We introduce a class of generalized geometric measures of entanglement. For pure quantum states of N elementary subsystems, they are defined as the distances from the sets of K-separable states (K = 2, …, N). The entire set of generalized geometric measures provides a quantification and hierarchical ordering of the different bipartite and multipartite components of the global geometric entanglement, and allows to discriminate among the different contributions. The extended measures are applied to the study of entanglement in different classes of N-qubit pure states. These classes include W and GHZ states, and their symmetric superpositions; symmetric multi-magnon states; cluster states; and, finally, asymmetric generalized W-like superposition states. We discuss in detail a general method for the explicit evaluation of the multipartite components of geometric entanglement, and we show that the entire set of geometric measures establishes an ordering among the different types of bipartite and multipartite entanglement. In particular, it determines a consistent hierarchy between GHZ and W states, clarifying the original result of Wei and Goldbart that W states possess a larger global entanglement than GHZ states. Furthermore, we show that all multipartite components of geometric entanglement in symmetric states obey a property of self-similarity and scale invariance with the total number of qubits and the number of qubits per party.

I. INTRODUCTION

Quantification of pure state bipartite entanglement, a concept that emerged immediately after the first systematization of quantum mechanics [1], is by now well understood in terms of the entropic content in the reduced states of the constituent subsystems, as lucidly pointed out for the first time by Schrödinger [2]. The universal properties that any bona fide measure of entanglement has to satisfy have been thoroughly discussed and characterized in recent years [3, 4, 5, 6]. For pure states of bipartite systems, the von Neumann entropy is the unique measure of entanglement, and all other consistent measures are monotonic functions of the former [7]. However, this uniqueness is lost in bipartite mixed states: In this context, measures that differ according to their definitions and/or operational meaning, such as, for instance, the entanglement of formation, the distillable entanglement, the relative entropy of entanglement, and the negativity [8, 9, 10], quantify different forms of entanglement. In fact, very few of these quantities can be computed explicitly for mixed quantum states, even in the simplest instances. A notable exception is the celebrated Wootters formula for the entanglement of formation of arbitrary two-qubit mixed states, obtained in terms of the concurrence [10, 11].

The situation becomes even more complex in the multipartite instance, already at the level of pure states in finite-dimensional Hilbert spaces. Progress has been achieved mainly in understanding the different ways in which multipartite systems can be entangled. The intrinsic nonlocal character of entanglement imposes invariance and monotonicity constraints under local quantum operations. Equivalence classes of entangled states can be defined with respect to the group of reversible stochastic local quantum operations assisted by classical communication (SLOCC) [12]. Such an approach has allowed to demonstrate that three and four qubits can be entangled, respectively, in two and nine different inequivalent ways [13, 14]. In the case of three qubits, the representatives of the two inequivalent classes are, notoriously, the W and GHZ states [13, 15].

Simplifying to the essential, in a multipartite scenario a legitimate quantification of entanglement can be achieved by identifying a positive function that is an entanglement monotone (vanishing on separable states and not increasing under SLOCC), and is endowed with some kind of operational interpretation. Several measures satisfying these requirements have been proposed. For a system of three qubits, Wootters and co-workers defined the so-called residual entanglement, or 3-tangle, a quantity constructed as the difference between the squared three-qubit concurrence and the squared concurrences of the reduced two-qubit states [16]. While successfully detecting the genuine tripartite entanglement in the state |GHZ(3)⟩, the 3-tangle (or residual tangle) vanishes if computed for the state |W(3)⟩, thus being not appropriate for the quantification of tripartite entanglement in this class of states. In other words, a non vanishing
residual tangle is a sufficient but not necessary condition for the detection of genuine multipartite entanglement. The Schmidt measure, defined as the minimum of $\log_2 r$ with $r$ being the minimum of the number of terms in an expansion of a quantum state in product basis, has been proposed by Eisert and Briegel as an alternative measure of multipartite entanglement \[17\]. Other proposals are given as functions of the various bipartite entanglements contained in a multipartite state \[18,19,20,21,22\]. The seed representative of this class of measures is the global entanglement of Meyer and Wallach, that for an $N$-qubit state is defined as the sum of all the possible two-qubit concurrences \[18\].

A different set of entanglement quantifiers is defined in purely geometric terms. The relative entropy of entanglement (generalized for multipartite settings) and the so-called geometric entanglement belong to this class \[23,24,25\]. The relative entropy of entanglement is defined as the distance of a given state from the set of fully separated states, quantified in terms of the quantum relative entropy \[23\]. The geometric entanglement was originally defined as the euclidean distance of a given multipartite state to the nearest fully separable state \[24,25,26\]. This last measure can be considered as one of the most reliable quantifiers of global multi-particle entanglement \[27\]. It exhibits interesting connections with other measures \[28,29\] and can be efficiently estimated by quantitative entanglement witnesses amenable of experimental verification \[29,30\]. Given an $N$-partite pure state $|\Psi\rangle$, the geometric measure of entanglement introduced by Wei and Goldbart \[26\] is defined as:

$$E_G(|\Psi\rangle) = 1 - \max_{|\Phi\rangle} \left|\langle \Phi | \Psi \rangle \right|^2,$$

where the maximum is taken with respect to all pure states that are fully factorized, i.e. the $N$-separable states

$$|\Phi\rangle = \bigotimes_{s=1}^{N} |\Phi_s\rangle,$$

where the states $|\Phi_s\rangle$ are single-qubit pure states. This measure is intrinsically geometric because it coincides with the distance (in the Hilbert-Schmidt norm) between a given pure state and the set of fully separable (i.e. fully product) pure states. The Wei-Goldbart geometric measure is thus a global quantifier of entanglement, including all the bipartite and multipartite contributions.

The geometric measure can be extended by the convex roof procedure to the case of mixed states, and, analogously to the Meyer-Wallach global entanglement, is a proper multipartite entanglement monotone. Remarkably, the geometric measure can be effectively exploited to quantify the entanglement of two distinct multipartite bound entangled states \[31\] and to study the behavior of global entanglement at the approach of quantum phase transitions \[32,33,34\]. However, notwithstanding the very appealing properties and the important results cited above, the global nature of the Wei-Goldbart geometric entanglement constitutes a limitation insofar as it does not allow to distinguish and discriminate among the different bipartite and multipartite contributions to the overall entanglement, to determine their properties, and to establish a systematic hierarchy among them. It is the aim of the present work to fill this gap.

In this paper, we define and study in detail a natural and powerful multipartite generalization of the geometric measure of entanglement for pure states of many-qubit systems. We first introduce a compact and convenient parametrization to express analytically general $K$-separable states of $N$-qubit systems ($K \leq N$). We then analyze the behavior of the distance between pure $N$-qubit states and the set of $K$-separable states ($K = 2, \ldots, N$) in order to determine and distinguish the different multipartite contributions to the geometric entanglement and characterize their ordering. The different distances, corresponding to $K = 2, \ldots, N$, quantify hierarchically the different forms of multipartite entanglement present in the given $N$-qubit state. In Section \[II\] we define the multi-component generalization of the geometric measure, we review the known results in the case of full separability and, for this latter case, we also present some further extended results. In Section \[III\] we evaluate explicitly the generalized multi-component geometric measure of entanglement, considering genuine $K$-separable states ($K \leq N$). We analyze the detailed behavior of the different forms of geometric entanglement for various relevant classes of $N$-qubit states, establishing some generic and asymptotic properties, and we determine the explicit hierarchy holding for $W$, GHZ, cluster, and multi-magnon states. In the case of $W$ and GHZ states, the established relations between the different forms of multipartite geometric entanglement clarify the original result of Wei and Goldbart that $W$ states possess a larger total entanglement content than GHZ states, when quantified by the geometric measure. Moreover, in the case of $N$-qubit $W$ states, we find that the geometric entanglement is scale-invariant (self-similar) as the total number of qubits grows at the same rate as the number of subsystems in each party. We show that the property of self-similarity is enjoyed by other symmetric states as well, as a direct consequence of the invariance under permutation of any two qubits, which is the characterizing property of symmetric states. We then analyze and determine the different multipartite components of geometric entanglement for arbitrary symmetric superpositions of $N$-qubit GHZ and $W$ states. In Section \[IV\] we compute the multipartite geometric measures for classes of generalized $W$ states beyond the single-excitation regime: these are general symmetric states, the so-called magnon states, that are of crucial importance, for instance, in the theory of magnetism. Furthermore, we determine the multipartite components of geometric entanglement in generalized, asymmetric $W$-like superposition states. In this and related cases, at variance with most of the symmetric instances, a complete characterization of entanglement re-
II. GEOMETRIC ENTANGLEMENT: K-SEPARABILITY VS. FULL SEPARABILITY

