Aspirin-triggered resolvin D1 reduces mucosal inflammation and promotes resolution in a murine model of acute lung injury

O Eickmeier¹, H Seki¹, O Haworth¹, JN Hilberath¹, F Gao², M Uddin¹, RH Croze¹, T Carlo¹, MA Pfeffer¹ and BD Levy¹,²

Acute lung injury (ALI) is a severe illness with excess mortality and no specific therapy. Protective actions were recently uncovered for docosahexaenoic acid-derived mediators, including D-series resolvins. Here, we used a murine self-limited model of hydrochloric acid-induced ALI to determine the effects of aspirin-triggered resolvin D1 (AT-RvD1; 7S,8R,17R-trihydroxy-4Z,9E,11E,13Z,15E,19Z-docosahexaenoic acid) on mucosal injury. RvD1 and its receptor ALX/FPR2 were identified in murine lung after ALI. AT-RvD1 (~0.5–5 µg kg⁻¹) decreased peak inflammation, including bronchoalveolar lavage fluid (BALF) neutrophils by ~75%. Animals treated with AT-RvD1 had improved epithelial and endothelial barrier integrity and decreased airway resistance concomitant with increased BALF epinephrine levels. AT-RvD1 inhibited neutrophil–platelet heterotypic interactions by downregulating both P-selectin and its ligand CD24. AT-RvD1 also significantly decreased levels of BALF pro-inflammatory cytokines, including interleukin (IL)-1β, IL-6, Kupffer cells, and tumor necrosis factor-α, and decreased nuclear factor-κB-phosphorylated p65 nuclear translocation. Taken together, these findings indicate that AT-RvD1 displays potent mucosal protection and promotes catabasis after ALI.

INTRODUCTION

Acute lung injury (ALI) and the acute respiratory distress syndrome (ARDS) are life-threatening disorders that contribute significantly to critical illness.¹ Approximately 75,000 patients die from ARDS each year in the United States.² Respiratory failure from ALI or ARDS is a frequent cause of admission to intensive care units, often requiring ventilatory support. Despite advances in understanding ARDS pathophysiology, no medical interventions have proven effective in improving the outcome of patients with ALI/ARDS.³,⁴ Aspiration pneumonitis is one of the leading causes of ALI/ARDS that in most instances is self-limited,⁵ suggesting the existence of endogenous, host-protective mechanisms.

Although the cellular events that return the injured lung to homeostasis have been described by histopathology, there remains only a limited understanding of the molecular mechanisms underlying this catabatic process. Polyunsaturated fatty acids appear to play important roles in ALI and its resolution. Activation of pulmonary leukocytes leads to increased generation of arachidonic acid-derived eicosanoids that can serve as important mediators of inflammation, vascular leak, and tissue catabasis.⁶–⁸ In contrast, ω-3 fatty acid-based nutritional supplementation can significantly improve oxygenation and decrease the length of stay in an intensive care unit, time on mechanical ventilation, occurrence of new organ failure, and mortality.⁹–¹¹

Airway mucosa is enriched with the ω-3 fatty acid docosahexaenoic acid (DHA).¹² Resolvin D1 (RvD1) is a DHA-derived mediator first identified in resolving peritoneal exudates.¹³ Aspirin acetylates cyclooxygenase-2 to lead to the formation of aspirin-triggered mediators, including the 17R-epimer of RvD1 termed aspirin-triggered RvD1 (AT-RvD1; 7S,8R,17R-trihydroxy-4Z,9E,11E,13Z,15E,19Z-docosahexaenoic acid)¹³,¹⁴ that decreases leukocytic infiltration in murine peritonitis to a greater extent than RvD1 and is more resistant to catalysis than RvD1.¹⁴ Of interest, both cyclooxygenase-2 and aspirin may have beneficial actions in ALI/ARDS.¹⁵,¹⁶ Here, in a non-lethal model of ALI, AT-RvD1 decreased lung inflammation after mucosal

injury and promoted ALI resolution by enhancing restitution of barrier integrity, decreasing circulating neutrophil–platelet heterotypic interactions, and regulating inflammatory mediators and nuclear factor-κB (NF-κB) activation.

