - x_2|^2 + d^2})}{\sqrt{|x_1 - x_2|^2 + d^2}} \right]
\]

For low-energy modes, we again approximate \( e^{-\sqrt{\epsilon_x^2 L} \sqrt{\Delta^2 + \omega^2}} \) by \( e^{-\frac{\omega^2}{2 \epsilon_x^2 L}} \), resulting in

\[
I_c = -\frac{m_e \Delta^2 \omega L T_{sc}^2}{16 \pi \alpha^4} \int dx_1 dt_1 dx_2 dt_2 \int d\epsilon_x d\epsilon_t \left( \frac{\epsilon_x^2 L}{\alpha^4} \right) T_{x,t}^2 \left[ e^{i[\Phi(x_1,t_1) - \Phi(x_2,t_2)]} e^{i[\Phi(x_1,t_1) + \Phi(x_2,t_2)]} \right]
\]

\[
\times \sin(k_{F,sc} \sqrt{|x_1 - x_2|^2 + d^2})e^{-\frac{\omega^2}{2 \epsilon_x^2 L}} \int d\omega e^{-\frac{\omega^2}{2 \epsilon_x^2 L}} \left[ \frac{\sin(k_{F,sc} \sqrt{|x_1 - x_2|^2 + d^2})}{\sqrt{|x_1 - x_2|^2 + d^2}} \right]
\]

where \( K_0(p) = \int_0^\infty \frac{\cos}px \frac{dx}{\sqrt{x^2 + 1}} \) is the modified Bessel function of the second kind. We assume again \( \Delta \) to be \( \omega \)-independent, which is a good approximation for our low-energy theory. We change the coordinates to center-of-mass coordinates \( X = (x_1 + x_2)/2, T = (t_1 + t_2)/2, x = x_1 - x_2, \) and \( t = t_1 - t_2 \). We also introduce \( (z_1 + z_2)/2 = z_c \) where \( (z_1, z_2) \) are the complex coordinates as defined in previous Sec. D 1 a. We again change the cutoff from \( \alpha \) to \( \alpha + \Delta \) for the RG analysis and switch \((x,t)\) to the polar coordinates \((r,\theta')\), such that we need to calculate the integral only for \( \alpha < r < \alpha + \Delta \). We make use of the following OPE:

\[
T \left[ e^{i[\Phi(x_1,t_1) - \Phi(x_2,t_2)]} e^{i[\Phi(x_1,t_1) + \Phi(x_2,t_2)]} \right] \approx \frac{1}{|z|^2} \frac{1}{|r|^2} e^{i\Phi(x_1,t_1) - \Phi(x_2,t_2) + \Phi(x_1,t_1) + \Phi(x_2,t_2)} + \cdots.
\]
Here, the scaling dimensions of \( e^{i\phi(x-z)-\theta(x,z)} e^{i\phi(x-z)+\theta(x,z)} \) and \( e^{i(\phi(x-z)-\theta(x,z)+\phi(x,z)+\theta(x,z))} \) are \( c_r = (K + 1/K_3)/4, c_I = (K + 1/K_4)/4, \) and \( c = (K + 1/K_3 + K_4 + 1/K_4)/4, \) respectively. This yields the following correction coming from Eq. (D21) to the partition function,

\[
I_{c}^{da} = -\frac{m_e \Delta u^2 T_\text{int}^2 \xi^2 L}{8 \pi^3 \alpha^4} \int dX dT \frac{1}{|z/\alpha|^{\gamma+c-e}} \frac{\sin(k_{F,\text{sc}} \sqrt{|x|^2 + d^2} e^{-\frac{\sqrt{|x|^2+d^2}}{r_{\gamma,e}}})}{\sqrt{|x|^2 + d^2}} K_0(|r| \Delta),
\]

As a result, we rewrite \( I_c \) as

\[
I_{c}^{da} = \int dX dT e^{i(\phi(X,T)-\theta(x,T)+\phi(X,T)+\theta(x,T))} I_{c}^{da},
\]

\[
I_{c}^{da} = -\frac{m_e \Delta u^2 T_\text{int}^2 \xi^2 L}{8 \pi^3 \alpha^4} \int dX dT \frac{1}{|z/\alpha|^{\gamma+c-e}} \frac{\sin(k_{F,\text{sc}} \sqrt{|x|^2 + d^2} e^{-\frac{\sqrt{|x|^2+d^2}}{r_{\gamma,e}}})}{\sqrt{|x|^2 + d^2}} K_0(|r| \Delta).
\]

