We consider parameterized concurrent systems consisting of a finite but unknown number of components, obtained by replicating a given set of finite state automata. Components communicate by executing atomic interactions whose participants update their states simultaneously. We introduce an interaction logic to specify both the type of interactions (e.g. rendez-vous, broadcast) and the topology of the system (e.g. pipeline, ring). The logic can be easily embedded in monadic second order logic of $\kappa \geq 1$ successors ($\text{WS}_\kappa S$), and is therefore decidable.

Proving safety properties of such a parameterized system, like deadlock freedom or mutual exclusion, requires to infer an inductive invariant that contains all reachable states of all system instances, and no unsafe state. We present a method to automatically synthesize inductive invariants directly from the formula describing the interactions, without costly fixed point iterations. We experimentally prove that this invariant is strong enough to verify safety properties of a large number of systems including textbook examples (dining philosophers, synchronization schemes), classical mutual exclusion algorithms, cache-coherence protocols and self-stabilization algorithms, for an arbitrary number of components.

1 Introduction

The problem of parameterized verification asks whether a system composed of $n$ replicated processes is safe, for all $n \geq 2$. By safety we mean that every execution of the system stays clear of a set of global error configurations, such as deadlocks or mutual exclusion violations. Even if we assume each process to be finite-state and every interaction to be a synchronization of actions without exchange of data, ranging over large or infinite domains, the problem remains challenging because we ask for a general proof of safety, that works for any number of processes.

In general, parameterized verification is undecidable, even if processes only manipulate data from a bounded domain [6]. Various restrictions of communication and architecture\textsuperscript{3} define decidable subproblems [16,29,25,5]. Seminal works consider rendez-vous communication, with participants placed in a ring [16,25] or a clique [29] of arbitrary size. Recently, MSO-definable graphs (with bounded tree- and clique-width) and point-to-point rendez-vous communication have been considered [5]. Most approaches to define decidable problems focus on manually proving a cut-off bound $c \geq 2$ such that

\textsuperscript{**} Institute of Engineering Univ. Grenoble Alpes

\textsuperscript{3} We use the term architecture for the shape of the graph along which the interactions take place.
correctness for at most \( c \) processes implies correctness for any number of processes \([16,25,24,7,31]\). Other methods identify systems with well-structured transition relations \([29,1,27]\). An exhaustive chart of decidability results for verification of parameterized systems is drawn in \([12]\). When decidability is not of concern, over-approximating and semi-algorithmic techniques such as regular model checking \([33,2]\), SMT-based bounded model checking \([4,19]\), abstraction \([10,14]\) and automata learning \([17]\) can be used to deal with more general classes of systems.

The efficiency of a verification method crucially relies on its ability to synthesize an inductive safety invariant, i.e., an infinite set of configurations that contains the initial configurations, is closed under the transition relation, and excludes the error configurations. In general, automatically synthesizing invariants requires computationally expensive fixpoint iterations \([20]\). In the particular case of parameterized systems, invariants can be either global, relating the local states of all processes \([21]\), or modular, relating the local states of a few processes whose identity is irrelevant \([35,18]\).

Our Contributions. The novelty of the approach described in this paper is three-fold:

1. The architecture of the system is not fixed a priori, but given as a parameter of the verification problem. In fact, we describe parameterized systems using the Behavior-Interaction-Priorities (BIP) framework \([9]\), in which processes are instances of finite-state component types, whose interfaces are sets of ports, labeling transitions between local states, and interactions are sets of strongly synchronizing ports, described by formulae of an interaction logic. An interaction formula captures the architecture of the interactions (pipeline, ring, clique, tree) and the communication scheme (rendez-vous, broadcast), which are not hardcoded, but rather specified by the designer of the system.

2. We synthesize parameterized invariants directly from the interaction formula of a system, without iterating its transition relation. Such invariants depend only on the structure (and not on the operational semantics) of an infinite family of Petri Nets, one for each instance of the system, being thus structural invariants. Essentially, the invariants we infer use the traps\(^4\) of the system, which are sets \( W \) of local states with the property that, if a process is initially in a state from \( W \), then always some process will be in a state from \( W \). Following \([11,15]\), we call them (parameterized) trap invariants. Computing trap invariants only requires a simple syntactic transformation of the interaction formula and the result is expressed using \( \text{WS}_{\kappa}S \), the weak monadic second order logic of \( \kappa \geq 1 \) successor functions. Thus invariant computation is very cheap, and the verification problem (proving the emptiness of the intersection between the invariant and the set of error states) is reduced to the unsatisfiability of a \( \text{WS}_{\kappa}S \) formula with a single quantifier alternation. In practice, this check can be carried out quite efficiently by existing tools, such as Mona \([30]\).

3. We refine the approach by considering another type of invariants, called 1-invariants, that can also be derived cheaply from the interaction formula of the system. We show that 1-invariants in conjunction with trap invariants successfully verify additional examples.

