Abstract

Glaucoma is a group of eye diseases that can cause vision loss. Prostaglandin analogues (PGAs) are known to be the first line for treatment of patients with glaucoma. Latanoprost is a good, efficient & tolerated PGA that currently available as latanoprost with Benzalkonium chloride (BAC) (Xalatan) and preservative-free (PF) prostaglandins analogue latanoprost (Monopost). Lately, utilizing of PF anti-glaucoma agents is considered an essential procedure for enhancing glaucoma care. This study aims to analyze the histological changes within the corneal tissue with the use of currently available preserved prostaglandins (PG) - derived eye drops, and PF prostaglandins analogue. In this study, forty male guinea pigs were distributed into four equal groups. Control group, Latanoprost with 0.02% BAC treated group, Recovery group and PF Latanoprost treated group. After two months, the corneal tissues of guinea pigs were prepared for light and electron microscopic studies, morphometric and statistical studies were performed. Our results indicate that guinea pigs treated with latanoprost with BAC exhibited ocular surface changes, there was epithelial thinning with desquamation, the stroma showed irregularly arranged collagen fibers and small keratocytes. Morphometrically, there was a marked decrease in the thickness of epithelium and number of keratocytes. Negative PAS reaction was observed in some parts of the epithelial
basement membrane. The epithelium gives a strong positive immunoreactivity for Bax. Guinea pigs left to recover exhibited improvement, while treatment of animals with PF latanoprost revealed nearly normal corneal structure. In conclusion, PF prostaglandin anti-glaucoma medication seems to be better and protective on cornea of male guinea pigs than prostaglandins with BAC preservative.

**Key words: Glaucoma, Cornea, Guinea pigs, Prostaglandins analogues, PAS, BAX**

**INTRODUCTION**

Glaucoma is an optic neuropathy, that considered the main cause of blindness in the world by affecting approximately sixty-seven million people world-wide [6, 30]. Glaucoma often occurs due to elevated intraocular pressure (IOP) that leads to damage of the optic nerve which can progress to irreversible vision loss, when left without treatment [36].

Intraocular pressure (IOP) is an essential risk factor and is the main aim for the currently certain glaucoma treatment through the use of topical ocular hypotensive drops [21] that, should be taken through life to inhibit or stop loss of retinal ganglion cell and visual impairment [31].

Prostaglandin analogues (PGAs) are one of the most important drugs utilized for ocular hypertension and glaucoma treatment [26]. These compounds are known to be highly effective in decreasing intraocular pressure (IOP) [19].

Uzunel [39] reported that PGAs stimulate drainage of aqueous humor through the uveoscleral outflow pathway and facilitate the trabecular outflow resulting in reducing IOP. Five different prostaglandins (PGs) are known to be used for treatment of glaucoma namely, isopropyl unoprostone, latanoprost, travoprost, bimatoprost, and tafluprost [16].

Long-term local treatment with these anti-glaucoma drugs is always associated with ocular surface disease such eye color change, darkening of eyelid skin, droopy eyelids, sunken eyes, eye redness, and itching [32].

Kim et al. [16] referred these side effects to the components of these topical hypotensive drops such as Benzalkonium chloride (BAC) preservative. BAC is the most common
applied preservative in eye drops having highly effective anti-microbial features. It is a quaternary ammonium salt, a cationic surfactant and tension-active compound. It breaks up the lipid layer of tear film and cell membranes of corneal surface. BAC acts also, by denaturing proteins and disrupting the cell membrane thus, improving the active compounds penetration so, it could be employed as a penetration enhancer [25, 2]. It has the advantage of being relatively well tolerated with few allergic side effects [6]. Having very slow turnover, BAC remains within the ocular tissues after a single drop administration about 48 hours [16].

BAC side effects seemed to be time and dose dependent, rising with larger amounts utilized over prolonged periods [42, 22]. With rising attention on the ocular surface side effects of this preservative, other types of preservatives-containing PGs and new preservative-free (PF) PGs have been advanced [38].

So, this current study was designed to analyze the histological alterations within the corneal tissue with the use of currently available (PGs)- derived eye drops, namely latanoprost with BAC (Xalatan) and PF PGA latanoprost (Monopost) in male guinea pigs.