RESULTS

RvD1 and 17(S)-hydroxy-DHA are generated after mucosal injury
To determine if endogenous DHA is converted to RvD1 after ALI, murine lungs were obtained 12 h after ALI from intratracheal HCl (0.1 N, pH 1.5) and lipids were extracted from lung homogenates for analyses (see Methods). Both RvD1 and its biosynthetic precursor 17(S)-hydroxy-DHA were identified by liquid chromatography with tandem mass spectrometry-based metabololipidomics analysis (Figure 1a–c). At this time point, RvD1 was present in pg quantities.

ALX/FPR2 receptors are expressed on lung epithelial cells and macrophages
RvD1 and AT-RvD1 are anti-inflammatory and pro-resolving agonists at ALX/FPR2 receptors;17,18 thus, the expression of ALX/FPR2 was determined by immunohistochemistry in murine lung at baseline and after ALI (Figure 1d–g). ALX/FPR2 receptors were expressed at low levels in uninjured lungs, in particular in airway epithelial cells and alveolar macrophages (MACs) (Figure 1d and e). As early as 2 h after ALI, there was an evident increase in mucosal epithelial cell ALX/FPR2 expression (Figure 1f) that was further increased 12 h after ALI (Figure 1g).

AT-RvD1 reduces leukocyte recruitment after airway mucosal injury
With both RvD1 and its receptor ALX/FPR2 present in murine lung, we determined the impact of exogenous AT-RvD1 on inflammatory responses after ALI. Because RvD1 is rapidly inactivated,14 its epimer AT-RvD1, which partially resists metabolic inactivation, was chosen for study. Like RvD1, AT-RvD1 is an agonist at ALX/FPR2 receptors.18 In a first series of experiments, AT-RvD1 or a vehicle control (0.1% ethanol (vol/vol)) were administered intravenously 15 min before instillation of HCl (0.1 N, pH 1.5) into the left mainstem bronchus (Figure 2a). AT-RvD1 led to significant and dose-dependent decrements in total bronchoalveolar lavage fluid (BALF) cell numbers 12 h after ALI (67500±15880 total BALF cells (AT-RvD1 10 ng, n = 5); 53810±7836 total BALF cells (AT-RvD1 100 ng, n = 10); mean±s.e.m.) relative to vehicle control mice (129800±10230 total BALF cells; mean±s.e.m., n = 12, P < 0.01) (Figure 2b). In particular, AT-RvD1 decreased BALF neutrophils (polymorphonuclear leukocytes (PMNs)) (11550±4841 PMNs (AT-RvD1 10 ng, n = 5); 8258±2988 PMNs (AT-RvD1 100 ng, n = 10); mean±s.e.m.) relative to vehicle (36650±5649 PMNs (n = 12); mean±s.e.m., P < 0.01) (Figure 2c). BALF MACs were also decreased with AT-RvD1 (44470±7846 MACs (AT-RvD1 100 ng, n = 10); mean±s.e.m.) in comparison to vehicle (91130±10890 MACs; mean±s.e.m., n = 12, P < 0.01) (Figure 2d).

In a second series of experiments to determine its pro-resolving and potential therapeutic properties, AT-RvD1 was given 2 h after airway injury (Figure 2e). When administered post-injury, AT-RvD1 also mediated significant decreases in total BALF cells (87860±14550 (100 ng, n = 7); 130000±7935 (vehicle, n = 6); mean±s.e.m., P < 0.05) (Figure 2f) and BALF PMNs (10520±1404 (100 ng, n = 7); 33410±4885 (vehicle, n = 6); mean±s.e.m., P < 0.01) (Figure 2g). No significant changes in the numbers of BALF MACs were present when AT-RvD1 (100 ng) was given after injury (Figure 2h).

In a third series of experiments to investigate AT-RvD1’s impact on early leukocyte trafficking after ALI, airway inflammation was monitored by BAL 2 and 6 h after ALI. Although no significant differences in the numbers of total BALF cells were identified between AT-RvD1 dosing before (−15 min) or after (+2 h) ALI, there was a lower amplitude and earlier decrease in airway inflammation in mice that received AT-RvD1 before ALI. These changes in early BALF cell numbers were correlated with BALF MACs, as significant numbers of BALF PMNs were not evident until 12 h after ALI (Figure 2i–k).

AT-RvD1 decreases lung edema and neutrophil accumulation after ALI
ALI from HCl instillation led to increased alveolar edema and inflammation (PMNs identified as Ly-6G+ by immunostaining) (Figure 3a). Administration of AT-RvD1 (100 ng) either before (Figure 3b) or 2 h after (Figure 3c) intratracheal acid instillation decreased both alveolar edema and the numbers of Ly-6G+ cells relative to control mice receiving only vehicle.

