Interactions and influence of world painters from the reduced Google matrix of Wikipedia networks

Samer El Zant¹, Katia Jaffrès-Runser¹, Klaus M. Frahm² and Dima L. Shepelyansky²

Abstract—This study concentrates on extracting painting art history knowledge from the network structure of Wikipedia. Therefore, we construct theoretical networks of webpages representing the hyper-linked structure of articles of 7 Wikipedia language editions. These 7 networks are analyzed to extract the most influential painters in each edition using Google matrix theory. Importance of webpages of over 3000 painters are measured using PageRank algorithm. The most influential painters are enlisted and their ties are studied with the reduced Google matrix analysis. Reduced Google Matrix is a powerful method that captures both direct and hidden interactions between a subset of selected nodes taking into account the indirect links between these nodes via the remaining part of large global network. This method originates from the scattering theory of nuclear and mesoscopic physics and field of quantum chaos. From this study, we show that it is possible to extract from the components of the reduced Google Matrix meaningful information on the ties between these painters. For instance, our analysis groups together painters that belong to the same painting movement and shows meaningful ties between painters of different movements. We also determine the influence of painters on world countries using link sensitivity between Wikipedia articles of painters and countries. The reduced Google matrix approach allows to obtain a balanced view of various cultural opinions of Wikipedia language editions. The world countries with the largest number of top painters of selected 7 Wikipedia editions are found to be Italy, France, Russia. We argue that this approach gives meaningful information about art and that it could be a part of extensive network analysis on human knowledge and cultures.

Index Terms—Big Data, Google matrix, Markov chains, Wikipedia networks

I. INTRODUCTION

"The art is the expression or application of human creative skill and imagination, typically in a visual form such as painting or sculpture, producing works to be appreciated primarily for their beauty or emotional power" (1). Artists use different approaches and techniques to create emotions. Since the beginning of mankind, painters have offered masterpieces in the form of paintings and drawings to the world. Depending on historical periods, cultural context and available techniques, painters have followed different art movements. Art historians group painters into art movements to capture the fact that they have worked in the same school of thought. But a painter could be placed in several movements as his works evolve with time and its individual intellectual path development (2)–(8).

The major finding of this paper is to show that it is possible to automatically extract this common knowledge on art history by analyzing the hyper-linked network structure of the global and free online encyclopedia Wikipedia (9). The analysis conducted in this work is solely based on a graph representation of the Wikipedia articles where vertices (nodes) represent the articles and the edges (links) provide the hyperlinks linking these articles together. The actual content of articles is never processed in our developments.

Wikipedia has become the largest open source of knowledge being close to Encyclopædia Britannica (10) by the accuracy of its scientific entries (11) and overcoming the later by the enormous quantity of available information. A detailed analysis of strong and weak features of Wikipedia is given in (12), (13). Unique to Wikipedia is that articles make citations to each other, providing a direct relationship between webpages and topics. As such, Wikipedia generates a large directed network of article titles with a rather clear meaning. For these reasons, it is interesting to apply algorithms developed for search engines of World Wide Web (WWW), those like the PageRank algorithm (14) (see also (15), (16)), to analyze the ranking properties and relations between Wikipedia articles. For various language editions of Wikipedia it was shown that the PageRank vector produces a reliable ranking of historical figures over 35 centuries of human history (17)–(20) and a solid Wikipedia ranking of world universities (WRWU) (17), (21), (22). It has been shown that the Wikipedia ranking of historical figures is in a good agreement with the well-known Hart ranking (23), while the WRWU is in a good agreement with the Shanghai Academic ranking of world universities (24).

At present, directed networks of real systems can be very large (about 4.2 million articles for the English Wikipedia edition in 2013 (16) or 3.5 billion web pages for a publicly accessible web crawl that was gathered by the Common Crawl Foundation in 2012 (25). For some studies, one might be interested only in the particular interactions between a very small subset of nodes compared to the full network size. For instance, in this paper, we are interested in capturing the interactions of nodes using the networks extracted from 7 Wikipedia language editions (FrWiki, EnWiki, DeWiki, ItWiki, EsWiki, NlWiki and RuWiki). We use the network datasets of Wikipedia 2013 described in (20). The selected nodes (their Wikipedia articles) are embedded in a huge complex directed network with millions of nodes. Thus, the interactions between these selected sets of nodes should be correctly determined taking into account that there are many indirect links between the webpages via all other nodes of the

In this paper, we extract from $G_R$ and its decomposition into direct and indirect matrices a high-level reduced network of $N_R$ painters. This high-level network is computed with both direct and hidden (i.e. indirect) interactions. More specifically, we deduce from $G_R$ a fine-grained classification of painters that captures what we call the hidden friends of a given node. The structure of these graphs provides relevant information that offers new information compared to the direct network of relationships.

