Abstract
We perform a comprehensive analysis of a number of scalar field theories in an attempt to find analytically five-dimensional, localised-on-the-brane, black-hole solutions. Extending a previous analysis, we assume a generalised Vaidya ansatz for the five-dimensional metric tensor that allows for a time-dependent, non-trivial profile of the mass function in terms of the bulk coordinate and a deviation from the over-restricting Schwarzschild-type solution on the brane. In order to support such a solution, we study a variety of theories including single or multiple scalar fields, with canonical or non-canonical kinetic terms, minimally or non-minimally coupled to gravity. We demonstrate that for such a metric ansatz and for a carefully chosen energy-momentum tensor which is non-isotropic in five dimensions, solutions that have the form of a Schwarzschild-(anti)de Sitter or Reissner–Nordstrom type of solution do emerge. However, the resulting profile of the mass function along the bulk coordinate, when allowed, is not the correct one for eliminating bulk singularities.

Key words: brane-worlds, black holes, localisation

(Some figures may appear in colour only in the online journal)

1. Introduction

The intriguing proposal that our world may be a four-dimensional hypersurface, a brane, embedded in a higher-dimensional spacetime, the bulk, was put forward several decades ago.
and has been revived in the context of more recent theories postulating the existence of extra space-like dimensions [3, 4]. Although the initial objective was to address the hierarchy problem, this was soon surpassed. These theories then became the framework in the context of which intensive investigation regarding implications on gravity, particle physics and cosmology was carried out.

The question of how extra space-like dimensions affect black-hole physics, in fact, preceded the aforementioned brane-world theories—even the oldest ones. Black-hole solutions in spacetime with an arbitrary number of extra space-like dimensions had been derived and their properties already investigated by the 1960s: higher-dimensional versions of the Schwarzschild solution, as well as of Kerr solutions, were derived in [5, 6], respectively. In these studies, the extra dimensions were assumed to be flat, or at most, uniformly curved due to the presence of a bulk cosmological constant. In any case, all space-like dimensions played the same role in the structure of the gravitational background, a concept which was also followed in the large extra dimensions scenario [3].

In the warped extra dimensions scenario [4], on the other hand, the structure of spacetime is distinctly different. The sole extra space-like dimension could be finite or infinitely long, and our brane was a slice of a five-dimensional anti-de Sitter spacetime. More importantly, the metric tensor along this particular fifth dimension exhibited warping—a feature that either helped to recast the hierarchy problem in the context of the two-brane model, or to localise gravity in the single-brane model.

How the properties of black holes emerging in the context of this theory are affected by the particular structure of spacetime remains, to a large extent, unclear. The main reason for this is that despite the time and energy invested in this question (for reviews, see [7]), no analytical solution describing a regular, localised-on-the-brane, five-dimensional black hole has been derived. The first such attempt appeared in [8] and the line-element had the form

$$\text{d}s^2 = e^{2A(y)} \left[ -\left(1 - \frac{2M}{r}\right)\text{d}t^2 + \left(1 - \frac{2M}{r}\right)^{-1}\text{d}r^2 + r^2 \left(d\theta^2 + \sin^2\theta \, d\varphi^2\right) \right] + dy^2, \quad (1)$$

where $y$ denotes the coordinate along the fifth dimension and $A(y)$ is the warp factor. In the above, $M$ is a constant quantity identified with the black-hole mass—indeed, for $A(y) = -k \, |y|$ [4], with $k$ the AdS curvature, the projected line-element on the brane, located at $y = 0$, assumed the form of a Schwarzschild solution. However, the above line-element does not describe a regular black hole from the five-dimensional point-of-view: the corresponding curvature invariant quantities are plagued by the presence of singularities extending along the extra coordinate; for instance, we find that

$$R^{MNR\alpha}R_{MNR\alpha} = \frac{48e^{-A(y)}M^2}{r^6} + \ldots \quad (2)$$

The above reveals the existence of a singularity at $r = 0$ at every point along the extra dimension; in addition, for $A(y) = -k \, |y|$, or for any other decreasing warp function, the above quantity increases in magnitude as we move away from the brane. In the single-brane model, it actually becomes infinite at $y$-infinity—this is indeed ironic in the context of a model that aims at keeping gravity localised close to the brane so that four-dimensional physics is restored despite the presence of an infinitely extended extra dimension. The above solution is clearly not a black-hole solution but a black-string one—a class of solutions first discovered in the context of string theory and found to be unstable both in the absence or presence of a bulk cosmological constant [9, 10].

Since then, numerous attempts have been made in the literature to derive a regular, five-dimensional black hole located on the brane (for some of them, see [11–22]) but no such
analytical solution has been derived in closed form. Although analytical solutions of this type have been found in the context of lower-dimensional models [23, 24], their five-dimensional analogues remained elusive. Numerical solutions did emerge [25–27] in the context of five- and six-dimensional warped models, but these only described black holes with a horizon radius smaller than, or at most, of the order of the AdS length $\ell = 1/k$. Several arguments that supported the idea of the existence [28–31] or non-existence [32–39] of these black-hole solutions were expressed at length. Novel numerical solutions that have appeared in recent years [40, 41] describing both large and small black holes reinforce the arguments in favour of the existence of brane-world black holes—but the absence of an analytic solution has left the study of their properties incomplete.

In this work, we return to an idea that first appeared in [13, 14] according to which a regular, five-dimensional, localised-on-the brane black hole may emerge if a new type of line-element—one that would admit a non-trivial profile of the mass function along the extra dimension—is assumed. In this case, if the constant quantity $M$ appearing in the line-element (1) is replaced by a function $m = m(y)$ that decreases faster than $e^{4A}$, then the singularities present in the curvature invariant quantities—as in equation (2)—would be eliminated, hopefully at a short distance from the brane. In [13, 14], it was also demonstrated that not any type of brane line-element could be used; instead the Vaidya-type line-element was singled out as the most appropriate one as it keeps the number of bulk singularities to a minimum. Such a line-element, of course, is not a vacuum solution: the non-trivial dependence of the four-dimensional part of the metric on the extra coordinate made it imperative to introduce some form of matter to the bulk. Alternative attempts—either analytical or numerical—to derive regular, localised black holes also assumed some form of matter, either in the bulk [13, 14, 16, 31], or on the brane [18–20, 30, 39, 42], or even additional geometrical terms [12, 43].

The form of matter necessary for localising black-hole topology close to the brane, although shown to be well-behaved everywhere in the bulk, was left unspecified in the context of [13, 14]—it was nevertheless demonstrated that conventional forms of matter, expressed in the form of ordinary field theories involving minimally-coupled scalar or gauge degrees of freedom could not perform this task. In a recent work [44], a variety of non-conventional scalar field theories were investigated, including single or multiple scalar fields either minimally or non-minimally coupled to gravity. The background assumed the form of a generalised Vaidya-type of line-element with a $y$-dependence as well as a time dependence of the mass function—the first would help to localise the black-string singularity while the second would allow for potential non-static solutions to emerge. Once again, it was found that even these forms of matter were unable to support this type of background.

Given the existence of localised black holes found numerically over the years, and the absence of any analytical expression able to describe them, here we return to our previous analysis [44] and adopt the most general type of Vaidya-type line-element. Now, we allow the mass function to have an additional dependence on the radial coordinate. In this way, the projected-on-the-brane line-element is allowed to deviate from the perhaps over-restricting Schwarzschild-type of background and one is assumed where additional terms—as the ones associated with an effective cosmological constant or tidal charges—are present. The time dependence and dependence on the fifth coordinate will be kept, as in our previous work, to make our analysis as general as possible. Due to the radical change in the line-element, we will study a plethora of theories starting from the simplest one, namely, a model with only a cosmological constant in the bulk. We will then move on to a series of theories with single or multiple minimally-coupled scalar fields, interacting or non-interacting, with canonical or non-canonical kinetic terms. We will finish with the theory of a non-minimally coupled scalar
field coupled to the Ricci scalar through a general coupling function. We will try to determine the features of the theory that allow for a viable solution to emerge, and we will investigate the type of solutions that we get in each case, their characteristics, and the possibility of localising the black-string singularity close to the brane.

