Abstract

In lexical semantics, full-sentence segmentation and segment labeling of various phenomena are generally treated separately, despite their interdependence. We hypothesize that a unified lexical semantic recognition task is an effective way to encapsulate previously disparate styles of annotation, including multiword expression identification/classification and supersense tagging. Using the STREUSLE corpus, we train a neural CRF sequence tagger and evaluate its performance along various axes of annotation. As the label set generalizes that of previous tasks (PARSEME, DiMSUM), we additionally evaluate how well the model generalizes to those test sets, finding that it approaches or surpasses existing models despite training only on STREUSLE. Our work also establishes baseline models and evaluation metrics for integrated and accurate modeling of lexical semantics, facilitating future work in this area.

1 Introduction

Many NLP tasks traditionally approached as tagging focus on lexical semantic behavior—they aim to identify and categorize lexical semantic units in running text using a general set of labels. Two examples are supersense tagging of nouns and verbs as formulated by Ciaramita and Altun (2006), and verbal multiword expression (MWE) identification and classification in the multilingual PARSEME shared tasks (Savary et al., 2017; Ramisch et al., 2018, 2020). By analogy with named entity recognition, we can use the term lexical semantic recognition (LSR) for such chunking-and-labeling tasks that apply to lexical meaning generally, not just entities. This disambiguation can serve as a foundational layer of analysis for downstream applications in natural language processing, and provides an initial level of organization for compiling lexical resources, such as semantic nets and thesauri.

In this paper, we tackle a more inclusive LSR task of lexical semantic segmentation and disambiguation. The STREUSLE corpus (see §2) contains comprehensive annotations of MWEs (along with their holistic syntactic status) and noun, verb, and preposition/possessive supersenses. We train a neural CRF tagger (Lafferty et al., 2001) using BERT embeddings (Devlin et al., 2019) and find that it obtains strong results as a first baseline for this task in its full form.

In addition, we ask: Does a tagger trained on STREUSLE generalize to evaluations like the PARSEME shared task on verbal MWEs (Ramisch et al., 2018) and the DiMSUM shared task on MWEs and noun/verb supersenses (Schneider et al., 2016)? Results show our LSR model based on STREUSLE is general enough to capture different types of analysis consistently, and suggest an integrated full-sentence tagging framework is valuable for explicit modeling of lexical semantics in NLP.1

2 LSR Tagging Frameworks

Our tagger is based on STREUSLE (Supersense-Tagged Repository of English with a Unified Semantics for Lexical Expressions; Schneider and Smith, 2015; Schneider et al., 2018),2 a corpus of web reviews annotated comprehensively for lexical semantic units and supersense labels. Specifically, there are three annotation layers: multiword expressions, lexical categories, and supersenses. The supersenses apply to noun, verb, and prepositional/possessive units. Figure 1 shows an example.

Many of the component annotations have been applied to other languages: verbal multiword expressions (Savary et al., 2017; Ramisch et al., 2018), noun and verb supersenses (e.g., Picca et al.,

---

1 Code, pretrained models, and model and scorer output (all train/dev/test splits) can be found at https://nelsonliu.me/papers/lexical-semantic-recognition
2 https://github.com/nert-nlp/streusle
2008; Qiu et al., 2011; Schneider et al., 2013; Martínez Alonso et al., 2015; Hellwig, 2017), and adposition supersenses (Hwang et al., 2017; Zhu et al., 2019). In this paper we focus on English, where comprehensive annotation is available.

2.1 STREUSLE Annotation Layers

STREUSLE comprises the entire 55K-word Reviews section of the English Web Treebank (Bies et al., 2012), for which there are gold Universal Dependencies (UD; Nivre et al., 2020) graphs, and adopts the same train/dev/test split.

The lexical-level annotations do not make use of the UD parse directly, but there are constraints on compatibility between lexical categories and UPOS tags (see §3).

Multitword expressions (MWEs; Baldwin and Kim, 2010) are expressed as groupings of two or more tokens into idiomatic or collocational units. As detailed by Schneider et al. (2014a,b), these units may be contiguous or gappy (discontinuous). Each unit is marked with a binary strength value: idiomatic/noncompositional expressions are strong; collocations that are nevertheless semantically compositional, like “highly recommended”, are weak.