The aforementioned networks of direct and hidden interactions can be calculated for different Wikipedia language editions. In this paper, reduced Google matrix analysis is applied to the set of 30 painters and the set of 40 painters with 40 countries, from seven different Wikipedia language editions (English, French, German, Spanish, Russian, Italian and Dutch). We will refer to these editions using EnWiki, FrWiki, DeWiki, EsWiki, RuWiki, ItWiki and NlWiki in the remainder of this paper. In total we analyzed the list of 3249 painters taken from \cite{10}, restricted to the ones that are present in all 7 language editions. Moreover, we provide hereafter, an analysis of the influence of top PageRank painters.

2The networks of EnWiki, FrWiki, RuWiki, DeWiki, EsWiki, ItWiki, RuWiki and NlWiki contain 4,212, 1,353 , 0.966, 1.533, 1.017, 0.974 and 1.14 millions of articles respectively.

network. In previous works, a solution to this general problem has been proposed in \cite{26,27,28} by defining the reduced Google matrix theory. Main elements of reduced Google matrix $G_R$ will be presented in Section \S This approach develops the ideas of scattering theory of nuclear and mesoscopic physics and quantum chaos adapted to Markov chains and Google matrix \cite{26,27}.

In a few words, $G_R$ captures in a $N_R$-by-$N_R$ Perron-Frobenius matrix the full contribution of both direct and indirect interactions existing in the regular Google matrix model of the network, but only for the reduced set of $N_R$ nodes. The number $N_R$ is in the order of a few tens of nodes, which is considerably smaller that the size of the full Wikipedia network which contains millions of nodes. Elements of reduced matrix $G_R(i,j)$ can be interpreted as the probability for a random surfer starting at webpage $j$ to arrive in webpage $i$ using direct and indirect interactions. Indirect interactions refer to paths composed in part of webpages different from the $N_R$ ones of interest. Even more interesting and unique to reduced Google matrix theory, we show here that intermediate computation steps of $G_R$ offer a decomposition of $G_R$ into matrices that clearly distinguish direct from indirect interactions. As such, it is possible to extract a meaningful probability for an indirect interaction between two nodes to happen as shown in the results of \cite{27,28}. Thus the reduced Google matrix theory is a perfect candidate for analyzing the direct and indirect interactions between the selected painters.
Fig. 1. Geographic birthplace distribution of the 223 painters that appear at least one time in the PageRank top 100 painters of one of 7 language editions analyzed. Top panel represents 223 painters for all centuries till present, while bottom panel represents 88 painters having middle-age year less than year 1800; countries in gray have zero painters. The birth place is attributed to country borders of 2013.

This paper introduces first the main elements of reduced Google matrix theory in Section II. Next, Section III presents the ranking and selection of painters based on the PageRank algorithm. In Section IV the reduced Google matrices are calculated and described for selected sets for seven different language editions. Specific emphasis is given to the very different English, French and German editions. Then, networks of friendship from direct and hidden interaction matrices are created and discussed in Section V. We show that the networks of friends completely capture the well-established history of painting by i) interconnecting densely painters of the same movement and ii) showing reasonable links between painters of different movements. We also obtain the global ranking of painters averaged over all 7 Wikipedia editions and analyze the interactions between them. The influence of painters on world countries is analyzed in Section VI. Finally, Section VII discusses featured results and concludes this paper.

II. REDUCED GOOGLE MATRIX THEORY

It is convenient to describe the network of $N$ Wikipedia articles by the Google matrix $G$ constructed from the adjacency matrix $A_{ij}$ with elements 1 if article (node) $j$ points to article (node) $i$ and zero otherwise. Elements of the Google matrix take the standard form $G_{ij} = \alpha S_{ij} + (1 - \alpha)/N$ [14]–[16], where $S$ is the matrix of Markov transitions with elements $S_{ij} = A_{ij}/k_{out}(j)$, $k_{out}(j) = \sum_{i=1}^{N} A_{ij} \neq 0$ being the node $j$ out-degree (number of outgoing links) and with $S_{ij} = 1/N$ if $j$ has no outgoing links (dangling node). The quantity $0 < \alpha < 1$ is the damping factor which for a random surfer determines the probability $(1 - \alpha)$ to jump to any node; below we use the standard value $\alpha = 0.85$. The right eigenvector of $G$ with the unit eigenvalue gives the PageRank probabilities $P(j)$ to find
a random surfer on a node \( j \). We order nodes by decreasing probability \( P \) getting them ordered by the PageRank index \( K = 1, 2, \ldots, N \) with a maximal probability at \( K = 1 \). From this global ranking we capture the top 50 painters mentioned in Tab. I for 7 editions.

Reduced Google matrix is constructed for a selected subset of nodes (articles) following the method described in [26]–[28] and based on concepts of scattering theory used in different fields including mesoscopic and nuclear physics, and quantum chaos. It captures in a chaos. It captures in a given as well. It derives from \( G_{Initial} \), the matrix average of the individual \( G_N \) of all 7 editions.

### III. Selection of Painters

#### A. Top PageRank painters

We are interested in this part in selecting the most influential painters representative of the seven investigated Wikipedia editions. Importance of nodes is measured in this selection process with the PageRank centrality.