The outline of our paper is as follows: in section 2, we present the geometrical background and discuss its main features. In section 3, we address the simplest case of a bulk filled only with a cosmological constant. In the following section, we proceed to study a plethora of theories with minimally-coupled scalar fields, and in section 5 we investigate the theory of a non-minimally coupled scalar field. We discuss our results and present our conclusions in section 6.

2. The geometrical background

Motivated by the attractive features of the Vaidya metric pointed out in a previous work [14], we will also assume here that the five-dimensional gravitational background is given by the generalised form

$$\text{d}s^2 = e^{2\Lambda(v,y)} \left[-\left(1 - \frac{2m(v,y)}{r}\right) dv^2 + 2dvdr + r^2 (d\theta^2 + \sin^2 \theta \, d\phi^2)\right] + dy^2. \quad (3)$$

In the above, apart from the $(v,y)$-dependence of the mass function introduced in [14], an additional dependence on the radial coordinate is postulated that will allow our metric background to deviate from the Schwarzschild form. As mentioned in the introduction, such a modification may allow for terms proportional to an effective cosmological constant or for terms of various forms associated with tidal charges to emerge. Terms of this type often arise in the context of five-dimensional or four-dimensional effective (projected-on-the-brane) analyses; demanding that these terms are zero, as was implicitly assumed in our previous work [44], may have caused the over-restriction of the set of field equations and, unavoidably, the elimination of a viable solution.

The components of the Einstein tensor $G^M_N$ for the aforementioned generalised form of the Vaidya metric (3) are:

$$G^v_v = G^r_r = 6\Lambda'^2 + 3\Lambda'' - \frac{2}{r^2} e^{-2\Lambda} \partial_v m, \quad G^\theta_\theta = G^\phi_\phi = 6\Lambda'^2 + 3\Lambda'' - \frac{1}{r} e^{-2\Lambda} \partial_v^2 m,$$

$$G^r_v = \frac{2}{r^2} e^{-2\Lambda} \partial_v m - \frac{1}{r} \left( \partial_r^2 m + 4\Lambda' \partial_r m \right),$$

$$G^r_\gamma = e^{2\Lambda} G^r_\gamma = \frac{1}{r^2} \partial_r m + \frac{1}{r} \partial_r \partial_r m, \quad G^\gamma_\gamma = 6\Lambda'^2 - e^{-2\Lambda} \left( \frac{2}{r^2} \partial_r m + \frac{1}{r} \partial_r^2 m \right).$$

$$G^r_r = G^v_v = G^\theta_\theta = G^\phi_\phi = 0. \quad (4)$$

We observe that as expected, for $\partial_r m = 0$, the above expressions smoothly reduce to the ones of the $r$-independent case studied in [44].

The expressions of the five-dimensional curvature invariant quantities will also play a central role in our analysis: any viable solution should eliminate any singularities in the bulk at a finite distance from the brane, thus leaving behind a regular anti-de Sitter spacetime and a
localised five-dimensional black-hole solution close to the brane. For our metric ansatz (3), these are given by the following expressions:

\[ R = -20A'^2 - 8A'' + \frac{2e^{-2A}}{r} \left( \partial_r^2 m + \frac{2}{r} \partial_r m \right). \]  

(5)

\[ R_{MN}R^{MN} = 80A'^4 + 64A'^2A'' + 20A'^2 \]

\[- \frac{4e^{-2A}}{r} \left( \partial_r^2 m + \frac{2}{r} \partial_r m \right) (A'' + 4A'^2) + \frac{2e^{-4A}}{r^4} \left[ \left( \partial_r^2 m \right)^2 + \frac{4}{r^2} (\partial_r m)^2 \right]. \]

(6)

and finally

\[ R_{MNR}R^{MNR} = 40A^4 + 32A'^2A'' + 16A'^2 \]

\[ + \frac{48e^{-4A}m^2}{r^6} - \frac{8A'^2 e^{-2A}}{r} \left( \partial_r^2 m + \frac{2}{r} \partial_r m \right) \]

\[ + \frac{4e^{-4A}}{r^2} \left[ \left( \partial_r^2 m \right)^2 + \frac{4m}{r^2} \left( \partial_r^2 m - \frac{4}{r} \partial_r m \right) - \frac{4}{r} \partial_r m \partial_r^2 m + \frac{8}{r^2} (\partial_r m)^2 \right]. \]

(7)

For a constant mass function \( m \), the above expressions reduce to the ones for a black string [8] with an infinitely extended singularity along the fifth dimension. For \( m = m(y) \) only, the first two invariants are well-defined everywhere while the third one still has a singular term of the form \( e^{-4A}m^2/r^6 \); an appropriately chosen function \( m(y) \)—i.e. decreasing faster than \( e^{4A} \) with \( y \)—could help localise the black-hole singularity close to the brane. Unfortunately, the set of field equations were shown not to accept such a solution in the context of a variety of field theory models [13, 14, 44]. As mentioned above, we will extend our assumption here so that our metric function admits forms that may deviate from the Schwarzschild form. Although this will make the system of field equations more flexible, the \( r \)-dependence of the mass function leads to the appearance of additional singular terms in curvature-invariant quantities. However, these terms could also be eliminated, similarly to the black-string singular terms, if a solution with a fast-enough decreasing profile of the mass function is found.

In the following sections, we consider a variety of scalar field theory models and investigate whether these theories admit solutions whose geometrical background is described by the line-element (3).

### 3. A bulk filled with a cosmological constant

For the sake of a comprehensive analysis, we start our study with the case of a bulk that contains no scalar fields but only a cosmological constant \( \Lambda_B \). As we will see, this model cannot support a black-hole spacetime of the form (3). However, this case and some of its constraints will serve as prototypes from which the more elaborate models considered subsequently will try to deviate in an effort to find a viable solution.

The action functional in this case will simply be

\[ S = \int d^4x \, dt \, \sqrt{-g} \left( \frac{R}{2\kappa_5^2} - \mathcal{L}_m \right). \]  

(8)

where, \( g_{MN} \) and \( R \) are the metric tensor and Ricci scalar, respectively, of the five-dimensional spacetime (3), and \( \kappa_5^2 = 8\pi G_5 \) the five-dimensional gravitational constant. Also, in this case, the general Lagrangian associated with the distribution of matter/energy in the spacetime is \( \mathcal{L}_m = \Lambda_B \), where \( \Lambda_B \) is the bulk cosmological constant. The field equations resulting from the
aforementioned action have the form

\[ G_{MN} \equiv R_{MN} - \frac{1}{2} g_{MN} R = \kappa^2 T_{MN}, \]  

(9)

with \( T_{MN} \) being the energy-momentum tensor defined as

\[ T_{MN} \equiv \frac{2}{\sqrt{-g}} \frac{\delta}{\delta g^{MN}} \left( \sqrt{-g} L_m \right) = -g_{MN} \Lambda_B. \]  

(10)

The cosmological constant introduces the same contribution to all diagonal, mixed components of \( T_{MN} \): \( T^{tt} = T^{rr} = T^{\theta \theta} = T^{\phi \phi} = -\Lambda_B \). A similar relation should then hold for the corresponding components of the Einstein tensor; then, from the constraint \( G_{tt} = G_{rr} = G_{\theta \theta} = G_{\phi \phi} \) and the expressions (4), we obtain the simple equation

\[ \partial^2 m = \frac{2}{r} \partial_r m \]  

