INTRODUCTION: Primary malignant hepatic mesotheliomas are extremely rare. We report the case of a patient with primary intrahepatic malignant mesothelioma who was treated in our department.

PRESENTATION OF CASE: A 66-year old male patient was admitted to our department for the evaluation of anemia. An abdominal computed tomography scan revealed a large space occupying lesion in the right liver lobe.

DISCUSSION: The tumor was subsequently resected and a diagnosis of primary intrahepatic malignant mesothelioma was made after pathologic examination. The patient did not receive adjuvant therapy and is currently alive and free of disease, 36 months after the resection.

CONCLUSION: To our knowledge this is the eighth adult case of primary intrahepatic malignant mesothelioma reported in the literature. These tumors are rarely diagnosed preoperatively. Absence of previous asbestos exposure does not exclude malignant mesothelioma from the differential diagnosis. Proper surgical treatment may offer prolonged survival to the patient, without adjuvant therapy.

1. Introduction

Mesothelioma is an insidious neoplasm arising from the mesothelial surfaces of the pleural and peritoneal cavities, the tunica vaginalis, or the pericardium. Eighty percent of all cases are pleural in origin. The predominant cause of malignant mesothelioma is inhalational exposure to asbestos. The annual incidence of mesothelioma in the United States is estimated to be approximately 3300 cases per year. Primary malignant mesotheliomas arising in the liver are extremely rare. We present the case of a 66-year old male patient with primary intrahepatic malignant mesothelioma who was treated in our department.

2. Presentation of case

A 66-year old male patient was referred to our department in November 2011 with a history of malaise during the previous two months. The patient’s medical history was significant only for arterial hypertension, being treated with two antihypertensive drugs. The patient had no history of prior asbestos exposure or chronic liver disease. Previous laboratory examinations had revealed anemia (Hb = 8.5 g/dL, Hct% = 29.3%) and the patient had received oral iron supplementation for two months with no improvement. Colonoscopy and gastroscopy had no significant findings, apart from mild gastritis and hemorrhoids.

Upon presentation, physical examination revealed a palpable mass in the right upper abdomen. There were no signs of jaundice or abdominal tenderness. Significant results of laboratory tests on admission were as follows: hemoglobin = 7.5 g/dL, hematocrit = 23.8%, INR = 1.4, alkaline phosphatase (ALP) = 227 IU/L (normal range 40–150), total proteins = 9.1 g/dL (normal range 6.7–8.8), albumin = 2.3 g/dL (normal range 3.5–5), C-reactive protein = 67 mg/L (normal range <5), carcinoembryonic antigen (CEA) = 1.9 µg/L (normal range <5), α-fetoprotein (AFP) = 2.4 µg/L (normal range <20), Ca19-9 = 2 u/mL (normal range <37), Ca125 = 259.7 u/mL (normal range <35), Ca15-3 = 69 u/mL (normal range <30). The rest of the laboratory examinations were within normal range.

The patient underwent computed tomography of the chest and abdomen, which revealed an extensive space occupying lesion in the right liver lobe, measuring 17 cm in diameter. The tumor displayed abnormal enhancement following intravenous administration of contrast material (Figs. 1 and 2). A core needle biopsy which was performed was not helpful as it contained only necrotic material without evidence of malignancy.

On November 7, 2011 the patient underwent exploratory laparotomy which revealed a sizable mass in the right liver lobe without evidence of metastatic disease in the abdomen. A typical right hepatectomy was undertaken. In the first postoperative
day liver function tests revealed a sudden increase in bilirubin and transaminases levels, which was attributed to hemolysis and transient liver failure. Liver function tests returned progressively to normal and the patient was discharged on the seventh postoperative day.

On gross examination the lobectomy specimen was massively infiltrated by a brown, partly hemorrhagic tumor, with soft consistency, measuring 18 × 15.5 × 8 cm, extending to the capsular surface (Fig. 3). Microscopically, the tumor was composed of tubular or cord like arrangements of epithelioid cells with eosinophilic cytoplasm and atypical nuclei (Fig. 4). Immunohistochemically, tumor cells were positive for EMA, CK-7, CK 5/6, Calretinin (Fig. 5), Pankeratin and Vimentin, but negative for CEA (monoclonal), P-63, CD-10, Synaptophysin, Chromogranin, CD-56, TTF-1, HepPar-1, HBsAg, CD-15, CD-30, PLAP and β-HCG. Immunohistological analysis of the proliferation marker Ki-67 showed expression in 15–20% of the tumor cells. These findings were consistent with our diagnosis of primary intrahepatic malignant mesothelioma of the epithelioid type. Resection margins were free of disease.

After oncology consultation, the patient did not receive adjuvant chemotherapy postoperatively. He remains alive and free of disease 36 months after the operation.

3. Discussion

Primary intrahepatic malignant mesotheliomas are extremely rare. To our knowledge this is the eighth adult case of primary intrahepatic malignant mesothelioma reported in the literature.2–8 There have been reports of mesotheliomas originating in the
Table 1 summarizes the seven cases of primary intrahepatic malignant mesotheliomas reported in the literature.

### 4. Conclusion

In conclusion, malignant mesothelioma of the liver is rarely diagnosed preoperatively, as there are no specific radiologic features for this tumor. Absence of previous asbestos exposure does not exclude malignant mesothelioma from the differential diagnosis. Proper surgical treatment may offer prolonged survival to the patient, without adjuvant therapy.

**Conflict of interest statement**

I. Perysinakis, A. Nixon, I. Spyridakis, G. Kakiopoulos, C. Zorzos and I. Margaris have no conflicts of interest or financial ties to disclose.

**Funding**

None.

**Ethical approval**

Written informed consent was obtained from the patient for publication of this case report and accompanying images. A copy of the written consent is available for review by the Editor-in-Chief of this journal on request.
