Abstract

The wounded quark-diquark model predictions for charged pions multiplicities in $PbPb$ and $pPb$ collisions in the central rapidity region at $\sqrt{s} = 17.3$ GeV c.m. energy are presented.

1. The NA49 collaboration published precise results\(^1\) on inclusive production of charged pions in $pp$ collisions at $\sqrt{s} = 17.3$ GeV [1].

This measurement allows to investigate the consequences of the wounded quark-diquark model [2] for particles production in the central rapidity region of $pPb$ and $PbPb$ collisions at the same energy. We conclude that the model provides rather precise predictions (at the level of 2\(-3\%\)) for the production of charged pions in nuclear collisions.

2. We follow closely the Ref. [3] where the predictions of the model in $pPb$ and $PbPb$ collisions at the LHC energy are presented. Here we only list the parameter values used in the present calculation and show the final results.

In our calculations for the nuclear density we take the standard Woods-Saxon formula with the nuclear radius $R_{Pb} = 6.62$ fm and the skin depth $d = 0.546$ fm [4].

For the total inelastic $pp$ cross section at $\sqrt{s} = 17.3$ GeV we take the value obtained by the NA49 collaboration $\sigma_{in} = 31.46$ mb [1]. We assume the differential inelastic $pp$ cross section $\sigma_{in}(s)$ to be in a Gaussian form with $\sigma_{in}(0) = 0.92$ [5].\(^2\)

The average number of wounded quarks and diquarks in a single $pp$ collision $w_{p}^{(q+d)} = 1.18$ (per one colliding proton)\(^3\). Finally we take $p_{q} = w_{p}^{(q+d)}/3$ and $p_{d} = 2p_{q}$ where $p_{q}$

---

\(^{1}\)Total systematic uncertainty of 2.0\% (quadratic sum) and 4.8\% (upper limit).

\(^{2}\)We checked that different values of $\sigma_{in}(0)$ hardly influence final results.

\(^{3}\)At $\sqrt{s} = 23$ GeV $w_{p}^{(q+d)} \approx 1.182$ and changes very slowly with energy [2].
and $p_d$ are the probabilities for a quark and a diquark to interact in a single $pp$ collision, respectively.\footnote{As discussed in \cite{3} the specific relation between $p_d$ and $p_q$ is not important.}

3. In Fig. 1 we present the predicted relation between $R_{pA} \equiv N_{pA}(0)/N_{pp}(0)$ and the number of wounded nucleons $w$ \cite{6}. $N_{pA}(0)$ and $N_{pp}(0)$ are the midrapidity particle densities measured in $pPb$ and $pp$ collisions, respectively.

\caption{Prediction of the wounded quark-diquark model for the midrapidity ratio $R_{pA}$ compared with prediction of the wounded nucleon model.}
\end{figure}

In Fig. 2 the wounded quark-diquark model prediction for the ratio $R_{AA}/(w/2)$ vs the number of wounded nucleons $w$ is presented. $R_{AA} \equiv N_{AA}(y)/N_{pp}(y)$ where $N_{AA}(y)$ is the particle density measured in $PbPb$ collision. As explained in \cite{2,3} this ratio does not depend on $y$, unless we are close to the fragmentation regions. It would be very interesting to verify this strong consequence of the model when the data are available.

Multiplying $R_{pA}$ and $R_{AA}/(w/2)$ by the charged pions, $\pi^+ + \pi^-$, midrapidity density in $pp$ collisions $N_{pp}(0)|_{\pi^+ + \pi^-} = 1.413$ (with the reasonable uncertainty of 3\%) \cite{1} we obtain our final predictions for the charged pions midrapidity densities presented in Fig. 3.

Acknowledgements

We would like to thank A. Rybicki for useful discussions on the NA49 data. This investigation was supported in part by the Polish Ministry of Science and Higher Education, grant No. N202 034 32/0918.

\footnote{In the present approach we cannot provide the separate predictions for $\pi^+$ and $\pi^-$ multiplicities. At $\sqrt{s} = 17.3$ GeV the ratio $\pi^+/\pi^-$ is strongly influenced by the isospin effect \cite{7}.}