MATERIALS AND METHODS

Animals and experimental protocol

The present experimental study was conducted at Research Center in Menoufia University, Egypt. Study protocols was reviewed and observed via the Animal Ethics Committee of the Research Laboratory of Experimental Animals at Faculty of Medicine, Menoufia University, Egypt. Forty male adult guinea pigs, weighting 400-450g were employed in the current work. They were stayed in cages at room temperature. The water and food were available. Strict hygiene was followed to keep a healthy medium for the guinea pigs.

Animal groups

The animals were distributed randomly into four groups, each included 10 guinea pigs.
**Group I (Control group):** The guinea pigs were left without treatment during the experimental period.

**Group II (Latanoprost with BAC treated group):** They were treated topically with latanoprost preserved with 0.02% benzalkonium chloride (0.005% Xalatan 125µg/2.5ml, Pfizer, New York, USA).

**Group III (Recovery group):** They were treated as group II and left for two weeks without treatment for recovery.

**Group IV (PF Latanoprost treated group):** The guinea pigs in this group were treated topically with preservative free latanoprost (Monopost 50 µg/ml, Thea Pharmaceuticals Ltd, UK).

All guinea pigs received treatment as a single eye drop (1.5 µg latanoprost) in both eyes daily for two months [14].

At the assigned time of scarification for each group, cardiac perfusion was done under anesthesia using sodium pentobarbital, 40 mg/kg by intraperitoneal injection [15]. From each animal, both eyeballs were enucleated rapidly and the corneal tissues were prepared for light and transmission electron microscopic studies.

**Light microscopic study**

From each animal, the right eye ball was fixed in 10% formaldehyde solution and processed for paraffin sections of about 7µm thick. Sections were obtained and stained with hematoxylin and eosin to demonstrate the histological details & Mallory’s trichrome stain to detect the collagen fibers [3]. For histochemical study, the corneal sections were processed to be stained by Periodic acid Schiff reaction for determination of carbohydrate (epithelial basement membrane) [3]. For immunohistochemical study, Bax immune-staining was carried out (a marker of apoptosis), paraffin sections were put within monoclonal BAX antibody (Ab-14 Golden, Lab Vision Clone B-9; Santa Cruz Biotechnology Inc., USA). Negative control sections were processed by replacing the primary antibody with buffer alone. Hodgkin’s lymphoma was used as a positive control. Brown cytoplasmic staining was scored as a positive reaction. Counterstaining was performed by using Meyer's hematoxylin [29].
Transmission electron microscopic study

The cornea of the left eye was dissected. Small corneal specimens were obtained and rapidly fixed in 3% gluteraldehyde with 0.1 M phosphate buffer at PH 7.4. Then, processed for examination, using a Jeol electron microscope (Seo-Russia) in Tanta E.M Center at Faculty of Medicine, Tanta University [12].

Morphometric study and statistical analysis

From each animal in all groups, the cornea was examined under light microscope using objective lens x 40. Thickness of corneal epithelium in µm and keratocytes number was measured in 10 high power fields (HPFs) in each specimen.

The morphometric results were analyzed and compared by student's t-test. P-value was utilized to estimate the significant change in each parameter in the experimental animals in comparison with the control group. Then, the data were tabulated as mean ± SD and then, analyzed utilizing statistical package for the Social Science Software (SPSS). P value was set at 0.05, P>0.05 was considered non-significant, P value<0.05 was considered significant and P value <0.001 was considered highly significant [28].

RESULTS

Effects of preservative- free and preserved prostaglandin analogues on corneal morphology