A Matlab script has been written to retrieve all the painters’ names from the “List of painters by name” webpage [30] edited by Wikipedia that lists painters from all ages and various parts of the world. We have collected 3334 names. Next, we get their nodes’ number in our network representation of each Wikipedia edition. Note that some names are not necessarily known for their painting art production (e.g., Hitler). Thus we have made a second check to remove such cases from our list of painters. This initial sorting leads to a group of 3249 distinct names for our 7 selected editions enlisted in [31].

A Google matrix is constructed for each Wikipedia edition following the standard rules described in Section II. From the Google matrix of a given edition, PageRank index \( K \) of all \( N \) nodes is determined. From this vector of \( N \) values, we extract PageRank nodes of identified painters and we reorder them by decreasing PageRank value getting local PageRank index of painters. Tab. I shows the list of the top 50 PageRank painters captured individually by the 7 selected Wikipedia editions. Not surprisingly, the order of top painters changes with respect to

| \( \Theta_P \) rank | \( K_{av} \) rank | Painter | \( \Theta_P \) rank | \( K_{av} \) rank | Painter |
|-------------------|------------------|--------|------------------|------------------|--------|
| 1                 | 1                | Vinci  | 1                | 18               | Botticelli |
| 2                 | 2                | Picasso| 2                | 22               | Kandinsky |
| 3                 | 6                | Van Gogh| 3                | 23               | Botticelli |
| 4                 | 4                | Dürer  | 4                | 24               | Caravaggio |
| 5                 | 5                | Rubens | 5                | 25               | Velasquez  |
| 6                 | 8                | Durer  | 6                | 26               | Degas     |
| 7                 | 9                | Titian | 7                | 27               | Bruegel Eld |
| 8                 | 11               | Monet  | 8                | 28               | Degas     |
| 9                 | 12               | Dali   | 9                | 29               | Reim  |
| 10                | 14               | Cézanne| 10               | 30               | Chagall |
| 11                | 3                | Michelangelo| 11               | 31               | Lautrec |
| 12                | 7                | Raphael| 12               | 32               | Vermeer |
| 13                | 10               | Goya   | 13               | 33               | Poussin |
| 14                | 13               | Vasari | 14               | 34               | Turner |
| 15                | 16               | Titian | 15               | 35               | Braque |
| 16                | 15               | Warhol | 16               | 36               | Blake |
| 17                | 17               | Delacroix| 17               | 37               | Greco |
| 18                | 22               | Manet  | 18               | 38               | Miró |
| 19                | 20               | David  | 19               | 39               | Munch |
| 20                | 24               | Gauguin| 20               | 40               | Eyck |
the editions due to cultural bias but there are some main trends, e.g.:
- Leonardo Da Vinci ranks first place in 5 out of 7 editions,
- Michelangelo and Picasso belong to the top 4 in all editions,
- Russian painters, like Viktor Vasnetsov and Ivan Aivazovsky, are in the top 20 of RuWiki but don’t appear before rank 50 in other editions.

Using the PageRank of all 3249 painters computed for 7 language editions, we have extracted 223 painters by creating the union set of top 100 painters of each language edition. The top panel of Fig. 1 illustrates the statistics of birth countries for these 223 painters (country borders are taken for year 2013). There is a clear predominance of European painters in this selection with a strong part of Russian artists as well.

B. Global ranking of painters

The above results demonstrate different cultural views on the importance of painters in the different language edition of Wikipedia. To get a global, multi-cultural importance of painters we use the approach proposed in [19], [20]. It defines a global rank $\Theta_P$ with:

$$\Theta_P = \sum_E (101 - R_{P,E}).$$

Here $R_{P,E}$ is the rank of the top 100 painters $P$ in Wikipedia edition $E$ retrieved with PageRank algorithm. The painters with the largest $\Theta_P$ score are the most important ones for $E$ Wikipedia editions. Based on $\Theta_P$ score, we have selected two different sets of painters for our investigations.

a) Top 40 painters: From the $\Theta_P$ score calculated for the $E = 7$ Wikipedia editions of interest (e.g. EnWiki, FrWiki, RuWiki, DeWiki, ItWiki, EsWiki and NlWiki), we have selected the top 40 painters enlisted in Tab. II by order of importance.

b) Painting categories network: This second set has been chosen to illustrate the existence of painting movements and how the reduced Google matrix analysis captures them automatically. This set is composed of 30 painters that belong to the six following painting categories: Cubism, Impressionism, Fauvism, Great masters and Modern art (20th century).