Let us consider a $N$-qubit system, corresponding to a tensor-product state space $\mathcal{H}^{d_N}$ of dimension $d_N = 2^N$. For such a system, let us introduce the integer $K$, $2 \leq K \leq N$, and the ordered sequence of integers $\{M_1, M_2, \ldots, M_K\}$, where $M_1 \leq M_2 \leq \ldots \leq M_K$, and $\sum_{s=1}^{K} M_s = N$. Let us consider the K-partition of the system in $K$ subsystems described by the sets $\{Q_s\}_{s=1}^{K}$. Let each set $Q_s$ be composed of $M_s$ elementary parties, i.e., $Q_s = \{i_1^{(s)}, i_2^{(s)}, \ldots, i_{M_s}^{(s)}\}$, where $i_j^{(s)} \in \{1, \ldots, N\}$ is a discrete index labeling the $N$ elementary parties, and $Q_s \cap Q_{s'} = \emptyset$ for $s \neq s'$. Given a generic K-partition $Q_1|Q_2| \ldots |Q_K$ of the $N$-qubit system, any K-separable state associated to such a partition is defined as the tensor product of $K$ $M_s$-qubit pure states $|\Psi^{(Q_s)}\rangle$. Each state $|\Psi^{(Q_s)}\rangle$ belongs to the Hilbert space $\mathcal{H}^{d_{Q_s}}$ of dimension $d_{Q_s} = 2^{M_s}$. A K-separable state can then be written as

$$|\Psi^{(Q_s)}\rangle = \bigotimes_{s=1}^{K} |\Psi^{(Q_s)}\rangle. \quad (3)$$

Correspondingly, the Hilbert space $\mathcal{H}^{d_N}$ is decomposed in the tensor product $\bigotimes_{s=1}^{K} \mathcal{H}^{d_{Q_s}}$. Varying the integers $M_s$, one obtains different K-partitions $Q_1|Q_2| \ldots |Q_K$ and, correspondingly, different possible K-separable states. It is worth noticing that even at fixed $M_1|M_2| \ldots |M_K$, there exist different K-partitions associated with the different arrangements of the elementary parties in the sets $Q_s$; in fact, from a given initial K-partition, a certain number of different K-partitions can be generated through permutations of the elementary parties belonging to different sets $Q_s$. We then denote by $S_K$ the set of all K-separable states, defined as

$$S_K = \bigcup_{\{Q_1, \ldots, Q_K\}} S_K(Q_1|\ldots|Q_K), \quad (4)$$

where $S_K(Q_1|Q_2| \ldots |Q_K)$ is the set of all the K-separable states associated to a fixed K-partition. We can now define the relative (i.e., partition-dependent) and the absolute (i.e., partition-independent) geometric measures of entanglement with respect to K-separable pure states for an arbitrary $N$-qubit pure state $|\Psi^{(N)}\rangle$, respectively, as:

$$E_G^{(K)}(Q_1|\ldots|Q_K) = 1 - \Lambda_K^2(Q_1|\ldots|Q_K), \quad (5)$$

where the squared overlap

$$\Lambda_K^2(Q_1|\ldots|Q_K) = \max_{|\phi\rangle \in S_K(Q_1|\ldots|Q_K)} \left| \langle \phi | \Psi^{(N)} \rangle \right|^2, \quad (6)$$

and

$$E_G^{(K)}(|\Psi^{(N)}\rangle) = 1 - \Lambda_K^2(|\Psi^{(N)}\rangle), \quad (7)$$

where the squared overlap

$$\Lambda_K^2(|\Psi^{(N)}\rangle) = \max_{|\phi\rangle \in S_K} \left| \langle \phi | \Psi^{(N)} \rangle \right|^2. \quad (8)$$

By Eqs. (5), (6), (8), the quantity (7) measures the absolute minimum distance of a state from the set of all K-separable states. Equivalently, $E_G^{(K)}(|\Psi^{(N)}\rangle) = \min_{|\Psi\rangle \in S_K(Q_1|\ldots|Q_K)} E_G^{(K)}(|\Psi\rangle)$ for $Q_1|Q_2| \ldots |Q_K$. Trivially, for any N-partition (i.e. $K = N$), one has $M_1 = M_2 = \ldots = M_N = 1$ and N-separability coincides with full separability, while 1-separability is a common feature of any state, i.e., $E_G^{(1)} = 0$ for all states $|\Psi^{(N)}\rangle$. In the particular instance of symmetric states, that are states invariant under the permutation of any two qubits, the quantities $E_G^{(K)}(Q_1|\ldots|Q_K)$ and $\Lambda_K^2(Q_1|\ldots|Q_K)$ satisfy the same invariance property. Therefore, in such a case, in the definitions (5) and (6), the symbols $Q_s$ can be replaced by the indices $M_s$ as the multi-index $M_1|M_2| \ldots |M_K$ completely determines the particular component of geometric entanglement. In Ref. [27], the quantity (6) is defined only in the simplest instance of N-separability. In this case, we may write the general expression for (normalized) K-separable state $|\Phi\rangle$, Eq. (2), in the following Hartree form:

$$|\Phi\rangle = \bigotimes_{i=1}^{N} \left( \cos \Gamma_i |0\rangle_i + e^{i\Delta_i} \sin \Gamma_i |1\rangle_i \right), \quad (9)$$

with $\Gamma_i$ and $\Delta_i$ real. By using Eq. (9) with $\Delta_i = 0$, the geometric measure of entanglement can be analytically computed for the classes of GHZ and W states. The definition of these states for the N-qubit case reads:

$$|GHZ^{(N)}\rangle = \frac{1}{\sqrt{2}} \sum_{i=1}^{2} \delta_{i,2} \delta_{i,2} \ldots \delta_{i,2}, \quad (10)$$

$$|W^{(N)}\rangle = \frac{1}{\sqrt{N}} \sum_{i=1}^{N} \delta_{i,1} \delta_{i,2} \ldots \delta_{i,N}, \quad (11)$$

where $\delta_{i,j}$ denotes the Kronecker delta, and $|e^{(1)}e^{(2)} \ldots e^{(N)}\rangle \equiv |e^{(1)}\rangle_1 |e^{(2)}\rangle_2 \ldots |e^{(N)}\rangle_N$ ($e^{(j)} = 0, 1$). The GHZ and W states are fully symmetric, i.e. invariant under the exchange of any two qubits, and greatly differ from each other in their correlations properties. On general grounds [17], one can expect that N-qubit GHZ states must possess N-partite entanglement but no K-partite one for $K < N$. On the other hand, the N-qubit W states do possess K-partite entanglement for $K < N$. The determination of the properties and typical behaviors of the geometric entanglement, and examine some outlooks on possible future lines of research.
For the total geometric entanglement of states $|GHZ(N)\rangle$ and $|W(N)\rangle$, measured with respect to the set of $N$-separable (i.e. fully separable) states, the following relations hold [26]:

$$\Lambda^2_N(|GHZ(N)\rangle) = \frac{1}{2}, \quad (12)$$

$$\Lambda^2_N(|W(N)\rangle) = \left(\frac{N-1}{N}\right)^{N-1}. \quad (13)$$

In particular, Eq. (13) is obtained by setting $\Gamma_l = \arcsin(1/\sqrt{N})$, with $l = 1, \ldots, N$. Therefore, for the $|GHZ(N)\rangle$ states, the total geometric entanglement takes the constant value 1/2, independently from $N$. On the other hand, for the $|W(N)\rangle$ states, the total geometric entanglement grows with $N$, converging to a simple function of the Neper number in the asymptotic limit:

$$E_G^{(3)}(|W^{(3)}\rangle) = \frac{5}{9} \approx 0.555, \quad (14)$$

$$E_G^{(4)}(|W^{(4)}\rangle) = \frac{37}{64} \approx 0.578, \quad (15)$$

$$\cdots$$

$$E_G^{(N)}(|W^{(N)}\rangle) = 1 - \left(\frac{N-1}{N}\right)^{N-1}, \quad (16)$$

$$\lim_{N \to \infty} E_G^{(N)}(|W^{(N)}\rangle) = 1 - e^{-1} \approx 0.632. \quad (17)$$

Therefore, according to the measure of total geometric entanglement, the $W$ states are overall more entangled than $GHZ$ states for any $N$, notwithstanding the fact that the latter must always possess a larger amount of genuine $N$-partite entanglement. Moreover, the asymptotic limit acquired by the total geometric entanglement on $W$ states for large $N$ appears to point at some underlying topological structure.

In the first nontrivial multipartite case $N = 3$, interesting results have been obtained also for superposition states of the form [26]:

$$|W \tilde{W}^{(3)}\rangle = \cos \eta |W^{(3)}\rangle + e^{i\phi} \sin \eta |\tilde{W}^{(3)}\rangle, \quad (18)$$

$$|W GHZ^{(3)}\rangle = \cos \eta |W^{(3)}\rangle + e^{i\phi} \sin \eta |GHZ^{(3)}\rangle, \quad (19)$$

where the mixing angle $\eta$ lies in the range $[0, \pi/2]$, $\phi$ is a free relative phase, and $|\tilde{W}^{(3)}\rangle = \frac{1}{\sqrt{3}}(|110\rangle + |101\rangle + |011\rangle)$. The geometric entanglement is computed with respect to the fully three-separable state (Eq. 13 with $N = 3$). In Fig. 1, $E_G^{(3)}$ for the states (18) and (19) is plotted as a function of $\eta$. The geometric entanglement of the state (18) attains its maximum 5/9 at $\eta = 0, \pi/2$ and its minimum at $\eta = \pi/4$, and is independent of the phase $\phi$; on the contrary, for the state (19) it exhibits an explicit dependence on $\phi$ that is maximized for $\phi = \pi$ and attains its maximum value 5/9 at $\eta = 0$.

![FIG. 1: (Color online) $E_G^{(3)}$ for the superposition of $|W^{(3)}\rangle$ and $|\tilde{W}^{(3)}\rangle$ states, Eq. (13), and for the superposition of $|W^{(3)}\rangle$ and $|GHZ^{(3)}\rangle$ states, Eq. (19), as a function of the mixing angle $\eta$. $E_G^{(3)}$ for the state (18) is plotted for the following choices of the free relative phase $\phi$: $\phi = 0$ (round points, in red), $\phi = \pi$ (diamond points, in green), and $\phi$ taking random values in the range $[0, \pi]$ (triangle points, in grey). $E_G^{(3)}$ for the state (19) does not depend on $\phi$ (box points, in blue). All plotted quantities are dimensionless.](image)

The free relative phase $\phi$ cannot be eliminated by local unitary operations (in the sense of being of dimension less than $N$) for the states of the form (18), but only by means of global $N$-dimensional transformations. Therefore, the global entanglement content of these states must necessarily depend on $\phi$, and the latter thus acquires the meaning of a global geometric phase.