7µm paraffin corneal sections stained with hematoxylin and eosin of the different experimental groups to analyze the histological alterations with the use of latanoprost with BAC (Xalatan) and PF PGA latanoprost (Monopost) in male guinea pigs was done. Group I (control) showed well defined corneal layers, these were: the outer epithelium, Bowman's membrane, stroma, Descemet's membrane and inner endothelium. The corneal epithelium was stratified squamous non-keratinized epithelium with smooth upper surface. It consisted of basal layer of a single columnar cells with basal oval nuclei, intermediate layer consisting of polyhedral cells with central rounded nuclei arranged in 2 to 3 rows and superficial layer consisting of one to two rows of flattened squamous cells with flat nuclei. Under the epithelium, an acidophilic homogenous membrane appeared, Bowman’s
membrane. The stroma constituting the most corneal thickness, formed of bundles of collagen fibers which arranged regularly and keratocytes appeared as flat cells with flattened nuclei, scattered between collagen fibers (Fig. 1A). While, the corneal sections from Group II (Latanoprost with BAC treated group) exhibited epithelial thinning with flat nuclei (Fig. 1B). The thickness of corneal epithelium showed a highly significant decrease as compared with control group (P<0.001) (Table1, Fig. 3A). Some surface epithelial cells were exfoliated and desquamated and other epithelial cells exhibited vacuolated cytoplasm and their nuclei revealed variable degrees of degeneration, karyolysis and pyknosis (Fig. 1C). The stroma demonstrated irregularly arranged collagen fibers which were separated by wide spaces (Figs. 1B&1C) and small dark keratocytes were seen (Fig. 1C) The mean number of keratocytes was highly significant decreased in comparison with the control group (P<0.001) (Table 1, Fig.3B). Cellular infiltration, Neovascularization (Fig. 2B) and congested blood vessels (Fig. 1C) were also observed in the stroma. Group III (Recovery group) revealed less degenerative changes in the form of slight superficial epithelial cells desquamation and corrugated basement membrane. The stroma consisted of collagen bundles arranged regularly and spindle shaped keratocytes with pale nuclei in between. Some keratocytes appeared small in size with condensed nuclei (Fig. 1D). The corneal epithelial thickness and the mean number of keratocytes were improved compared to group II (P<0.05) (Table1, Figs. 3A& 3B). Group IV (PF latanoprost treated group) revealed better corneal structure that appeared almost similar to that of the control group (Fig. 1E). There was a non-significant difference (P>0.05) in corneal epithelial thickness and the mean number of keratocytes when compared to control group. While these animals revealed a highly significant decrease in these parameters in comparison with group II (P<0.001) (Table 1, Figs. 3A& 3B). Regarding to the posterior aspect of the cornea, Group I displayed flat endothelial cells arranged in one layer and supported via a homogenous acellular Descemet's membrane (Fig. 2A). While, Group II showed Apparently few endothelial cells with small pyknotic nuclei. Stroma with irregularly arranged collagen fibers and with wide spaces in between were seen. The keratocytes appeared small in size with dark nuclei (Fig. 2B). Group III revealed few endothelial cells separated from the Descemet's membrane (Fig. 2C). Moreover, Group IV displayed acellular Descemet's membrane lined by a single layer of endothelial cells (Fig. 2D).
In order to visualize changes in collagen fiber architecture Mallory trichrome stained corneal sections of the different experimental groups were performed. Group I (control) revealed regularly arranged collagen fibers (Fig. 4A). However, in group II (latanoprost with BAC treated group), there was widely separated and irregularly arranged collagen fibers (Fig. 4B). While group III (recovery group) exhibited regularly arranged collagen fibers. Wide space between collagen fibers was observed (Fig. 4C). In group IV (PF latanoprost treated group), there was regular arrangement of collagen fibers similar to control (Fig. 4D).

For determination of carbohydrate (epithelial basement membrane) PAS stained corneal sections of the different experimental groups were done. Group I (control group) exhibited strong positive reaction in the epithelial basement membrane (Fig. 5A). However, mild positive PAS reaction in some parts and negative in other parts of the basement membrane were seen in group II (latanoprost with BAC treated group) (Fig. 5B). Group III (recovery group) revealed mild positive reaction (Fig. 5C). In group IV (PF latanoprost treated group), there was strong positive PAS reaction in the basement membrane similar to control group (Fig. 5D).

For detection of apoptosis immunohistochemically in corneal tissue, Bax immune-marker expression was determined. There was a negative Bax expression in the corneal tissue of group I (Fig. 6A). While in group II, strong positive cytoplasmic Bax reaction in the epithelium and mild reaction in keratocytes were observed (Fig. 6B). However, group III, exhibited moderate Bax reactivity in the corneal epithelial cells and mild reaction in keratocytes (Fig. 6C). In group IV, there was negative reaction in the epithelium and stroma similar to control animals (Fig. 6D).