(11)

with the solution

\[ m(v, r, y) = B(v, y) r^3 + C(v, y). \]  

(12)

Therefore, the metric tensor in (3) describes a solution with a \( C(v, y)/r \) Schwarzschild-type term, with a non-trivial profile along the \( y \)-coordinate, and an additional term \( O(r^2) \) typical of a cosmological constant. Although this Schwarzschild–(anti)de Sitter solution is a physically interesting one, describing a black hole on the brane and a warped black string off the brane, it is not supported by the off-diagonal components. The equation \( G_{tt} = T_{tt} \), or, equivalently

\[ \frac{1}{r^2} \partial_r m + \frac{1}{r} \partial_r^2 m = 0, \]  

(13)

leads to the result \( 4r^3 \partial_r B + \partial_r C = 0 \), which cannot be satisfied unless \( \partial_r B = \partial_r C = 0 \). However, this means that the non-trivial profile of the mass function along the extra coordinate necessary to localise the black-hole singularity close to the brane is eliminated. The above result holds for any sign or value of the cosmological constant \( \Lambda_B \), and thus it is valid for all cases of five-dimensional (anti)-de Sitter or Minkowski spacetimes.

4. A field theory with minimally-coupled scalars

In this section, we will study a variety of models with minimally-coupled scalar fields with a general form of Lagrangian. We will start with the case of a single scalar field and then proceed to the case of two interacting fields—in both cases, a general kinetic term will be considered which will allow for both canonical and non-canonical kinetic terms, as well as a general potential.

4.1. A single scalar field with a general Lagrangian

In the case of a single scalar field \( \phi \), the general Lagrangian \( L_m \) of the action (8) will now be replaced by

\[ L_\phi = \sum_{n=1}^{\infty} f_n(\phi) \left( \partial^M \phi \partial_M \phi \right)^n + V(\phi), \]  

(14)

where \( f_n(\phi) \) are arbitrary, smooth functions of the scalar field \( \phi \), and \( V(\phi) \) is a general potential that may include the cosmological constant \( \Lambda_B \). For \( n = 1 \) and \( f_1(\phi) = 1 \), the above reduces to a Lagrangian of a scalar field with a canonical kinetic term; for arbitrary \( n \), it describes a
general field theory of a scalar field with a mixture of canonical and non-canonical kinetic terms. The analysis, aiming to investigate whether such a theory supports a spacetime of the form (3), follows the same lines independently of the form of the kinetic term—therefore, we keep the most general expression given by equation (14) here and present a unified analysis.

The Lagrangian (14) leads to the following expression for the energy-momentum tensor

$$T_{MN} = 2 \sum_{n=1}^{\infty} f_n(\phi) \left( \partial^P \phi \partial_P \phi \right)^{\alpha-1} \partial_M \phi \partial_N \phi - g_{MN} \mathcal{L}_\phi.$$  \hspace{1cm} (15)

The scalar field is assumed to be spherically symmetric and, in principle, to depend on all remaining coordinates, i.e. \( \phi = \phi(v, r, y) \). However, an important simplification is imposed through the off-diagonal equation \( G^r_v = T^r_v \) that takes the explicit form

$$2 e^{-2A} \sum_{n=1}^{\infty} n f_n(\phi) \left( \partial^P \phi \partial_P \phi \right)^{\alpha-1} \left( \partial_r \phi \right)^2 = 0.$$  \hspace{1cm} (16)

For a non-trivial warp factor and a non-trivial scalar kinetic term, the above demands that the scalar field is not a function of the radial coordinate, i.e. \( \partial_r \phi = 0 \). Assuming henceforth that \( \phi = \phi(v, y) \), and turning to the diagonal components \( G^r_r = T^r_r \) and \( G^\theta_\theta = T^\theta_\theta \), we obtain

$$6A'^2 + 3A'' - \frac{2}{r^2} e^{-2A} \partial_r m = -\mathcal{L}_\phi,$$  \hspace{1cm} (17)

$$6A'^2 + 3A'' - \frac{1}{r} e^{-2A} \partial_r^2 m = -\mathcal{L}_\phi,$$  \hspace{1cm} (18)

respectively. Combining the above two equations, we arrive again at the differential equation (11) for the mass function and thus to the general solution (12). Using this solution in the off-diagonal equation \( G^r_v = T^r_v \), we find

$$4r \partial_r B + \frac{\partial_r C}{r^2} = 2 \sum_{n} n f_n(\phi) \left( \partial_{P^r} \phi \partial_P \phi \right)^{\alpha-1} \partial_r \phi \partial_r \phi.$$  \hspace{1cm} (19)

Since the scalar field is independent of \( r \), the right-hand side of the above equation will be also \( r \)-independent. However, due to the explicit dependence of the left-hand side on the radial coordinate, a mathematical inconsistency immediately arises. The only way forward would be to assume that the mass functions \( B \) and \( C \) are again \( y \)-independent which is, however, in contradiction of our basic assumption for the behaviour of the metric function.

We notice that despite our general ansatz for the Lagrangian describing the dynamics of the scalar field (note that the form of the potential was also kept general), this model shared a basic characteristic with the (A)dS-Minkowski case considered in section 3: due to the constraint \( \partial_r \phi = 0 \), it also satisfied the property \( T^r_r = T^\theta_\theta \); this inevitably led again to equation (11) and to the solution (12). In an attempt to find a viable model, in the next subsection, we present a two-scalar field theory that deviates from the aforementioned restrictive property of the energy-momentum tensor.

### 4.2. Two interacting scalar fields

We will first investigate the case of two interacting scalar fields with canonical kinetic terms and will extend our analysis to cover the case of non-canonical kinetic terms at the end of this subsection. The dynamics and interactions of the two fields \( \phi \) and \( \chi \) are described by the following Lagrangian

\[ 1 \] For simplicity, we will henceforth set \( \kappa^2_\lambda = 1 \).
\( \mathcal{L}_{\text{sc}} = f^{(1)}(\phi, \chi) \partial^M \phi \partial_M \phi + f^{(2)}(\phi, \chi) \partial^M \chi \partial_M \chi + V(\phi, \chi), \)  

(20)

where \( f^{1,2} \) are arbitrary smooth functions of the two fields, and \( V(\phi, \chi) \) is a general potential.

The corresponding energy-momentum tensor has the form

\[
T_{MN} = 2f^{(1)}(\phi, \chi) \partial_M \phi \partial_N \phi + 2f^{(2)}(\phi, \chi) \partial_M \chi \partial_N \chi - g_{MN} \mathcal{L}_{\text{sc}}.
\]

(21)

The vanishing of the off-diagonal components \( T_{r \theta}, T_{r \phi} \) and \( T_{\phi \psi} \), due to the vanishing of the corresponding components of the Einstein tensor (4), now leads to two independent constraints, namely

\[
f^{(1)}(\phi, \chi) \left( \partial_r \phi \right)^2 + f^{(2)}(\phi, \chi) \left( \partial_r \chi \right)^2 = 0,
\]

(22)

\[
f^{(1)}(\phi, \chi) \partial_r \phi \partial_r \phi + f^{(2)}(\phi, \chi) \partial_r \chi \partial_r \chi = 0.
\]

(23)

On the other hand, the diagonal field equations \( G^r_r = T^r_r \) and \( G^\theta_\theta = T^\theta_\theta \) now take the form

\[
6A'^2 + 3A'' - \frac{2}{r^2} e^{-2A} \partial_r m = 2e^{-2A} \left[ f^{(1)}(\phi, \chi) \partial_r \phi \partial_r \phi + f^{(2)}(\phi, \chi) \partial_r \chi \partial_r \chi \right] - \mathcal{L}_{\text{sc}},
\]

