1. Introduction

The increasing number of cases of multidrug-resistant infections difficult to diagnose and treat pose a major concern to public health care. To overcome these problems, developing new and safe antimicrobial agents with better effectiveness is required (Coates et al., 2002). One of several routes to find new chemotherapeutic agents is to modify the chemical structure of existing medicines which could result in broadening of their spectrum of activity and reducing their toxicity to human body (Moellering, 2011). In our research we decided to synthesized nitrofurazone analogues, because nitrofurazone is important antibacterial agent (McCalla et al., 1970) and in its structure we found the hydrazide-hydrazone moiety which is of our interest due to its promising biological activity (Fig. 1) (Rollas and Küçükülgöz, 2007; Bala et al., 2013).

Recently we have published interesting results concerning antibacterial activity of hydrazide-hydrazone derivatives (Popiołek et al., 2014, 2016a,b; Popiołek and Biernasiuk, 2016a,b). Hydrazide-hydrazones of 3-methoxybenzoic acid showed significant antibacterial activity against Gram-positive bacterial strains, especially against Bacillus spp. ATCC (Popiołek and Biernasiuk, 2016a). In addition to this we have reported that hydrazide-hydrazone derivatives of 2-substituted acetic acid displayed potent bactericidal activity against Gram-positive and Gram-negative bacterial strains (Popiołek and Biernasiuk, 2016b).

It is worth to add that beside antibacterial activity (Küçükülgöz et al., 2002, 2003; Özkay et al., 2010; Deep et al., 2010; Rasras et al., 2010; Kumar et al., 2011; Rutkauskas et al., 2013; Pieczonka et al., 2013; Cukurovali and Yilmaz, 2014; Satyanarayana et al., 2014; Morjan et al., 2014; Rambabu et al., 2015), hydrazide-hydrazone derivatives have attracted much attention thanks to their usability as intermediates in organic synthesis (Rollas and Küçükülgöz, 2007; Bala et al., 2013) and they display a wide spectrum of such interesting biological properties as antifungal (Loncle et al., 2004; Dee et al., 2004; Backes et al., 2014), antitubercular (Koçyiğit-Kaymakçıoğlu et al., 2006, 2009; Pavan et al., 2010; Velezeva et al., 2016), antiviral (Şenkardes et al., 2016), anticancer (Kumar et al., 2012; Çıkla et al., 2013; Wardakkhan et al., 2013; Nasr et al., 2014; Küçükülgöz et al., 2015; He et al., 2016; Mukherjee et al., 2016), anti-inflammatory (Moldovan et al., 2011) and analgesic activity (Mohareb et al., 2010).

Based on the afore mentioned facts, and in an attempt to find new potent antimicrobial agents thanks to this research we synthesized and evaluated for their in vitro antimicrobial activity 21 analogues of nitrofurazone and we discovered that they showed very high bactericidal activity, particularly against Staphylococcus spp. ATTC and Bacillus spp. ATCC (MIC = 0.002–7.81 μg/ml and MBC = 0.002–31.25 μg/ml). The levels of activity of several compounds were far better than those of nitrofurantoin, ciprofloxacin or cefuroxime.
2. Materials and methods

2.1. Chemistry

Reagents and solvent used in this research were purchased from Sigma-Aldrich (Munich, Germany) and Merck Co. (Darmstadt, Germany) and were used without further purification. Melting points were determined on Fisher-Johns blocks melting point apparatus (PC, Gdańsk, Poland). The results of elemental analysis (C, H, N) and purity of obtained compounds were monitored by TLC, using many) and were used without further purification. Melting points were determined on Fisher-Johns blocks melting point apparatus (PC, Gdańsk, Poland). The results of elemental analysis (C, H, N) were within ±0.4% of the calculated values.

2.1.1. Preparation of carboxylic acid hydrazides (9–13, 20)

The compounds 11, 12, 13 were prepared using the procedures reported earlier (Popiołek et al., 2016b). Compound 9, 10, 20 were synthesized by following procedure: 0.01 mol of appropriate ethyl ester of carboxylic acid was dissolved in ethanol and heated under reflux with 0.011 mol of 100% hydrazine monohydrate for 2 h. After that the solution was allowed to cool at room temperature and then was placed in refrigerator for 12 h. Subsequently the precipitation created was filtered off and recrystallized from ethanol.

Physico-chemical and spectral data of compounds 9–13, 20 are presented in Supplementary Materials.