**Effects of preservative-free and preserved prostaglandin analogues on corneal ultrastructure**

Electron microscopic results was done to confirm the light microscopic findings. Group I (control group), the corneal epithelium had basal columnar cells with euchromatic rounded nuclei. Hemi-desmosomes appeared as electron dense spots and seen on the basal sides of these cells, facing the basement membrane. While, the intermediate cells had rounded euchromatic nuclei. The superficial cells were flattened with flat nuclei. All epithelial cells were connected together by many electron dense desmosomes, allowing narrow intercellular spaces. Under the epithelium, there was the Bowman's membrane.
which appeared as a thick collagen fibers layer (Figs. 7A & 7B). The stroma had regularly arranged collagen fibers parallel to the corneal surface. The keratocytes appeared as spindle shaped cells with scanty cytoplasm and moderately electron dense oval nucleus. They appeared squeezed in-between collagen fibers (Fig. 7C). The Descemet's membrane displayed as homogenous acellular electron-dense layer and lined by a single layer of endothelial cell which appeared as flat cells having oval nuclei and their cytoplasm contained rough endoplasmic reticulum cisterna and mitochondria (Fig. 7D).

Group II (latanoprost with BAC treated group), marked alterations including the various corneal layers were seen. As the basal and intermediate epithelial cells appeared with cytoplasmic vacuoles, free ribosomes, distorted mitochondria, wide perinuclear space and shrunken nuclei (Figs. 8A & 8B). Moreover, the cells were separated by wide intercellular space (Fig. 8B). The superficial epithelial cells showed flat euchromatic nuclei with irregular contour. Wide intercellular spaces with partial loss of desmosomal junctions between some superficial epithelial cells were seen (Fig. 8C). The stroma exhibited keratocytes which were widely separated from the collagen fibers. The keratocyte appeared with cytoplasmic processes and their cytoplasm contained shrunken nuclei, dilated rough endoplasmic reticulum cisterna and lysosomes (Fig. 8D). Moreover, small areas in the stroma contained little amount of collagen fibers (Figs. 9A & 9B) with appearance of blood vessel were found (Fig. 9A). The endothelial cells appeared with discontinued cell membrane and distorted mitochondria (Fig. 9B).

Group III (recovery group), exhibited superficial epithelial cells with euchromatic nuclei and desmosomal junctions in between. Wide intercellular spaces with loss of desmosomes between some superficial epithelial cells were observed (Fig. 9C). The stroma exhibited regularly arranged collagen fibers. The keratocyte appeared with indented nucleus and abundant cytoplasm containing rough endoplasmic reticulum. Wide space between collagen fibers and keratocyte was observed (Fig. 9D). The Descemet's endothelial cells appeared with cytoplasmic vacuoles and distorted mitochondria (Fig. 10A).

Group IV (PF Latanoprost treated group), revealed corneal structure similar to that of the control group. The superficial epithelial cells were well organized with preserved desmosomal junctions (Fig. 10B). The stroma showed regularly arranged collagen fibers. The keratocyte with oval nucleus and rough endoplasmic reticulum in their cytoplasm was
observed. The Descemet’s endothelial cells appeared with flat nucleus and mitochondria (Fig. 10C).

**DISCUSSION**

PGAs are the first treatment used for glaucoma as a monotherapy or with other hypotensive agents. PGAs are preferable than other ocular hypotensive agents as during long-term clinical use, there is no systemic side effects [16].

Among all the types of available PGAs, latanoprost was chosen in the present study as this drug has good efficacy. Latanoprost is an esterified pro-drug of PGF2α, more lipophilic than other PGAs this means that it is better absorbed through the cornea. Latanoprost is well tolerated. So, patients receiving latanoprost treatment are more persistent than other ocular prostaglandins hypotensive medications [35]. Latanoprost is the first PGAs that has an improved recently produced formulation without BAC [1].

In this study, the histological changes within the corneal tissue with the use of currently available PG- derived eye drops, namely latanoprost (Xalatan) and PF PGA latanoprost (Monopost) in male guinea pigs was evaluated by light and electron microscope.

In the current study, the light microscopic corneal changes are confirmed by electron microscope. Corneal tissue from guinea pigs treated with latanoprost with BAC revealed toxic changes that considered to be related to the preservative, BAC as previously reported by Trzeciecka et al. [38].