(24)

\[
6A'^2 + 3A'' - \frac{1}{r} e^{-2A} \partial_r^2 m = -\mathcal{L}_{\text{sc}},
\]

(25)

respectively. We observe that no constraint demands the vanishing of the expression inside the square brackets on the right-hand side of equation (24) and thus the restrictive condition \( T^r_r = T^\theta_\theta \) is now avoided. Rearranging the above two equations, we obtain

\[
\frac{1}{r} \partial_r^2 m - \frac{2}{r^2} \partial_r m = 2 \left[ f^{(1)}(\phi, \chi) \partial_r \phi \partial_r \phi + f^{(2)}(\phi, \chi) \partial_r \chi \partial_r \chi \right].
\]

(26)

It is straightforward to exclude the following particular cases:

- One of the two fields does not depend on the radial coordinate: if, for example, \( \partial_r \phi = 0 \), then necessarily, from the constraint (22), \( \partial_r \chi = 0 \). But in that case, equation (26) reduces to (11) leading again to the solution (12). For the present model, the \( \tilde{r}^\psi_\nu \) component of the field equations has the form

\[
\frac{\partial_m}{r^2} + \frac{\partial_m \partial_r m}{r} = 2 \left[ f^{(1)}(\phi, \chi) \partial_r \phi \partial_r \phi + f^{(2)}(\phi, \chi) \partial_r \chi \partial_r \chi \right].
\]

(27)

with the right-hand side again being \( r \)-independent. However, using the solution (12) on the left-hand side and demanding mathematical consistency, we are again led to the conditions \( \partial_r B = \partial_r C = 0 \), which unfortunately eliminate the assumed \( \gamma \)-dependence of the mass function.

- One of the two fields does not depend on the extra coordinate: if, for example, \( \partial_\psi \phi = 0 \), then, from the constraint (23), we obtain either \( \partial_\psi \gamma = 0 \) or \( \partial_\psi \chi = 0 \). According to the analysis above, the first choice leads to a mathematical inconsistency, and we should therefore choose \( \partial_\psi \chi = 0 \). In this case, the right-hand side of equation (27) vanishes, and upon integration, the following solution is obtained

\[
m(v, r, \gamma) = \frac{E(v, \gamma)}{r} + D(v, r).
\]

(28)

The metric tensor then includes a modified Schwarzschild term \( D(v, r)/r \) together with a Reissner–Nordstrom-type term \( E(v, \gamma)/r^2 \). Employing the above expression for the mass function in equation (26), and demanding that the right-hand side is not a function of the
y-coordinate, we are inevitably led to the condition that the function $E$—and therefore the mass function altogether—should also be $y$-independent.

From the analysis above, it is clear that if one of the two fields were not to depend on either $r$ or $y$, neither would the other one. This is not the case with the dependence on $v$—no inconsistency arises if only one of the fields is assumed to be $v$-dependent. Nevertheless, one of the fields must necessarily do so, otherwise equations (26) and (27) reduce to (11) and (13), respectively, of section 3 leading to a non-viable solution. Similarly to the simpler case considered in [44], it seems that if a solution exists with a non-trivial profile for the mass function along the extra coordinate, the corresponding scalar-field configuration must necessarily be dynamical.

In what follows, and in order to address the most general case, we will assume that the two fields depend on all coordinates, i.e. $\phi = \phi(v, r, y)$ and $\chi = \chi(v, r, y)$. Focusing on the two off-diagonal constraints (22)–(23), we observe that by solving the first one in terms of one of the coupling functions $f^{(1,2)}$, namely

$$f^{(1)} = -f^{(2)} \frac{(\partial_r \chi)}{(\partial_e \phi)^2},$$

and substituting into the second, we obtain the alternative constraint

$$\partial_r \phi \partial_r \chi - \partial_r \chi \partial_r \phi = 0.$$  

Finally, there is an additional diagonal component of the field equations, namely $G^r_r = T^r_r$, that we have not considered yet. This takes the explicit form

$$6A^2 = -\frac{e^{-2A}}{r^2} \left( \partial_r^2 m + \frac{2}{r} \partial_r m \right) = 2 \left[ f^{(1)} (\phi, \chi) \left( \partial_e \phi \right)^2 + f^{(2)} (\phi, \chi) \left( \partial_e \chi \right)^2 \right] - L_{\text{NC}}.$$  

However, using the relations (29) and (30) in the above equation, we find that the expression inside the square brackets on the right-hand side trivially vanishes. Then, after combining equations (25) and (31), we obtain the simple equation

$$\frac{2}{r^2} \partial_r m = -3A^\prime e^{2A},$$

that, upon integration with respect to $r$, yields

$$m(v, r, y) = -\frac{A^\prime}{2} e^{2A} + m_0(v, y).$$

We observe that we again obtain the Schwarzschild–(A)dS type solution for the metric function; however, once again this turns out to be incompatible with the remaining equations. In particular, when the above is substituted into equation (26), the left-hand side trivially vanishes leading to the additional constraint

$$f^{(1)} \partial_r \phi \partial_r \phi + f^{(2)} \partial_r \chi \partial_r \chi = 0,$$

or, by using equation (29),

$$\partial_r \phi \partial_r \chi - \partial_r \chi \partial_r \phi = 0.$$  

When equations (30) and (35) are used in equation (27), its right-hand side vanishes too. Employing then the solution for the mass function (33) on its left-hand side, we obtain the condition
which is again inconsistent with the assumptions of the model. Therefore, the theory of two interacting scalar fields with canonical kinetic terms fails to support a viable solution. Note that although this particular field theory was constructed so that, in principle, it would avoid the restrictive condition $\mathcal{T}^\nu = 0$, the system of field equations itself imposes this condition, or equivalently the constraint (34).

We may quite easily demonstrate that the above negative result also holds in the case where non-canonical kinetic terms are assumed for the two scalar fields. The Lagrangian of the theory then reads

$$\mathcal{L}_{nc} = \sum_{n=1}^{2} f^{(1)}(\phi, \chi)(\partial^M \phi \partial_M \phi)^n + \sum_{n=1}^{2} f^{(2)}(\phi, \chi)(\partial^M \chi \partial_M \chi)^n + V(\phi, \chi),$$

(37)

while the energy momentum tensor assumes the form

$$T_{MN} = 2 \sum_{n=1}^{2} n f^{(1)}(\phi, \chi) \left( \partial^p \phi \partial_p \phi \right)^{n-1} \partial_M \phi \partial_N \phi$$

$$+ 2 \sum_{n=1}^{2} n f^{(2)}(\phi, \chi) \left( \partial^p \chi \partial_p \chi \right)^{n-1} \partial_M \chi \partial_N \chi - g_{MN} \mathcal{L}_{nc}.$$

(38)

One could proceed to derive the diagonal and off-diagonal components of the field equations and the corresponding constraints that these give; however, we observe that, upon defining the new functions

$$\tilde{f}^{(1)}(\phi, \chi) = \sum_{n=1}^{2} n f^{(1)}(\phi, \chi) \left( \partial^M \phi \partial_M \phi \right)^{n-1},$$

(39)

$$\tilde{f}^{(2)}(\phi, \chi) = \sum_{n=1}^{2} n f^{(2)}(\phi, \chi) \left( \partial^M \chi \partial_M \chi \right)^{n-1},$$

(40)

the expression of the energy-momentum tensor (38) reduces to the one of equation (21) with the $f^{(1,2)}(\phi, \chi)$ coupling functions being replaced by $\tilde{f}^{(1,2)}(\phi, \chi)$. As the exact expressions of the coupling functions never played a role for the existence or not of a viable solution, the analysis presented above for the two scalar fields with canonical kinetic terms still holds, and leads to the absence of a solution with the assumed $y$-dependence of the mass function even in the context of the more general theory (37).