We use the term lexical unit for any expression that is either a strong MWE grouping of multiple tokens, or a token that does not belong to a strong MWE. Every token in the sentence thus belongs to exactly one lexical unit. The other layers of semantic annotation augment lexical units, and weak MWEs are groupings of (entire) lexical units.

Lexical categories (lexcats) describe the syntax of lexical units. They are similar to UPOS tags available in the UD annotations of the corpus, but are necessary in order to (a) express refinements relevant to the criteria for the application of supersenses, and (b) account for the overall syntactic behavior of strong MWEs, which may not be obvious from their internal syntactic structure. Appendix A gives the full list of lexcats.

Supersenses semantically classify lexical units and provide a measure of disambiguation in context. There are 3 sets of supersense labels: nominal, verbal, and prepositional/possessive. The lexcat determines which of these sets (if any) should apply.5 The MWE, lexcat, and supersense information over lexical units is serialized as per-token tags in a BIO-based encoding (details in §2.1.1).

2.1.1 Tag Serialization

STREUSLE specifies token-level tags to allow modeling lexical semantic recognition as sequence tagging. The Bb110o_~ tagging scheme (Schneider et al., 2014a) consists of 8 positional flags indicating MWE status: 0 applies to single-word expressions, B to the start of a new MWE, L to the continuation of a strong MWE, and I~ to the continuation of a weak MWE (if not continuing a strong MWE). The lower-case counterparts o, b, i, l~ are the same except they are used within the gap of a discontinuous MWE. For MWE identification, local constraints on tag bigrams—e.g., that the bigrams (b, B) and (B, 0) are invalid, and that the sentence must end with L, I~, or 0—ensure a valid overall segmentation into units (Schneider and Smith, 2015).

The lexcat and (where applicable) supersense information is incorporated in the first tag of each lexical unit.6

5Some preposition units are labeled with two supersenses drawn from the same label set: the scene role label represents the semantic role of the prepositional phrase marked by the preposition, and function label represents the lexical contribution of the preposition in itself (Schneider et al., 2018). The scene role and the function are identical by default.

6Though in named entity recognition it is typical to include the class label on every token in the multiword unit, STREUSLE does not do this because it would create a non-local constraint across gaps (that the tags at either end have matching lexcat and supersense information). A tagger would either need to use a more expensive decoding algorithm or would need to greatly enhance the state space so within-gap tags capture information about the gappy expression.

In STREUSLE there is actually a slight limitation due to the verbal lexcats, which distinguish between single-word and strong multiword expressions (see Appendix A); if a B~ or I~ tag is followed by a gap, there is no local indication of whether the expression will be strong or weak (strength is indicated only after the gap). If the expression being started is strong, then one of the verbal MWE subtypes (v.VID, etc.)
beginning of an MWE whose lexcat is N and super-

sense is N.ARTIFACT. L_ and i_ tags never contain
lexcat or supersense information as they continue a
lexical unit, whereas O, B, I~, o, b, and i~ always
do. Figure 2 illustrates the full tagging. All told,
STREUSLE has 601 complete tags.

### 2.2 Related Frameworks

The Universal Semantic Tagset takes a similar ap-

proach (Bjerva et al., 2016; Abzianidze and Bos,
2017; Abdou et al., 2018), and defines a cross-
linguistic inventory of semantic classes for content
and function words, which is designed as a sub-
strate for compositional semantics, and does not
have a trivial mapping to STREUSLE categories.

However, two shared task datasets consist of
subsets of the categories used for STREUSLE an-
notations, on text from different sources.

**PARSEME Verbal MWEs.** The first such
dataset is the English test set for the PARSEME 1.1
Shared Task (Ramisch et al., 2018), which cov-
ers several genres (including literature and several
web genres) and is annotated only for verbal mul-
tiword expressions. The STREUSLE lexcats for
verbal MWEs are identical to those of PARSEME;
thus, a tagger that predicts full STREUSLE-style
annotations can be evaluated for verbal MWE iden-
tification and subtyping by simply discarding the
supersenses and the non-verbal MWEs and lexcats
from the output.

**DiMSUM.** The second shared task dataset is
DiMSUM (Schneider et al., 2016), which was an-
notated in three genres—TrustPilot web reviews,
TED talk transcripts, and tweets—echoing the an-
notation style of STREUSLE when it contained
only MWEs and noun and verb supersenses. DiM-
SUM does not contain prepositional/possessive su-
persenses or lexcats. It also lacks weak MWEs.