Epstein et al. [9] demonstrated that preservatives which are exist in eye drops, like BAC changes the permeability of the ocular surface epithelium, even at very low doses, BAC gives rise to cell membranes lysis at the ocular surface.

Thinning of epithelial covering with desquamation of some surface cells was detected in the present study, this finding was confirmed morphometrically by showing highly significant decrease within the corneal epithelial thickness in comparison with the control animals. These results coincided with other authors [10, 22, 39] who reported a decrease in the number of corneal epithelial layers with highly significant decrease in the central corneal thickness following long term treatment with BAC containing eye drops. This
might be due to degeneration of corneal epithelial cells with dead cells loss and failure of cellular regeneration and proliferation following long term treatment with BAC containing eye drops.

Guo et al. [13] and Soliman et al. [37] illustrated that the corneal epithelial cells desquamation with intracellular ATP depletion is accelerated by BAC. Among the various effects of ATP depletion, regulatory light chain of myosin II (MLC) phosphorylation has been detected. It is proven that the corneal epithelial cells exposure to BAC results in MLC phosphorylation, that leads to contraction of the cytoskeleton of the epithelial cells leading to distortion the corneal barrier integrity.

Latanoprost with BAC treated guinea pigs revealed variable degrees of degeneration within the nuclei of the epithelial cells, endothelial cells and stromal keratocytes. This might be due to deoxyribonucleic acid (DNA) damage occurring in corneal cells after treatment of BAC containing eye drops as previously demonstrated with Kobayashi et al. [17] and Soliman et al. [37].

These results were also, in accordance with Barzilai and Yamamoto [4] and Baudouin et al. [5] who stated that BAC caused oxidative stress leading to free radicals generation like hydroxyl radicals and superoxide anion and reactive oxygen species (ROS) as singlet oxygen and hydrogen peroxide. Over production of ROS can induce cellular damage, particularly the DNA through the mitochondrial damage which causes activation of endonuclease and apoptogenic proteases resulting in apoptosis.

Rosin and Bell [33] referred decreasing number of keratocytes within the stroma detected within corneal tissues from guinea pigs treated with latanoprost with BAC to their contraction, apoptosis and death of these cells after exposure to BAC. This finding was supported morphometrically as showing a highly significant decrease in the keratocytes number as compared with that of the control animals.

Disarrangement and loss of collagen fibers in some areas within the stroma in this study, may be due to keratocytes loss as they synthesize and preserve stromal collagen, thus keratocytes loss leads to less collagen secretion [23]. Another explanation of damaged corneal stromal cells following prolonged BAC exposure was that, PGAs are known to reduce IOP by upregulation of Matrix Metalloproteinases (MMPs) which are collagen
degradation enzymes induced by prostaglandin F2-alpha [34, 39], causing connective tissue remodeling and degeneration of extracellular matrix (ECMs), involving collagens of the sclera and ciliary muscle, resulting in lowering resistance of uveo-scleral outflow thus, improving aqueous humor outflow [18].

Stromal neovascularization (NV) and congested blood vessels detected in the present study might be due to corneal stromal cells activation and migration to the site of injury following exposure to BAC. These stromal cells express vascular endothelial growth factor (VEGF) that induces angiogenesis with new blood vessels formation as previously explained by Mahmoud et al. [20].

It was also suggested by Destafeno and kim [8] that stromal NV might be due to unbalancing between angiogenic factors like VEGF, fibroblast growth factor and anti-angiogenic ones like angiostatin in the cornea.

Inflammatory cellular infiltration of the stroma detected within corneal sections from guinea pigs treated with latanoprost with BAC may be considered as a trial for healing and protection against infection which become easier with disturbance of the normal corneal epithelial barrier with prolonged treatment of BAC containing hypotensive eye drops.

Yang et al. [41] reported that inflammatory cellular infiltration of the stroma might be due to the expression of several inflammatory factors, such as chemotactic factors: monocyte chemo-attractant protein 1, macrophage inflammatory protein-1 alpha and growth-regulated protein alpha which increased after treatment with BAC within a week. These inflammatory factors have chemotactic activity for eosinophils monocytes and neutrophils, either separately or together.