Regulation of lung neutrophil recruitment by AT-RvD1
To investigate the PMN recruitment pattern with AT-RvD1, its influence on intravascular and interstitial PMNs was determined (see Methods). Just before harvesting murine lungs 12 h after ALI, a PMN-specific Gr-1 antibody was injected intravenously to label intravascular PMNs. After BAL, the lungs were collected, prepared for FACS, and stained with a second PMN-specific antibody (NIMP-14R) (see Methods). PMNs were identified by forward/side scatter profiles and cells that were Gr-1+NIMP-14R were consistent with intravascular PMNs and cells that were Gr-1−NIMP-14R were consistent with interstitial PMNs (Figure 4a). The percent interstitial and intravascular PMNs at this time point were decreased only slightly with AT-RvD1 (100 ng) relative to vehicle control, and these differences did not reach statistical significance (Figure 4b and c). Of interest, the number of circulating PMNs (1255±108 PMNs per μl, mean±s.e.m.) and monocytes (monos) (468±37 monos per μl, mean±s.e.m.) were markedly increased 12 h after ALI relative to control animals without injury (243±56 PMNs per μl; 153±57 monos per μl, n = 5, P < 0.05) (Figure 4d–g). Intravenous AT-RvD1 significantly decreased the numbers of PMNs (866±59 PMNs per μl, mean±s.e.m.) and monos (240±63 monos per μl, mean±s.e.m.) in the peripheral blood of acid-injured mice (n = 5, P < 0.05) (Figure 4d–g).
AT-RvD1 reduces lung resistance in ALI
To investigate whether treatment with AT-RvD1 had a measurable effect on lung mechanics, we determined lung function in mechanically ventilated, anesthetized mice. Because of the unilateral and mild nature of the ALI in this model, marked changes in tissue elastance are not observed, and no significant differences were evident with AT-RvD1 relative to vehicle controls (Figure 5a). Of interest, the increased lung resistance 12 h after ALI in this model was significantly reduced by AT-RvD1 (100 ng) given either before (0.65 ± 0.05 cmH₂O·s·ml⁻¹, mean±s.e.m., n = 12) or after ALI (0.56 ± 0.02 cmH₂O·s·ml⁻¹, mean±s.e.m., n = 6) in comparison to vehicle (0.90 ± 0.08 cmH₂O·s·ml⁻¹, mean±s.e.m., n = 10, P < 0.05) (Figure 5b).

AT-RvD1 enhances restitution of barrier function after ALI
Because leakage permeability changes are integral to acute inflammation and ALI, and lung histology revealed that AT-RvD1 decreased alveolar edema (Figure 3), the actions of AT-RvD1 on both epithelial and endothelial barrier integrity were next determined. To measure the effects of AT-RvD1 on the restitution of epithelial barrier function after direct mucosal injury by HCl, fluorescently labeled dextran was instilled intratracheally and 10 min later BALF and right ventricular blood were obtained for measurement of fluorescence (see Methods). The ratio of fluorescence in the serum to BALF provided an index of epithelial permeability. At 12 h after acid instillation, epithelial permeability is increased and control mice receiving only vehicle gave serum/BALF fluorescence ratio of 0.36 ± 0.07.
Art. 2: Aspirin-triggered resolvin D1 (AT-RvD1) reduces leukocyte recruitment after airway mucosal injury. (a) AT-RvD1 (10, 100 ng) or vehicle alone (0.1% ethanol in 0.9% NaCl (vol/vol)) were given intravenously 15 min before acute lung injury (ALI). After 12 h, bronchoalveolar lavage (BAL) was performed and (b) total cells, (c) polymorphonuclear leukocytes (PMNs), and (d) macrophages (MACs) in BAL fluids (BALFs) were enumerated (see Methods). (e) In a separate cohort, the impact of AT-RvD1 (100 ng) or vehicle (0.1% ethanol in 0.9% NaCl (vol/vol)) given 2 h after ALI was determined on BALF (f) total cells, (g) PMNs, and (h) MACs 12 h after ALI was initiated. (i–k) Early leukocyte recruitment to the lung was assessed in the presence of AT-RvD1 (100 ng, intravenously) or vehicle (0.1% ethanol in 0.9% NaCl (vol/vol)) given 15 min before or 2 h after ALI. Values represent the mean ± s.e.m. for n = 5 mice. *P < 0.05 vs. vehicle group. I.t., intratracheally.