### 4.3. Two interacting scalar fields with mixed kinetic terms

Let us now address a more complex model of two scalar fields $\phi$ and $\chi$ that have minimal but mixed kinetic terms. Then, the Lagrangian reads:

$$\mathcal{L}_{nc} = f^{(1)}(\phi, \chi) \partial^M \phi \partial_M \phi + f^{(2)}(\phi, \chi) \partial^M \chi \partial_M \chi + f^{(3)}(\phi, \chi) \partial^M \phi \partial_M \chi + V(\phi, \chi).$$

(41)

For the above scalar theory, the energy-momentum tensor reads:

$$T_{MN} = 2 f^{(1)}(\phi, \chi) \partial_M \phi \partial_N \phi + 2 f^{(2)}(\phi, \chi) \partial_M \chi \partial_N \chi$$

$$+ f^{(3)}(\phi, \chi) \left[ \partial_M \phi \partial_N \chi + \partial_M \chi \partial_N \phi \right] - g_{MN} \mathcal{L}_{nc}.$$

(42)
\[ f^{(1)}(\phi, \chi) \left( \frac{\partial_r \phi}{\partial \chi} \right)^2 + f^{(2)}(\phi, \chi) \left( \frac{\partial_r \chi}{\partial \chi} \right)^2 + f^{(3)}(\phi, \chi) \frac{\partial_r \phi}{\partial \chi} \frac{\partial_r \chi}{\partial \chi} = 0, \]  \hspace{1cm} (43)

\[ 2 f^{(1)}(\phi, \chi) \frac{\partial_r \phi}{\partial \chi} \frac{\partial_r \chi}{\partial \chi} + 2 f^{(2)}(\phi, \chi) \frac{\partial_r \chi}{\partial \chi} \frac{\partial_r \phi}{\partial \chi} + f^{(3)}(\phi, \chi) \left[ \frac{\partial_r \phi}{\partial \chi} \frac{\partial_r \chi}{\partial \chi} + \frac{\partial_r \chi}{\partial \chi} \frac{\partial_r \phi}{\partial \chi} \right] = 0. \]  \hspace{1cm} (44)

As in the previous model, and the following similar steps, it is easy to exclude the particular cases where one of the fields (or both) does not depend on either \( r \) or \( y \). In both cases, we are again forced to abandon the assumption of a non-trivial profile of the mass function along the extra coordinate. Therefore, we address directly the most general case where \( \phi = \phi(v, r, y) \) and \( \chi = \chi(v, r, y) \). The two off-diagonal constraints (43)–(44) can now be solved to yield the values of two coupling functions in terms of the third one—for example,

\[ f^{(2)} = f^{(1)} \left( \frac{\partial_r \phi}{\partial \chi} \right)^2, \quad f^{(3)} = -2 f^{(1)} \frac{\partial_r \phi}{\partial \chi}. \]  \hspace{1cm} (45)

Using the above relations, the \((yy)\) and \((rv)\)-components may be rewritten as

\[ \frac{\partial_r m}{r^2} + \frac{\partial_r \partial_r m}{r} = 2 f^{(1)} \left( \frac{\partial_r \phi}{\partial \chi} \right)^2 \left( \frac{\partial_r \phi}{\partial \chi} - \frac{\partial_r \phi}{\partial \chi} \right) \left( \frac{\partial_r \phi}{\partial \chi} - \frac{\partial_r \phi}{\partial \chi} \right) \]  \hspace{1cm} (46)

\[ \frac{2 \partial_r m}{r^2} - \frac{e^{2A}}{r} \left( 4A' \partial_r m + \partial_r^2 m \right) = \frac{2 f^{(1)}}{\left( \frac{\partial_r \phi}{\partial \chi} \right)^2} \left( \frac{\partial_r \phi}{\partial \chi} - \frac{\partial_r \phi}{\partial \chi} \right)^2, \]  \hspace{1cm} (47)

respectively. Similarly, the rearrangement of the diagonal \((\theta\theta)\) and \((yy)\) components, takes the form

\[ \frac{2 e^{-2A}}{r^2} \partial_r m + 3 A' = -\frac{2 f^{(1)}}{\left( \frac{\partial_r \phi}{\partial \chi} \right)^2} \left( \frac{\partial_r \phi}{\partial \chi} - \frac{\partial_r \phi}{\partial \chi} \right)^2, \]  \hspace{1cm} (48)

We now take the square of equation (46) and combine it with equations (47) and (48). By doing so, we obtain a differential equation for the mass function with no dependence on the fields and their coupling functions, having the form

\[ \left( \frac{\partial_r m}{r^2} + \frac{\partial_r \partial_r m}{r} \right)^2 = \frac{2 e^{-2A}}{r^2} \partial_r m + 3 A' \left[ \frac{e^{2A}}{r} \left( 4A' \partial_r m + \partial_r^2 m \right) - \frac{2 \partial_r m}{r^2} \right]. \]  \hspace{1cm} (49)

Any expression for the mass function, consistent with the complete set of equations should satisfy the above constraint.

However, the expression of the mass function can be found through another equation resulting from the rearrangement of the \((rv)\) and \((\theta\theta)\) components, i.e. the following

\[ \frac{1}{r} \partial_r^2 m - \frac{2}{r^2} \partial_r m = 2 f^{(3)} \partial_r \phi \partial_r \phi + 2 f^{(2)} \partial_r \chi \partial_r \chi + f^{(3)} \left( \partial_r \phi \partial_r \chi + \partial_r \chi \partial_r \phi \right). \]  \hspace{1cm} (50)

Using again the relations (45), one may see that the combination of terms on the right-hand side of the above equation vanishes, and the solution (12) for the mass function is thus recovered. Substituting that solution into the constraint (49), and equating the coefficients of the same powers of the radial coordinate on both sides, we are led again to the constraint \( \partial_r C = 0 \). In this case, although a \( y \)-dependence remains in the expression of the mass function, this is restricted only in the coefficient \( B \) of the \( r^3 \) term; the Schwarzschild coefficient \( C \), that is associated with the singular terms in the curvature invariants, is not allowed to have a non-trivial profile along the extra coordinate in contradiction with our assumptions.
We conclude this section by noting that the above analysis also holds in the case where non-minimal forms for all kinetic terms in equation (41) are included in the theory.

5. A field theory of a non-minimally-coupled scalar

Let us finally consider the case of a non-minimally coupled scalar field that propagates in the bulk. The action of this theory has the form

\[ S = \int d^4x \sqrt{-g} \left[ \frac{f(\Phi)}{2\kappa_5^2} R - \frac{1}{2} (\nabla \Phi)^2 - V(\Phi) - \Lambda_B \right]. \]  

(51)

where \( f(\Phi) \) is a general, smooth, positive-definite function of the scalar field \( \Phi \). The field equations following from the above action have the covariant form

\[ f(\Phi) \left( R_{MN} - \frac{1}{2} g_{MN} R \right) = \kappa_5^2 \left( \nabla^M \nabla_N f(\Phi) - g_{MN} \nabla^2 f(\Phi) \right). \]  

(52)

with \( T^{(\Phi)}_{MN} \) being the generalized energy-momentum tensor of the scalar field defined as

\[ T^{(\Phi)}_{MN} \equiv \nabla_M \nabla_N \Phi - g_{MN} \left[ \frac{1}{2} (\nabla \Phi)^2 + V(\Phi) \right] + \frac{1}{\kappa_5^2} \left[ \nabla_M \nabla_N f(\Phi) - g_{MN} \nabla^2 f(\Phi) \right]. \]  