Negri et al. [24] referred the inflammatory cellular infiltration of corneal stroma to the effect of BAC in lipooxygenase activation and secretion of inflammatory mediators, and multiple cytokines as interleukin (IL)-1α, tumor necrosis factor-α, IL-8, leading to irritation and allergic reaction.

In the current study, widely separated irregularly arranged collagen fibers in Mallory’s trichrome stained corneal sections from guinea pigs treated with latanoprost with BAC might be due to degradation of its collagen fibers by active MMPs which are produced by
prolonged exposure to BAC. These findings were in agreement with Gaton et al. [11] and Park et al. [26] who reported that PGAs cause up regulation of MMPs that leads to degradation of ECM, including collagens of the ciliary muscle and sclera.

Another explanation of wide spaces in-between collagen fibers is that prolonged treatment with hypotensive eye drops containing BAC resulted in intracellular and extracellular edema as previously explained by Collin and Collin [7].

Histochemically, corneal sections of this group revealed mild positive PAS reaction in some parts and negative in other parts of the basement membrane. These results indicated reduction or even depletion of carbohydrates within the basement membrane of corneal epithelium.

Immunohistochemically, a marked immune positive cytoplasmic reaction for Bax in the covering epithelial cells and stromal keratocytes within corneal sections from guinea pigs treated with latanoprost with BAC was observed. This is could be due to apoptosis of these cells. Bax is a nuclear-encoded protein that can penetrate the mitochondrial membrane and thus, mediate cell death via apoptosis. So, increase reactivity for Bax indicates cellular apoptosis [40].

Guinea pigs left to recover without treatment for two weeks after treatment with latanoprost with BAC shows mild improvement of the histological changes of the cornea. However, some histological alterations were still persisting as desquamation of the superficial epithelial cells and corrugated Bowman's membrane. Small keratocytes with dark nuclei were noticed. Few endothelial cells appeared separated from the Descemet's membrane. These findings were in harmony with Soliman et al. [37] who demonstrated that there was mild recovery within the corneal sections of rats left for recovery after 0.02% BAC treatment with minimal decrease of the thickness of corneal epithelium and stromal degeneration.

On the other hand, light and electron microscopic studies of corneal sections from guinea pigs treated with PF latanoprost revealed nearly normal corneal structure. Moreover, these results were in harmony with Pauly et al. [27] and Yang et al. [41] who reported that rat corneal tissue presented better tolerance with PF latanoprost therapy. This improvement
could be referred to absence of the BAC preservative from PGAs which in turn might improve the structure and function of the corneal epithelial barrier.

CONCLUSIONS

Prostaglandins with BAC preservative derived eye drops result in many histological alterations in the corneal tissue. These alterations might be improved by withdrawal of the preservative. PF prostaglandin medication seems to be alternative to those preserved with BAC formulations.

Table 1. Comparison between control group and other studied groups

|                | Group I       | Group II      | Group III     | Group IV      | P value          |
|----------------|---------------|---------------|---------------|---------------|-----------------|
| Corneal epithelial thickness | 41.2±1.2      | 26.1±1.2      | 38.4±3.8      | 41.1±1.2      | P1=0.000        |
|                |               |               |               |               | P2=0.010        |
|                |               |               |               |               | P3=0.713        |
|                |               |               |               |               | P4=0.000        |
| No. of keratocytes | 24.3±1.7      | 16.5±2.5      | 20.9±5.2      | 23.7±0.6      | P1=0.000        |
|                |               |               |               |               | P2=0.022        |
|                |               |               |               |               | P3=0.157        |
|                |               |               |               |               | P4=0.000        |

P1: Comparison was done between group 1 (control group) and group II (latanoprost with BAC treated group)

P2: Comparison was done between group I (Control group) and group III (recovery group)

P3: Comparison was done between group I (Control group) and group IV (PF latanoprost treated group)

P4: Comparison was done between group IV (PF latanoprost group) and group II (latanoprost with BAC treated group)

p˂0.001 was considered highly significant. p˂0.05 was considered significant. P ˃0.05 was considered non significant.