Following an average ranking $\Theta_P$ score calculated for 3 Wikipedia editions (EnWiki, FrWiki and DeWiki), we have selected the top 5 painters of each category. They are enlisted in Tab. III by order of appearance. This Table also lists local PageRank index for painters in the French, English and German Wikipedia editions. Painters that belong to the same movement or having a common piece of history may

| Name     | Category  | Colour | FrWiki | EnWiki | DeWiki |
|----------|-----------|--------|--------|--------|--------|
| Picasso  | Cubism    | Red    | 1      | 2      | 2      |
| Monet    | Impressionists | Green  | 4      | 9      | 11     |
| Cezanne  | Impressionists | Green  | 8      | 12     | 9      |
| Manet    | Impressionists | Green  | 12     | 13     | 16     |
| Renoir   | Impressionists | Green  | 15     | 14     | 17     |
| Degas    | Impressionists | Green  | 18     | 16     | 21     |
| Pissarro | Impressionists | Green  | 23     | 19     | 23     |
| da Vinci | Great masters | Orange | 2      | 1      | 1      |
| Michelangelo | Great masters | Orange | 5      | 3      | 4      |
| Raphael  | Great masters | Orange | 5      | 4      | 5      |
| Rembrandt| Great masters | Orange | 9      | 5      | 6      |
| Rubens   | Great masters | Orange | 10     | 7      | 7      |
| Durer    | Great masters | Orange | 14     | 8      | 3      |
| Dali     | Modern 20-21 | Pink   | 21     | 18     | 15     |
| Kandinsky| Modern 20-21 | Pink   | 20     | 17     | 10     |
| Chagall  | Modern 20-21 | Pink   | 21     | 18     | 15     |
| Miró     | Modern 20-21 | Pink   | 26     | 23     | 14     |
probably exhibit stronger interactions in Wikipedia. As such, we have created a color code that groups together painters that either belong to the same movement (e.g. Fauvism, Cubism, Impressionists) or share a big part of history (e.g. Great Masters, Modern). Color code is as follows: Red, Blue, Green, Orange and Pink represents Cubism, Fauvism, Impressionists, Great masters and Modern (20-21st century), respectively.

IV. REDUCED GOOGLE MATRICES

To illustrate the matrices derived by the reduced Google matrix analysis, we plot $G_R$, $G_{rr}$ and $G_{qrnd}$ in Fig. 2 for the set of 30 painters composing the Painting categories network in Tab. III. The targeted edition is EnWiki.

Columns and lines are ordered with the order set in Tab. III. Following observations can be made. $G_R$ is per-column normalized and dominated by the projector $G_{pr}$ contribution, which is proportional to the global PageRank probabilities (for more details see in [25], [27]). As such, we clearly see that the density of each line of $G_R$ is proportional to the importance of the painter in the full network. The matrices are interpreted in the following way: painter of column $j$ is linked with the probability of element $(i, j)$ to the painter of line $i$.

The matrix $G_{rr}$ provides information only on direct links between painters. In other words, it represents the probability for a random surfer to reach the painter of line $i$ from the article of the painter of column $j$ using a hyperlink linking article $j$ to article $i$ in Wikipedia. On the contrary, $G_{qrnd}$ offers a much more unified view of painters interactions as it captures more general indirect (or hidden) interactions via the $N - N_r$ other nodes of the full Wikipedia network. In other words, it represents the probability linking the painter of column $j$ to the painter of line $i$ related to all indirect paths linking article $j$ to article $i$ in the full network. An indirect path starts with a hyperlink linking the article of painter $j$ to an article $k$ that doesn’t belong to the $N_r$ nodes and ends with a hyperlink ending on the article of node $i$.

Reading Fig. 2 we can extract strong and meaningful interactions between painters. New links appearing in $G_{qrnd}$ and being absent from $G_{rr}$ exist. As an example we list the links between Picasso and Braque, Pissaro and Monet, Rouault and Matisse. These relationships are very well known in art history, but looking at the pure structure of the network (i.e. reading $G_{rr}$ matrix), they are absent. They appear clearly in the higher order mathematical analysis of the network using $G_{qrnd}$. For instance, it is common knowledge that since his visit to Picasso’s studio, Braque became impressed by Picasso's paintings. They even became friends [32], which confirms our result. Pissaro and Monet are both impressionists. Monet succeeded in reaching England after entrusting a number of his works to Pissaro [33]. Rouault and Matisse were both students of Gustave Moreau [34] and were deeply influenced by him throughout their life [35]. Their relationship began in 1906 and lasted all their life. All these interactions can be extracted from the network of Wikipedia webpages using $G_{qrnd}$ matrix.

In order to simplify the reading and interpretation of these matrices, we have introduced in [26]–[28] a set of tools that captures essential features of the reduced network. In Section V we build the friendship networks for our sets of painters and in Section VI we analyze the influence of painters on countries using the PageRank sensitivity analysis of $G_R$.