2.1.2. Preparation of nitrofurazone analogues (28–48)

2.1.2.1. General procedure. 0.01 mol of previously obtained carboxylic acid hydrazides (9–13, 20) or commercially available hydrazides (7, 8, 14–19, 21–27) were dissolved in 10–20 ml of ethanol and then 0.011 mol of 5-nitro-2-furaldehyde was added. The mixture was heated under reflux for 3 h. After that the solution was allowed to cool at room temperature and then was placed in refrigerator for 12 h. Subsequently the precipitation created was filtered off and recrystallized from ethanol.

Physico-chemical and spectral data of compounds 28–48 are presented in Supplementary Materials.

2.2. Microbiology

2.2.1. In vitro antimicrobial assay

The examined compounds were screened in vitro for antibacterial and antifungal activities using the broth microdilution method based on European Committee on Antimicrobial Susceptibility Testing (EUCAST) (EUCAST discussion document E. Dis 5.1, 2003) and Clinical and Laboratory Standards Institute guidelines (M27-S4, 2012).

In this research a panel of reference and clinical or saprophytic strains of microorganisms was used. This included Gram-positive bacteria (Staphylococcus aureus ATCC 25923, Staphylococcus aureus ATCC 43300, Staphylococcus aureus ATCC 6538, Staphylococcus epidermidis ATCC 12228, Bacillus subtilis ATCC 6633, Bacillus cereus ATCC 10876, Micrococcus luteus ATCC 10240), Gram-negative bacteria (Escherichia coli ATCC 25922, Klebsiella pneumoniae ATCC 13883, Proteus mirabilis ATCC 12453, Bordetella bronchiseptica ATCC 4617, Salmonella typhimurium ATCC 14028, Pseudomonas aeruginosa ATCC 9027) and fungi belonging to yeasts (Candida albicans ATCC 10231, Candida parapsilosis ATCC 22019).

The antimicrobial assays were performed like in our previous research concerning in vitro screening of hydrazide-hydrazone derivatives (Popiołek and Biernasiuk, 2016a,b). Nitrofurantoin, ciprofloxacin, and cefuroxime (Sigma-Aldrich) were used as reference antibacterial compounds. Fluconazole (Sigma-Aldrich) was used as reference antifungal positive control. All the experiments were repeated three times and representative data were presented.

The MBC/MIC or MFC/MIC ratios were used to determine bactericidal/fungicidal (MBC/MIC < 4, MFC/MIC < 4) or bacteriostatic/-fungistatic (MBC/MIC > 4, MFC/MIC > 4) effect of the tested compounds (Wiegand et al., 2008).
Table 1A
The activity data expressed as MIC (MBC or MFC) [µg/ml] and (MBC/MIC or MFC/MIC ratio) against the reference strains of microorganisms. The standard chemotherapeutics agents: nitrofurantoin (NIT), ciprofloxacin (CIP), ceftroxime (CFX) and fluconazole (FLU) were used as positive control.

3. Results and discussion

3.1. Chemistry

Nitrofurazone analogues analyzed in this study were obtained in the condensation reaction of appropriate carboxylic acid hydrazides (7–27) with 5-nitro-2-furaldehyde. The reactions were performed by heating substrates under reflux for 3 h. In the case of the synthesis of nitrofurazone analogues 28, 29, 35–40, 42–48 commercially available hydrazides of carboxylic acids (7, 8, 14–19, 21–27) were used. Whereas for the synthesis of nitrofurazone analogues (30–34, 41) we initially conducted the synthesis of hydrazides (9–13, 20) by the reaction of appropriate ethyl esters (1–6) with hydrazine monohydrate.

Chemical structures of synthesized compounds were confirmed on the basis of 1H NMR and 13C NMR spectroscopy. The spectra of the compounds we obtained gave satisfactory results and confirmed the formation of expected products. In the 1H NMR spectra of compounds (28–48) two singlet signals for =CH and NH groups appeared at δ 7.92–8.74 ppm and δ 10.95–12.40 ppm, respectively. As for the 13C NMR spectra, signals for =CH group were found in the range of δ 151.6–152.8 ppm, and for the carbonyl group (C=O) at δ 160.1–174.9 ppm. Signals for other aliphatic and aromatic groups in compounds (28–48) were observed at expected regions. Reactions conducted in this study were performed according to the steps presented in the Scheme 1.