Figure 1. Photomicrographs of haematoxylin and eosin stained corneal sections of the different experimental groups; 1A. Control group: illustrating non keratinized stratified squamous epithelium (E) resting on clear basement membrane (blue arrow) and consists of basal layer of columnar cells (C) with basal oval nuclei, intermediate layers of polyhedral cells (P) with central rounded nuclei and superficial layer of flattened cells (A) with flat nuclei. The Bowman's membrane (black arrow) appears as an acidophilic homogenous layer under the epithelium. The stroma (SM) consists of collagen fibers arranged regularly with spindle shaped keratocytes with flat nuclei (red arrows) in-between; 1B,1C. Group II: -Group II: 1B. illustrating all epithelial layers (E) appear with flattened nuclei (black arrow). The stroma shows irregularly arranged collagen fibers (blue arrow) and neovascularization (red arrows). Notice, cellular infiltration (I) within the stroma. -Group II: 1C. illustrating desquamation of the superficial epithelium (star) is observed, the
epithelial cells appear with vacuolated cytoplasm (V) and their nuclei show variable degrees of degeneration, karyolysis (red arrows) & pyknosis (blue arrows). The stroma shows wide spaces (S) in between collagen fibers, congested blood vessels (BV) and small dark keratocytes (arrow heads). Notice, discontinuation of basement membrane (double arrow); 1D. Group III: illustrating stratified squamous non-keratinized epithelium (E) resting on corrugated basement membrane (blue arrow). The superficial cells appear with slight desquamation (star). The stroma is formed of parallel arranged collagen fibers (F) with spindle shaped keratocytes with pale nuclei in between (arrow head). Notice, some keratocytes appear small with condensed nuclei (red nuclei); 1E. Group IV: illustrating preserved corneal epithelium (E). The stroma appears with regularly arranged collagen fibers (F) with keratocytes (arrows) in between. Haematoxylin and eosin X400.

**Figure 2.** Photomicrographs of haematoxylin and eosin stained corneal sections of the different experimental groups; 2A. Control group: illustrating the posterior aspect of the cornea Descemet's membrane (blue arrow) appears as a homogenous acellular membrane and lined by a single layer of endothelial cells with flat nuclei (red arrow); 2B. Group II: illustrating apparently few endothelial cells with small pyknotic nuclei (blue arrow). The stroma appears with irregularly arranged collagen fibers (red arrows) with wide spaces in between (S). Small keratocytes (arrow heads) with dark nuclei are observed. Note, appearance of neovascularisation (black arrows) in the stroma; 2C. Group III: illustrating some endothelial cells (arrows) separated from the Descemet's membrane. Notice, some small-sized keratocytes (arrow heads) with condensed nuclei in the stroma; 2D. Group IV: illustrating Descemet's membrane (blue arrow) which appears as a homogenous acellular membrane and lined by a single layer of endothelial cells (red arrow). Notice, normal appearance of stroma (SM). Haematoxylin and eosin X400.

**Figure 3.** A histogram showing mean values of the corneal epithelial thickness [3A] and keratocytes number [3B] of the different experimental groups.

**Figure 4.** Photomicrographs of Mallory's trichrome stained corneal sections of the different experimental groups; 4A. Control group: illustrating regularly arranged collagen fibers (F); 4B. Group II: illustrating, widely separated (S) and irregularly arranged
collagen fibers (F); 4C. Group III: illustrating, regularly arranged collagen fibers (F). Notice, wide space between collagen fibers (S); 4D. Group IV: illustrating, regular arrangement of collagen fibers (F) similar to control group. Mallory's trichrome X400.

Figure 5. Photomicrographs of PAS stained corneal sections of the different experimental groups; 5A. Control group: illustrating strong positive PAS reaction in the epithelial basement membrane (arrow); 5B. Group II: illustrating, mild positive PAS reaction in some parts (blue arrow) and negative in other parts (red arrow) of the epithelial basement membrane; 5C. Group III: illustrating, mild positive PAS reaction in the basement membrane (arrow); 5D. Group IV: illustrating, strong positive PAS reaction in the basement membrane (arrow). PAS X400.

Figure 6. Photomicrographs of Bax immune-stained corneal sections of the different experimental groups; 6A. Control group: illustrating negative Bax reaction in the epithelium and stroma; 6B. Group II: illustrating, strong positive cytoplasmic Bax reaction in the epithelium (blue arrow) and mild reaction (red arrow) in the keratocyte; 6C. Group III: illustrating, moderate Bax reactivity in the corneal epithelial cells (blue arrows) and mild reaction in the keratocytes (red arrow); 6D. Group IV: illustrating, negative Bax reaction in the epithelium and stroma. Bax X1000.