### III. MULTIPARTITE COMPONENTS OF GEOMETRIC ENTANGLEMENT

As discussed above, the distance of a $N$-partite state $|\Psi^{(N)}\rangle$ from the set of fully separable (i.e. $N$-separable) states is a legitimate quantifier of a global form of entanglement, encompassing $N$-partite, $(N - 1)$-partite, ..., and bi-partite components in an indistinguishable way. This observation motivates the search for a more refined geometric quantification of entanglement, in order to distinguish the different multipartite contributions. To this end, we proceed to study the distances of $|\Psi^{(N)}\rangle$ from the various sets of $K$-separable states, as defined in the previous section. For a fixed $K$ ($K = 2, \ldots, N$), the distance Eq. 17 quantifies the $N-$, ..., $(N - K + 2)$-partite contributions to the global entanglement. Moreover, it is evident that, for each $K$,

$$S_{K-1} \supseteq S_K, \quad E_G^{(K-1)}(|\Psi^{(N)}\rangle) \leq E_G^{(K)}(|\Psi^{(N)}\rangle), \quad (20)$$

where the second inequality follows by the law of set inclusion. Some simple examples may be of help to elucidate the structure of this hierarchy. Let us take $N = 3$. In this case, we have two possibilities: $K = 2, 3$. For $K = 2$ one has information only on the pure three-partite...
(three-qubit) component of the geometric entanglement, while for \( K = 3 \) (distance from the fully separable states) one has undistinguishable information on both three- and two-qubit entanglement. Moreover, as already mentioned above, since the set of biseparable states \( S_2(1|2) \) contains the set of three-separable states \( S_3(1|1|1) \), it follows that \( E_G^{(2)}(|\Psi(3)\rangle) \leq E_G^{(3)}(|\Psi(3)\rangle) \). If equality holds, it then follows that the entire content of entanglement is due only to the three-party contribution. The extension to higher dimensions \( N \geq 4 \) is straightforward, although the number of possible partitions quickly grows. On the other hand, we will show that the genuine \( N \)-partite entanglement of GHZ and \( W \) states is always associated to the distance from the set of biseparable states \( S_2(1|N - 1) \).

We shall now introduce some concise notations that will be useful in the following. Let us denote by \( |\chi^{(M)}\rangle \) an arbitrary \( M \)-partite qubit state, that can be expressed in the form

\[
|\chi^{(M)}\rangle = \sum_{j_1,\ldots,j_M=0}^1 c_{j_1,\ldots,j_M} |j_1\ldots j_M\rangle , \tag{21}
\]

where \( c_{j_1,\ldots,j_M} \) are complex parameters satisfying the normalization constraint \( \sum_{j_1,\ldots,j_M=0}^1 |c_{j_1,\ldots,j_M}|^2 = 1 \). In order to simplify the notation, we substitute the multi-index \( (j_1,\ldots,j_M) \) by the single index \( J = \sum_{q=1}^M 2^{M-q} j_q \) (i.e. summation in the binary system), so that Eq. (21) reads

\[
|\chi^{(M)}\rangle = \sum_{J=0}^{d_M-1} c_J |J\rangle_M . \tag{22}
\]

Obviously, one has \( 0 \leq J \leq d_M - 1 = 2^M - 1 \). This notation provides a useful ordering of the states based on the binary numbering. In fact, the index \( J = 0,1,2,\ldots,2^M - 1 \) labels, respectively, the states \( |00\ldots0\rangle, |00\ldots01\rangle, |00\ldots10\rangle,\ldots,|11\ldots1\rangle \). Let us note that all the states \( |J\rangle_M \) satisfy the orthonormality relation, i.e. \( M \langle J|J'\rangle_M = \delta_{J,J'} \); moreover, each \( M \)-qubit state \( |J\rangle_M \) can be written in the decomposed form \( |J\rangle_M = |J_1\rangle_{M_1} \otimes |J_2\rangle_{M_2} \), where \( M = M_1 + M_2 \), and \( J = 2^{M_1} J_1 + J_2 \). Using the Euler representation and eliminating an irrelevant global phase factor, the parameters \( c_J \) can be cast in the form \( c_J = r_J e^{i\phi_J} \), where \( r_J = |c_J| \), \( \phi_J = 0 \), and the phases \( \phi_J \) are arbitrary for \( J > 1 \). It is worth noting that the fully separable state \( |\emptyset\rangle_M \) is a particular realization of \( |\chi^{(M)}\rangle \) for \( M = N \). The \( K \)-separable state given by Eq. (4), can be explicitly expressed by using, for each state \( |\Phi^{(M)}_s\rangle \), the general form (22) and the hyperspherical parametrization introduced in Appendix \[A\] see Eq. (A11). The hyperspherical parametrization will then prove extremely convenient in the computation of Eq. (8) for any value of the index \( K \). By using the notation in terms of the binary-numbering index, Eqs. (10) and (11) can be recast as:

\[
|GHZ^{(N)}\rangle = \frac{1}{\sqrt{2}} (|0\rangle_N + |2^N - 1\rangle_N) , \tag{23}
\]

\[
|W^{(N)}\rangle = \frac{1}{\sqrt{N}} \sum_{p=0}^{N-1} |2^p\rangle_N . \tag{24}
\]

In the next subsections we will determine the different multipartite contributions for some relevant classes of states symmetric under exchange of any pair of qubits.

### A. Three-qubit pure states

We begin by considering three-qubit pure states, the simplest nontrivial instance of multipartite states. In this case, given the tensor product Hilbert space \( \mathcal{H}^{(3)} = \mathcal{H}^{(2)} \otimes \mathcal{H}^{(2)} \otimes \mathcal{H}^{(2)} \), associated to a system of \( N = 3 \) qubits, there are only two sets of separable states: The set \( S_2 \) of biseparable states \( (K = 2) \), and the set \( S_3 \) of three-separable states \( (K = 3, \text{ full separability}) \), with \( S_2 \supseteq S_3 \). The distance \( E_G^{(3)} \) from the set \( S_3 \) measures the global geometric entanglement of Wei and Goldbart, while the distance \( E_G^{(2)} \) from the set \( S_2 \) measures the genuine three-party contribution to the global geometric entanglement: \( E_G^{(2)} \leq E_G^{(3)} \), with equality holding when all the entanglement is due only to the genuine tripartite component and there is no bipartite component. The general expression for any biseparable state \( |\Phi\rangle \) is of the form:

\[
|\Phi\rangle = |\Phi_1^{(1)}\rangle_k \otimes |\Phi_2^{(2)}\rangle_{ij} , \tag{25}
\]

where

\[
|\Phi_1^{(1)}\rangle = \left( \cos \Gamma |0\rangle_0 + e^{i\Delta} \sin \Gamma |1\rangle_0 \right) , \tag{26}
\]

\[
|\Phi_2^{(2)}\rangle = \left( \cos \delta_0 |00\rangle_{ij} + e^{i\phi_2} \sin \delta_1 \cos \delta_2 |01\rangle_{ij} + e^{i\phi_3} \sin \delta_1 \sin \delta_2 \sin \delta_3 |11\rangle_{ij} \right) , \tag{27}
\]

where, in Eqs. (26) we have dropped the subscripts \( i,j,k = 1,2,3 \) (\( i \neq j \neq k \)) denoting the three parties, because in the following we will deal with states invariant under permutation of any two qubits. In order to evaluate \( E_G^{(2)} \) for the three-qubit \( |W^{(3)}\rangle \) and \( |GHZ^{(3)}\rangle \) states we take advantage of the fact that the coefficients appearing in the definition of these states are all positive constants. Therefore, maximization of the overlaps with the states (26) does not depend on the phases, that can then be put to zero: \( \Delta = \phi_q = 0 \) (\( q = 2,3,4 \)). From Eq. (8), we get the following expression of the overlap for the state \( |W^{(3)}\rangle \):

\[
\Lambda_2^2(|W^{(3)}\rangle) = \max_{\{\alpha,\beta,\gamma\}} \frac{1}{3} \left[ \cos \delta_1 \sin \Gamma + \cos \Gamma \sin \delta_1 \times \cos \delta_2 + \sin \delta_2 \cos \delta_3 \right]^2 . \tag{27}
\]
The maximization in Eq. (27) yields the absolute maximum $\Lambda^3_2(\langle W^{(3)} \rangle) = 2/3$. For instance, this value is reached when $\delta_1 = \frac{\pi}{4}$, $\delta_2 = \frac{\pi}{2}$, $\delta_3 = 0$, $\Gamma = 0$. It is then straightforward to verify that he three-partite component of the geometric entanglement present in the three-qubit W state is

$$E^{(2)}_G(\langle W^{(3)} \rangle) = \frac{1}{3}.$$  

(28)

We see that for three-partite W states the purely three-partite contribution is strictly lower than the geometric entanglement: $E^{(2)}_G(\langle W^{(3)} \rangle) = 1/3 < E^{(3)}_G(\langle W^{(3)} \rangle) = 5/9$. On the other hand, for the state $|GHZ^{(3)}\rangle$ the maximum overlap with the biseparable states is

$$\Lambda^3_2(\langle GHZ^{(3)} \rangle) = \max_{\{\delta_1, \delta_2, \delta_3, \Gamma\}} \frac{1}{2} \left( \cos \delta_1 \cos \Gamma + \sin \Gamma \sin \delta_1 \sin \delta_2 \sin \delta_3 \right)^2. \quad (29)$$

Direct computation yields

$$E^{(2)}_G(\langle GHZ^{(3)} \rangle) = \frac{1}{2}. \quad (30)$$

Thus, in the case of GHZ states we verify that the three-partite and the global content of geometric entanglement coincide: $E^{(2)}_G(\langle GHZ^{(3)} \rangle) = \frac{1}{2}$. This result is an independent proof that GHZ states possess only genuine tripartite entanglement. Moreover, we see that the tripartite entanglement of W states is less than the one of GHZ states: $E^{(2)}_G(\langle W^{(3)} \rangle) < E^{(2)}_G(\langle GHZ^{(3)} \rangle)$. This result clarifies the original finding by Wei and Goldbart that the global geometric entanglement $E^{(3)}_G(\langle W^{(3)} \rangle)$ of W states is larger than the one, $E^{(3)}_G(\langle GHZ^{(3)} \rangle)$, of GHZ states, and establishes a proper entanglement hierarchy between the two classes of states.

We now show how the structure of K-separability allows to clarify the nature of the geometric phases in the entanglement of superpositions. To this aim, let us calculate the distance $E^{(3)}_G$ for the superpositions (19) and (18); the corresponding behavior is reported in Fig. 2 as a function of $\eta$. Comparing with Fig. 1, we note that both $E^{(3)}_G$ and $E^{(2)}_G$ exhibit the same symmetric behavior for the superposition (18), and acquires a minimum at $\eta = \frac{\pi}{4}$. On the other hand, for the state (19) we observe that $E^{(2)}_G$, contrary to $E^{(3)}_G$, is independent of the phase $\phi$. This implies that the nonlocal nature of the phase $\phi$ is limited to the set $S_2$ of biseparable states.