(53)

As usual, we will assume that the scalar field shares the same spherical symmetry of the spacetime but depends on all other three spacetime coordinates, i.e. \( \Phi = \Phi(v, r, y) \). Then, calculating the components of the energy-momentum tensor (53) and combining them with the ones of the Einstein tensor (4), we obtain the field equations of the theory. First, the off-diagonal components \((v, r)\), \((y, r)\), \((y, v)\) and \((r, v)\) assume the form

\[ (1 + f'') \left( \partial_r \Phi \right)^2 + f' \partial_r^2 \Phi = 0, \]  

(54)

\[ (1 + f'' \partial_r \Phi \partial_r \Phi + f' \partial_r \partial_r \Phi - A' f' \partial_r \Phi = 0, \]  

(55)

\[ (1 + f'') \partial_r \Phi \partial_r \Phi + f' \partial_r \partial_r \Phi - A' f' \partial_r \Phi - \frac{\partial_r m}{r} f' \partial_r \Phi \]  

\[ = f_\Phi \left( \frac{\partial_r m}{r} + \partial_r \partial_r m \right). \]  

(56)

\[ \left[ 1 - \frac{2m}{r} \right] \left[ (1 + f'') \partial_r \Phi \partial_r \Phi + f' \partial_r \partial_r \Phi \right] + \left[ (1 + f'') \partial_r \Phi \partial_r \Phi + f' \partial_r \partial_r \Phi - \frac{\partial_r m}{r} f' \partial_r \Phi \right] \]  

\[ + \frac{f'}{r} \partial_r \Phi \left( \partial_r m - \frac{m}{r} \right) + \frac{\partial_r m}{r} \frac{e^{2A}}{r} \partial_r \Phi = f_\Phi \left[ \frac{2}{r^2} \partial_r m - \frac{e^{2A}}{r} \left( \partial_r^2 m + 4A' \partial_r m \right) \right]. \]  

(57)

respectively. In the above, \( f' \) denotes the derivative of the coupling function with respect to \( \Phi \) and \( A' \) the derivative of the warp-factor function with respect to \( y \). For simplicity, we have absorbed the five-dimensional gravitational constant \( \kappa_5^2 \) inside \( f(\Phi) \). We should note here that the components \((v, y)\) and \((r, y)\) are not independent but lead again to equations (55) and (56), respectively.

In addition, not all the diagonal components are independent, but lead to three different field equations, namely
\[ e^{-2A} \left[ (1 + f') \partial_v \Phi \partial_r \Phi + f' \partial_v \partial_r \Phi + \frac{f'}{r} \partial_r \Phi \left( \frac{m}{r} - \partial_r m \right) \right] \\
+ A' f' \partial_r \Phi - (\mathcal{L}_\Phi + \Box f + \Lambda_B) = f \left( 6A'^2 + 3A'' - \frac{2e^{-2A}}{r^2} \partial_r m \right) , \]  
\( \mathcal{L}_\Phi \equiv \frac{1}{2}(\nabla \Phi)^2 + V(\Phi) = \frac{e^{-2A}}{2} \left[ 2 \partial_r \Phi \partial_r \Phi + \left( 1 - \frac{2m}{r} \right)(\partial_r \Phi)^2 \right] + \frac{1}{2} \left( \partial_r \Phi \right)^2 + V(\Phi) , \]
\( \Box f = e^{-2A} \partial_v \partial_v f + \frac{e^{-2A}}{r^2} \partial_r \left[ r^2 \partial_v f + r^2 \left( 1 - \frac{2m}{r} \right) \partial_r f \right] + e^{-4A} \partial_r \left( e^{4A} \partial_r f \right) . \)

respectively. An alternative constraint that does not contain these complicated expressions can be derived by combining equations \((58)\) and \((59)\); this has the form
\[ (1 + f') \partial_v \Phi \partial_r \Phi + f' \partial_v \partial_r \Phi = \frac{f}{r} \left[ \partial_r \Phi + \frac{3}{2} \partial_r m - \frac{3}{2} \partial_r m \right] . \]

One may attempt to simplify the above set of equations by assuming a simpler configuration for the bulk scalar field \(\Phi\). Unfortunately, configurations that depend solely on one of the coordinates \((v, r, y)\) can quite easily be shown not to be supported by the set of equations. For instance, if \(\Phi\) depends only on the radial coordinate \(r\), then equation \((55)\) demands the triviality of either the warp factor \((A' = 0)\) or the coupling function \((f' = 0)\). The former choice removes the warping of the five-dimensional spacetime and is thus excluded; the latter corresponds to the minimal coupling case that was investigated in section 4, and shown not to lead to the desired type of solution. On the other hand, if \(\Phi\) only depends on the time coordinate \(v\), then equations \((58)\) and \((60)\), when combined, give the simple equation
\[ \partial_v^2 m = -3e^{2A}A'' r , \]
which upon integration yields
\[ \partial_v m = -\frac{3}{2} e^{2A}A'' r^2 + m_0(v, y) . \]
The above when substituted in the constraint (63) leads to the relation
\[ \frac{\partial_r f}{f} - \frac{2}{r} m_0(v, y) = 0. \]  
(66)

Since \( f = f(v) \), the above cannot be satisfied due to its explicit dependence on \( r \). Finally, if \( \Phi \) only depends on the bulk coordinate \( y \), the left-hand side of equation (56) trivially vanishes while its right-hand side, upon integration, yields
\[ m(v, r, y) = \frac{C(v, y)}{r} + D(v, r). \]  
(67)

The above, when substituted into equation (63), leads to the demand that the function \( C \) be \( y \)-independent. However, admitting that \( C \) is not a function of the bulk coordinate contradicts our main assumption that the mass function has a non-trivial profile along the extra dimension.

We are thus forced to assume that the bulk scalar field depends on a pair of coordinates at least. Let us investigate each case in detail:

– \( \Phi \) depends on the set \((v, r)\). But then, equation (55) again reduces to the constraint \( A' f' = 0 \). As discussed above, neither of the two choices, \( A' = 0 \) or \( f' = 0 \), is consistent with our assumptions.

– \( \Phi \) depends on the set \((v, y)\). Then, equation (63) takes the simplified form
\[ \frac{\partial^2 m}{r^2} - \frac{2}{r} \partial_r m = -\frac{f'}{f} \partial_r \Phi. \]  
(68)

According to our assumption, the right-hand side of the above equation does not depend on the radial coordinate. Identifying it with an arbitrary function \( C(v, y) \), and integrating the above equation twice with respect to \( r \), we obtain the following expression for the mass function
\[ m(v, r, y) = -C(v, y) \frac{r^2}{2} + D(v, y) \frac{r^3}{3} + E(v, y), \]  
(69)

where \( D(v, y) \) and \( E(v, y) \) are also arbitrary functions. Furthermore, combining equations (58) and (60), we obtain the constraint
\[ (1 + f'') (\partial_r \Phi)^2 + f' \partial_r^2 \Phi - A' f' \partial_r \Phi + 3 f A'' = -\frac{f}{r} e^{-2A} \partial_r^2 m. \]  
(70)

Since \( A = A(y) \) and \( f = f(\Phi(v, y)) \), the left-hand side of the above equation is not a function of the radial coordinate. When the expression for the mass function (69) found above is used, we conclude that the only way its right-hand side is not a function of \( r \) either is to impose the condition \( C(v, y) \equiv 0 \). However, from equation (68), it holds that \( C(v, y) \propto \partial_r \Phi \), and according to our assumption, the latter is not zero. As a result, this case also leads to an inconsistency.