(mean ± s.e.m., n = 5) (Figure 5c). AT-RvD1 (100 ng) significantly improved epithelial barrier disruption 12 h after mucosal injury with decreased serum/BALF fluorescence ratios relative to vehicle controls when the compound was given either before injury (0.08 ± 0.03, mean ± s.e.m., n = 3, P < 0.05) or 2 h after injury (0.09 ± 0.02, mean ± s.e.m., n = 5, P < 0.01) (Figure 5c). Direct actions of the compound on epithelial barrier integrity in vitro were not identified, as AT-RvD1 (1–100 nM) did not significantly change the trans-epithelial electrical resistance of Calu-3 human bronchial epithelial cells in culture. AT-RvD1 improved vascular permeability changes in vivo, as the amount of Evans blue dye that extravasated into BALF was significantly decreased in mice receiving AT-RvD1 (100 ng) either before injury (4.7 ± 0.2 µg ml⁻¹, mean ± s.e.m., n = 3, P < 0.01) or 2 h after injury (4.6 ± 0.8 µg ml⁻¹, mean ± s.e.m., n = 3, P < 0.05) in comparison to vehicle control mice (8.5 ± 0.8 µg ml⁻¹, n = 4) (Figure 5d).

AT-RvD1 decreases neutrophil–platelet interactions

Vascular inflammation with heterotypic interactions between PMNs, platelets, and endothelial cells are important early
AT-RvD1 decreases pro-inflammatory mediator release after ALI

To determine the impact of AT-RvD1 on inflammatory mediators after ALI, BALF levels of select cytokines, chemokines, and lipid mediators were determined. BALF tumor growth factor-$\beta$ was significantly increased when AT-RvD1 was administered 2 h after ALI (Figure 6b). BALF levels of the counter-regulatory mediators lipoxin A$_4$ (LXA$_4$) and interleukin (IL)-10 did not increase with AT-RvD1 relative to vehicle; however, the LXA$_4$ and IL-10 levels were significantly different between the two AT-RvD1 treatment strategies (Figure 6c and d). When AT-RvD1 was given before HCl, LXA$_4$ and IL-10 levels decreased, but there was no significant change in LXA$_4$ and IL-10 levels when AT-RvD1 was given 2 h after injury (Figure 6c and d). Several pro-inflammatory mediators were significantly decreased in AT-RvD1-treated mice, including IL-1$\beta$, IL-6, keratinocyte chemotactrant, and tumor necrosis factor-$\alpha$ (Figure 6e–h). No significant changes were observed in BALF chemokine (C–C motif) ligand 3, chemokine (C–X–C motif) ligand 2, chemokine (C–X–C motif) ligand 10, and leukotriene B$_4$ (Figure 6i–l). In addition, levels of 8-isoprostane, a sensitive marker of oxidative stress, are low at this time point in this model, and there were no significant changes apparent with AT-RvD1 (data not shown).

AT-RvD1 decreases NF-$\kappa$B p65 translocation after ALI

Because AT-RvD1 markedly decreased several pro-inflammatory cytokines, the impact of AT-RvD1 on NF-$\kappa$B activation and the cellular targets for AT-RvD1 counter-regulatory actions were next determined by immunohistochemistry of lung sections. NF-$\kappa$B activation and nuclear translocation was identified using a phosphorylated p65 (serine 276) antibody (see Methods). There was an increase in NF-$\kappa$B phosphoserine p65 abundance and nuclear translocation in airway epithelial cells and lung macrophages that was evident 2 h after ALI (Figure 7a–c) and markedly increased 12 h after ALI (Figure 7d). Both dosing strategies for AT-RvD1 decreased the abundance of NF-$\kappa$B phosphoserine p65 in epithelial cells and macrophages 12 h after HCl (Figure 7e and f).