![FIG. 2: (Color online) Behavior of $E^{(2)}_G$ for the superpositions of $|W^{(3)}\rangle$ and $|GHZ^{(3)}\rangle$ (blue line with squares), Eq. (18), and for the superpositions of $|W^{(3)}\rangle$ and $|GHZ^{(3)}\rangle$ (red line with circles), Eq. (19), as a function of $\eta$, and for arbitrary phase $\phi$. All plotted quantities are dimensionless.](image)

Concerning GHZ states, it is easily verified that, for any $N$,

$$E^{(K)}_G(\langle GHZ^{(N)} \rangle) = \frac{1}{2}, \quad K = 2, \ldots, N. \quad (31)$$

Therefore, if we determine the various forms of bipartite and multipartite entanglement by the geometric measure (7), we obtain that the N-qubit GHZ states possess only N-partite entanglement.

Considering $|W^{(N)}\rangle$ states, for a given $N$ all the bipartite and multipartite components of the geometric entanglement can be evaluated analytically with respect to the different $K$-separable states. First we study in detail the N-partite entanglement quantified by the distance $E^{(2)}_G(\langle M_1|M_2 \rangle)$ from the set of biseparable states $|\Phi\rangle = |\Phi^{(M_1)}_1\rangle \otimes |\Phi^{(M_2)}_2\rangle$, for a fixed bipartition $M_1, M_2 = N - M_1$, with $1 \leq M_1 \leq M_2 \leq N - 1$. In this case, using Eq. (22), $|\Phi\rangle$ takes the following form

$$|\Phi\rangle = \sum_{J_1 = 0}^{d_{M_1} - 1} c^{(1)}_{J_1} |J_1\rangle \otimes |\sum_{J_2 = 0}^{d_{M_2} - 1} c^{(2)}_{J_2} |J_2\rangle \rangle_{M_2}, \quad (32)$$

with $c^{(s)}_{J_s} = r^{(s)}_{J_s} e^{i\phi^{(s)}_{J_s}}$, $s = 1, 2$, and, without loss of generality, we let $\phi^{(s)}_{J_s} = 0$, $s = 1, 2$. By exploiting the decomposition:

$$\sum_{p=0}^{N-1} |2^p\rangle_N = \sum_{p=0}^{M_2-1} |0\rangle_M \otimes |2^p\rangle_M + \sum_{p=0}^{M_1-1} |2^p\rangle_M \otimes |0\rangle_M,$$

one has that the overlap $\Lambda^{2}_2(M_1|M_2)$ can be expressed in the form:

$$\Lambda^{2}_2(M_1|M_2) = \max_{(r^{(s)}_{J_s})} \frac{1}{N} \left[ \sum_{p=0}^{M_2-1} r^{(2)}_{2p} + \sum_{p=0}^{M_1-1} r^{(1)}_{2p} \right]^2. \quad (33)$$

B. Symmetric states: $GHZ^{(N)}$ and $W^{(N)}$ states

In this section we study the properties of the measure (7) for the states $|GHZ^{(N)}\rangle$ and $|W^{(N)}\rangle$ for arbitrary $N$. 

The maximization procedure is reported in Appendix B, see Eq. (B3). Using this result, in the case of 2-separability with respect to the partitioning $M \otimes (N-M)$, with $M \leq N-M$, the $K=2$-component of the geometric entanglement in the states $|W^{(N)}\rangle$ is

$$E_G^{(2)}(M|N-M) = \frac{M}{N}. \quad (34)$$

In the particular instance $M = 1$, it immediately follows that the expression \[\text{realizes the absolute minimum Eq. (7), and therefore one has } E_G^{(2)}(1|N-1) = 1/N, showing that the genuine $N$-partite geometric entanglement vanishes asymptotically for large $N$. On the other hand, for the partition obtained by setting $M = [N/2]$, where $[x]$ denotes the integer part of $x$, the $K=2$-component of the geometric entanglement tends to the asymptotic limit $1/2$ for large $N$. The limit coincides with the maximum possible value, attained by the $|GHZ^{(N)}\rangle$ states.

We turn now to the determination of the generic $K$-components of the (relative) multipartite geometric entanglement quantified, for arbitrary $K$, by the distance $E_G^{(K)}(M_1 \ldots |M_K)$ from the set of $K$-separable states for a given partition. We begin by rewriting the generic $K$-separable state in the form

$$|\Phi\rangle = \bigotimes_{s=1}^{K} \sum_{J_s = 0}^{d_{M_s} - 1} r_{J_s}^{(s)} |J_s\rangle |M_s\rangle, \quad (35)$$

where we remind that the ordering is $1 \leq M_1 \leq M_2 \leq \ldots \leq M_K \leq N-K+1$, with $\sum_{s=1}^{K} M_s = N$. In analogy with the previous analysis for the case $K = 2$, it is not difficult to show that the squared overlap $A^2_K(M_1 \ldots |M_K)$ can be recast in the form

$$A^2_K(M_1 \ldots |M_K) =$$

$$\max_{\{r_{J_s}^{(s)}\}} \frac{1}{N} \left[ r_0^{(1)} r_0^{(2)} \cdots r_0^{(K-1)} \sum_{p=0}^{M_{K-1}} r_{2p}^{(K)} \right.$$

$$+ r_0^{(1)} r_0^{(2)} \cdots \sum_{p=0}^{M_{K-1}} r_{2p}^{(K-1)} r_0^{(K)} + \ldots$$

$$+ \sum_{p=0}^{M_{K-1}} r_{2p}^{(1)} r_0^{(2)} \cdots r_0^{(K-1)} r_0^{(K)} \left. \right]^2. \quad (36)$$

By a partial maximization, see Appendix B, Eq. (B6), reduces to

$$A^2_K(M_1 \ldots |M_K) = \max_{\{r_{J_s}^{(s)}\}} \frac{1}{N} \left[ \cos \delta_0^{(1)} \cos \delta_0^{(2)} \cdots \times$$

$$\times \cos \delta_0^{(K-1)} \sin \delta_0^{(K)} \sqrt{M_K} + \cos \delta_0^{(1)} \cos \delta_0^{(2)} \cdots \times$$

$$\times \cos \delta_0^{(K-2)} \sin \delta_0^{(K-1)} \cos \delta_0^{(K)} \sqrt{M_K-1} + \ldots$$

$$+ \sin \delta_0^{(1)} \cos \delta_0^{(2)} \cdots \cos \delta_0^{(K-1)} \cos \delta_0^{(K)} \sqrt{M_1} \right]^2. \quad (37)$$

The explicit solution of the problem cannot be given for generic $K$: One needs to assign a specific value of $K$ in order to solve the problem completely. In principle, full analytic solutions can always be obtained; however, the complexity of the problem grows with $K$, so that for sufficiently large values of $K$ the help of numerical codes may become necessary. On the other hand, resorting to numerics, when necessary, poses no particular problem, as all the equations are rigorously defined and their recursive structures completely determined. Therefore, the complete analytic and numerical solutions can always be obtained on demand, for each arbitrarily assigned value of $K$ and $N$, and according to the specific physical problem and type of multipartite state one is looking at.

Remarkably, from Eq. (37) it follows that the multipartite geometric entanglement of $|W^{(N)}\rangle$ states satisfies a property of self-similarity and scale invariance. Namely, given a $N$-qubit $|W^{(N)}\rangle$ state associated to a partition $M_1 |M_2 \ldots |M_K$, let us take an integer $L$ and consider the $LN$-qubit state $|W^{(LN)}\rangle$ associated to the scaled partition $LM_1 |LM_2 \ldots |LM_K$. By Eq. (37), one immediately has that

$$A^2_K(M_1 \ldots |M_K) = A^2_K(LM_1 |LM_2 \ldots |LM_K). \quad (38)$$

Thus, the $K$-partite geometric measures of entanglement enjoy the following property of scale invariance:

$$E_G^{(K)}(M_1 \ldots |M_K) = E_G^{(K)}(LM_1 |LM_2 \ldots |LM_K). \quad (39)$$

Since relation (39) applies for any partition, it follows that it holds true for the absolute minimum, Eq. (7), as well. Finally, it is worth noticing that the property of scale invariance of the geometric measures of entanglement is trivially enjoyed by every $GHZ$ state.

Proceeding in the discussion of the general case, we report the explicit analytic expression for the $K$-component, with $K = 3$, of the multipartite geometric entanglement of $|W^{(N)}\rangle$ states. The absolute minimum distance $E_G^{(3)}(|W^{(N)}\rangle)$ from the set of all three-separable states, that measures the $N$- and $(N-1)$-partite entanglement of $|W^{(N)}\rangle$ states, reads

$$E_G^{(3)}(|W^{(N)}\rangle) =$$

$$\min \left\{ E_G^{(3)}(M_1 |M_2 |M_3), E_G^{(3)}(M_1 |M_2 |M_3) \right\}. \quad (40)$$
where

\[ E_G^{(3)}(M_1|M_2|M_3) = 1 - \frac{M_3}{N}, \quad M_3 \geq M_1 + M_2, \]  
(41)

\[ E_G^{(3)}(M_1|M_2|M_3) = 1 - \frac{4M_1M_2M_3}{N^2}, \quad M_3 \leq M_1 + M_2, \]  
(42)

with \( \Sigma = 2(1 + 1 + 1) \) and \( \Sigma = 2(1 + 1 + 2) \). The two expressions coincide when \( M_3 = M_1 + M_2 \).