We compute the integral \( I_{c}^{da} \) within \( \alpha < r < \alpha + da \) (where \( da = adl \)). Using \( \int_{\alpha}^{\alpha+da} dr f(r) = da f(\alpha) \) and considering the fact that \( d \gg \alpha \) (we keep only the most singular terms in \( \alpha \) small before we scale \( \alpha \) up), we get

\[
I_{c}^{da} = \left( \frac{u da}{\alpha^2} \right) \frac{m_e \Delta T_\text{int}^2 \xi^2 L}{2 \pi^2} \int_0^{\pi/2} d\theta' \sin(k_{F,\text{sc}} d) e^{-\frac{\pi}{2 \alpha} d} K_0 \left( \frac{\alpha \sin(\theta') \Delta}{u} \right),
\]

which leads us to \( I_{c}^{da} \) in the form

\[
I_{c}^{da} = \left( \frac{u da}{\alpha^2} \right) \frac{m_e \Delta T_\text{int}^2 \xi^2 L}{2 \pi^2} \int_0^{\pi/2} d\theta' K_0 \left( \frac{\alpha \sin(\theta') \Delta}{u} \right) \frac{d \alpha}{\alpha}. \]

Again, \( I_{c}^{da} \) contributes to the crossed Andreev superconducting pairing \( \tilde{\Delta}_c \) in first order. With \( d l = \frac{da}{d} \Rightarrow \alpha = a_0 e^l \), and the coherence length given by \( \xi = \frac{\hbar}{k_{F,\text{sc}}} \), we conclude with the following relation for the contribution to the flow in \( \tilde{\Delta}_c \):

\[
\frac{d \tilde{\Delta}_c}{dl} = \frac{m_e T_\text{int}^2 v_{F,\text{sc}}^2}{\pi^2 \alpha^4} \frac{L |\sin(k_{F,\text{sc}} d)| e^{-\frac{\pi}{2 \alpha} d}}{\alpha \sin(\theta') \Delta} \int_0^{\pi/2} d\theta' K_0 \left( \frac{|\alpha \sin(\theta') \Delta|}{u} \right) = S_c T_\text{int}^2.
\]

After putting back the \( \hbar \) factors, the expression for \( S_c \) takes the form

\[
S_c = \frac{m_e v_{F,\text{sc}}^2 L |\sin(k_{F,\text{sc}} d)| e^{-\frac{\pi}{2 \alpha} d}}{\pi^2 \alpha^4} \int_0^{\pi/2} d\theta' K_0 \left( \frac{|\alpha \sin(\theta') \Delta|}{\hbar u} \right).
\]

2. Contribution to the direct superconducting pairing \( \Delta_1^{\text{ext}} \) induced at exterior branches of the spectrum

In this section, we calculate the contribution from the tunneling Hamiltonian given by Eq. (32) to the flow equation of \( \Delta_1^{\text{ext}} \). In the partition function \( Z \), we expand the action up to second order in the tunneling term, which results in a first-order contribution to the proximity-induced superconducting pairing of the type \( \sum \Delta_{\text{int}}^{\text{ext}} / \alpha \int dx \{ R_i L_i^\dagger + L_i R_i^\dagger \} \Delta^{\text{ext}} \) a dimensionless coupling constant, see Eq. (9). Without loss of generality, we focus on the first term in the first NW, i.e., on \( L_{11} R_{11} \). We again start from the partition function given by

\[
Z = Z_0 \left( 1 - \frac{\tilde{\Delta}_1^{\text{ext}}}{\pi \alpha^2} \int \cos[2\phi_1(x,t)] dx dt + I + I^\dagger + \cdots \right)_0.
\]
where $I^i$ is the Hermitian conjugate of the second-order contribution $I$ written as

$$
i = \frac{1}{2} \int dx_1 dt_1 dx_2 dt_2 d\mathbf{x} d\mathbf{x}' u^2 \left( \frac{\xi^2 L}{\alpha^3} \right)^2 \text{Tr} T[L_{11}(x_1,t_1)R_{11}(x_2,t_2)] \langle T[\Psi^\dagger_i(x,t)\Psi_i(x',t)] \rangle \times \delta(x_1-x_2)\delta(x_1-x_2)\delta(x_1-x_2). \tag{D31}$$