V. FRIENDSHIP NETWORKS

A. FRIENDSHIP NETWORK CONSTRUCTION

It is possible to extract from $G_{rr}$ and $G_{qrnd}$ a network of friendship to conveniently illustrate direct and hidden links in the network, or a combination of both. Direct links are extracted from $G_{rr}$, while hidden (i.e. indirect) are extracted from $G_{qrnd}$. The network of friends is built by considering larger matrix elements in a column $j$ of a given painter as top friends (i.e. there is a high probability to end in node $i$ from node $j$). It is true that the word friend usually represents a symmetrical relationship. But we have chosen this denomination for its ease of use. Clearly, in this paper, a friend represents a node that is an attractor for the node of interest. From the notion of friendship, we derive the networks of friends shown in Fig. 3 and Fig. 4. In Fig. 3 the set of top 40 painters is analyzed while in Fig. 4 the painting categories set is investigated. Both networks of friends have been derived in the following way:
Fig. 3. **Friendship networks for the top 40 painters data set** listed in Tab. II. Top panel: Friendship network extracted from $G_{rr} + G_{qrnd}$ computed with FrWiki. Bottom panel: Friendship network extracted from the matrix $G_{rrav} + G_{qrndav}$, where $G_{Rav}$ is the average of the $G_{R}$ matrices obtained for all 7 Wikipedia editions. For each painter in the set, arrows are drawn to its top 4 friends. Arrows are colored in red if component $G_{qrnd}$ is larger than component $G_{rr}$, and in black otherwise. Both graphs are automatically plotted using Yifan Hu layout with Gephi.\[1\]
Fig. 4. **Friendship networks for the painting categories data set** listed of Tab. III Results are extracted from the $G_{qrnd}$ matrix derived from EnWiki (left), FrWiki (middle) and DeWiki (right). Red, Blue, Green, Orange and Pink nodes represents Cubism, Fauvism, Impressionists, Great masters and Modern(20-21) respectively. The top painter node points with a bold black arrow to its top 4 friends. Red arrows represent the friends of friends interactions computed until no new edges are added to the graph. All graphs are automatically plotted using Yifan Hu layout with Gephi.

- For Fig. 3 arrows representing 4 outlinks are drawn from each painter to its top 4 friends in the matrix $G_{rr} + G_{qrnd}$. In this figure, we mark arrows in red if the $G_{qrnd}$ component (i.e. indirect link probability) is larger than the $G_{rr}$ component (i.e. direct link probability). Black arrows thus represent the opposite case. The graphs are automatically plotted with Gephi [42] using the Yifan Hu algorithm. In other words, for each painter $j$ of Tab. III we extract from sum of both matrices the top 4 Friends given by the 4 strongest elements of column $j$. This figure represents two different views: i) a regional view (top panel) as $G_{rr} + G_{qrnd}$ are computed for FrWiki and ii) a unified view (bottom panel) as the friendship network is built from $G_{rrav} + G_{qrndav}$ which is defined as the average of the corresponding matrices computed over all 7 Wikipedia editions.

- In Fig. 4 we capture for the Painting categories data set the sole indirect interactions provided by $G_{qrnd}$ between the 5 categories of painters. Therefore, we have selected the most influential painter in each category. This category leader is the one with the best (i.e. smallest) average ranking score over all 6 selected Wikipedia editions. The top painters are Pablo Picasso for Cubism, Henri Matisse for Fauvism [36], Claude Monet for Impressionists [37], Leonardo Da Vinci for Great Masters and Dali for Modern. The networks of Fig. 4 are created by marking with black arrows the link between each leading painter and its top 4 friends in $G_{qrnd}$. Red arrows represent the friends of friends interactions computed until no new edges are added to the graph. Three networks are plotted, originating from EnWiki, FrWiki and EnWiki.

We discuss next the interesting results observed for both networks of painters.

B. Top 40 painters networks

This part discusses the friendship networks of Fig. 3. The point of our analysis is to underline the relative importance of direct and indirect interactions. For black arrows, the direct component $G_{rr}$ is stronger than the indirect one $G_{qrnd}$. For red arrows, the indirect component is the strongest.

The top panel presents the French Wikipedia view of this painter network. A large proportion of arrows are red, meaning that in this case the indirect interaction between nodes is contributing a lot to building the network. The graph has a clear structure of three main clusters: painters who worked in France (right part around Matisse-Picasso-Monet-Van Gogh), the ones that have worked in Italy (left top corner with Da Vinci-Titian-Botticelli) and the ones that have worked in the Netherlands and Belgium (bottom left corner with Rubens-Rembrandt Van Rijn-van Dyck). This shows that our network analysis captures realistic relations between painters.
However, the above presentation takes into account only the opinion of the FrWiki edition with a dominance of French culture linked to French language. It is interesting to have the network structure which takes into account the opinions of all 7 editions. In fact the approach of the reduced Google matrix is well suited for this. Indeed, to perform the average over different cultures we take $G_{R}$ for 40 painters (size 40) and its components and take the average of these 7 matrices with equal democratic weights getting in this way the average $G_{R_{av}}$ and its average 3 components. Of course, after averaging $G_{R_{av}}$ still belongs to the class of Google matrices. The network structure obtained from $G_{R_{av}} + G_{qrand}_{av}$ is shown in the bottom panel of Fig. 3. In global the two centers with painters worked in France (on the right) and in Italy (left) is similar to the case of FrWiki in the top panel. However, the number of indirect links (red arrows) is decreased. We attribute this to increased number of direct links present in all 7 editions.

We also note that $G_{R_{av}}$ has now a new average PageRank vector $P_{av}(K_{av})$, which takes into account opinions of all 7 cultures (it is different from the simple averaged probabilities of 7 individual PageRank vectors). This average rank index $K_{av}$ is shown in Tab. [I]. The top two positions are the same as for $\Theta$-rank, however, there is a noticeable change of order in positions 3-12 with more importance given to ancient Italian masters like Michelangelo, Raphael, Titian who moves to the top $K_{av}$ positions while more recent painters such as Van Gogh, Monet, Dali are getting larger $K_{av}$ values. We attribute this to the fact that the ancient historical figures are on average better reviewed in various cultures and Wikipedia editions.