In the following we present and discuss the solutions of Eq. (34). We will determine the associated \( E_G^{(K)}(M_1|M_2|\ldots|M_K) \) for various choices of \( N \) and \( M_1, \ldots, M_K \), and compare them with respect to a reference standard fixed by the \( GHZ^{(N)} \) state. Finally, we will establish for each \( N \) the absolute minimum yield-\( E_G^{(K)}(|W^{(N)}\rangle) \). In Table I we report the exact values

| \( GHZ^{(4)} \) | \( W^{(4)} \) | \( W^{(6)} \) |
|-----------------|--------|--------|
| \( E_G^{(4)}(1|1|1|1) \) | 1/2    | 37/64  |
| \( E_G^{(4)}(1|1|2) \) | 1/2    | 1/2    |
| \( E_G^{(4)}(2|2) \) | 1/2    | 1/4    |
| \( E_G^{(4)}(1|3) \) | 1/2    | 1/4    |

TABLE I: Geometric measures of entanglement \( E_G^{(K)}(M_1|\ldots|M_K) \), with \( K = 2, 3, 4 \), for the 4-qubit states \( |GHZ^{(4)}\rangle \) and \( |W^{(4)}\rangle \).

of the different geometric entanglements corresponding to all the possible \( K \)-partitions in the case \( N = 4 \). As already stated, in the \( |GHZ^{(4)}\rangle \) state the various components all coincide with the genuine 4-particle entanglement. In the \( |W^{(4)}\rangle \) state one has that for \( K = 3 \) and \( K = 4 \), due to the symmetry under exchange of any pair of qubits, there is a unique way to partition the system, and the relative component of the geometric entanglement coincides with the absolute component. In the case \( K = 2 \) one has two inequivalent possible partitions, and, as already proved in the general case, the absolute minimum is attained for the partition \( |1\rangle|3\rangle \).

In Tables II and III we report the different multipartite components of the geometric entanglement, respectively in the \( |W^{(5)}\rangle \) and \( |W^{(6)}\rangle \) states. The fixed reference value \( 1/2 \) of the \( GHZ \) states is not reported. From Tables II and III we see that for \( N \geq 5 \) there appear sets \( S_K(M_1|\ldots|M_K) \) containing inequivalent partitions also for \( K > 2 \). Moreover, we observe that the relative distances do not obey a definite hierarchy; for instance, from Table III we see that \( E_G^{(3)}(2|2|2) > E_G^{(4)}(1|1|1|3) \). However, and more importantly, the hierarchy of absolute distances is never violated. For instance, \( \min E_G^{(3)}(M_1|M_2|M_3) < \min E_G^{(4)}(M_1|M_2|M_3|M_4) \), in perfect agreement with the general ordering established by Eq. (20). Finally, we re-

| \( W^{(5)} \) | \( W^{(5)} \) |
|-----------------|--------|
| \( E_G^{(5)}(1|1|1|1|1) \) | 0.590  |
| \( E_G^{(5)}(1|1|1|2) \) | 0.550  |
| \( E_G^{(5)}(1|2|2) \) | 0.250  |
| \( E_G^{(5)}(1|3) \) | 1/3    |

TABLE II: Geometric measures of entanglement \( E_G^{(K)}(M_1|\ldots|M_K) \), with \( K = 2, 3, 4, 5 \), for the state \( |W^{(5)}\rangle \).

mark that all the measures evaluated analytically are rational numbers, and that the ones computed numerically appear to be approximations of rational numbers. Therefore, we conjecture that, for every finite \( N \), all the relative and absolute multipartite geometric measures of entanglement are expressed by rational numbers.

C. Superpositions of \( W^{(N)} \) and \( GHZ^{(N)} \) states

It is of interest to investigate symmetric states constituted by generic superpositions of \( W \) and \( GHZ \) states:

\[ |WGZH^{(N)}\rangle = \cos \eta |W^{(N)}\rangle + \sin \eta |GHZ^{(N)}\rangle, \]  
(43)

where the \( N \)-qubit \( GHZ^{(N)} \) and \( W^{(N)} \) states are defined by Eqs. (23) and (24), respectively. The squared overlap \( \Lambda_5^2(M_1|M_2) \) associated with the set of bi-separable states \( \{32\} \) can be computed exactly. One has:

\[ \Lambda_5^2(M_1|M_2) = \max_{\{32\}} \left[ \frac{\cos \eta}{\sqrt{N}} \left( r_0^{(1)} \sum_{p=0}^{M_1-1} r_2^{(2)} + r_0^{(2)} \sum_{p=0}^{M_2-1} r_2^{(2)} \right) \right] \]  
(44)

As shown in Appendix B, a partial maximization procedure reduces the above relation to:

\[ \Lambda_5^2(M_1|M_2) = \max_{\{32\}} \left[ \frac{\cos \delta_0^{(1)} \sin \delta_0^{(2)} \sin \delta_1^{(2)} \times \sqrt{M_2 + \sin \delta_0^{(1)} \sin \delta_1^{(2)} \sqrt{M_1}} + \frac{\sin \eta}{\sqrt{2}} \left( \cos \delta_0^{(1)} \times \cos \delta_0^{(2)} + \sin \delta_0^{(1)} \cos \delta_0^{(1)} \sin \delta_0^{(2)} \cos \delta_0^{(2)} \right) \right] \]  
(45)
It is rather straightforward to prove that Eq. (45) and the associated geometric measure of entanglement enjoy a property of scale invariance: \( \Lambda^2 N (M_1 |M_2) = \Lambda^2 (LM_1 |LM_2) \) (with \( L \) integer), where \( \Lambda^2 (LM_1 |LM_2) \) is the squared overlap associated to the \( LN \)-qubit superposition state \( |WGHZ(LN)\rangle \). At fixed values of \( \eta \), \( M_1 \), and \( M_2 \), numerical evaluation of Eq. (45) can always be carried out easily. Being particularly interested in the quantification of genuine multipartite entanglement, we evaluate the geometric measure \( E_G^{(2)}(1|N-1) \), and report it in Fig. 3 for different values of \( N \). For \( N = 2 \), the state 

\[ |WGHZ(2)\rangle \quad \text{reduces to the superposition of Bell states.} \]

In this case, \( E_G^{(2)}(1|1) \) attains the maximum value 1/2 at \( \eta = 0, \frac{\pi}{2} \). For \( N = 3 \), the curve coincides with the one plotted in Fig. 2. Let us notice that in the instances \( N = 2, 3 \), absolute minima exist in the interval \((0, \frac{\pi}{2})\). For \( N \geq 4 \), \( E_G^{(2)}(1|N-1) \) increases monotonically from the value 1/N attained in the \( |W(N)\rangle \) state to the value 1/2 attained in the \( |GHZ(N)\rangle \) state.

**D. \( N = 4 \) cluster state**

In this subsection we apply the formalism previously introduced to the determination of the multipartite geometric entanglement of \( N \)-qubit cluster states \([33]\) in the case \( N = 4 \), the only nontrivial instance that allows an explicit closed expression. In fact, the \( N = 4 \) cluster state can be expressed as a superposition of the form

\[ |Cls^{(4)}\rangle = \frac{1}{2} (|0000\rangle + |0011\rangle + |1100\rangle - |1111\rangle). \] (46)

Recently, this state has been produced and characterized experimentally \([36, 37]\), as a relevant representative of the class of stabilizer states, which are very important both from a theoretical perspective and from a practical point of view for their property of entanglement persistency and for the implementation of one-way quantum computation \([38]\).

In Table IV we report the values of the different components of the geometric entanglement in the \( N = 4 \) cluster state corresponding to all the possible \( K \)-partitions of the 4-partite system. We observe that in the case of \( N = 4 \) cluster states there is a degeneracy in the geometric structure, as the absolute minimum is realized not only by the genuine four-partite components of entanglement \( E_G^{(2)}(1|3) \) and \( E_G^{(2)}(2|2) \), but also by the three-partite component \( E_G^{(3)}(1|3) \). The latter coincides with \( E_G^{(2)}(1|3) \). On the other hand, as \( E_G^{(4)}(1|2) > E_G^{(3)}(1|3) \), the 4-qubit cluster state possesses also a bipartite component besides the genuine four-partite contribution.

**E. Magnon states**

Going further towards higher generalizations that are physically significant, we discuss the class of symmetric \( N \)-qubit entangled states expressed as superpositions of magnon states \([39, 40]\). A magnon is an elementary excitation of magnetic materials, i.e. a quantum of a spin wave, and \( W \) states are actually the simplest superpositions of all possible magnon states containing only one excitation. In the generic case of \( k \) excitations on \( N \) particles, the multi-magnon superposition states can be written in the form:

\[ |M^N_g_k\rangle = \left( \begin{array}{c} N \\ k \end{array} \right)^{-1/2} \sum_{p_k = k-1}^{N-1} \sum_{p_{k-1} = k-2}^{p_k-1} \cdots \sum_{p_1 = 0}^{p_2-1} |2^{p_k} + 2^{p_{k-1}} + \cdots + 2^{p_1}\rangle_N, \] (47)

For the sake of illustration, let us consider explicitly the case \( k = 2 \), i.e. the superpositions of all possible \( N \)-qubit states containing two elementary excitations. Such states can be expressed in the form:

\[ |M^N_g_2\rangle = \left( \begin{array}{c} N \\ 2 \end{array} \right)^{-1/2} \sum_{p=1}^{N-1} \sum_{q=0}^{p-1} |2^p + 2^q\rangle_N, \] (48)

with \( N \geq 4 \).

In Table IV we report the values, computed numerically,
of the different components of the geometric entanglement in the 4-qubit two-magnon state $|Mg_2^{(4)}\rangle$. By comparing Tables VI and XVII, we see that, with respect to the $|W^{(4)}\rangle$ state, the $|Mg_2^{(4)}\rangle$ state possesses enhanced genuine multipartite entanglement:

$$E_G^{(2)}(|Mg_2^{(4)}\rangle) = \min\{E_G^{(2)}(2/2) ; E_G^{(2)}(1/3)\} = 1/3 > E_G^{(2)}(|W^{(4)}\rangle) = 1/4.$$ 

Analogously, the three-partite component $E_G^{(3)}(|1\rangle|2\rangle|3\rangle)$ is enhanced in the magnon state compared to the $W$ state. On the contrary, the $|Mg_2^{(4)}\rangle$ state possesses a smaller amount of genuine multipartite entanglement compared to the $|\text{Cls}^{(4)}\rangle$ state, while the three-partite component $E_G^{(3)}(|1\rangle|2\rangle|3\rangle)$ is larger.