Comparison to related work. Trap invariants have been very successfully used in the verification of non-parameterized systems \([11,26,13]\). The technique was lifted to pa-

---

\( ^4 \) Called in this way by analogy with the notion of traps for Petri Nets \([36]\).
rameterized systems in [15], but the work there is only applicable to clique architectures, in which processes are indistinguishable, and the system can be described by one single Petri Net with an infinite family of initial markings. Here, for the first time, we show that the trap technique can be extended to pipelines, token rings and trees, where the system is defined by an infinite family of Petri Nets, each with a different structure. These systems cannot be analyzed using the techniques of [29,1,27], because they do not yield well-structured transition systems. Contrary to [16,25,24,7,31], our approach does not require a manual cut-off proof. Contrary to regular model checking and automata learning [2,17], it does not require any symbolic state-space exploration. Finally, our approach produces an explanation of why the property holds in terms of the trap invariant and 1-invariants used. Summarizing, our approach provides a comparatively cheap technique for parameterized verification, that succeeds in numerous cases. It is ideal as preprocessing step, that can very quickly lead to success with a very clear explanation of why the property holds, and otherwise provides at least a strong invariant that can be used for further analysis.

\[ \Gamma_{\text{philo}} = (g(i) \land t(i) \land t(\text{succ}(i))) \lor (p(i) \land \ell(i) \land \ell(\text{succ}(i))) \] 

(1)

where the free variable \( i \) refers at some arbitrary component index.

**Running Example.** Consider the dining philosophers system in Fig. 1, consisting of \( n \geq 2 \) components of type Fork and Philosopher respectively, placed in a ring of size \( 2n \). The \( k \)-th philosopher has a left fork, of index \( k \), and a right fork, of index \( (k + 1) \mod n \). Each component is an instance of a finite state automaton with states \( f(\text{ree}) \) and \( b(\text{usy}) \) for Fork, respectively \( w(\text{aiting}) \) and \( e(\text{ating}) \) for Philosopher. A fork goes from state \( f \) to \( b \) via a \( t(\text{ake}) \) transition and from \( f \) to \( b \) via a \( \ell(\text{ave}) \) transition. A philosopher goes from \( w \) to \( e \) via a \( g(\text{et}) \) transition and from \( e \) to \( w \) via a \( p(\text{ut}) \) transition. The \( g \) action of the \( k \)-th philosopher is executed jointly with the \( t \) actions of the \( k \)-th and \( [(k + 1) \mod n] \)-th forks, in other words, the philosopher takes both its left and right forks simultaneously. Similarly, the \( p \) action of the \( k \)-th philosopher is executed simultaneously with the \( \ell \) action of the \( k \)-th and \( [(k + 1) \mod n] \)-th forks, i.e. each philosopher leaves both its left and right forks at the same time. We describe these interactions by the interaction formula:

\[ \Gamma_{\text{philo}} = (g(i) \land t(i) \land t(\text{succ}(i))) \lor (p(i) \land \ell(i) \land \ell(\text{succ}(i))) \]
Intuitively, the transitions of the system with \( n \) dining philosophers and \( n \) forks are given by the minimal models of the disjuncts of \( \Gamma_{\text{philo}} \) with universe \( \{0, 1, \ldots, n-1\} \), and succ interpreted as “successor modulo \( n \)”. In particular, for each \( 0 \leq k \leq n-1 \) the first disjunct has a minimal model that interprets the predicates \( g \) and \( t \) as the sets \( \{k\} \) and \( \{k, (k+1) \mod n\} \). This model describes the interaction in which the \( k \)-th philosopher takes a \( g \)-transition (from waiting to eating), while, simultaneously, the \( k \)-th and \( (k+1) \)-th forks take \( t \)-transitions (from free to busy). This is graphically represented by one of the dashed lines in Fig. 1. Observe that the ring topology of the system is implicit in the modulo-\( n \) interpretation of the successor function.

Since philosophers can only grab their two forks simultaneously, the system is deadlock-free for any number \( n \geq 2 \) of philosophers. An automatic proof requires to compute an invariant, and prove that it has an empty intersection with the set of deadlock configurations defined by the WS\( \alpha \)S formula

\[
deadlock(X_w, X_e, X_f, X_b) = \forall i . \left[ \neg X_w(i) \lor \neg X_f(i) \lor \neg X_f(\text{succ}(i)) \right] \land \left[ \neg X_e(i) \lor \neg X_b(i) \lor \neg X_b(\text{succ}(i)) \right] \tag{2}
\]

where \( X_w, X_e, X_f, X_b \) are set variables, the intended meaning of \( X_w(i) \) resp. \( X_e(i) \) is that the \( i \)-th philosopher is waiting, resp. eating, and the intended meaning of \( X_f(i) \) resp. \( X_b(i) \) is that the \( i \)-th fork is free, resp. busy. Our method automatically computes from \( \Gamma_{\text{philo}} \) the formula

\[
\text{trap-pred}_S(X_w, X_e, X_f, X_b) = \forall i . \left[ X_w(i) \lor X_f(i) \lor X_f(\text{succ}(i)) \right] \leftrightarrow \left[ X_e(i) \lor X_b(i) \lor X_b(\text{succ}(i)) \right] . \tag{3}
\]

Contrary to other approaches, the computation does not require any state-space exploration. The method guarantees that its set of models is an inductive invariant. Since the conjunction \( \text{deadlock} \land \text{trap-pred}_S \) is unsatisfiable, which can be automatically checked, the system is deadlock-free, for any number of philosophers.