DISCUSSION

Alveolar edema and PMN recruitment and activation are early events in acute mucosal inflammation and ALI/ARDS. These cellular events are subject to regulation by lipid mediators, and here RvD1 was generated after HCl-initiated ALI. The RvD1 receptor ALX/FPR2 is expressed on PMNs, monos, macrophages, and airway epithelial cells. Murine ALX/FPR2 lung expression was evident in airway epithelial cells and macrophages, and its abundance markedly increased after ALI. The RvD1 epimer AT-RvD1 displayed properties of both an anti-inflammatory and pro-resolving mediator in decreasing the severity of HCl acid-initiated ALI. Given either before or shortly after mucosal injury, AT-RvD1 reduced several parameters of alveolar edema 12 h after ALI, including by histological evidence, and measures of epithelial and endothelial permeability. There was an increase in lung tissue resistance after intratracheal administration of HCl that was reduced by AT-RvD1 and...
associated with AT-RvD1-mediated increases in endogenous BALF epinephrine levels. In addition to these actions on mucosal tissue-resident cells, AT-RvD1 also displayed potent leukocyte-directed actions, including decreased circulating PMNs and monos, vascular PMN–platelet heterotypic interactions, airway PMN infiltration, BALF pro-inflammatory mediator levels, and NF-κB p65 activation in airway epithelial cells and macrophages. Taken together, these findings indicate that in lung tissue and inflammatory cells AT-RvD1 harnessed several cell type-specific protective mechanisms to decrease ALI severity. AT-RvD1’s regulation of vascular PMN–platelet interactions, permeability changes, and epinephrine levels emphasize the importance of vascular inflammatory events in the pathogenesis of early ALI.

Retrospective analyses of patients with ARDS have identified aspirin as a protective exposure that decreases ARDS morbidity and mortality.16 In addition to inhibiting platelet function, aspirin triggers the formation of specific pro-resolving mediators,24 including AT-RvD1 from DHA in inflamed murine and human tissues.14 In murine models of acute inflammation, AT-RvD1 decreases the production of pro-inflammatory mediators and regulates leukocyte trafficking to inflammatory sites (reviewed in ref. 25), including in experimental models of arthritis and colitis.26,27 Here, AT-RvD1 decreased lung PMN infiltration and decreased inflammatory responses by tissue-resident cells, including endothelial and epithelial barrier function and levels of several pro-inflammatory mediators in the injured lung. AT-RvD1 2 hours after injury gave similar protection as a dose given 15 min before injury, indicating that AT-RvD1 could accelerate the resolution of ALI.