### 3 Modeling

We develop and evaluate a strong neural sequence
tagger on the full task of lexical semantic recog-
nition with MWEs and noun/verb/preposition/pos-
sessive supersenses to assess the performance of
modern techniques on the full joint tagging task.

Our tagger feeds pre-trained BERT representations
(Devlin et al., 2019) through a biLSTM. An affine
transformation followed by a linear chain condi-
tional random field produces the final output. For
further implementation details, see Appendix B.

The predicted tag for each token is the conjunc-
tion of its MWE, lexcat, and supersense.\(^7\) There
are 572 such tags in the STREUSLE training set,
and only 12 unique conjoined tags in the develop-
ment set are unseen during training (≈5% of the
development set tagging space, corresponding to
≈0.2% of the tokens in the development set).

**Constrained Decoding.** A few hard constraints
are imposed in tagging. To enforce valid MWE
chunks, we use first-order Viterbi decoding with
the appropriate corpus-specific constraints (e.g.,
for STREUSLE MWEs, the BbIiOo_~ tagset; see
§2.1.1). The MWE constraint is applied during
training and evaluation. In addition, a given token’s
possible lexcats are constrained by the token’s
POS tag and lemma. For instance, a token with the
AUX UPOS tag can only take the
AUX lexcat. However,
if the token’s UPOS is
AUX and its lemma is “be”,
it can take either the
AUX or V lexcats.

The POS and lemma constraints are only ap-
died during evaluation; to avoid relying on gold
POS/lemma annotations at test time we use an off-
the-shelf system (Qi et al., 2018).

### 3.1 Experiments

We train the tagger on version 4.3 of the En-

glish STREUSLE corpus and evaluate on the
STREUSLE, English PARSEME, and DiMSUM
test sets (§2). The latter two are (zero-shot) out-of-
domain test sets; the tagger is not retrained on the
associated shared task training data.

We also compare to a model with static word
representations by replacing BERT with the con-
catenation of 300-dimensional pretrained GloVe
embeddings (Pennington et al., 2014) and the out-
put of a character-level convolutional neural net-
s should apply; whereas the correct lexcat for a single-word
verb is plain V. In practice this is not a problem.

\(^7\)For prepositions and possessives, the supersense is either
a pair of labels, or a single label serving dually as scene role
and function (fn. 5).
Table 1: STREUSLE test set results (%). (Gold): gold POS/lemmas (used in constraints only). (Pred.): predicted POS/lemmas. (None): MWE constraints only. –: excluding lexical category. SS: excluding supersense. Labeled F: labeled identification F₁-score. SNACS: preposition supersenses. MWE LinkAvg P, R, F: evaluates MWE identification with partial credit. Identification of verbal MWEs (exact match) is equivalent to the PARSEME MWE-based metric. Schneider et al. (2018): previous best full SNACS tagger, reported on STREUSLE 4.0.

Table 2: PARSEME and DiMSUM zero-shot test set results (%) for BERT models from table 1, compared to prior published results on the tasks. GloVe F₁ scores (not shown) are 17–20 points below the corresponding BERT scores for PARSEME, and 14–15 for DiMSUM. Kirilin et al. (2016): the best performing system from Schneider et al. (2016). Kirilin et al. (2016) and other shared task systems had access to gold POS/lemmas and Twitter training data in addition to all of STREUSLE for training. Nerima et al. (2017): a rule-based system which performed best for English in the shared task (Ramisch et al., 2018). Taslimipoor et al. (2019), Rohanian et al. (2019): more data in addition to all of STREUSLE for training. Nerima et al. (2017): a rule-based system which performed best for English in the shared task (Ramisch et al., 2018). Taslimipoor et al. (2019), Rohanian et al. (2019): more recent results on the test set (both used ELMo and dependency parses; only some scores were reported).

3.2 Results and Discussion

Table 1 shows all standard STREUSLE evaluation metrics on the test set. For preposition supersenses (SNACS), we compare to the results in Schneider et al. (2018), who performed MWE identification and supersense labeling for prepositions only. Note that Schneider et al. (2018) used version 4.0 of the STREUSLE corpus, which is slightly different from the version we use (some of the SNACS annotations have been revised). However, our baseline tagger, even with GloVe embeddings, outperforms Schneider et al. (2018) on that subset. Using BERT embeddings with constraints POS tags and lemmas improves performance substantially; on preposition supersense tagging, it even outperforms using gold POS tags and lemmas. Liu et al. (2019) also found that BERT embeddings improved SNACS labeling on STREUSLE 4.0, although they study a simplified setting (gold preposition identification, and only considering single words).