2 Parameterized Component-based Systems

A component type is a tuple \( C = (P, S, s_0, A) \), where \( P = \{p, q, r, \ldots\} \) is a finite set of ports, \( S \) is a finite set of states, \( s_0 \in S \) is an initial state and \( A \subseteq S \times P \times S \) is a set of transitions denoted \( s \xrightarrow{p} s' \), for \( s, s' \in S \) and \( p \in P \). We assume there are no two different transitions with the same port.

A component-based system \( S = \langle C^1, \ldots, C^n, \Gamma \rangle \) consists of a fixed number \( N \geq 1 \) of component types \( C^i = (P^i, S^i, s_0^i, A^i) \) and an interaction formula \( \Gamma \). In the dining philosophers there are two component types, Philosopher and Fork, each with two states and two transitions, as shown in Fig. 1. We assume that \( P^i \cap P^j = \emptyset \) and \( S^i \cap S^j = \emptyset \), for all \( 1 \leq i < j \leq N \). We denote the component type of a port \( p \) or a state \( s \) by \( \text{type}(p) \) and \( \text{type}(s) \), respectively. For instance, in Fig. 1 we have \( \text{type}(p) = \text{type}(g) = \text{type}(w) = \text{type}(e) = \text{Philosopher} \) and \( \text{type}(t) = \text{type}(f) = \text{type}(b) = \text{Fork} \).

The interaction formula \( \Gamma \) determines the family of systems we can construct out of these components. It does so by specifying, for each possible number of replicated instances (for example, 3 philosophers and 3 forks), which are the possible interactions between them. An interaction consists of a set of transitions that are executed simultaneously. For example, in an interaction philosopher 3 executes a \( g \text{(et)} \) transition
simultaneously with (take) transitions of the forks 2 and 3. Before formalizing this, we introduce the syntax and semantics of Interaction Logic.

**Interaction Logic.** For a constant $\kappa \geq 1$, fixed throughout the paper, the **Interaction Logic** $\mathsf{IL}$ is built on top of a countably infinite set $\mathsf{Var}$ of variables, the set $\mathsf{Pred} = \bigcup_{i=1}^{N} P^i$ of monadic predicate symbols ranged over by $\mathsf{pr}$ (i.e. the logic has a predicate symbol for each port), the binary predicate $\leq$, and the successor functions $\mathsf{succ}_0, \ldots, \mathsf{succ}_{\kappa-1}$, of arity one. The formulae of $\mathsf{IL}$ are generated by the syntax

$$
t := i \in \mathsf{Var} \mid \mathsf{succ}_0(t) \mid \ldots \mid \mathsf{succ}_{\kappa-1}(t) \\
\phi := t_1 \leq t_2 \mid \mathsf{pr}(t) \mid \phi_1 \land \phi_2 \mid \neg \phi_1 \mid \exists i . \phi_1 \mid \phi$$

Abbreviations like $\leq$, $\phi$ assigns a node to each variable and a set of nodes to each predicate in an interpretation. The tree is the empty word $\epsilon$, the root of the tree is interpreted as the node $\mathsf{pr}$ and $t$, respectively, and $\mathsf{succ}_0, \ldots, \mathsf{succ}_{\kappa-1}$ have the usual fixed interpretations: If $t$ and $t'$ are interpreted as $w$ and $w'$, then $t_1 \leq t_2$ holds iff $w$ is a prefix of $w'$, and $\mathsf{succ}_k(t)$ is interpreted as the node $w_i$, if $wi \in \mathfrak{U}$, and as the root $\epsilon$ otherwise. So, loosely speaking, successor functions wrap around to the root.

When $\kappa = 1$, formulae are interpreted on languages $\{\epsilon, 0, 00, \ldots, 0^{n-1}\}$ for some number $n$. To simplify notation, in this case we assume that they are interpreted over the set $\{0, 1, \ldots, n-1\}$, and $\mathsf{succ}_0$ is the usual successor function on numbers, modulo $n$.

Intuitively, a universe $\mathfrak{U}$ determines an instance of the component-based system, with one instance of each component for each $w \in \mathfrak{U}$. So, for example, for $\kappa = 1$ and $\mathfrak{U} = \{0, 1, 2, \ldots, n-1\}$ we have in our running example philosophers $0, 1, \ldots, n-1$ and forks $0, 1, \ldots, n-1$. Generally, with $\kappa = 1$ we can describe pipeline and token-ring architectures, whereas higher values describe tree-shaped architectures.

**Interaction formulae.** A formula of $\mathsf{IL}$ is an *interaction formula* if it is the conjunction of the following formula:

$$\forall i \forall j . \bigwedge_{p,q \in \mathsf{Pred}} \bigwedge_{\mathsf{type}(p) = \mathsf{type}(q)} p(i) \land q(j) \rightarrow i \neq j$$

with a finite disjunction of formulae of the form:

$$\mathsf{C}(i_1, \ldots, i_n) \overset{\text{def}}{=} \phi \land \bigwedge_{j=1}^{n} p_j(i_j) \land \bigwedge_{j=1}^{n} \forall k . \psi_j \rightarrow q_j(k)$$

where $\psi, \psi_1, \ldots, \psi_m$ are conjunctions of atomic formulae of the form $t_1 \leq t_2$ and their negations. Intuitively, formula (4) is a generic axiom that prevents two ports of the same instance of a component type from interacting. The formulae of form (5) are called the *clauses* of the interaction formula.