Neutrophil activation can cause bystander tissue damage that contributes to the pathogenesis of ALI/ARDS;28 thus, decreasing lung PMN accumulation and pro-inflammatory mediators would be predicted to have synergistic benefit for tissue protection and catabasis after acid injury. To this end, inhibition of PMN function in animal studies attenuates lung injury induced by models of gastric acid aspiration.29,30 RvD1 transduces potent anti-inflammatory actions for PMNs. Single-cell PMN assays in microfluidic chambers have uncovered direct PMN actions...
for RvD1, but not the parent fatty acid DHA, to stop rapidly PMN migration towards the chemotractant IL-8,21 and RvD1 can regulate PMN lung recruitment in response to lipopolysaccharide.32 Here, early administration of AT-RvD1 appeared to reduce the amplitude and duration of acid-initiated ALI and together with AT-RvD1’s regulation of NF-κB activation suggests that the compound’s reduction in airway inflammation is secondary to both direct actions on leukocytes and indirect actions to decrease the levels of inflammatory cytokines. In addition, AT-RvD1’s actions on leukocytes to decrease their lung recruitment in conjunction with regulation of vasoactive mediators likely accounts for the decrease in alveolar edema with AT-RvD1. In this regard, at ocular mucosal surfaces, RvD1 decreases cysteinyl leukotrienes,33 which also play a pivotal role in vascular permeability in HCl-induced ALI.8 LXs are arachidonic acid-derived mediators that display anti-inflammatory and pro-resolving actions, including inhibition of in vivo PMN activation, cytokine release, and angiogenesis (reviewed in ref. 25). These protective actions are mediated, in part, by the LXA4 receptor ALX/FPR2 that can also serve as an anti-inflammatory receptor for RvD1 and AT-RvD1.17,18,23 ALX/FPR2 receptor expression is increased in vitro after airway epithelial injury,21 and transgenic expression of human ALX/FPR2 receptors is protective from HCl-initiated ALI.15 Here, ALX/FPR2 receptor expression increased in vivo 12 h after ALI in both airway epithelial cells and lung macrophages, and AT-RvD1 administration markedly decreased NF-κB activation in these ALX/FPR2-expressing cells. Although apoptotic PMNs are difficult to identify in this model of ALI, RvD1 in other model systems are potent stimuli for macrophage efferocytosis during tissue catabasis17 and can promote host catabatic responses that in conjunction with antibiotics promotes the resolution of bacterial infection.34 Of interest, BALF levels of LXA4 were significantly decreased by AT-RvD1 administration before injury, which were significantly lower than LXA4 levels in mice that received AT-RvD1 after injury. There are two implications of this finding. First, AT-RvD1’s protective actions are independent of LXA4 generation, and second, the early events in host acute inflammatory responses to tissue injury are critical to endogenous biosynthesis of LXA4. Early pro-inflammatory mediator formation is pivotal to lipid mediator class switching for the later generation of anti-inflammatory mediators, such as LXA4.15,35 Administration of AT-RvD1 before injury dampened the early pro-inflammatory mediator production with reductions in endogenous LXA4 generation 12 h later. Because AT-RvD1 resists rapid inactivation14 and promoted ALI resolution, the decrements in LXA4 generation did not have adverse consequences on lung catabasis. This is in sharp contrast with chemical inhibitors of early inflammatory mediator generation, such as cyclooxygenase-2-specific inhibitors or 5-lipoxygenase chemical inhibitors of early inflammatory mediator generation, which can be “toxic” for tissue injury or inflammation.15,36 P-selectin (CD62P) is expressed by activated endothelial cells and platelets as a molecular regulator of heterotypic PMN–platelet and platelet–endothelial cell interactions.37 During secondary capture, PMNs interact with circulating or endothelial
adherent platelets to augment PMN–endothelial interactions in inflamed vascular beds for PMN tissue recruitment. Of note, platelet depletion leads to diminished leukocyte recruitment in tissue inflammation and ALI. As a measure of vascular inflammation, heterotypic cell–cell interactions between PMNs and platelets were monitored here in blood from the right ventricle, just before entering the pulmonary vasculature. The peripheral blood leukocytosis induced by ALI was decreased by AT-RvD1, and flow cytometry revealed a substantial reduction in PMN–platelet interactions with AT-RvD1. In addition, the expression of P-selectin (CD62P) and its PMN ligand CD24 was decreased by AT-RvD1 in lung homogenates after ALI. Blocking P-selectin’s potent anti-inflammatory and pro-resolving actions. Enteric feeding with DHA can markedly reduce ALI/ARDS morbidity and mortality, in part, via marked decreases in lung PMNs and inflammatory mediators. The potential for lung protection by DHA-derived mediators is also supported by evidence from fat-1 transgenic mice that are protected from ALI and allergic airway inflammation. These transgenic mice express the Caenorhabditis elegans ω-3 desaturase fat-1 gene and can endogenously generate ω-3 polyunsaturated fatty acids from ω-6 polyunsaturated fatty acids and resolvins. Moreover, AT-RvD1’s epimer RvD1 displays protective actions in a lipopolysaccharide model of acute lung inflammation and injury.

In summary, our findings have uncovered new roles for AT-RvD1 in promoting resolution of acid-initiated experimental

---

Figure 6 Impact of aspirin-triggered resolvin D1 (AT-RvD1) on inflammatory mediator levels after acute lung injury (ALI). Aliquots of bronchoalveolar lavage fluids (BALFs) obtained 12h after ALI were analyzed by enzyme-linked immunosorbent assay (ELISA) (a, b, c, d, e, f, g, h, i, j, k, l) or cytokine bead array (b, e–k). Values represent the mean ± s.e.m. for n=3 mice. *P<0.05 vs. vehicle (Veh) group. § P<0.05 vs. 100 ng AT-RvD1 group 15 min before ALI.
ALI. In this study, the DHA-derived lipid mediator AT-RvD1 decreased acid-initiated ALI by direct actions on circulating leukocytes and platelets with lung protective effects on barrier function, PMN accumulation, and pro-inflammatory mediator generation. Expression of ALX/FPR2 receptors and AT-RvD1’s regulation of NF-κB in lung mucosal epithelial cells and macrophages suggest important roles for these cells in lung tissue catastrophe that will serve as a focus of future studies. Taken together, these results suggest a potential new therapeutic approach to the important clinical problem of ALI/ARDS that emphasizes natural resolution signaling pathways.