### C. Paintings categories network

Fig. 4 illustrates the indirect interactions provided by $G_{qrand}$ in the painting categories network. The 5 leading painters are connected with black arrows to the top 4 friends. And these friends are connected to their top 4 friends with red arrows. Thus $G_{qrand}$ seems to emphasize finer-grained regional interactions and by looking at the interactions, we can see the strong relationship between Da Vinci, Michelangelo and Raphael which can be explained by the fact that they are the nucleus of fifteenth-century Florentine art. Another strong relation could be snapped between Mirò and Dali, as both are inspired by Picasso.

Impressionists, Fauvism, Cubism and Great masters create, in all editions, a cluster of nodes densely interconnected. The group of Modern painters plays a role by connecting the other categories:

1. Dali seems to be the common interconnection node between Fauvism and Cubism categories in EnWiki.
2. Kandinsky connects Fauvism and Cubism in FrWiki.
3. Munch connects Impressionists and Fauvism in DeWiki.

The networks of $G_{qrand}$ end up almost spanning the full set of 30 painters.

These links show that the interactions between the painters groups are coherent. These graphs picture the essence of painting history by grouping together painters that belong to the same movement and by interconnecting them in a reasonable and close-to reality way.

For instance, our graphs are consistent with the history of modern art which starts with the Impressionism movement (1870-1890) that searched for the exact analysis of the effects of color and light in nature. The painters we have selected are among the most important ones of the movement and they create a clear cluster of nodes in Fig. 4 (see green nodes) as they exhibit a tight relationship in $G_{R}$. The Fauvism movement emerged after impressionist (1899-1908) and Munch connects Impressionists and Fauvism in DeWiki.

Fauvist painters were concerned with the impression created with colors. This movement was inspired by different artists such as Matisse. The Fauves members were a loosely shaped group of artists with shared interests. Henri Matisse became later the leader of the group of artists. He introduced unnatural and intense color into their paintings to describe light and space. The fauvism movement is the precursor of the Cubism movement. Our result shows deep relationships between Fauvism and Cubism, noting that Braque is always the core of this interconnection. Cubism movement (1907-1922) is pretty distinct from Impressionism, which is underlined as well in our graphs with only a few red links connecting these two clusters of nodes.

### VI. INFLUENCE OF PAINTERS ON COUNTRIES

#### A. Datasets

Another complementary study is presented here to visualize the influence of painters on countries. To analyze the relation between painters and countries of the world we construct a reduced Google matrix with $N_{r} = 80$ nodes composed of the top 40 painters shown in Table I and the group of 40 countries listed in Table IV. The painters are the ones having top $\Theta_{P}$-score for $E = 7$: EnWiki, FrWiki, RuWiki, DeWiki, ItWiki, EsWiki and NiWiki. Table I only lists short names, however, the full painter names together with their $\Theta_{P}$-score, birth country and life period are available as well in [41]. The top 40 countries of EnWiki are presented in Table IV. The names of countries are given by ISO 3166-1 alpha-2 code (see [47]).

| Order | Country | Order | Country |
|-------|---------|-------|---------|
| 1     | US      | 21    | NO      |
| 2     | FR      | 22    | RO      |
| 3     | GB/UK   | 23    | TK      |
| 4     | DE      | 24    | ZA      |
| 5     | CA      | 25    | BE      |
| 6     | IN      | 26    | AT      |
| 7     | AU      | 27    | GR      |
| 8     | IT      | 28    | AR      |
| 9     | JP      | 29    | PH      |
| 10    | CN      | 30    | PT      |
| 11    | RU      | 31    | PK      |
| 12    | ES      | 32    | DK      |
| 13    | PL      | 33    | IL      |
| 14    | NL      | 34    | FI      |
| 15    | IR      | 35    | EG      |
| 16    | BR      | 36    | ID      |
| 17    | SE      | 37    | HU      |
| 18    | NZ      | 38    | TW      |
| 19    | MX      | 39    | KR      |
| 20    | CH      | 40    | UA      |
Fig. 5. Network structure of top 3 country friends for top 40 painter network for EnWiki. Painters are selected from the global rank list of 7 Wikipedia editions from Table II for top 40 PageRank countries of EnWiki from Table IV. Arrows are showing links only from a painter to top 3 countries, they are given by links of matrix elements $G_{rr} + G_{qrnd}$. Red arrow mark links when an element $G_{qrnd}$ is larger than element $G_{rr}$, black arrows are drown in opposite case. Countries and shown by red circles and painters are shown by yellow circles.

B. Networks of painters and countries

The three painters with the largest $\Theta_P$ score are:
1) Leonardo Da Vinci with $\Theta = 698$, born in Italy,
2) Pablo Picasso with $\Theta = 688$, born in Spain,
3) Vincent Van Gogh with $\Theta = 656$, born in the Netherlands.

