ABSTRACT

Objective: The study aimed to evaluate the viewpoints and perception about adverse drug reactions and antibiotics resistance among healthcare practitioners (HCPs) about self-medication of antibiotics.

Methods: A cross-sectional study was done using a validated research tool to obtain the required data. Data was obtained using different questions regarding viewpoints and perception of adverse drug reactions and antibiotics resistance from HCPs about antibiotics’ self-medication. Descriptive and inferential statistics were applied using the Statistical Package for Social Sciences (SPSS) version 24.0. A p-value < 0.05 was considered statistically significant.

Results: Different demographic characteristics were studied from the selected cohort of the HCPs. Around 153 (52.9%) of the studied HCPs were the females and 136 (47.1%) were males. The studied HCPs were of different professions, whereby 53 (18.3%) from medicine, 103 (35.6%) from pharmacy, 13 (4.45%) from dentistry, 98 (33.9%) from nursing, and 22 (7.6%) from others allied professions.
Conclusion: From the obtained results, it was concluded that all of the studied HCPs had varied viewpoints and different levels of perception about adverse drug reactions and antibiotics resistance. Still there is a greater need to strictly adhere with and follow the recommended and concerned guidelines regarding antibiotics usage to avoid any unwanted side effects, adverse drug reactions and antibiotics resistance.

Keywords: Self-medication; resistance; antibiotics; perception; HCPs.

1. INTRODUCTION

Self-medication is defined as the use of medical products by a user to self-treat well-known illnesses or symptoms, or the recurrent or sustained use of a medication normally prescribed by a physician for chronic or returning diseases without a physician prescription [1]. The major issue with self-medication is the lack of clinical assessment of the disorders by an experienced medical professional, which could result in unnoticed diagnosis and hinder suitable treatments [2,3]. Self-medication is a serious global health issue.

In literature, various studies reported that healthcare practitioners (HCPs) reported that their awareness regarding antibiotic use was not appropriate [4,5]. Another study found that more than 73% of pharmacists self-medicate using antibiotics [6]. However, awareness regarding antibiotics seems to be inconsistent among HCPs. Studies also found that HCPs demonstrated good knowledge regarding antibiotic use, however, there was also a gap between attitude and practice [6,7]. HCPs differ from the general population because of their awareness regarding disease and drugs. In developing countries such as Ethiopia and Nigeria, 68% and 52% of HCPs reportedly practice self-medication, respectively [8,9].

Limited studies are evident regarding the evaluation of knowledge, attitude, perceptions and practices of antibiotics’ self-medication among HCPs. Appropriate knowledge and awareness about antibiotics’ resistance among HCPs is crucial as they prescribe antibiotics to treat themselves and their patients. In addition, many times it happens where HCPs do use antibiotics for themselves to treat various infections which may not be an appropriate approach. Identifying factors that influence the self-usage practice of antibiotics among HCPs could help to overcome and antibiotics resistance. This study evaluated the viewpoints and perception about adverse drug reactions and antibiotics resistance among HCPs about self-medication of antibiotics.

2. MATERIALS AND METHODS

The study was conducted among HCPs using a research tool, and data was collected from those who met the inclusion criteria. The study subjects were screened for inclusion and exclusion criteria. For inclusion criteria, participants above 18 years, non-pregnant women and those who gave consent were included in the study. For exclusion criteria, those who did not meet the inclusion criteria were excluded from the study. A data collection form consisting of 10 questions was specially designed to collect the required information. There were different demographic characteristics observed among the study participant. A pilot study was also conducted to test the relevancy and appropriateness of the data collection form.

All statistical analyses were performed using Statistical Package for Social Sciences (SPSS) statistical software version 24. Descriptive statistics were used to describe demographic characteristics of the studied HCPs. Percentages and frequencies were used for categorical variables, while means and standard deviation were calculated for the continuous variables. Normality distribution was ascertained prior to each analysis and appropriate parametric or non-parametric tests were chosen accordingly.

3. RESULTS AND DISCUSSION

From the obtained results, the females were 153 (52.9%) and males were 136 (47.1%) in the studied population. All of the studied HCPs were from different age groups, i.e. 20-35 years were 165 (57.1%), 36-45 years were 88 (30.4%) and >45 years were 36 (12.5%). Professional degrees of the HCPs included, medicine 53 (18.3%), pharmacy 103 (35.6%), dentistry 13 (4.5%), nursing 98 (33.9%), and others allied HCPs 22 (7.6%). They had different levels of experiences i.e. ≤10 years 169 (58.5), 11-20 years 96 (33.2%) and >20 years 24 (8.3%). A detailed description of the demographic characteristics is provided in Fig. 1.
Fig. 1. Demographics of the study participants

Table 1 shows Cronbach alpha value, which was obtained to ascertain the reliability of the research tool used among the study participants. The internal consistency was measured by Cronbach's alpha and the value was 0.789.

| Item                  | Value  |
|-----------------------|--------|
| Cronbach alpha        | 0.789  |

Table 1. Reliability and validity of the research tool

Table 2 shows the awareness of antibiotics adverse drug reaction questions and their obtained results, which were asked from the HCPs to know their viewpoint about antibiotics' adverse drug reaction during self-medication. Data shows their responses about questions regarding awareness and perception of antibiotics' adverse drug reactions among HCPs about self-medication in different diseases.