– \( \Phi \) depends on the set \((r, y)\). In this case, equation (56) can be rewritten in the form
\[ (\partial_v f) \partial_r m + f \left( \frac{\partial_r m}{r} + \partial_r y \right) = 0. \]  
(71)

Similarly, the constraint (63) is simplified to
\[ (\partial_v f) \left( 1 - \frac{2m}{r} + \partial_r y \right) + f \left( \partial_r^2 m - \frac{2}{r} \partial_r m \right) = 0. \]  
(72)
The above system of equations may be considered as a linear, homogeneous system for
the set of quantities \( f, \partial f \); in order for it to be consistent, the determinant of the
elements should vanish. This leads to an equation involving only the mass function
and its derivatives, namely

\[
\left( \frac{\partial m}{r} + \partial_r \partial_m \right) \left( 1 - \frac{3m}{r} + \partial_r m \right) - \partial_r \left( \partial_r^2 m - \frac{2}{r} \partial_r m \right) = 0. \quad (73)
\]

Drawing inspiration from the form of the black-hole solutions in the context of general
relativity or from the projected-on-the-brane analytically-known solutions, we will now
make the assumption that the mass function can be written as the sum of a
finite number
of terms, each one being a power—either positive or negative—of the radial coordinate \( r \).
We will thus use the general form

\[
m(v, r, y) = \sum_n \alpha_n(v, y) r^n, \quad (74)
\]

where \( n \) is an integer number taking a finite number of values. Substituting the above
expression into the constraint \((73)\) we arrive at the relation

\[
\sum_\ell \left( \partial_\ell \alpha_\ell \right) r^{\ell - 1} \left[ (\ell + 1) + \sum_n \alpha_n r^{n - 1} (n - \ell + 1)(n - 3) \right] = 0. \quad (75)
\]

The above constraint is satisfied for all values of \( \ell \) (and \( n \)) for \( \partial_\ell \alpha_\ell = 0 \). If, however, we
insist that \( \partial_\ell \alpha_\ell \) is non-trivial, then it is the quantity inside the square brackets that should
vanish instead. The only values of \( n \) for which this holds are \( n = 1 \) and \( n = 3 \). However,
then the metric function \( 1 - 2m/r = 1 - 2\alpha_1 - 2\alpha_3 y^2 \) does not describe a black hole
but a modified dS/AdS spacetime.

Therefore, it is again the most general case—the one with \( \Phi = \Phi(v, r, y) \)—that remains
to be considered. We notice that equation \((54)\) can be solved to yield

\[
1 + f''(\Phi) = -f'(\Phi) \frac{\partial_r^2 \Phi}{(\partial_r \Phi)^2}, \quad (76)
\]

which can then be replaced into equation \((55)\) to obtain

\[
A' = \partial_\ell \left( \frac{\partial_\ell \Phi}{\partial_r \Phi} \right). \quad (77)
\]

We may easily integrate the above differential equation with respect to \( r \) to find

\[
\partial_r \Phi = \partial_r \Phi \left[ A'(y) r + F(v, y) \right], \quad (78)
\]

where \( F(v, y) \) is an arbitrary function. In \([44]\), the above relation was used to formulate a no-
go theorem according to which no viable solutions with \( m = m(v, y) \) exist, even for an
arbitrary coupling function \( f(\Phi) \). However, in the present case, the assumed \( r \)-dependence of
the mass function impedes the formulation of a similar argument as it makes further
integrations with respect to \( r \) impossible to perform. Thus, an alternative route must be
followed.

If we use equation \((78)\) to substitute \( \partial_r \Phi \) in equation \((56)\) and then combine it with the
constraint \((63)\), we obtain the following differential equation for the coupling function \( f \):
In addition, combining the diagonal components \( (59) \) and \( (60) \), and again using equation \( (76) \) to substitute \( 1 + f'' \) in the ensuing equation, we obtain a second differential equation for \( f \), namely

\[
\partial_f \left[ \left( A'r + F \right) \left( 1 - \frac{3m}{r} + \partial_r m \right) + r \partial_r F - \partial_r m + F \frac{\partial \Phi}{\partial \Phi} \right] + f \left[ \left( A'r + F \right) \left( \partial_r^2 m - \frac{2}{r} \partial_r m \right) - \frac{1}{r} \partial_r m - \partial_r \partial_r m \right] = 0. \tag{79}
\]

For the homogeneous system of equations \( (79) \) and \( (80) \) to be consistent, the determinant of the coefficients should be zero. If we denote the coefficients of \( \partial_f \) and \( f \), with \( A_1 \) and \( A_2 \) respectively in equation \( (79) \), and with \( B_1 \) and \( B_2 \) as the corresponding coefficients in equation \( (80) \), we should then have:

\[
\frac{A_1}{B_1} = \frac{A_2}{B_2} \equiv G(v, r, y), \tag{81}
\]

where \( G(v, r, y) \) is an arbitrary function. Focusing on the second equality of the above relation, we may thus write

\[
\left( A'r + F \right) \left( \partial_r^2 m - \frac{2}{r} \partial_r m \right) - \frac{1}{r} \partial_r m - \partial_r \partial_r m = G(v, r, y) \left( -3A'' r e^{2A} - \frac{2}{r} \partial_r m \right). \tag{82}
\]

At this point, we will again use the general polynomial form \( (74) \) of the mass function with respect to the radial coordinate. Employing this form, the coefficients \( A_2 \) and \( B_2 \) also take the form of polynomials. Then, through equation \( (81) \), the arbitrary function \( G \) will also be a polynomial, and we may thus write

\[
G(v, r, y) = \sum_{\ell} g_{\ell}(v, y) r^\ell, \tag{83}
\]

where \( \ell \) is again an integer number taking a finite number of values. Using the above expression in equation \( (82) \) as well, we obtain the constraint

\[
\sum_n \left[ n(n - 3)\alpha_n A' - (n + 1) \partial_n \alpha_n \right] r^{n-1} + \sum_n \alpha_n \ln \left( n - 3 \right) r^{n-2} = -3 \sum_{\ell} g_{\ell} A'' r^{\ell+1} - 2 \sum_{\ell,n} g_{\ell} \alpha_n \ln r^{\ell+n-2}. \tag{84}
\]

The most general choice of two integer numbers that satisfies the above equation is \( (n = 3, \ell = 1) \); however, in this case the metric function \( 1 - 2m(v, r, y)/r \) does not describe a black hole on the brane any longer, but a modified dS/AdS background. More particular solutions also arise: for instance, the choice \( (n = 4, \ell = 1) \) causes the four terms of equation \( (84) \) to form two pairs of the same power of \( r \)—again, the resulting metric function does not describe a black hole on the brane. The choice \( n = 0 \) also leads to mathematically consistent solutions, however, from the physical point of view it fails since it leads us back to the case with \( m = m \) \((v, y)\) studied in [44], or even to the black-string solutions [8] when the condition \( \partial_n \alpha_n = 0 \) is imposed on top.