**Example 1.** Consider a component-based system $\mathcal{S} = \langle C^1, C^2, \Gamma \rangle$, where $C^1$ and $C^2$ have ports $p_1$ and $p_2$, respectively, and $\Gamma$ has one single clause

$$\mathsf{C}(i, j, k) = (i < j \land k = \mathsf{succ}(j)) \land (p_1(i) \land p_2(j)) \land \forall i . i > k \rightarrow p_1(i)$$

$\Gamma$ states that an interaction consists of: the $i$-th process of type $C^1$ executes transition $p_1$; the $j$-th process of type $C^2$ executes $p_2$; and, for every $i > (j + 1) \bmod n$, the $i$-th process
of type \(C^i\) executes transition \(p_1\) as well; all this happens simultaneously in one atomic step. 

Loosely speaking, (5) states that in an interaction \(\ell\) components can simultaneously engage in a multiparty rendez-vous, together with a broadcast to the ports \(q_1, \ldots, q_m\) of the components whose indices satisfy the constraints \(\psi_1, \ldots, \psi_m\), respectively. An example of peer-to-peer rendez-vous with no broadcast is the dining philosophers system in Fig. 1, whereas examples of broadcast are found among the test cases in §5. In the next section we show that, despite this generality, it is possible to construct a trap invariant for any interaction formula in a purely syntactic way.

Observe that the formula does not explicitly specify that every other process remains idle. Formally, as we will see in the next section, the system has an interaction for each minimal model of (5), which allows us not to have to specify idleness. Given structures \(I_1 = (\mathcal{U}, I_1)\) and \(I_2 = (\mathcal{U}, I_2)\) sharing the same universe \(\mathcal{U}\), we say \(I_1 \sqsubseteq I_2\) if and only if \(\iota_1(pr) \sqsubseteq \iota_2(pr)\) for every \(pr \in \text{Pred}\). Given a formula \(\phi\), a structure \(I\) is a minimal model of \(\phi\) if \(I \models \phi\) and, for all structures \(I'\) such that \(I' \subseteq I\) and \(I' \neq I\), we have \(I' \not\models \phi\).

### 2.1 Execution Semantics of Component-based Systems

The semantics of a component-based system \(S = \langle C^1, \ldots, C^n, I \rangle\) is an infinite family of Petri Nets, one for each universe of \(I\). The reachable markings and actions of the Petri Net characterize the reachable global states and transitions of the system, respectively. To fix notations, we recall several basic definitions.

**Preliminaries: Petri Nets.** A Petri Net (PN) is a tuple \(N = (S, T, E)\), where \(S\) is a set of places, \(T\) is a set of transitions, \(S \cap T = \emptyset\), and \(E \subseteq (S \times T) \cup (T \times S)\) is a set of edges. The elements of \(S \cup T\) are called nodes. Given nodes \(x, y \in S \cup T\), we write \(E(x, y) \equiv 1\) if \((x, y) \in E\) and \(E(x, y) \equiv 0\), otherwise. For a node \(x\), let \(x^x \equiv \{y \in S \cup T \mid E(x, y) = 1\}\), \(x^\bullet \equiv \{y \in S \cup T \mid E(x, y) = 1\}\) and lift these definitions to sets of nodes.

A marking of \(N\) is a function \(m: S \to \mathbb{N}\). A transition \(t\) is enabled in \(m\) if and only if \(m(s) > 0\) for each place \(s \in \bullet t\). For all markings \(m, m'\) and transitions \(t\), we write \(m \xrightarrow{t} m'\) whenever \(t\) is enabled in \(m\) and \(m'(s) = m(s) - E(s, t) + E(t, s)\), for all \(s \in S\). Given two markings \(m\) and \(m'\), a finite sequence of transitions \(\sigma = t_1, \ldots, t_n\) is a firing sequence, written \(m \xrightarrow{\sigma} m'\) if and only if either (i) \(n = 0\) and \(m = m'\), or (ii) \(n \geq 1\) and there exist markings \(m_1, \ldots, m_{n-1}\) such that \(m \xrightarrow{t_1} m_1 \ldots m_{n-1} \xrightarrow{t_n} m'\).

A marked Petri Net is a pair \(N = (N, m_0)\), where \(m_0\) is the initial marking of \(N\). A marking \(m\) is reachable in \(N\) if there exists a firing sequence \(\sigma\) such that \(m_0 \xrightarrow{\sigma} m\). We denote by \(R(N)\) the set of reachable markings of \(N\). A marked PN \(N\) is 1-safe if \(m(s) \leq 1\), for each \(s \in S\) and \(m \in R(N)\). All PNs considered in the following will be 1-safe and we shall silently blur the distinction between a marking \(m: S \to \{0, 1\}\) and the boolean valuation \(\beta_m: S \to \{\top, \bot\}\) defined as \(\beta_m(s) = \top \iff m(s) = 1\). A set of markings \(M\) is an inductive invariant of \(N = (N, m_0)\) if and only if \(m_0 \in M\) and for each \(m \xrightarrow{t} m'\) such that \(m \in M\), we have \(m' \in M\).