A statistically non-significant association ($p=0.364$) was observed in the responses of the question regarding nausea as adverse drug reaction of antibiotics when used as self-medication among HCPs. Around 137 (47.4%) of the studied HCPs agreed that they perceive that nausea is a common adverse drug reaction of antibiotics when used as self-medication among HCPs. And around 120 (41.5%) of the HCPs perceived that vomiting is the major adverse reaction of antibiotics when used as self-medication among HCPs.

Around 153 (52.6%) of the HCPs reported that they perceive rashes as a major adverse drug reaction of antibiotics in self-medication and around 137 (47.4%) of them reported that they don't perceive rashes as a major adverse drug reaction of antibiotics in self-medication. There was a statistically non-significant difference ($p=0.147$) observed between both of the group among HCPs.

Fig. 2 presents viewpoints of the HCPs towards adverse drug reactions of the various classes/groups of the antibiotics. According to the obtained results, around 126 (43.6%) of HCPs believed that penicillins have higher ADRs as compared to the cephalosporins, which 54 (18.7%) of the HCPs believed having ADRs. In addition, around 12 (4.2%) of the studied HCPs also believed that aminoglycosides have ADRs.

In table 2, according to the current study findings regarding perception of antibiotics resistance, statistically non-significant difference ($p=0.574$) was observed between the responses to the questions regarding usage of antibiotics when they are not necessary among the studied cohort of the HCPs.
The current study findings also reported that statistically significant difference was observed in question of using antibiotics for cough & flu. Around 63 (21.8%) of the studied HCPs agreed that they perceive that these antibiotics can’t cause resistance when they are taken in cough and flu. And around 226 (78.2%) of the HCPs perceived that these antibiotics can’t cause resistance when they are taken in cough and flu.

**Table 2. Awareness of antibiotics’ adverse drug reactions**

| Qs            | N  | %     | p-Value |
|---------------|----|-------|---------|
| Nausea        |    |       |         |
| Yes           | 137| 47.4  | 0.364   |
| No            | 152| 52.6  |         |
| Vomiting      |    |       |         |
| Yes           | 120| 41.5  | 0.651   |
| No            | 169| 58.5  |         |
| Diarrhea      |    |       |         |
| Yes           | 189| 65.4  | 0.004*  |
| No            | 100| 34.6  |         |
| Rashes        |    |       |         |
| Yes           | 152| 52.6  | 0.572   |
| No            | 137| 47.4  |         |
| Other problems|    |       |         |
| Yes           | 170| 58.8  | 0.147   |
| No            | 119| 41.2  |         |

**Table 3. Perception of antibiotics’ resistance**

| Qs                                                   | N  | %     | p-Value |
|------------------------------------------------------|----|-------|---------|
| Using antibiotics when they are not necessary        |    |       |         |
| Yes                                                  | 214| 74.0  | 0.574   |
| No                                                   | 75 | 26.0  |         |
| Not completing the full course of antibiotics        |    |       |         |
| Yes                                                  | 246| 85.1  | 0.612   |
| No                                                   | 43 | 14.9  |         |
| Using antibiotics without a physician’s prescription |    |       |         |
| Yes                                                  | 144| 49.8  | 0.002*  |
| No                                                   | 145| 50.2  |         |
| Taking antibiotics before a meal                      |    |       |         |
| Yes                                                  | 10 | 3.5   | 0.788   |
| No                                                   | 279| 96.5  |         |
It is of greatest significance to know the exact level of awareness and perception of HCPs about antibiotics’ adverse drug reactions and their resistance when they are used as self-medication to treat their ailments. However, the obtained results showed that there is also a need to update the current knowledge of HCPs to better understand antibiotics’ adverse drug reactions and their resistance when they are self-used among HCPs. Antibiotics’ improper usage pattern or their use without prescriptions from a registered HCP could lead to various side effects and a greater level of resistance among the population. Advanced level of awareness about antibiotics usage and perceptions about their side effects and drug interactions could further improve their efficacy and efficiency. In total, appropriate knowledge and precise usage pattern of antibiotics are essential in order to combat numerous infectious diseases. This could further help in improving individuals’ overall health-related quality of life [10-14].

4. CONCLUSION

This study concluded that all of the studied HCPs had varied viewpoints and different levels of perception about adverse drug reactions and antibiotics resistance. Still there is a greater need to strictly adhere with and follow the recommended and concerned guidelines regarding antibiotics usage to avoid any unwanted side effects, adverse drug reactions and antibiotics resistance.

ACKNOWLEDGEMENT

The publication was supported by the Deanship of Scientific Research at Prince Sattam bin Abdulaziz University, Alkharj, Saudi Arabia.

CONSENT

For inclusion criteria, participants above 18 years, non-pregnant women and those who gave consent were included in the study.

ETHICAL APPROVAL

It is not applicable.

COMPETING INTERESTS

Authors have declared that no competing interests exist.