Next, we generalize the previous analysis to the case of $N$-qubit two-magnon states with arbitrary $N$, and determine the geometric measure of entanglement $E_G^{(2)}(M_1|M_2)$, i.e. the distance from the set of 2-separable states of the form $\langle 0^N | (2^p + 2^q) \rangle_{M_2}$. By exploiting the decomposition:

$$\sum_{p=1}^{M_1-1} \sum_{q=0}^{M_2-1} |2^p + 2^q\rangle\langle 0^N | M_1 \otimes |2^p + 2^q\rangle M_2$$

the squared overlap $\Lambda_2^2(M_1|M_2)$ writes:

$$\Lambda_2^2(M_1|M_2) = \left(\frac{N}{2}\right)^{-1} \max_{\{r^{(2)}_{i,j}\}} \left[r^{(1)}_{0} \sum_{p=1}^{M_1-1} \sum_{q=0}^{M_2-1} r^{(2)}_{2p+2q} + r^{(2)}_{0} \sum_{p=0}^{M_1-1} \sum_{q=0}^{M_2-1} r^{(2)}_{2p}\right]^2. \quad (50)$$

The mathematical details concerning the maximization of Eq. (50) are treated in Appendix C. From Eq. (C3), fixing $M = M_1 \leq M_2 = N - M$, we obtain:

$$\Lambda_2^2(M|N-M) = |(N(N-1))^{-1} \max\{(N-M)(N-M-1) ; 2M(N-M)\}. \quad (51)$$

As in the previous instances of symmetric states, the squared overlap $\Lambda_2^2(M_1|N_2)$ and the corresponding geometric measure satisfy the property of scale invariance also for magnon states. One has: $\Lambda_2^2(M_1|N_2) = \Lambda_2^2(LM_1|LN_2)$ (with $L$ integer), $\Lambda_2^2(LM_1|LN_2)$ being the squared overlap associated with the LN-qubit two-magnon state $|Mg_L^{(LN)}\rangle$. For $M_1 = 1$ and $M_2 = N - 1$, the relation (51) reduces to $E_G^{(2)}(1|N-1) = 2/N$, with $N \geq 4$. Therefore, the genuine $N$-partite geometric entanglement contained in two-magnon states vanishes asymptotically in the limit of large $N$, analogously to the case of $N$-qubit $W$ states. This property is expected to hold in every multi-magnon state: At any fixed, finite value of $k$, the genuine $N$-partite entanglement contained in a $k$-magnon state vanishes in the limit of large $N$.

### IV. ASYMMETRIC STATES: GENERALIZED $W$-LIKE SUPERPOSITION STATES

In this Section, we evaluate the geometric measure of entanglement for the class of asymmetric, generalized $N$-qubit $W$-like superposition states defined as

$$|\psi_W^{(N)}\rangle = N^{-1} \sum_{p=0}^{N-1} \gamma_p e^{i\xi_p + 1} |2^p\rangle_N,$$ 

where $\gamma_p$ are real parameters, $\xi_p$ are real phases, and the normalization factor is $N^{-1} = \sum_{p=0}^{N-1} \gamma_p^2)^{-1/2}$. These states play a relevant role in quantum information science according to the following considerations. It is well known that true tripartite entanglement of the state of a system of three qubits can be classified on the basis of stochastic local operations and classical communications. Such states can then be classified into two categories corresponding to the GHZ and $W$ states. It is known that GHZ states can be used for teleportation and superdense coding, but the standard symmetric $W$ states cannot. However, it has been shown that the class of asymmetric, generalized $W$-like superposition states $\langle 52 \rangle$ can be used as entangled resources for the implementation of perfect teleportation and superdense coding $\langle 11 \rangle$. Moreover, several methods for their preparation have been proposed $\langle 12 \rangle$.

Without loss of generality and information content in the definition of the state, we assume $\gamma_p \in [0, 1]$ and $\xi_p \in [0, 2\pi]$. Moreover, in the following, we will let $\xi_p = 0$ as it can be shown that the phases are irrelevant in the calculation of the geometric measures, being always canceled by the free phases of the $K$-separable states in the maximization procedure. The states $\langle 12 \rangle$ are asymmetric, i.e. not invariant with respect the permutation of any couple of qubit. We first give explicit examples of application for the three-qubit and four-qubit instances, Eq. (52) with $N = 3, 4$ respectively. In the three-qubit case, proceeding as in subsection III A, we compute the squared overlap $\langle 10 \rangle$ for the state $|\psi_W^{(3)}\rangle$. Dealing with
asymmetric states, we have to specify the elementary qubits contained in the two sets $Q_1$ and $Q_2$ which determine the set $S_d(Q_1|Q_2)$ of the 2-separable states. Thus, we compute the quantity $\Lambda_2^{(2)}(i|j,k)$, where $i, j, k = 1, 2, 3$, with $i \neq j \neq k$ denote the three elementary qubits. The calculation of this quantity yields:

$$\Lambda_2^{(2)}(i|j,k) = N_1^2 \max\{\gamma_i^2, \gamma_j^2 + \gamma_k^2\}.$$  \hfill (53)

In Fig. 4 we plot the relative geometric measure $E_{G}^{(2)}(1|2,3)$ for the state $|\psi^{(3)}_W\rangle$ as a function of the variables $\gamma_1$ and $\gamma_2$, at a fixed value of $\gamma_3$. We see that $E_{G}^{(2)}(1|2,3)$ is formed by two surfaces whose curve of separation stays at the maximum attainable value $1/2$. Similar plots can be obtained for $E_{G}^{(2)}(2|1,3)$ and $E_{G}^{(2)}(3|1,2)$. The absolute geometric measure of entanglement, as defined in Eq. (51), is given by $E_{G}^{(2)}(|\psi^{(3)}_W\rangle) = \min_{\{i,j,k\}\{E_{G}^{(2)}(i|j,k)\}}$ with $i, j, k = 1, 2, 3$ and $i \neq j \neq k$; the absolute minimum is evaluated with respect to all possible permutations of the indices, as the state is not symmetric under the exchange of any two qubits. The absolute measure of geometric entanglement with respect to biseparable states is plotted in Fig. 5. The surface describing $E_{G}^{(2)}(|\psi^{(3)}_W\rangle)$ is formed by the contributions of three surfaces whose common intersection is at the absolute maximum $1/3$. Let us notice that this absolute maximum is always achieved for $\gamma_1 = \gamma_2 = \gamma_3$. In the case $N = 4$, besides the bipartition $1|3$, we also have to take into account the bipartition $2|2$. Direct evaluation yields:

$$\Lambda_2^{(3)}(i|j, k, l) = N_1^2 \max\{\gamma_i^2, \gamma_j^2 + \gamma_k^2 + \gamma_l^2\},$$  \hfill (54)

$$\Lambda_2^{(3)}(i, j|k, l) = N_1^2 \max\{\gamma_i^2 + \gamma_j^2, \gamma_k^2 + \gamma_l^2\}.$$  \hfill (55)

The relative geometric measures $E_{G}^{(2)}(1|2,3,4)$ and $E_{G}^{(2)}(1,2|3,4)$ are plotted in Figs. 6 and 7 respectively, as functions of $\gamma_1$ and $\gamma_2$, at fixed $\gamma_3$ and $\gamma_4$. Similarly to the plot in Fig. 4, these three-dimensional plots are characterized by two surfaces whose separation curve is set at the maximum value $1/2$. The absolute geometric measure $E_{G}^{(2)}(|\psi^{(4)}_W\rangle)$ exhibits a behavior similar to that observed for the three-qubit instance, see Fig. 5. We finally consider the general instance of $N$-qubit states, expressed by Eq. (52) for arbitrary $N$ (with $\xi_{p+1} = 0$). We compute the squared overlap $\Lambda_2^{(N)}(Q_1|\ldots|Q_K)$ associated with the $K$-separable state $5$. For simplicity, we choose $Q_1 = \{1, \ldots, M_1\}$, $Q_2 = \{M_1 + 1, \ldots, M_1 + M_2\}$, $\ldots$, $Q_K = \{M_1 + \ldots + M_{K-1} + 1, \ldots, N\}$. Direct eval-

**FIG. 6:** (Color online) The relative measure of geometric entanglement $E_{G}^{(2)}(1|2,3,4)$ for the state $|\psi^{(4)}_W\rangle$, plotted as a function of $\gamma_1$ and $\gamma_2$, at fixed $\gamma_3 = 2/3$ and $\gamma_4 = 1/6$. All plotted quantities are dimensionless.
Eq. (57), results \[33, 55, \text{and} \] 59 are immediately recovered as particular cases.

V. CONCLUSIONS AND OUTLOOK

In this work we have introduced and discussed a class of generalized geometric measures of entanglement. For pure quantum states of \(N\) elementary subsystems, these extended measures are defined as the distances from the sets of \(K\)-separable states \((K = 2, \ldots, N)\). In principle, the entire set of these \(N - 1\) geometric measures provides a complete quantification and a hierarchical ordering of the different bipartite and multipartite components of the global geometric entanglement, and allows to discriminate among the different multi-party contributions. After introducing and elucidating the fundamental properties of the generalized geometric measures, we have investigated in detail multipartite pure states of \(N\)-qubit systems. For the multi-qubit case, we have derived some general properties of the extended geometric measures and discussed a systematic method for their evaluation in symmetric states including \(W(N)\) states, \(GHZ(N)\) states, and their superpositions; symmetric cluster states; and multi-magnon states. Moreover, considering asymmetric states, we have introduced a method for the systematic determination of the multipartite components of geometric entanglement in a large class of generalized \(W\)-like superposition states. We have identified a property of self-similarity and scale-invariance holding for all types of geometric entanglement and symmetric multipartite pure states of many-qubit systems. Finally, in a series of mathematical appendices, we have sketched the main mathematical framework needed for the exact numerical and/or analytical evaluation of the bipartite and multipartite components of geometric entanglement in any, arbitrarily chosen, pure state of many-qubit systems.