**Petri Net Semantics of Component-Based Systems.** We define the semantics of a component-based system as an infinite family of 1-safe Petri Nets. Let \(S = \langle C^1, \ldots, C^n, I \rangle\)
be a system with component types $C^u = (P^u, S^u, s_0^u, d^u)$, for every $k = 1, \ldots, N$. Fix a universe $U$ of $I$. We define a marked Petri Net $N^U_S \equiv (\langle S, T, E \rangle, m_0)$ as follows:

- $S \equiv \left( \bigcup_{k=1}^N S^k \right) \times U$ that is, the net has a place $(s, u)$ for each state $s$ of each component type, and for each node $u$.
- For each minimal model $T = (U, t)$ of a clause $C$ of $I$, the set $T$ contains a transition $t_i \in T$, and the set $E$ contains edges $((s, u), t_i)$ and $(t_i, (s', u))$ for every $s \xrightarrow{t_i} s' \in \left( \bigcup_{k=1}^N d^k \right)$ such that $u \in t_i(p)$. Nothing else is in $T$ or $E$. Intuitively, $t_i$ “synchronizes” all the transitions $s \xrightarrow{\cdot} s'$ of the different components occurring in the interaction.
- For each $1 \leq k \leq N$, each $s \in S^k$ and each $u \in U$, $m_0((s, u)) = 1$ if $s = s_0^k$ and $m_0((s, u)) = 0$, otherwise that is, $m_0$ contains the places $(s, u)$ such that $s$ is an initial state.

It follows immediately from this definition that $N^U_S$ is a 1-safe Petri Net. Indeed, for every $u \in U$, for every component-type $C^u$, and for every reachable marking $m$, we have $\sum_{s \in S^u} m((s, u)) = 1$. This reflects that the instance of $C^u$ at $u$ is always in exactly one of the states of $S^u$; if $s$ is that state, then $(s, u)$ is the place carrying the token.

**Example 2.** Consider our running example, with $U = \{0,1,\ldots,n-1\}$, i.e., $n$ philosophers and $n$ forks. Since the interaction formula (1) has no constants, its models are pairs $(U, t)$, where $t$ gives the interpretation of the free variable $i$ and the predicates $g, t, e$ etc. The first disjunct of (1) is $[g(i) \land t(i) \land t(succ(i))]$. It has a minimal model for each $k \in U$, namely the model with $t(i) = k$, $t(g) = [k]$ and $t(e) = [k, (k+1) \mod n]$. In the interaction produced by this model, the $k$-th philosopher executes transition $g(\epsilon i)$, the forks with numbers $k$ and $(k+1) \mod n$ execute transition $\epsilon a(k)$, and all other philosophers and forks remain idle. The second disjunct yields the interactions in which a philosopher puts down its forks. Fig. 2 shows the Petri Net $N^U_S$ for universe $U = \{0,1,2\}$. For clarity,

![Petri Net](image)

Fig. 2: Petri Net of the dining philosophers for the universe $U = \{0,1,2\}$. In reality, the two pink and green places are only one place.

the places $(f,0)$ and $(b,0)$ have been duplicated; in reality the two copies are merged.
The places of each philosopher are \{(w, i), (e, i)\} for \(i = 0, 1, 2\). For example, transition \(i_3\) corresponds to the minimal model \(\{(g, 1), (t, 1), (t, 2)\}\), in which philosopher 1 takes forks 1 and 2.

3 Trap Invariants

Given a Petri Net \(N = (S, T, E)\), a set of places \(W \subseteq S\) is called a trap if and only if \(W^\bullet \subseteq \bullet W\). A trap \(W\) of \(N\) is an initially marked trap (IMT) of the marked PN \(N = (N, m_0)\) if and only if \(m_0(s) = \top\) for some \(s \in W\).

Example 3. The Petri Net of Fig. 2 has many traps. Examples are \(\{(f, 1), (b, 1)\}\) and \(\{(f, 0), (b, 1), (f, 2), (e, 2)\}\).

An IMT defines an invariant of the Petri Net, because some place in the trap will always be marked, no matter which sequence of transitions is fired. The trap invariant of \(N\) is the set of markings that mark each IMT of \(N\). Clearly, since marked traps remain marked, the set of reachable markings is contained in the trap invariant. Hence, to prove that a certain set of markings is unreachable, it is sufficient to prove that the this set has empty intersection with the trap invariant. For self-completeness, we briefly discuss the computation of the trap invariant for a given marked Petri Net of fixed size, before explaining how this can be done for the infinite family of marked Petri Nets defining the executions of parameterized systems.