We follow the same procedure as described above in previous subsections. Then, $I^{da}$ similarly to Eq. (D11) is given by

$$I^{da} = -\frac{\Delta}{2\pi^2} \int d\mathbf{x} dt \int d\mathbf{x}' dt' \frac{1}{|x|} \left| \frac{\sin(k_{F,sc}|x|)}{x} \right| \cos(k_{F,x}) e^{-\frac{i\Delta}{\Delta}} K_0(|r| \Delta). \tag{D32}$$

The only difference between Eqs. (D11) and (D32) is an extra factor of $e^{i\theta_{r,x}^1}$ and $\phi \rightarrow \phi_1$. We add both $(I^{da}$ and $(I^{dax})$ contributions to calculate the renormalization of $\Delta_{1}^{ext}$, and get

$$I^{da} + (I^{dax}) = \frac{m_e \Delta}{2 \pi^2} \int d\mathbf{x} dt \int d\mathbf{x}' dt' \frac{1}{|x|} \left( \frac{\sin(k_{F,sc}|x|)}{x} \right) \cos(k_{F,x}) e^{-\frac{i\Delta}{\Delta}} K_0(|r| \Delta) \cos[2\phi_1(X,T)]. \tag{D33}$$

We follow the same procedure as used in Eqs. (D12)–(D15) and calculate the integral in the range $\alpha < r < \alpha + d\alpha$, as a result, Eq. (D33) takes the following form:

$$I^{da} + I^{dax} = \left( \frac{u d\alpha}{\alpha^3} \right) \frac{m_e \Delta}{\pi^2} \int \frac{\pi/2}{\alpha} d\theta' \sin(k_{F,sc}|x|) \cos(k_{F,x}) e^{-\frac{i\Delta}{\Delta}} K_0 \left( \frac{\alpha \sin(\theta') \Delta}{u} \right)$$

$$\times K_0 \left( \frac{\alpha \sin(\theta') \Delta}{u} \right). \tag{D34}$$

By using $dl = \frac{d\alpha}{u}$ and $\xi = v_{F,sc}/\Delta$, we arrive at the RG flow equation for $\Delta_{1}^{ext}$ in the form

$$\frac{d\Delta_{1}^{ext}}{dl} = -\frac{m_e v_{F,sc}^2 L}{\pi^2} \Delta \int_0^{\pi/2} d\theta' \sin(k_{F,sc} |x|) \cos(k_{F,x}) e^{-\frac{i\Delta}{\Delta}} K_0 \left( \frac{\alpha \sin(\theta') \Delta}{u} \right)$$

$$= -\frac{m_e v_{F,sc}^2 L}{\pi^2} \Delta \int_0^{\pi/2} d\theta' \sin(k_{F,sc} + k_{F,x}|x|) + \sin(k_{F,sc} - k_{F,x}|x|) e^{-\frac{i\Delta}{\Delta}} K_0 \left( \frac{\alpha \sin(\theta') \Delta}{u} \right). \tag{D35}$$

$$S_{ext} = -\frac{m_e v_{F,sc}^2 L}{2 \pi^2} \Delta \int_0^{\pi/2} d\theta' \sin(k_{F,sc} + k_{F,x}|x|) \cos(\theta') e^{-\frac{i\Delta}{\Delta}} K_0 \left( \frac{\alpha \sin(\theta') \Delta}{u} \right)$$

$$+ \int_0^{\pi/2} d\theta' \sin(k_{F,sc} - k_{F,x}|x|) \cos(\theta') e^{-\frac{i\Delta}{\Delta}} K_0 \left( \frac{\alpha \sin(\theta') \Delta}{u} \right) = -\frac{m_e v_{F,sc}^2 L}{2 \pi^2} \Delta \Delta \alpha \frac{K_0 \left( \frac{\alpha \Delta}{u} \right)}{u}. \tag{D36}$$

We again split the integral into two parts $\int_0^{\pi/2} = \int_0^{\pi/2} + \text{small contributions}$, where $\theta'_x = \cos^{-1}(\frac{\pi}{2(k_{F,sc} + k_{F,x})}) = \pi/2 - \sin^{-1}(\frac{\pi}{2(k_{F,sc} + k_{F,x})}) = \pi/2 [1 - \frac{1}{2(k_{F,sc} + k_{F,x})}]$. We use $\int_0^{\pi/2} f(\theta)d\theta' = -f(\pi/2) \delta(\theta)'$ and approximate the integral in $S_{ext}$ as