A challenge of great potential interest is to extend the mathematical framework and the recursive computation schemes developed for multi-qubit states to higher-dimensional quantum systems. A further significant issue concerns the extension of the geometric setting to mixed states, beyond the immediate, but in practice not very useful, procedures based on the convex hull construction. Devising alternative, but conceptually equally satisfactory, extensions would be especially important in order to establish a deeper understanding of the possible operational characterizations for the set of geometric measures of entanglement in the presence of classical noise and non unitary quantum operations. Finally, it would be important to investigate to what extent the novel multi-component measures of geometric entanglement defined in the present work could be exploited to construct geometric monotones obeying a structure of shared entanglement and monogamy bounds for distributed entanglement, and their role in the understanding of quantum critical phenomena and quantum cooperative systems.
APPENDIX A: HYPSHERICAL PARAMETRIZATION

A very convenient parametrization for the moduli \( r_J \) in Eq. (22), that automatically solves the normalization constraint, is the representation in hyperspherical coordinates in \( d_M \) dimensions:

\[
\begin{align*}
v_0 &= \cos \delta_0, \\
v_1 &= \sin \delta_0 \cos \delta_1, \\
&\vdots \\
v_{d_M-2} &= \sin \delta_0 \cdots \sin \delta_{d_M-3} \cos \delta_{d_M-2}, \\
v_{d_M-1} &= \sin \delta_0 \cdots \sin \delta_{d_M-3} \sin \delta_{d_M-2},
\end{align*}
\]

where \( \delta_L \) are angles with values in the interval \([0, \pi]\). Let us notice that the one-to-one mapping between \( r_J \) and \( v_L \) (with \( J, L = 0, \ldots, d_M - 1 \)), or equivalently between the indices \( J \) and \( L \), can be chosen by following a suitable ordering. In fact, the term \( v_L \) will be constituted by a product of \( L \) trigonometric functions; thus, it would be convenient to have expressions involving parameters \( v_L \) with low values of the index \( L \). Considering the state (22), the most immediate choice for \( r_J \) is obtained by letting \( r_J = v_J \) for \( J = 0, \ldots, d_M - 1 \).

Interpreting the two levels 0 and 1 of the single qubit as the ground and the excited levels, respectively, of the elementary system, a further useful choice for the mapping between \( J \) and \( L \) can be obtained by associating the parameter \( v_L \) with the coefficient \( r_J \) of the \( N \)-qubit ket in the order of growing number of excitations. Let us recall that, for an arbitrary \( N \)-qubit state, the global ground state \( |00 \ldots 0 \rangle \) is labeled by the index \( J = 0 \); the kets with single excitation, e.g. of the form \( |010 \ldots 0 \rangle \), are labeled by the indices \( J = 2^p \) with \( p = 0, \ldots, N - 1 \); the kets with two excitations, e.g. of the form \( |01010 \ldots 0 \rangle \), are labeled by the indices \( J = 2^q + 2^p \) with \( q = 1, \ldots, N - 1 \) and \( p = 0, \ldots, s - 1 \); and so on. One can decide to choose the following mapping for the parametrization:

\[
\begin{align*}
r_0 &= v_0, \\
r_{2^p} &= v_{p+1}, \quad p = 0, \ldots, N - 1, \\
r_{2^q+2^p} &= v_{N+q+s}, \quad q = 1, \ldots, N - 1, s = 0, \ldots, q - 1, \\
&\text{.........}
\end{align*}
\]

Clearly, the choice of the mapping between \( r_J \) and \( v_L \) can be suitably done by looking at the terms that survive in the squared overlap (3).

APPENDIX B: EVALUATION OF EQS. (33), (36), (44), AND (56)

Here we outline the analytical evaluation of the squared overlaps (33), (36), (44), and (56). The quantity \( \Lambda_2^2(M_1|M_2) \) in Eq. (33) involves only coefficients of the form \( r_0^{(s)} \) and \( r_{2^p}^{(s)} \) \( (s = 1, 2) \). Therefore, when using the hyperspherical representation (A1), by exploiting the freedom in the ordering, we choose the mapping given in Eq. (A2), specifically

\[
\begin{align*}
r_0^{(s)} &= v_0^{(s)} = \cos \delta_0, \\
r_{2^p}^{(s)} &= v_{p+1}^{(s)} = \sin \delta_0 \cdots \sin \delta_p \cos \delta_{p+1}, \\
p &= 0, \ldots, M_s - 1.
\end{align*}
\]

Such parametrization leads to the explicit expression

\[
\begin{align*}
\Lambda_2^2(M_1|M_2) &= \max_{\{\delta_L^{(s)}\}} \frac{1}{N} \{\cos \delta_0^{(1)} \sin \delta_0^{(2)} [\cos \delta_1^{(2)} + \sin \delta_1^{(2)} \sin \delta_2^{(1)}] + \cos \delta_0^{(2)} \sin \delta_0^{(1)} \cos \delta_1^{(1)} + \sin \delta_1^{(1)} \times \\
&\times \cos \delta_2^{(1)} + \sin \delta_2^{(1)} \cdots [\cos \delta_{M_s-1}^{(1)} + \sin \delta_{M_s-1}^{(1)} \times \\
&\times \cos \delta_{M_s-1}^{(1)}])\}^2.
\end{align*}
\]

Analyzing the structure of the \(|W^{(N)}\) states, it is convenient, given a generic integer \( M \) and a set of generic variables \( \delta_i, \quad i = 1, \ldots, M \), to introduce the following function:

\[
\begin{align*}
f(\delta_1^{(1)}, \ldots, \delta_M^{(1)}) &= \cos \delta_1^{(1)} + \sin \delta_1^{(1)} \cos \delta_2^{(2)} + \sin \delta_2^{(2)} \times \\
&\times \cdots [\cos \delta_{M_s-1}^{(1)} + \sin \delta_{M_s-1}^{(1)} \cos \delta_{M_s-1}^{(1)}].
\end{align*}
\]

By means of Eq. (133), the expression (132) can be recast in the more compact form

\[
\begin{align*}
\Lambda_2^2(M_1|M_2) &= \max_{\{\delta_L^{(s)}\}} \frac{1}{N} \{\cos \delta_0^{(1)} \sin \delta_0^{(2)} \times \\
&\times f(\delta_1^{(2)}, \ldots, \delta_{M_s}^{(2)}) + \cos \delta_0^{(2)} \sin \delta_0^{(1)} \times \\
&\times f(\delta_1^{(1)}, \ldots, \delta_{M_s}^{(1)})) \}^2.
\end{align*}
\]

To proceed, we first maximize the function \( f(\delta_1^{(1)}, \ldots, \delta_{M_s}^{(1)}) \), i.e. Eq. (133), over the \( M_s \) independent variables \( \delta_h^{(1)} \) \( (h = 1, \ldots, M_s) \). This task can be accomplished as follows: First, trivially, \( \delta_M^{(s)} = 0 \) maximizes \( \cos \delta_M^{(s)} \). Next, the contribution \( \cos \delta_{M_s-1}^{(s)} + \sin \delta_{M_s-1}^{(s)} \) reaches the maximum value \( \sqrt{2} \) for \( \delta_{M_s-1}^{(s)} = \frac{\pi}{4} \). After the elimination of the parameters \( \delta_{M_s-1}^{(s)} \) and \( \delta_M^{(s)} \), the term \( (\cos \delta_{M_s-2}^{(s)} + \sin \delta_{M_s-2}^{(s)} \sqrt{2}) \) appears. Observing that terms of the form \( (\cos \theta + \sin \theta \theta^q) \) acquire the maximum value \( \sqrt{1 + n} \) for \( \theta = \arcsin \sqrt{\frac{n}{1+n}} \), the cascade maximization procedure yields that Eq. (133) is maximized at the value \( \sqrt{M_s} \) for \( \delta_{M_s-h}^{(s)} = \arcsin \sqrt{\frac{h}{1+h}} \), with \( h = 0, 1, \ldots, M - 1 \).
Reminding that $1 \leq M_1 \leq M_2 = N - M_1$, and performing the final maximization in Eq. (B2) yields
\[ \Lambda^2_2(M_1|M_2) = \frac{M_2}{N}. \quad (B5) \]
The above maximum overlap squared is reached for the values $\delta_0^{(1)} = 0$, $\delta_0^{(2)} = \frac{\pi}{2}$, $\delta_0^{(2)} = \frac{\pi}{2}$, $\delta_0^{(2)} = \frac{\pi}{2}$, with $h = 0, 1, \ldots, M_2 - 1$.

One can now consider the squared overlap $\Lambda^2_2(M_1 \ldots |M_K)$, Eq. (36). Proceeding as for Eq. (33), and thus using, for any $s$, the hyperspherical representation (A1) with the mapping given by Eq. (A1), one can express Eq. (36) in terms of the angular parameters $\delta_s^{(s)}$. Moreover, by using definition (B9),
\[ \Lambda^2_2(M_1 \ldots |M_K) = \max_{\{\delta_{s}^{(s)}\}} \frac{1}{N} \left[ \cos \delta_0^{(1)} \cos \delta_0^{(2)} \cdots \cos \delta_0^{(K-1)} \times \sin \delta_0^{(K)} f(\delta_1^{(K)}), \ldots, \delta_{M_K}^{(K)} + \cos \delta_0^{(1)} \cos \delta_0^{(2)} \cdots \times \cos \delta_0^{(K-2)} \sin \delta_0^{(K-1)} f(\delta_1^{(K-1)}, \ldots, \delta_{M_{K-1}}^{(K-1)}) \cos \delta_0^{(K)} + \ldots + \sin \delta_0^{(1)} f(\delta_1^{(1)}, \ldots, \delta_{M_1}^{(1)}) \times \cos \delta_0^{(2)} \cdots \cos \delta_0^{(K-1)} \cos \delta_0^{(K)} \right]^2. \quad (B6) \]

The maximization of the functions $f$, corresponding to the replacement $f(\delta_1^{(s)}, \ldots, \delta_{M_s}^{(s)}) \to \Gamma_{M_s}$, reduces relation (36) to Eq. (57).