Figure 7. Electron micrographs of the cornea of control group illustrating: 7A: A basal columnar epithelial cells with euchromatic rounded nuclei (N) resting on clear intact Bowman’s membrane (B). The epithelial cells are connected to each other by numerous desmosomes (black arrows) with narrow intercellular spaces. Notice, hemi-desmosomes appear as electron dense spots (red arrow) fixing the basal cells to the underlying basement membrane (blue arrow). X4000; 7B: The intermediate cells have rounded euchromatic nuclei (N). The superficial cells are flattened with flat nuclei (n). All epithelial cells are connected with each other by electron dense desmosomes (arrows). X4000; 7C: A spindle shaped keratocyte with scanty cytoplasm and moderately electron dense oval nucleus (N) is seen squeezed between regularly arranged collagen fibers in longitudinal (L) and transverse (T) directions. X5000; 7D: A single endothelial cell layer with flat nucleus (N) and abundant cytoplasm containing mitochondria (M) and rough
endoplasmic reticulum cisterna (arrows) is observed. The endothelial cells line thick homogenous electron-dense Descemet's membrane (DM). X15000.

**Figure 8.** Electron micrographs of the cornea of Group II illustrating: 8A: Basal and intermediate epithelial cells. One cell appears with cytoplasmic vacuoles (V) and condensed nuclei (n). Some cells have an euchromatic nuclei (N), while, others have shrunken nuclei (K) and wide perinuclear space (red arrow). Notice, the cell membranes are interdigitated and connected by desmosomal junctions (black arrows). X4000; 8B: Epithelial cells with euchromatic nucleus (N) and wide perinuclear space (red arrow) are seen. The cytoplasm shows multiple vacuoles (V), free ribosomes (arrows) and distorted mitochondria (M). The cells are separated by wide intercellular space (S). X15000; 8C: The superficial epithelial cells have flat euchromatic nuclei (N) with irregular contour, some cells show preserved desmosomal junctions (black arrows). Notice, wide intercellular spaces with loss of junctions between some epithelial cells (red arrows). X5000; 8D: The keratocyte has shrunken nucleus (N), variable sized cytoplasmic vacuoles (red arrows), dilated rough endoplasmic reticulum cisterna (black arrows) and lysosomes (blue arrow). The keratocyte is widely separated (S) from regularly arranged collagen fibers (F) of stroma. X5000.

**Figure 9.** Electron micrographs of the cornea of Group II (9A,9B) and Group III (9C,9D); 9A. Group II: illustrating small areas in the stroma containing little amount of collagen fibers (black arrows) with appearance of blood vessel (BV). X5000; 9B. Group II: illustrating, discontinued endothelial cell membrane (black arrow) with distorted mitochondria (M). The stroma displays little amount of collagen fibers (red arrow). X5000; 9C. Group III: illustrating, superficial epithelial cells with flat euchromatic nuclei (N) and preserved desmosomal junctions in between (black arrows). Wide intercellular spaces between some superficial cells with loss of desmosomes are observed (red arrows). X15000; 9D. Group III: illustrating stroma with regularly arranged collagen fibers in longitudinal (L) and transverse (T) directions. The keratocyte appears with indented nucleus (N) and abundant cytoplasm containing rough endoplasmic reticulum cisterna (black arrow). Notice, wide space (S) between keratocyte and collagen fibers. X5000.
**Figure 10.** Electron micrographs of the cornea of Group III (10A) and Group IV (10B, 10C): 10A. Group III: Descemet's membrane (DM) lined by a single endothelial cell layer. The endothelial cell appears with flat nucleus (N) and abundant cytoplasm containing distorted mitochondria (M) and vacuoles (black arrows). X15000; 10B. Group IV: illustrating normal appearance of superficial epithelial cells with preserved desmosomal junctions (black arrows). X5000; 10C. Group IV: illustrating stroma with regularly arranged collagen fibers (F). The keratocyte appears with oval nucleus (N) and rough endoplasmic reticulum (black arrow). The Descemet's membrane (DM) is lined by endothelial cells having flat nucleus (n) and mitochondria (M). X5000.