METHODS

Acid-initiated ALI and treatment with AT-RvD1. All mice were maintained under specific pathogen-free conditions. All studies were reviewed and approved by the Harvard Medical Area standing committee on animals (protocol no. 03618). As in Fukunaga et al., hydrochloric acid (0.1 N HCl, pH 1.5, 50 μl, endotoxin free; Sigma-Aldrich, St Louis, MO) was instilled selectively into the left mainstem bronchus of anesthetized mice (FVB, male, 10–12 weeks; Charles River, Wilmington, MA) via a 24-G angiocatheter inserted intratracheally. Some mice received AT-RvD1 (10 or 100 ng) or vehicle or (e, f) AT-RvD1 (100 ng). Insets, higher magnification to show nuclear staining. Arrowheads, epithelial cells; arrows, macrophages. Results are representative from n = 3. Original magnification ×400.

**Figure 7** Aspirin-triggered resolvin D1 (AT-RvD1) decreased acute lung injury (ALI)-induced nuclear factor-κB (NF-κB) p65 activation and nuclear translocation in murine lung. Immunohistochemical analysis to detect NF-κB localization was performed by staining lung tissue (a) without injury using NF-κB-phosphorylated p65 antibody (phospho-S276, 1/50) or (b) IgG control antibody and (c) 2 h after ALI. Lungs were also obtained 12 h after ALI from mice exposed to (d) vehicle or (e, f) AT-RvD1 (100 ng). Insets, higher magnification to show nuclear staining. Arrowheads, epithelial cells; arrows, macrophages. Results are representative from n = 3. Original magnification ×400.

**Leukocyte recruitment after ALI.** The total cell counts and leukocyte differential in BALFs were determined as described previously. Briefly, total cells in BALFs were counted using a hemocytometer, and a leukocyte differential count was performed after Wright–Giemsa staining.

To determine intravascular and interstitial PMNs, FITC-Gr-1 (Clone RB6-8C5; eBioscience, San Diego, CA) was intravenously injected 5 min before lung harvest (similar to that in ref. 19). After BAL, the lungs were removed, dispersed, and passed through a 70-μm cell strainer (as in ref. 42). PMNs were identified during flow cytometry by their forward/side scatter profiles and their expression of NIMP-14R (Santa Cruz Biotechnology, Santa Cruz, CA) and Gr-1. Isotype control antibodies were used for compensation for nonspecific binding. The FITC-Gr-1 Ab was used to identify PMNs in the intravascular (NIMP-14R*Gr-1+) and interstitial (NIMP-14R*Gr-1+) compartments. Flow cytometry was performed using a BD FACS Canto II flow cytometer (Becton Dickinson, San Jose, CA) and data were analyzed using the FlowJo software (Tree Star, Ashland, OR).

**Complete blood count and differential count.** Murine blood was drawn from the inferior vena cava and lysed with RBC lysis buffer (eBioscience). Leukocytes were counted with a hemocytometer and differential count was performed after Wright–Giemsa staining. For the leukocyte differential, a minimum of 200 cells were counted per slide.

**Neutrophil–platelet interactions.** Whole blood was collected from mice that received either AT-RvD1 (100 ng) or vehicle 2 h after ALI. Blood was lysed using 10 volumes of red blood cell lysis buffer (eBioscience) as per the manufacturer’s instructions. For flow cytometry, cells were blocked with CD16/32 Fc block (eBioscience) and then stained with Ly6G (eBioscience), CD41 (eBioscience), or CD62P (eBioscience) for 20 min on ice. CD24 and P-selectin protein abundance in lung homogenates was determined by western blot analyses. β-Actin was used as a control. Antibodies were used as per the manufacturer’s recommended concentrations (1 μg ml⁻¹) (Santa Cruz Biotechnology).