Next, we consider the squared overlap (14). By choosing the following mapping
\[ r_0^{(s)} = \theta_0^{(s)} = \cos \delta_0^{(s)}, \]
\[ r_{2M_s-1}^{(s)} = \theta_1^{(s)} = \sin \delta_0^{(s)} \cos \delta_1^{(s)}, \]
\[ r_{2p}^{(s)} = \theta_{p+2}^{(s)} = \sin \delta_0^{(s)} \cdots \sin \delta_{p+1}^{(s)} \cdots \cos \delta_{M_s}^{(s)}, \]
\[ p = 0, \ldots, M_s - 1, \quad (B7) \]
we obtain the relation:
\[ \Lambda^2_2(M_1|M_2) = \max_{\{\delta_{s}^{(s)}\}} \left[ \cos \eta \sqrt{N} \left( \cos \delta_0^{(1)} \sin \delta_0^{(2)} \sin \delta_1^{(2)} \times \right. \right. \]
\[ f(\delta_2^{(2)} \ldots, \delta_{M_s+1}^{(2)}) + \sin \delta_0^{(1)} \sin \delta_1^{(2)} \sin \delta_0^{(2)} \times \]
\[ f(\delta_1^{(1)}, \ldots, \delta_{M_1+1}^{(1)}) \sin \eta \sqrt{2N} \left( \cos \delta_0^{(1)} \cos \delta_0^{(2)} + \sin \delta_0^{(1)} \times \right. \]
\[ \cos \delta_1^{(1)} \sin \delta_0^{(2)} \sin \delta_1^{(2)} \right)^2 \cdot \quad (B8) \]

By maximizing the functions $f$, we arrive at the final expression Eq. (57).

Coming to the squared overlap $\Lambda^2_2(Q_1 \ldots |Q_K)$, i.e. Eq. (50), one can proceed as for Eq. (36) in order to obtain a relation identical to Eq. (56) with the functions $f$ replaced by the functions $F$ defined as:
\[ F(\delta_1^{(s)} \ldots, \delta_{M_s}^{(s)}) = \Gamma_1^{(s)} \cos \delta_1^{(s)} + \sin \delta_1^{(s)} \Gamma_2^{(s)} \cos \delta_2^{(s)} + \sin \delta_2^{(s)} [ \ldots \Gamma_{M_s-1}^{(s)} \cos \delta_{M_s-1}^{(s)} + \sin \delta_{M_s-1}^{(s)} \times \Gamma_{M_s}^{(s)} \cos \delta_{M_s}^{(s)} ] \], \quad (B9) \]
where $\Gamma_{p+1}^{(s)} = \gamma_{p+1}^{(s)} M_s+1 \ldots M_K$, with $p = 0, \ldots, M_s - 1$.

It is straightforward to notice that the following relation holds:
\[ \max_\delta \{ x \cos \delta + y \sin \delta \} = \sqrt{x^2 + y^2}, \quad (B10) \]
where $x$ and $y$ are real parameters. By exploiting iteratively the maximization procedure to the terms of this form, we find that Eq. (B9) is maximized at the value $\sqrt{\sum_{p=0}^{M_s-1} \Gamma_{p+1}^{(s)} M_s+1 \ldots M_K}$. Finally, maximizing all the functions $F$, the squared overlap (50) reduces to Eq. (77).

**APPENDIX C: EVALUATION OF EQ. (50)**

In order to compute the squared overlap $\Lambda^2_2(M_1|M_2)$, Eq. (50), we exploit again the hyperspherical coordinates (A1), and we introduce the following mapping
\[ \theta_0^{(s)} = v_0^{(s)} = \cos \delta_0^{(s)}, \]
\[ v_{2p+2}^{(s)} = \theta_{l(p,q)}^{(s)} = \sin \delta_0^{(s)} \cdots \sin \delta_{l(p,q)+1}^{(s)} \cos \delta_{l(p,q)+1}^{(s)}, \]
\[ l(p,q) = 0, \ldots, L_s - 1, \quad p = 1, \ldots, M_s - 1, \quad q = 0, \ldots, p - 1, \]
\[ v_{2p}^{(s)} = v_{p+1+L_s}^{(s)} = \sin \delta_0^{(s)} \cdots \sin \delta_{p+1}^{(s)} \cos \delta_{p+1}^{(s)} \cos \delta_{p+1}^{(s)} \cos \delta_{p+1}^{(s)}, \quad p = 0, \ldots, M_s - 1, \quad (C1) \]
where $L_s = \left( \frac{M_s}{2} \right) = \frac{M_s(M_s-1)}{2}$. Furthermore, by defining the function:
\[ g(\delta_1^{(s)}, \ldots, \delta_{L_s}^{(s)}) = \sin \delta_0^{(s)} \cdots \sin \delta_{L_s}^{(s)}, \quad (C2) \]
Eq. (50) is recast in the form
\[ \Lambda^2_2(M_1|M_2) = \max_{\delta_{s}^{(s)}} \left| \sin \delta_0^{(1)} \cos \delta_0^{(2)} f(\delta_1^{(1)}, \ldots, \delta_{L_1}^{(1)}) + \cos \delta_0^{(1)} \sin \delta_0^{(2)} f(\delta_1^{(2)}, \ldots, \delta_{L_2}^{(2)}) + \sin \delta_0^{(1)} \sin \delta_0^{(2)} \times \right. \]
\[ \left. \times g(\delta_1^{(1)}, \ldots, \delta_{L_1}^{(1)}) f(\delta_1^{(L_1+1)}, \ldots, \delta_1^{(L_1+1)}) \times \right. \]
\[ \left. \times g(\delta_1^{(2)}, \ldots, \delta_2^{(2)}) f(\delta_1^{(L_2+1)}, \ldots, \delta_2^{(L_2+1)}) \right|^2. \quad (C3) \]
The functions \( f(\delta^{(s)}_{L_1}, \ldots, \delta^{(s)}_{L_2}) \) in the last term of Eq. (C3) can be maximized at the value \( \sqrt{\Lambda_2} \). It is quite straightforward to observe that the functions \( f \) and \( g \) are connected by the relation
\[
f(\delta^{(s)}_1, \ldots, \delta^{(s)}_{L_2}) = f(\delta^{(s)}_1, \ldots, \delta^{(s)}_{L_1-1}) + g(\delta^{(s)}_1, \ldots, \delta^{(s)}_{L_1-1}) \cos \delta_{L_1}.
\]
(C4)

By using property (C4) and applying the maximization relation (B10) to the variables \( \delta^{(1)}_L, \delta^{(1)}_{L-1}, \ldots, \delta^{(1)}_1, \delta^{(1)}_0 \), Eq. (C3) reduces to
\[
\Lambda_2^2(M_1|M_2) = \max_{\delta^{(2)}_{L_2}} \left( \frac{N}{2} \right)^{-1} \left\{ \cos^2 \delta^{(2)}_{L_1} \sin^2 \delta^{(2)}_{L_2} \times \left[ f^2(\delta^{(2)}_1, \ldots, \delta^{(2)}_{L_2}) + g^2(\delta^{(2)}_1, \ldots, \delta^{(2)}_{L_2})M_1M_2 \right] \right\}.
\]
(C5)

Observing that \( L_1 < L_2, M_1 M_2 \), a further maximization on the variable \( \delta^{(2)}_0 \) yields
\[
\Lambda_2^2(M_1|M_2) = \max_{\delta^{(2)}_{L_2}} \left( \frac{N}{2} \right)^{-1} \left[ f^2(\delta^{(2)}_1, \ldots, \delta^{(2)}_{L_2}) \right. + \left. g^2(\delta^{(2)}_1, \ldots, \delta^{(2)}_{L_2})M_1M_2 \right].
\]
(C6)

In order to maximize Eq. (C6), one has to find the conditions for the vanishing of the first partial derivatives with respect to each variable \( \delta^{(2)}_q \) with \( q = 1, \ldots, L_2 \), and to select the absolute maximum in the intervals \( 0 \leq \delta^{(2)}_q \leq \pi/2 \). Without reporting the whole set of the calculations, we only outline briefly the main steps of the maximization procedure. The first partial derivative with respect to \( \delta^{(2)}_{L_2} \) yields the following condition:
\[
g(\delta^{(2)}_1, \ldots, \delta^{(2)}_{L_2}) f(\delta^{(2)}_1, \ldots, \delta^{(2)}_{L_2}) - M_1 M_2 g(\delta^{(2)}_1, \ldots, \delta^{(2)}_{L_2}) \cos \delta^{(2)}_{L_2} = 0.
\]
(C7)

By using Eq. (C7) together with all the other partial derivatives with respect to \( \delta^{(2)}_q \) (\( q = 1, \ldots, L_2 - 1 \)), it is not difficult to verify that the absolute maximum of \( \Lambda_2^2(M_1|M_2) \) is given by
\[
\Lambda_2^2(M_1|M_2) = \left( \frac{N}{2} \right)^{-1} \max \{ L_2, M_1 M_2 \}.
\]
(C8)

Indeed, from Eq. (C7) one has that if \( g(\delta^{(2)}_1, \ldots, \delta^{(2)}_{L_2}) = 0 \), then Eq. (C6) reduces to the maximization of the function \( f(\delta^{(2)}_1, \ldots, \delta^{(2)}_{L_2}) \), i.e. \( \sqrt{\Lambda_2} \). On the other hand, if \( f(\delta^{(2)}_1, \ldots, \delta^{(2)}_{L_2}) = M_1 M_2 g(\delta^{(2)}_1, \ldots, \delta^{(2)}_{L_2}) \) cos \( \delta^{(2)}_{L_2} \), then the maximum is reached for \( \delta^{(2)}_2 = \frac{\pi}{2} \), i.e. \( f\left(\frac{\pi}{2}, \ldots, \frac{\pi}{2}\right) = 0 \) and \( g\left(\frac{\pi}{2}, \ldots, \frac{\pi}{2}\right) = 1 \). It can be verified that all the other values of \( \delta_2 \) leading to the vanishing of the first partial derivatives are associated with relative maxima.