The following painters are the most important one for their country of birth:
- Peter Paul Rubens for Germany with $\Theta = 651$ (but worked mainly in Netherlands),
- Claude Monet for France with $\Theta = 605$,
- Wassily Kandinsky for Russia with $\Theta = 515$,
- Joseph Mallord William Turner for United Kingdom (UK or GR) with $\Theta = 386$.

The top 6 countries with the largest number of painters from the global list of 223 painters are Italy (50), France (45), Russia (27), Germany (26), USA (14), Spain (11) (note that the 223 other countries are listed as well in [31]).

The geopolitical relations between painters and countries has been analyzed more precisely for EnWiki, FrWiki and DeWiki data. Therefore, we have plotted a network of friendship between our 40 painters and their top 3 most friendly countries. This network has been calculated using $G_{rr}$ and $G_{qrnd}$ for the union of 40 painters and 40 countries.

Resulting networks are shown in Figure 5, 6 and 7 for EnWiki, FrWiki and DeWiki, respectively. The network structure is different for each edition due to different cultural views and preferences. However, the central role of France and Italy is well visible in all 3 editions.

C. Influence of painters on countries

To analyze in a more direct way the world influence of painters we average $G_R$ matrix and its three components $G_{pr}$, $G_{rr}$, $G_{qr}$ over 7 Wikipedia editions that allows us to account for different cultural views on selected 40 painters of Table II and 40 countries of Table IV. The reduced Google matrix $G_{Rav}$ averaged over these 7 different editions allows us to obtain a balanced view of various cultural opinions of Wikipedia language editions for a selected group of nodes representing Wikipedia articles. We determine the PageRank probability of this averaged $G_R$ matrix and compute its logarithmic derivative (sensitivity) with respect to a weight variation of a selected link going from a specific painter to a specific country. For instance, we vary the intensity in $G_R$ of the link going from Picasso to Spain, and observe the variation of PageRank for other countries. This PageRank probability variation is defined as the sensitivity $D(i)$ of a node $i$ to a link.
Grigoris E. Papadopoulos, Konstantinos M. Tsipras, Charalampos K. Zacharakis, and Vassilis S. Verykios

change. We refer the reader to [29] for a precise definition of $D$ ($D$ essentially is given by a logarithmic derivative of PageRank probability in respect to a relative link weight variation).

a) Influence of Picasso link to Spain and France: Figure 8 shows the sensitivity $D$ of 40 world countries with respect to a link variation from Picasso to Spain (top panel) and from Picasso to France (bottom panel). Pablo Picasso, the son of the Spanish painter Don José Ruiz y Blanco, was born in Spain in 1881. Pablo began painting since he was eight, and in 1896, he has joined the art and design school of Barcelona "Escola de la Llotja". In 1904, Picasso married Fernande Olivier a French painter. He has worked at that time with Emile Bernard, Henri de Toulouse-Lautrec, Georges Seurat, Paul Signac and Gauguin. These relationships and the work achieved by Van Gogh in France explain our results in the top panel of Figure 9 which shows that France is strongly influenced by a link variation from Van Gogh to the Netherlands.

The Italian painter Leonardo Da Vinci learned painting in the workshop of Verrochio in Florence, and crafted there its first painting between 1472 and 1474. Da Vinci was based in Italy until 1516, when Francois I (King of France) invited him to join the Royal court as: "The King’s First Painter, Engineer and Architect". Da Vinci died in France four years after his arrival. Da Vinci’s works was highly noted by French statesmen. Louis XII and (later) Napoleon though to bring “The Last Supper” to France. “Madonna of the Yarnwinder” is a painting done by Da Vinci to respond the demand of the secretary of state of Louis XII of France. Leonardo brought a version of the "Virgin of the Rocks" to France. One of the most important painting of Da Vinci is "Mona Lisa", currently displayed at Louvre Museum in Paris, was finalized in the Royal court of Francois I. All these elements about the relations between Da Vinci, France and Italy, explain the fact that Italy is strongly influenced by a link variation from Da Vinci to France, as shown in the bottom panel of Figure 9.

c) Diagonal sensitivity of countries: Finally in Figure 10 we present the diagonal sensitivity of countries to their links with painters. This measure is computed by calculating the 2-way sensitivity of Eq. (2) for each painter/country couple. It is the sum of the logarithmic PageRank sensitivity for the painter to country link and the one for the country to painter link. In Eq. (2), $c$ is the index of a country and $p$ of a painter.

$$D_{(p\rightarrow c)}(c) = D_{(p\rightarrow c)}(c) + D_{(c\rightarrow p)}(c)$$ (2)

Also, in Figure 11 we represent the same diagonal sensitivity of countries to Da Vinci and Picasso influence using a world map. In other words, we color the countries with the intensities found on the Da Vinci line (top panel) and the Picasso line (bottom panel) of the matrix of Figure 10. We have previously discussed the relationship between Picasso and Spain and the relation between Da Vinci and Italy which are most sensitive countries in Figure 11 respectively. In this figure, we picture the secondly affected countries for each painter using the 2-way sensitivity metric for a the same bidirectional link variations. It is seen in Figure 11 (bottom) that Poland is greatly impacted by Picasso. The reason is that the Mermaid of Warsaw is a symbol of Warsaw represented on city’s coat as well as in a many imagery and statues. Picasso’s drawing of Warsaw Mermaid explains the weight of 2-way sensitivity between Picasso and Poland and clarify why Poland is highly linked to Picasso [19]. On the other hand, from Figure 11 (top) we find that the second most influenced country by Da Vinci is Switzerland, possibly due to the fact that a central masterpiece of Da Vinci is to be found in Switzerland: Isabella d’Este [50].