Table 2 shows standard PARSEME and DiMSUM test set evaluation metrics, for models trained on the STREUSLE training set, in a zero-shot out-of-domain evaluation setting. On the PARSEME test set, our BERT-based model approaches the state-of-the-art MWE-based F-score and exceeds the best reported fully-supervised token-based F-score. However, on the DiMSUM test set, the BERT model did not outperform the best shared task system, likely owing to the comparative difficulty of the full lexical semantic recognition task versus the restricted DiMSUM setting.

These results demonstrate that pre-training contextualized embeddings on large corpora can help models generalize to out-of-domain settings.8

Constrained decoding does not substantially impact the performance of our BERT model. In general, constraints with gold POS/lemmas perform the best, while not using POS/lemma constraints is 8A small fraction of sentences in the PARSEME test set (194/3965) are EWT reviews sentences that also appear in STREUSLE’s dev set. The rest of the PARSEME test set contains other web and non-web genres (Walsh et al., 2018), and thus it is mostly out-of-domain relative to STREUSLE. None of the PARSEME training set overlaps with STREUSLE.
I have a new born daughter and she helped me with a lot of tasks.

Go down 1 block to Super 8.

Beware they will rip you off.

Figure 3: Selected examples where the model without MWE constraints (first row under each sentence) produces a structurally invalid tagging. Incorrect tags are red; the ones that render the tagging structurally invalid are bold. The last row under each sentence is the gold annotation, and the middle row (if different from gold) is the model prediction with MWE constraints. (The first sentence ends with a period, omitted for brevity.)

often better than using predicted POS/lemmas. Removing the MWE constraints yields models with slightly higher overall tag accuracy, but results in invalid segmentations for a large proportion of sentences: 14% of STREUSLE sentences in the fully unconstrained model and 17% of sentences if only predicted POS and lemmas are used for constraints.

Three sentences out of those 17% appear in figure 3. The first shows both an omission of a “B-” tag needed to start an MWE (“new”) and a false positive gap without members of an MWE on either side (“me”). When the full set of constraints is used, the gold tagging is recovered. In the second sentence, there is a false positive yet structurally valid MWE (“Go down”) as well as an invalid start to an MWE that is never continued (“Super”), perhaps because it is rare for a number to continue an MWE (this happens <20 times in the entire corpus). Finally, in the third sentence, the model constrained only by POS and lemma is inclined toward the literal meaning of “rip”, whereas the MWE-constrained model recovers the gappy verb–particle construction “rip off”. Naturally, in other sentences, the MWE-constrained model sometimes suffers from false positive or false negative MWEs, but always produces a coherent segmentation.

4 Related Work

The computational study of MWEs has a long history (Sag et al., 2002; Diab and Bhutada, 2009; Baldwin and Kim, 2010; Ramisch, 2015; Qu et al., 2015; Constant et al., 2017; Bingel and Søgaard, 2017; Shwartz and Dagan, 2019), as does supersense tagging (Segond et al., 1997; Ciaramita and Altun, 2006). Vincze et al. (2011) developed a sequence tagger for both MWEs and named entities in English. Schneider and Smith (2015); Schneider et al. (2016) featured joint tagging of MWEs and noun and verb supersenses with feature-based sequence models. Richardson (2017) trained such a model on STREUSLE 3.0 as a noun, verb, and preposition supersense tagger (without modeling MWEs). For preposition supersenses, Gonen and Goldberg (2016) incorporated multilingual cues; Schneider et al. (2018) experimented with feature-based and neural classifiers; and Liu et al. (2019), modeling supersense disambiguation of single-word prepositions only, found pre-trained contextual embeddings to be much more effective even with simple linear probing models.

5 Conclusion

We study the lexical semantic recognition task defined by the STREUSLE corpus, which involves joint MWE identification and coarse-grained (supersense) disambiguation of noun, verb, and preposition expressions; this task subsumes and unifies the previous PARSEME and DiMSUM evaluations. We develop a strong baseline neural sequence model, and see encouraging results on the task. Furthermore, zero-shot out-of-domain evaluation of our baselines on partial versions of the task yields scores comparable to the fully-supervised in-domain state of the art.
