Rapid communication

We estimated vaccine effectiveness (VE) against severe COVID-19 during October 2021, using Slovenian surveillance data. For people fully vaccinated with any vaccine in age groups 18–49, 50–64, ≥ 65 years, VE was 86% (95% CI: 79–90), 89% (85–91), and 77% (74–81). Among ≥ 65 year-olds fully vaccinated with mRNA vaccines, VE decreased from 93% (95% CI: 88–96) in those vaccinated ≤ 3 months ago to 43% (95% CI: 30–54) in those vaccinated ≥ 6 months ago, suggesting the need for early boosters.

To inform vaccination strategy it is important to understand the effectiveness of vaccination against severe coronavirus disease (COVID-19). In Slovenia, by the end of September 2021, the vaccination coverage against COVID-19 was rather low (47.2% among 18–49 year-olds, 63.5% among 50–64 year-olds, and 76.1% among ≥ 65 year-olds) and waning immunity may have occurred, especially among elderly people (≥ 65 year-olds) who were vaccinated first [1]. Here we estimated vaccine effectiveness (VE) against hospitalisation due to severe acute respiratory infection (SARI) COVID-19 during October 2021 (weeks 39 to 43; from 27 September to 31 October), when the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) Delta variant was predominant, by age groups, for all vaccines used and separately for mRNA vaccines and viral vector vaccines. Additionally, we estimated VE against hospitalisation due to SARI COVID-19 for mRNA vaccines by time since vaccination.

We used comprehensive national COVID-19 surveillance data and data on vaccination against COVID-19 collected at the National Institute of Public Health (Nacionalni inštitut za javno zdravje (NIJZ)).

Case definitions and other definitions
A SARI COVID-19 case was defined as an individual with SARI and a positive SARS-CoV-2 reverse transcription PCR (RT-PCR) or antigen test result at admission to hospital [2]. A case with a previous COVID-19 diagnosis was defined as an individual with a record of a positive SARS-CoV-2 RT-PCR in the national COVID-19 database more than 3 weeks before the week under observation. Fully vaccinated individuals were those who completed the primary recommended vaccination schedule with any vaccine used in Slovenia: Comirnaty (BNT162b2 mRNA, BioNTech-Pfizer, Mainz, Germany/New York, United States) or Spikevax (mRNA-1273, Moderna, Cambridge, United States) or Vaxzervia (ChAdOx1 nCoV-19, Oxford-AstraZeneca, Cambridge, United Kingdom) or Janssen vaccine (Ad26.COV2-S, Janssen-Cilag International NV, Beerse, Belgium) at least 14 days before the week under observation in the national EPISARI surveillance database. Unvaccinated individuals were defined as individuals who had not received any dose of vaccine against COVID-19.

Data sources
Three different sources were used in the analysis: (i) weekly numbers of SARI COVID-19 cases admitted to hospitals were extracted from EPISARI [2], (ii) vaccination status of all individuals vaccinated in Slovenia was obtained from the national Electronic registry of vaccinated individuals and adverse events following immunisation (eRCO) [3] and (iii) previous diagnosis of COVID-19 was retrieved from the national COVID-19 database. By using unique national identifiers, we were able to link the data from the three databases to ascertain the vaccination status of SARI COVID-19 cases admitted to hospitals and previous diagnosis of COVID-19 among fully vaccinated individuals.
Calculating vaccine effectiveness

To estimate VE against hospitalisation due to SARI COVID-19 for all vaccines used in Slovenia and separately for mRNA and viral vector vaccines (by age groups and by time since vaccination), we used the respective rates of SARI COVID-19 cases in fully vaccinated individuals without previous diagnosis of COVID-19 and respective rates of SARI COVID-19 cases in unvaccinated individuals without previous diagnosis of COVID-19.

Vaccine effectiveness was calculated using the formula: $(1 - \text{RR}) \times 100$, where RR was the ratio of severe COVID-19 cases rate in the fully vaccinated, to the equivalent rate in the unvaccinated.

To obtain denominators for fully vaccinated individuals without previous diagnosis of COVID-19, the number of fully vaccinated individuals with previous COVID-19 diagnosis was subtracted from the number of fully vaccinated individuals. To obtain estimates of denominators for unvaccinated individuals without previous diagnosis of COVID-19, we subtracted the number of individuals who have received at least one dose of any vaccine against COVID-19, and the number of individuals with previous COVID-19 diagnosis, from the total number of individuals in the Central Population Registry as of 1 of January 2021.

**Vaccine effectiveness against SARI COVID-19 hospitalisations**

During October 2021, VE for all vaccines as well as for mRNA and viral vector vaccines against SARI COVID-19 hospitalisations was lowest in the oldest age group (Table 1). Viral vector vaccines were less effective in preventing hospitalisations due to SARI COVID-19 in comparison to mRNA vaccines in all age groups.

Among individuals fully vaccinated with mRNA vaccines 6 months ago or longer, VE against hospitalisation due to SARS COVID-19 was substantially lower among those aged 65 years and older (43%; 95% CI: 31–54%) in comparison to those 50 to 64 years old (89%; 95% CI: 56–97%) (Table 2).

Ethical statement

Ethical approval was not necessary because all surveillance data used are mandatorily collected according to the law.