$$S = -\frac{m_e v_{F,sc}^2 L}{2 \pi^2} \Delta \alpha \left[ \int_{\pi/2}^{\pi/2} d\theta' \sin(k_{F,sc} + k_{F,x}|x|) \cos(\theta') e^{-\frac{i\Delta}{\Delta}} K_0 \left( \frac{\alpha \sin(\theta') \Delta}{u} \right) \right]$$

$$+ \int_{\pi/2}^{\pi/2} d\theta' \sin(k_{F,sc} - k_{F,x}|x|) \cos(\theta') e^{-\frac{i\Delta}{\Delta}} K_0 \left( \frac{\alpha \sin(\theta') \Delta}{u} \right) = -\frac{m_e v_{F,sc}^2 L}{2 \pi^2} \Delta \Delta \alpha \frac{K_0 \left( \frac{\alpha \Delta}{u} \right)}{u}. \tag{D37}$$

At the last step, we restore $\hbar$ and rewrite the final expression as $S = -\frac{m_e v_{F,sc}^2 L}{2 \pi^2} \Delta \alpha \frac{K_0 \left( \frac{\alpha \Delta}{u} \right)}{u}$. In Fig. 12, we show that the approximate value $(S)$ matches quite well with the exact one, $S_{ext}$. Thus, for simplicity, we can use $S$ when solving the RG flow equations numerically.
and $\alpha$ values are fixed to $\Delta_1$, respectively. Disregarding small oscillations, the flow parameter $l$ comes out to be similar to $S_{\text{ext},0}$ (green) and $S_{\text{ext},0}^2$ (red) represented as a function of the RG parameter $l$, which are calculated by using Eqs. (D36) and (D37), respectively. Disregarding small oscillations, the agreement between the two terms is fairly good. The parameter values are fixed to $t_0 = t_{\text{ext}}(0) = t_{\text{int}}(0) = 3.8 \times 10^{-5}$, $\Delta = 0.35 \text{ meV}$, $v_F = 10^5 \text{ m/s}$, $v_{\text{F,sc}} = 10^6 \text{ m/s}$, $\alpha_0 = 1 \text{ nm}$, $d = 15 \alpha_0$, and $\delta_0 = 1/k_{\text{F,sc}} = 1 \text{ Å}$. We use $k_{F,ext} = 1/\alpha_0$, which is much higher than the realistic value of $k_{F,ext}$, to capture the maximum effect from it on $S_{\text{ext}}$, however, for realistic values of $k_{F,ext}$, the functional form of $S_{\text{ext}}$ comes out to be similar to $S_{\text{int}}$ plotted in Fig. 11.

At the last step, we collect all contributions coming from the tunneling Hamiltonian. The operator proportional to $t_{\text{int}}$ contains either $R_{\uparrow}$ or $L_{\downarrow}$ [or $R_{\downarrow}$ or $L_{\uparrow}$], which in bosonic form are written as $e^{i(\phi_0 - \theta_0)}$ or $e^{i(\phi_0 + \theta_0)}$ or $e^{i(\phi_0 - \theta_0)}$ or $e^{i(\phi_0 + \theta_0)}$. For identical interactions in NWs, $K_3 = K_4$, the scaling dimension of $t_{\text{int}}$ is $K_{\text{ext}} = K_{\text{int}}$, see Eq. (B6). Similarly, the scaling dimension for $t_{\text{int}}$ is $K_{\text{ext}} = K_{\text{int}}$. For calculating the RG flow equations of the remaining parameters $\Delta_{\text{ext}}$, $\Delta_{\text{int}}$, $K_1$, and $K_3$, we follow the same procedure as in Appendix C and eventually obtain the RG equations given in Eq. (36) of the main text. Notably, in Eq. (36), we do not include direct contributions from the tunneling terms to the renormalization of the LL parameters $K_1, \ldots, K_4$ as they give rise to higher-order terms, which have negligible effect. Indeed, going to fourth order in $t_{\text{int}}/t_{\text{ext}}$ in Eq. (D1) and using OPE we find that the resulting renormalization of the kinetic terms, Eq. (B7), becomes proportional to $(S_{\text{int}}/t_{\text{int}})^2$. Such terms, however, vanish quickly under the RG flow, see Figs. 8 and 9 in the main text. Thus, compared to the rapidly growing proximity gaps $\Delta_{\text{ext}}$, $\Delta_{\text{int}}$, and $\Delta_e$, see Fig. 9, we can safely neglect such direct contributions to $K_1, \ldots, K_4$ in the RG equations (36).