The trap constraint of a Petri Net \(N = (S, T, E)\) is the formula:

\[
\Theta(N) \overset{\text{def}}{=} \bigwedge_{t \in T} \left( \bigvee_{x \in \bullet t} x \rightarrow \left( \bigvee_{y \in t} y \right) \right)
\]

where each place \(x, y \in S\) is viewed as a propositional variable. It is not hard to show\(^5\) that any boolean valuation \(\beta : S \rightarrow \{\bot, \top\}\) that satisfies the trap constraint \(\Theta(N)\) defines a trap \(W_\beta\) of \(N\) in the obvious sense \(W_\beta = \{s \in S \mid \beta(s) = \top\}\). Further, if \(m_0 : S \rightarrow \{0, 1\}\) is the initial marking of a 1-safe PN \(N\) and \(\mu_0 \overset{\text{def}}{=} \bigvee_{m_0(s) = 1} s\) is a propositional formula, then every valuation of \(\mu_0 \land \Theta(N)\) defines an IMT of \((N, m_0)\). Usually, computing invariants requires building a sequence of underapproximants whose limit is the least fixed point of an abstraction of the transition relation of the system [20]. This is not the case of the trap invariant, that can be directly computed from the trap constraint and the initial marking \([11, 15]\).

In the rest of the section we construct a parameterized trap constraint that characterizes the traps, not of one single net, as \(\Theta(N)\), but of the infinite family of Petri Nets obtained from a component-based system. The parameterized trap constraint is a formula of WS\(\kappa S\). In Section 3.1 we first explain how to embed our interaction logic into WS\(\kappa S\), and in Section 3.2 we construct the parameterized trap constraint.

3.1 From IL\(\kappa\) to WS\(\kappa S\)

We briefly recall the syntax and semantics of WS\(\kappa S\), the monadic second order logic WS\(\kappa S\) of \(\kappa\) successors (see e.g. [34]). Let SVar be a countably infinite set of second-

---

\(^5\) See e.g. [8] for a proof.
order variables (also called set variables), denoted as \(X, Y, \ldots\) in the following. The syntax of \(\text{WSxS}\) is:

\[
\begin{align*}
t &::= x \mid \text{succ}(t) \mid \ldots \mid \text{succ}\(_n\)(t) \\
\phi &::= t_1 \mid t_2 \mid \text{pr}(t) \mid X(t) \mid \phi_1 \land \phi_2 \mid \lnot \phi_1 \mid \exists x . \phi_1 \mid \forall x . \phi_1 \end{align*}
\]

So \(\text{WSxS}\) extends \(\text{IL}\), with the constant symbol \(\overline{e}\), atoms \(X(t)\) and monadic second order quantifiers \(\exists X . \phi\). We can consider w.l.o.g. equality atoms \(t_1 = t_2\) instead of the inequalities \(t_1 \leq t_2\) in \(\text{IL}\), because the latter can be defined in \(\text{WSxS}\) as usual:

\[
x \leq y \overset{\text{def}}{=} \forall X . \text{closed}(X) \land X(x) \rightarrow X(y)\quad \text{closed}(X) \overset{\text{def}}{=} \forall x . X(x) \rightarrow \bigwedge_{i=0}^{\kappa-1} X(\text{succ}\(_i\)(x))
\]

Like \(\text{IL}\), the formulae of \(\text{WSxS}\) are interpreted on ordered trees of arity \(\kappa\). The models of \(\text{WSxS}\) are structures \((\mathfrak{U}, i)\), where \(i\) assigns the root of the tree to \(\overline{e}\), a node \(i(x)\) to each variable \(x \in \text{Var}\) and a set \(i(X) \subseteq \mathfrak{U}\) to each set variable \(X \in \text{SVar}\). The satisfaction relation \((\mathfrak{U}, i) \models_{\text{WSxS}} \phi\) is defined as for \(\text{IL}\), with one difference: in \(\text{IL}\), the successor of a leaf of a tree is the root of the tree, while in \(\text{WSxS}\) the successor of leaf is, by convention, the leaf itself [34, Example 2.10.3]. This is the only reason why \(\text{IL}\) is not just a fragment of \(\text{WSxS}\).

We define an embedding of \(\text{IL}\) formulae, without occurrences of predicates and set variables, into \(\text{WSxS}\). W.l.o.g. we consider \(\text{IL}\) formulae that have been previously flattened, i.e. the successor function occurs only within atomic propositions of the form \(\text{succ}\(_i\)(x) = y\). This is done by replacing each atomic proposition of the form \(\text{succ}\(_1\)(\ldots \text{succ}\(_n\)(x)\ldots) = y\) by the formula \(\exists x_1 \ldots \exists x_n . x_n = \text{succ}\(_i\)(x_1) \land \ldots \land \text{succ}\(_i\)(x_{n-1}) \land y = \text{succ}\(_i\)(x_n)\). The translation of an \(\text{IL}\) formula \(\phi\) into \(\text{WSxS}\) is the formula \(\text{Tr}(\phi)\), defined recursively on the structure of \(\phi\), is homomorphic w.r.t. the first-order connectives and:

\[
\text{Tr}(\text{succ}\(_i\)(x) = y) \overset{\text{def}}{=} (\lnot \max(x) \land \text{succ}\(_i\)(x) = y) \lor (\max(x) \land y = \overline{e})
\]

We show that a formula \(\phi\) of \(\text{IL}\) and its \(\text{WSxS}\) counterpart \(\text{Tr}(\phi)\) are equivalent:

Lemma 1. Given an \(\text{IL}\) formula \(\phi\), for any structure \(\mathfrak{I} = (\mathfrak{U}, i)\), we have \(\mathfrak{I} \models_{\text{IL}} \phi \iff \mathfrak{I} \models_{\text{WSxS}} \text{Tr}(\phi)\).