**Identification of RvD1 in murine lung.** FVB mouse lungs were suspended in 1.0 ml cold methanol and gently ground, followed by protein precipitation for 12 h. Samples were next extracted by solid-phase extraction column and methyl formate fractions were taken for liquid chromatography with tandem mass spectrometry-based lipidomics. Liquid chromatography with tandem mass spectrometry was performed with an Agilent 1100 HPLC (Agilent Technologies, Santa Clara, CA) equipped with an Agilent Eclipse Plus C-18 column (4.6 mm×50 mm×1.8 μm) paired with an ABI Sciex Instruments 5500 QTRAP linear ion trap triple quadrupole mass spectrometer (Applied Biosystems, Foster City, CA). Instrument control and data acquisition were performed using...
the AnalystTM 1.5 software (Applied Biosystems). The mobile phase consisted of methanol/water/acetic acid (55/45/0.01; vol/vol/vol) and was ramped to 88/12/0.01 (vol/vol/vol) after 10 min, 100/0/0.01 (vol/vol/vol) after 18 min, and 55:45:0.01 (vol/vol/vol) after 1 min to wash and equilibrate the column. Mass spectrometry analyses were carried out in negative ion mode using multiple reaction monitoring of established specific transitions for 17(S)-hydroxy-DHA (m/z 343→245) and RvD1 (m/z 375→215). Identification was matching retention time and diagnostic ions to synthetic standards.42 Quantification was performed using standard calibration curves for each, and recoveries were calculated using deuterated internal standard (d₆-PGE₃).

**Histology and immunohistochemistry.** After dissection, lungs were perfusion-fixed at 20 cmH₂O in IHC zinc fixative buffer (BD Pharmingen, San Diego, CA). Tissue blocks were obtained from mid-sagittal slices of lungs embedded in paraffin for staining with hematoxylin and eosin (Sigma). For Ly-6G (1/100 dilution; BD Pharmingen) immunostaining, tissue sections were de-paraffinized and incubated for 1 h at room temperature with anti-mouse Ly-6G antibody to stain for PMNs. For ALX/FPR2 (1/50 dilution; Santa Cruz Biotechnology) and phosphorylated p65 subunit of NF-κB (phospho-S276, 1/50 dilution; Abcam) immunostaining, tissue sections were incubated overnight at 4°C.

**Determination of barrier integrity.** FITC-dextran was utilized as a marker of epithelial barrier disruption (as in ref. 42 with minor modification). Briefly, FITC-dextran (50 mg/kg-1 mouse) was given intratracheally via a 24-G angiocatheter. BAL with 1 ml phosphate-buffered saline was performed 10 min later with concurrent collection of blood from the right ventricle. BAL and serum were loaded onto a microwell plate and fluorescence was determined (excitation, 490 nm; emission, 520 nm). The ratio of serum to BALF fluorescence was used as an index of airflow epithelial permeability. To measure vascular permeability, Evans blue dye was utilized as a marker for endothelial barrier disruption (as in ref. 8). Briefly, Evans blue dye (40 mg/kg-1) was injected via tail vein and 30 min later BAL was performed with 1 ml phosphate-buffered saline. Extravasation of dye into BALFs was quantified by spectrophotometry (absorbance at 650 nm).

**Measurement of lung mechanics.** For measurement of tissue elastance and lung resistance, mice were anesthetized with pentobarbital (70 mg/kg⁻¹, intraperitoneally; Abbott Laboratories, North Chicago, IL) and mechanically ventilated with a flexiVent small animal ventilator (SCIREQ, Montreal, QC, Canada). Lung mechanics were determined in anesthetized, ventilated animals.

**Mediator levels in BALFs.** Select cytokines, chemokines, and total tumor growth factor-β1 were measured in aliquots of BALF by cytokine bead array (Aushon Biosystems, Billerica, MA). BALF ephrinephine, leukotriene B₄, 8-isoprostanate, IL-10, and LXA₄ levels were measured with specific enzyme-linked immunosorbent assays as per the manufacturer’s instructions (epinephrine, Rocky Mountain Diagnostics, Colorado Springs, CO; leukotriene B₄, 8-isoprostane, Cayman Chemical, Ann Arbor, MI; IL-10, eBioscience; LXA₄, Neogen, Lexington, KY).

**Statistical analysis.** Data are expressed as the mean values±s.e.m., unless otherwise indicated. Analysis of variance was used to determine significance for differences between more than two groups. For analyses between two groups, cohorts were compared by Mann–Whitney U-test. Significance was determined with P-values<0.05. Statistics were performed using GraphPad Prism 5 for Windows (San Diego, CA).

**ACKNOWLEDGMENTS**

We thank GuangLi Zhu and Bonna Ith for technical assistance. This research was supported in part by the US National Institutes of Health grants HL068669, A068804, and P01-GM095467, and postdoctoral fellowships from the American Lung Association and German Society of Pediatric Pulmonology.