Discussion

The effectiveness of COVID-19 vaccines has been recently intensively studied. Some reports suggested
decreased VE against infection by the SARS-CoV-2 Delta variant [4], others indicated modest differences in VE against symptomatic disease with the Delta variant as compared with the Alpha variant [5], and some studies found maintained VE against hospitalisation due to severe disease [6-8]. Our results suggest that vaccines used in Slovenia were effective against hospitalisation due to SARI COVID-19 in fully vaccinated individuals during October 2021 when the Delta variant was predominant. The estimated VE was 86% (95% CI: 79–90), 89% (95% CI: 85–91), and 77% (95% CI: 74–81) among age groups 18–49, 50–64, and ≥ 65 years, for vaccination with any vaccine used in Slovenia. For mRNA vaccines the VE point percentage values showed an even greater risk reduction of SARI COVID-19 hospitalisation in all age groups, even though the 95% confidence intervals overlapped. Similar effectiveness of mRNA vaccines against hospitalisation due to severe COVID-19 was observed by others [6-9], and the European Centre for Disease Prevention and Control estimated the effectiveness of the Comirnaty vaccine against hospitalisation due to SARI-confirmed COVID-19 during the pre-Delta period in elderly people (≥ 65 years) at 91% (95% CI: 80–96) [10].

The estimated VE against hospitalisation due to SARI COVID-19 in fully vaccinated Slovenian individuals during October 2021 for vector vaccines was statistically significantly lower compared with mRNA VE for all three age groups investigated here.

It is important to note that VE of mRNA vaccines against SARI COVID-19 hospitalisation decreased substantially with the increasing time since vaccination, especially in elderly people (≥ 65 years) to only 43% (95% CI: 31–54%) for those fully vaccinated 6 months or more ago. This finding suggested that more than half of the elderly people fully vaccinated 6 months or more ago were no longer sufficiently protected against hospitalisation due to severe COVID-19. Waning immunity has also been reported by others [11-13]. Thus, our results provide additional evidence of substantially declining protection with time since vaccination against hospitalisation due to severe COVID-19 in elderly people and the need for a timely booster dose, especially in this age group.

The strength of our study is in the real-world national surveillance data collected from all Slovenian hospitals (EPISARI), and data from official national registries (eRCO and COVID-19 database). Surveillance of SARI COVID-19 cases within EPISARI has some limitations, however, which have been described in detail elsewhere [2]. In brief, the data collection process is at the

---

**Table 2**

Vaccine effectiveness of mRNA vaccines against hospitalisation due to SARI COVID-19 by time since vaccination and age group, Slovenia, October 2021

| Age group (years) | Fully vaccinated individuals without previous COVID-19 | Unvaccinated individuals without previous COVID-19 | Vaccine effectiveness |
|------------------|--------------------------------------------------------|---------------------------------------------------|-----------------------|
|                  | Number of SARI COVID-19 cases | Rate per 100,000 population | Number of SARI COVID-19 cases | Rate per 100,000 population | % | 95% CI |
| Vaccinated ≤ 3 months ago | | | | | | |
| 18–49            | 3 | 1.7 | 179 | 55.8 | 97 | 90–99 |
| 50–64            | 14 | 12.7 | 270 | 229.9 | 94 | 91–97 |
| ≥ 65             | 17 | 31.3 | 383 | 438.2 | 93 | 88–96 |
| Vaccinated 4–5 months ago | | | | | | |
| 18–49            | 0 | 0.0 | 179 | 55.8 | NA | NA |
| 50–64            | 7 | 22.8 | 270 | 229.9 | 90 | 79–95 |
| ≥ 65             | 107 | 67.5 | 383 | 438.2 | 85 | 81–88 |
| Vaccinated ≥ 6 months ago | | | | | | |
| 18–49            | 5 | 42.8 | 179 | 55.8 | 23 | 0–69 |
| 50–64            | 2 | 25.0 | 270 | 229.9 | 89 | 56–97 |
| ≥ 65             | 119 | 248.3 | 383 | 438.2 | 43 | 30–54 |

CI: confidence interval; COVID-19: coronavirus disease; mRNA: messenger ribonucleic acid; NA: not applicable; SARI: severe acute respiratory infection; SARS: severe acute respiratory syndrome coronavirus 2.

4 Individuals without previous COVID-19 diagnosis were defined as individuals without a record of a positive SARS-CoV-2 RT-PCR in the national COVID-19 database more than 3 weeks before the week under observation within the SARI surveillance database known as EPISARI [2].

5 Fully vaccinated individuals with mRNA vaccines were defined as individuals who had received two doses of Comirnaty (BNT162b2 mRNA, BioNTech-Pfizer, Mainz, Germany/New York, United States) or Spikevax (mRNA-1273, Moderna, Cambridge, United States) vaccine at least 14 days before the week under observation.

6 Unvaccinated individuals were defined as individuals who had not received any dose of vaccine against COVID-19.

† SARI COVID-19 cases were defined as all SARI cases testing positive for SARS-CoV-2 by PCR or antigen test at admission to hospitals.

Data sources: EPISARI surveillance of severe acute respiratory infections within comprehensive COVID-19 surveillance [2], national electronic registry of vaccinated individuals and adverse events following vaccinations (eRCO), national COVID-19 dataset and Slovenian Central Population Registry.
Acknowledgements

We would like to thank the EPISARI Network members from the National Institute of Public Health and all 29 Slovenian hospitals for EPISARI data collection and management, and all vaccination teams in Slovenia to report vaccination data to ERCO.

Funding statement

Collecting of surveillance data is funded by the Slovenian Ministry of Health within the annual funding for the national programme implemented by the National Institute of Public Health (contract number C2711-21-708403).

Conflict of interest

None declared.

Authors’ contributions

Marta Grgč-Vitek, Irena Klavs, Veronika Učakar and Mario Fafangel designed the study, and planned analyses in collaboration with Mojca Serdt, Maja Mrzel and Marjana Vrh. Maja Mrzel and Marjana Vrh analysed the data. Marta Grgč Vitek prepared the first draft of the manuscript in collaboration with Irena Klavs, Veronika Učakar, and Mario Fafangel. All authors revised the manuscript, read and approved the final manuscript.