To finally conclude this analysis, we can underline that according to Figure 10 Da Vinci, Picasso and Michelangelo are the most influential painters for selected world countries.
Fig. 8. Sensitivity $D$ of 40 world countries to the link variation going from Picasso to Spain and Picasso to France. Top panel: Picasso to Spain and bottom panel: Picasso to France. Data is averaged over 7 Wikipedia editions. For a better visibility, sensitivity of Spain (top) and France (bottom) are given in Figure 10.

VII. DISCUSSION

This paper shows that our sensitivity analysis captures the importance of relationships on network structure. This analysis relies on the reduced Google matrix and leverages its capability of concentrating all Wikipedia knowledge in a small stochastic matrix. We stress that the friendship networks and the sensitivity analysis of influence of painters on countries helped us extract valuable and realistic knowledge from a pure mathematical analysis without any direct appeal to arts, political, economical and social sciences. In a certain sense the reduced Google matrix approach provides an artificial intelligence analysis (the authors have no specific education in arts) of interactions and influence of top painters on world countries using Wikipedia networks.

ACKNOWLEDGMENT

This work was supported by APR 2015 call of University of Toulouse and by Région Occitanie (project GOMOBILE). MASTODONS-2017 CNRS project APLIGOOGLE, (see http://www.quantware.ups-tlse.fr/APLIGOOGLE), EU CHIST-ERA MACACO project ANR-13-CHR2-0002-06 (see http://macaco.inria.fr) and in part by the Programme Investissements d’Avenir ANR-11-IDEX-0002-02, reference ANR-10-LABX-0037-NEXT (project THETRACOM); it was granted access to the HPC resources of CALMIP (Toulouse) under the allocation 2017-P0110. We would like to thank Dr. Hanah Tout from Lebanese University for her valuable comments and data validation.

Samer El Zant received an engineering degree (B.E.) in Communications and electronics from Beirut University in 2014 and a Master of engineering in Networks and systems from the University of Versailles, in 2015. He is currently an instructor at École nationale supérieure d’électrotechnique, d’électronique, d’informatique, d’hydraulique et des télécommunications (ENSEEIHT, Toulouse), and a PhD student at Institut national polytechnique de Toulouse (INPT, Toulouse). His researches focus on reduced Google matrix analysis on Big Data as Wikipedia, Twitter and genetic networks.

Katia Jaffrès-Runser received both a Dipl. Ing. (M.Sc.) in Telecommunications and a DEA (M.Sc) in Medical Imaging in 2002 and a Ph.D. in Computer Science in 2005 from the National Institute of Applied Sciences (INSA), Lyon, France. From 2002 to 2005 she was with Inria, participating in the ARES project while working towards her Ph.D. thesis. In 2006, she joined the Stevens Institute of Technology, Hoboken, NJ, USA, as a post-doctoral researcher. She is the recipient of a three-year Marie-Curie OIF fellowship from the European Union to pursue her work from 2007 to 2010. She currently holds a Maître de conférences (Associate Professor) at University of Toulouse, Toulouse INP-ENSEEIHT. She’s a member of the IRIT laboratory. She’s interested in the performance evaluation of networks.

Klaus M. Frahm received a Diplom degree in Physics in 1989 and his PhD in 1993 at the University of Cologne. After being a post-doctoral researcher at the CEA in Saclay and the University of Leiden he came to the University Paul Sabatier in Toulouse where he obtained in 1998 his HDR degree and is full professor since 2000. Currently he is member of the Laboratoire de Physique Théorique du CNRS in Toulouse (LPT, UMR 5152). His research focuses on random matrix theory with applications to chaotic scattering and quantum transport, localization and interactions, and Perron-Frobenius operators with applications to Google matrices of directed networks.
Fig. 11. Map representation of the diagonal sensitivity of countries to influence of Da Vinci (top panel) and Picasso (bottom panel).

Dima L. Shepelyansky received a Diplom degree in Physics in 1978 at Novosibirsk State University, PhD in 1982 and Russian Doctor Degree in 1989 at Institute of Nuclear Physics of Russian Academy of Sciences, Novosibirsk, Russia. He is a researcher at CNRS Toulouse, France from 1991 and Directeur de Recherche from 1994 at Laboratoire de Physique Théorique du CNRS, Toulouse. His research fields include classical and quantum chaos, nonlinear waves, dark matter dynamics, atom ionization in strong fields, electronic transport, quantum computing, Markov chains and Google matrix of directed networks.