### 3.2 Defining Parameterized Trap Invariants in \(\text{WSxS}\)

Fix a component-based system \(S = (C^1, \ldots, C^N, \Sigma, \Gamma)\) and recall that every universe \(\mathfrak{U}\) induces a Petri Net \(N^\mathfrak{U}\) whose set of places is \(\bigcup_{k=1}^N S^k \times \mathfrak{U}\). For every state \(s \in \bigcup_{k=1}^N S^k\), let \(X_s\) be a monadic second-order variable, and let \(\overline{X}\) be the tuple of these variables in an arbitrary but fixed order. We define a formula \(\text{trap-pred}_{S}(\overline{X})\), with \(\overline{X}\) as set of free variables, that characterizes the traps of the infinitely many Petri Nets \(N_{S}^{\mathfrak{U}}\) corresponding to \(S\). Formally, \(\text{trap-pred}_{S}(\overline{X})\) has the following property:

For every universe \(\mathfrak{U}\) and for every set \(P \subseteq \bigcup_{k=1}^N S^k \times \mathfrak{U}\) of places of \(N_{S}^{\mathfrak{U}}\),

\(P\) is a trap of \(N_{S}^{\mathfrak{U}}\) iff the assignment \(X_q \mapsto \{u \in \mathfrak{U} | (q, u) \in P\}\) satisfies \(\text{trap-pred}_{S}(\overline{X})\).

Observe that every assignment to \(\overline{X}\) encodes a set of places, and vice versa. So, abusing language, we can speak of the set of places \(\overline{X}\).

We define auxiliary predicates that capture the intersection of the set of places \(\overline{X}\) with the pre and postset of a transition in \(N_{S}^{\mathfrak{U}}\). For every clause \(C \in \Gamma\), of the form (5),
we define the WSxS formulae:

\[ \text{intersects-pre}^S_\Gamma (\bar{X}, x_1, \ldots, x_\ell) = \bigwedge_{j=1}^{\ell} X_{p_j} (x_j) \lor \bigwedge_{j=1}^{\ell+m} \exists x_j . \text{Tr}(\psi_j) \land X_{p_j} (x_j) \] and

\[ \text{intersects-post}^S_\Gamma (\bar{X}, x_1, \ldots, x_\ell) = \bigwedge_{j=1}^{\ell} X_{p_j} (x_j) \lor \bigwedge_{j=1}^{\ell+m} \exists x_j . \text{Tr}(\psi_j) \land X_{p_j} (x_j). \]

Now we can define \( \text{trap-pred}^S_\Gamma (\bar{X}) \) as the conjunction of the following formulae, one for each clause \( \ell \) in \( \Gamma \):

\[
\forall x_1 \ldots \forall x_\ell . \left[ \text{Tr}(\varphi) \land \text{intersects-pre}^S_\Gamma (\bar{X}, x_1, \ldots, x_\ell) \right] \\
\rightarrow \text{intersects-post}^S_\Gamma (\bar{X}, x_1, \ldots, x_\ell).
\]

(6)

So, intuitively, \( \text{trap-pred}^S_\Gamma (\bar{X}) \) states that for every transition of the Petri Net, if the set \( \bar{X} \) of places intersects the preset of the transition, then it also intersects its postset. This is the condition for the set of places to be a trap. Formally, we obtain:

**Lemma 2.** Given a component-based system \( S = (C^1, \ldots, C^N, I) \) and a structure \( I = (\mathbb{U}, i) \), where \( i \) is an interpretation of the set variables \( \bar{X} \), the set \( P = \bigcup_{k=1}^N S^k \times \mathbb{U} \) is a trap of \( \mathbb{N}^S \) if and only if \( (\mathbb{U}, i) \models_{\text{WSxS}} \text{trap-pred}^S_\Gamma (\bar{X}) \).

**Parameterized Trap Invariants in WSxS.** Loosely speaking, the intended meaning of \( \text{trap-pred}^S_\Gamma (\bar{X}) \) is “the set of places \( \bar{X} \) is a trap”. Our goal is to construct a formula stating: “the marking \( m \) marks all initially marked traps”.

Recall that the Petri Nets obtained from component-based systems are always 1-safe, and so a marking is also a set of places. Recall, however, that all reachable markings have the property that they place exactly one token in the set of places modeling the set of states of a component (loosely speaking, the set of places of the \( k \)-th philosopher is \((w, k)\) and \((e, k)\), and there is always one token in the one or the other). So we define a formula \( \text{marking}^S_\Gamma (\bar{X}) \) with intended meaning “the set of places \( \bar{X} \) is a legal marking”, and another one, \( \text{trap-invariant}^S_\Gamma (\bar{X}) \) with intended meaning “the set of places \( \bar{X} \) marks every initially marked trap (IMT)’’.

In addition to the tuple of set variables \( \bar{X} \) defined above, we consider now the “copy” tuple \( \bar{X}' = (X'_s)_{s \in S', 1 \leq s \leq N} \). Intuitively, \( \bar{X} \) and \( \bar{X}' \) represent one set of places each.