3.2. In vitro antimicrobial assay

The results of our study indicated that examined compounds (28–48) exhibited a wide spectrum of antimicrobial activity against tested reference bacteria and yeasts (Tables 1A and 1B). Among these compounds, 28, 29, 32–43, and 45–48 showed very strong, mainly bactericidal effect towards Staphylococcus spp. ATCC and Bacillus spp. ATCC (MIC = 0.002–7.81 µg/ml and MBC = 0.002–7.81 µg/ml) and {MBC/MIC or MFC/MIC ratio} of the tested compounds. 3.91 0.976 0.98 na 15.62 125 0.976 nd na.

Table 1B

The activity data expressed as MIC (MBC or MFC) [µg/ml] and [MIC/MIC or MFC/MIC ratio] against the reference strains of microorganisms. The standard chemotherapeutics agents: nitrofurantoin (NT), ciprofloxacin (CIP), cefuroxime (CFX) and fluconazole (FLU) were used as positive control.
31.25 μg/ml). Substances 38 and 45 were especially potent because of MIC < 1 μg/ml (0.002–0.98 μg/ml) against these bacteria. 

*Staphylococcus epidermidis* ATCC 12228 was the most sensitive to all compounds, while *Micrococcus luteus* ATCC 10240 was the least susceptible. The minimum inhibitory concentrations (MIC) of nitrofurazone analogues (with the exception of inactive 39, 40 and 41), which inhibited the growth of micrococci and killed them (MBC) ranged from 31.25 μg/ml to 1000 μg/ml and from 62.5 μg/ml to >1000 μg/ml, respectively.

The bioactivity of compounds 30, 31 and 44 against Gram-positive bacteria was lower (MIC = 3.91–500 μg/ml and MBC = 7.81 to >1000 μg/ml).

Some of the compounds showed activity towards Gram-negative bacteria. The all reference rods from Enterobacteriaceae family were susceptible to compounds 28–33, 36 and 48 at concentrations from 0.98 μg/ml (S. typhimurium ATCC 14028 and *E. coli* ATCC 25922 against 32) to 500 μg/ml (*P. mirabilis* ATCC 12453 against 30). The other compounds indicated mainly mild bioactivity or had no effect towards these bacteria. Among the studied compounds, derivatives 28, 30, and 31 exhibited also some activity against *P. aeruginosa* ATCC 9027 (MIC = 62.5–500 μg/ml and MBC = 125–1000 μg/ml). The same substances (28, 30, and 31) showed simultaneously the widest spectrum of antimicrobial activity against all tested reference Gram-positive and Gram-negative bacteria and fungi.

The activity of compounds 28, 29, 32–43, and 45–48 was from two to two thousand times higher, depending on the compounds and bacterial strains, in comparison with the activity of nitrofurazone (Table S1 in Supplementary Materials). It is worth to mention especially compounds 32 and 38, which showed almost two thousand times higher activity than nitrofurazone against *Bacillus subtilis* ATCC 6633 and *Staphylococcus epidermidis* ATCC 12228, respectively.

Compounds 32, 33, 36, 38, 39 and 40 showed from 2 to 61 times better activity than ciprofloxacin on the basis of MIC values. Especially, compound 38 can be considered as the best analogue because its MIC value was 61 times lower than the MIC of ciprofloxacin against *Staphylococcus epidermidis* ATCC 12228 (Table S2 in Supplementary Materials).

The antibacterial activity of all tested compounds (28–48) against Gram-positive bacteria was also in some cases higher, depending on the compounds and bacterial strains, than the activity of cefoxime (Table S3 in Supplementary Materials). Especially it is worth to mention compound 32 whose MIC value against *Bacillus subtilis* ATCC 6633 was almost 8000 times lower than the MIC of cefoxime.

Moreover 30, 31 and 36 possessed good fungidical or fungistatic bioactivity against yeasts belonging to *Candida* spp. ATTC with MIC = 31.25–125 μg/ml and MFC = 125–1000 μg/ml and it was higher than that of flucanazole used as the reference substance. The remaining newly synthesized compounds were less active or inactive towards reference fungi (Tables 1A and 1B).

4. Conclusions

In our research we synthesized and evaluated a series of 21 nitrofurazone analogues for in vitro antimicrobial activity. All synthesized compounds have been identified by means of 1H NMR and 13C NMR spectroscopy, and subjected to in vitro antimicrobial assays. Our antimicrobial screening results revealed that several synthesized compounds possessed very high bactericidal activity, mainly against Gram-positive bacteria. It is worth to stress that in many cases the activity of obtained derivatives was far better than the activity of commonly used chemotherapeutic agents.

Conflict of interest

The authors declare no conflict of interest.