There are also more special cases arising from the demand that the determinant \( A_1B_2 - B_1A_2 \) trivially vanishes. This happens, for example, when the two differential
equations for \( f \) reduce to one, and then \( G(\nu, r, y) = 1 \). In this case, the function \( G \) does not have an \( r \)-dependence anymore, and therefore \( \ell = 0 \). Equation (84) still applies in this case, giving either \( n = 2 \) only or \( n = 3 \) only—again, in both cases, the metric function does not describe a black hole on the brane. We should also check the case where one of the rows or columns of the determinant has zero entries: for \( A_2 = B_2 = 0 \), we again obtain the solution (33) for the mass function but with \( \partial_\nu m_0 = 0 \). This removes the \( y \)-dependence from the Schwarzschild term of the metric function altogether, and thus the possibility of removing the bulk singularities. The case \( A_1 = B_1 = 0 \), for non-trivial \( f \), unavoidably leads (through equations (79)–(80)) to the condition \( A_2 = B_2 = 0 \) and to the previous conclusion. In the case \( A_1 = A_2 = 0 \), the condition \( A_2 = 0 \) in conjunction with the general form (74) leads to the demand that \( F n(n - 3) = 0 \). For \( F = 0 \), we further obtain \( n = 1 \); however, for this value or the additional possible ones (\( n = 0 \) and \( n = 3 \)) we again lose the \( y \)-dependence of the metric since we are also led to the condition \( \partial_y a_0 = 0 \). The final case \( B_1 = B_2 = 0 \) is the most elaborate one: the condition \( B_2 = 0 \) again leads to solution (33) for the mass function; when this is substituted into the second condition \( B_1 = 0 \), we obtain

\[
\frac{\partial_y \Phi}{\partial_y} = \frac{2m_0(\nu, y)}{r} - 1 + r a_0 F e^{2A}.
\]

Substituting both the above result and the solution (33) for the mass function into the remaining equation (79), we obtain the constraint

\[
\sum_{\ell} f_\ell \ r^{\ell+2} \left( \frac{\ell + 4}{2} \partial_\nu (A' e^{2A}) + \sum_{\ell} f_\ell \ r^\ell \ (A' + \partial_\nu F + F \partial_y F e^{2A}) \right) - \sum_{\ell} f_\ell r^{\ell-1} \left[ 3\ell A' m_0 + (\ell + 1) \partial_y m_0 \right] - \sum_{\ell} f_\ell r^{\ell-2} \ell F m_0 = 0.
\]  

(86)

In the above, we have also assumed that due to the polynomial form of the coefficients \( A_1 \) and \( A_2 \), the function \( f \) should also be written as a polynomial with respect to the radial coordinate

\[
f(\nu, r, y) = \sum_{\ell} f_\ell (\nu, y) r^\ell.
\]

(87)

The mathematical consistency of equation (86) demands that each one of the terms should vanish. The most restricting is the last one leading to \( F m_0 = 0 \): accepting that \( F = 0 \) leads unavoidably to \( A' = 0 \) whereas the choice \( m_0 = 0 \) eliminates the black-hole form of the solution on the brane.

In light of all the above, we may thus conclude that even the most general, spherically-symmetric configuration of a non-minimally coupled bulk scalar field cannot support a localised black-hole solution of the form (3).

6. Conclusions and discussion

As the quest for finding five-dimensional, localised-on-the-brane, analytical black-hole solutions continues, in this work we extend a previous analysis of ours that aimed to find Schwarzschild-type black-hole solutions on the brane. In [44], a generalised Vaidya-type ansatz was used for the five-dimensional metric tensor that allowed for both time dependence and dependence on the bulk coordinate of the mass function. Several types of field theories were considered in [14, 44], ranging from ordinary to more exotic types, in an effort to find the field-theory framework that would support this particular type of five-dimensional gravitational background. Unfortunately, none of the theories considered led to a positive
result putting a big question-mark on the existence itself of localised, close-to-the-brane black holes in the context of warped brane-world models.

The present analysis aimed to extend both analyses [14, 44] by considering again a variety of scalar field-theory models—from the simplest to more complex ones—but assuming a less restrictive form for the metric tensor. Instead of the more traditional Schwarzschild form usually employed in the Vaidya metric, a more general form was postulated for the mass function with an additional dependence on the radial coordinate that would allow for all possible types of modifications and power-law terms to be present in the metric function. The increased complexity of the metric tensor was reflected in the more elaborate form of the five-dimensional quantities, and in the appearance of additional singular terms; however, these were of the same type as the black-string singular terms, with their elimination again being possible under the assumption that a solution with a fast-enough decreasing profile of the mass function could be found.

In order to pin-point the characteristics of a field-theory model that would potentially support such a gravitational solution, we first considered the case of a bulk filled only with a cosmological constant. Although this model allowed for a Schwarzschild–(A)dS type of metric function, the desired dependence of the mass-function on the bulk coordinate, which would succeed in localising the black-hole singularities close to the brane, was prohibited. This result held for any sign or value of bulk cosmological constant. This theory had the restrictive characteristic of an isotropic energy-momentum tensor along all five coordinates, a feature that clearly puts a restriction on the form of the solution.

The same characteristic was present in the theory of a single scalar field with either canonical or non-canonical kinetic terms studied next. Therefore, it was no surprise when the assumed $\gamma$-dependence of the mass function was also excluded. Moving to the case of two interacting scalar fields, the total isotropy of the energy-momentum tensor was at last avoided. However, the system of field equations implicitly imposed this by demanding that the terms that caused the differences between the components of the energy-momentum tensor should vanish. This result was independent of the canonical or non-canonical type of kinetic terms of the scalar fields as well as of the form of their common potential. The complexity of the model was increased further by allowing a mixed kinetic term of the two fields: in this case, the isotropy of the energy-momentum tensor was altogether avoided, and a Schwarzschild–(A)dS type of solution was indeed found that allowed for $\gamma$-dependence of the mass function; unfortunately, that $\gamma$-dependence was only allowed for the multiplicative coefficient of the cosmological constant term and not for the one of the Schwarzschild term associated with the bulk singular terms.

Having covered a wide variety of field theories of minimally-coupled scalar fields, in the last part of our paper we focused on the case of a non-minimally coupled scalar field with a general coupling function between the scalar field and the Ricci scalar. A bulk potential was also assumed to be present, together with the bulk cosmological constant, however, once again its exact expression did not affect the analysis in the least. Solutions for the mass function that resembled the ones of a Schwarzschild–(A)dS or a Reissner–Nordstrom black hole were found again; however, the complete set of equations trivialised either the assumed $\gamma$-dependence or the structure of the black-hole spacetime itself.

In light of our analysis, we may conclude that allowing for a more general form of the metric tensor that would make space for black-hole solutions different from the traditional Schwarzschild type, was not by itself capable of producing viable solutions. The form of the field theory considered in each case determined the form of the energy-momentum tensor, and, at times, annihilated the increased flexibility of the field equations and took us back to previous, singular solutions. It was only for the more involved models—of either minimally
or non-minimally coupled scalar fields—that more general black-hole solutions were allowed. However, the desired non-trivial profile of the mass function was excluded and thus the elimination of the bulk singularities could not take place. Nevertheless, it became apparent that it was only in the context of specific models, where the five-dimensional isotropy of the energy-momentum tensor was broken, that the y-dependence of the mass function was allowed at all. As a side observation, we should also note that the time dependence of the scalar field configurations again seemed to be necessary for the existence of a viable solution; however, this feature by itself failed to produce the desired solution in the context of the present models.

Novel solutions describing new types of black strings or regular brane-world models have arisen in the context of our analysis, and these will be studied in detail in a forthcoming work. However, the question of the existence of a five-dimensional, localised black hole in the context of a brane-world scenario still remains, and the chances of producing one in the framework of a legitimate field theory have become even thinner. Although valuable lessons have been learned—such as the role of the metric ansatz and form of the energy-momentum tensor—clearly more work and inspiration are still needed to achieve our goal.

Acknowledgments

We would like to thank Katarzyna Zuleta and Elizabeth Winstanley for useful discussions during the early stages of this work. This research has been co-funded by the European Union (European Social Fund—ESF) and Greek national funds through the operational programme ‘Education and Lifelong Learning’ of the National Strategic Reference Framework (NSRF)—Research Funding Program: ‘ARISTEIA Investing in the society of knowledge through the European social fund’. Part of this work was supported by the COST Action MP1210 ‘The String Theory Universe’.