We define a (1-safe) marking as a set of places that marks exactly one state of each copy of each component:

\[
\text{marking}^S_\Gamma (\bar{X}) = \forall x . \bigwedge_{1 \leq s \leq N} \bigvee_{s \in S_\Gamma} \left( X_s (x) \land \bigwedge_{s' \in S_\Gamma \setminus \{s\}} \neg X_{s'} (x) \right).
\]

Secondly, we give a formula describing the intersection of two sets of places:

\[
\text{intersection}^S_\Gamma (\bar{X}, \bar{X}') = \exists x . \bigvee_{s \in \bigcup_{1 \leq s \leq N} S'} (X_s (x) \land X'_s (x)).
\]

Finally, to actually capture IMTs we need to determine if a trap is initially marked. However, this can be easily described by the formula:

\[
\text{initially-marked}^S_\Gamma (X) = \exists x . \bigvee_{1 \leq s \leq N} X_{s0} (x).
\]

and so we can define the \( \text{trap-invariant} \) by the WSxS formula:

\[
\text{trap-invariant}^S_\Gamma (\bar{X}) = \forall \bar{X}' . \left[ \text{trap-pred}^S_\Gamma (\bar{X}') \land \text{initially-marked}^S_\Gamma (\bar{X}') \right] \\
\rightarrow \text{intersection}^S_\Gamma (\bar{X}, \bar{X}').
\]
Relying on Lemma 2 we are assured that the set represented by $\overline{X}$ intersects all IMTs. Further, let $\varphi(\overline{X})$ be any formula that defines a set of good global states of the component-based systems (or, equivalently, a good set of markings of their corresponding Petri nets), with the intuition that, at any moment during execution, the current global state of the component-based system should be good. We can now state the following theorem, that captures the soundness of the verification method based on trap invariants:

**Theorem 1.** Given a component-based system $S$ and a $\text{WS}_{\kappa}S$ formula $\varphi(\overline{X})$, if the formula

$$\exists \overline{X}. \text{marking}_{S}(\overline{X}) \land \text{trap-invariant}_{S}(\overline{X}) \land \neg \varphi(\overline{X}) \quad (8)$$

is unsatisfiable, then for every universe $\mathcal{U}$, the property defined by the formula $\varphi(\overline{X})$ holds in every reachable marking of $S^{\mathcal{U}}$.

In the light of the above theorem, verifying the correctness of a component-based system with any number of active components boils down to deciding the satisfiability of a $\text{WS}_{\kappa}S$ formula. The latter problem is known to be decidable, albeit in general, with non-elementary recursive complexity. A closer look at the verification conditions of the form (8) generated by our method suffices to see that the quantifier alternation is finite, which implies that the time needed to decide the (un)satisfiability of (8) is elementary recursive. Moreover, our experiments show that these checks are very fast (less than 1 second on an average machine) for a non-trivial set of examples.

### 4 Refining Trap Invariants

Since the safety verification problem is undecidable for parameterized systems [6], the verification method based on trap invariants cannot be complete. As an example, consider the alternating dining philosophers system, of which an instance (for $n = 3$) is shown in Fig. 3. The system consists of two philosopher component types, namely $\text{Philosopher}_{rl}$, which takes its right fork before its left fork, and $\text{Philosopher}_{lr}$, taking the left fork before the right one. Each philosopher has two interaction ports for taking the forks, namely $g\ell$ (get left) and $gr$ (get right) and one port for releasing the forks $p$ (put). The ports of the $\text{Philosopher}_{rl}$ component type are overlined, in order to be distinguished. The $\text{Fork}$ component type is the same as in Fig. 1. The interaction formula for this system $\Gamma_{\text{alt philo}}^{\text{alt}}$, shown in Fig. 3, implicitly states that only the 0-index philosopher component is of type $\text{Philosopher}_{rl}$, whereas all other philosophers are of type $\text{Philosopher}_{lr}$. Note that the interactions on ports $\overline{g\ell}$, $\overline{gr}$ and $\overline{p}$ are only allowed if $\text{zero}(x) \equiv \forall y. \ x \leq y$ holds, in other words if $x$ is interpreted as the root of the universe (in our case, 0 since $\mathcal{U} = \{0, \ldots, n-1\}$).

It is well-known that any instance of the parameterized alternating dining philosophers system consisting of at least one $\text{Philosopher}_{rl}$ and one $\text{Philosopher}_{lr}$ is deadlock-free. However, trap invariants are not enough to prove deadlock freedom, as shown by the global state $\{\langle b, 0 \rangle, \langle h, 0 \rangle, \langle b, 1 \rangle, \langle w, 1 \rangle, \langle f, 2 \rangle, \langle e, 2 \rangle\}$, marked with thick red lines in Fig. 3. Note that no interaction is enabled in this state. Moreover, this state intersects with any trap of the marked PN that defines the executions of this particular instance, as proved below. Consequently, the trap invariant contains a deadlock configuration, and the system cannot be proved deadlock-free by this method.
Proposition 1. Consider an instance of the alternating dining philosophers system in Fig. 3, consisting of components Fork(0), Philosopher$_r(0)$, Fork(1), Philosopher$_r(1)$, Fork(2) and Philosopher$_r(2)$ placed in a ring, in this order. Then each nonempty trap of this system contains one of the places $\langle b,0\rangle, \langle h,0\rangle, \langle b,1\rangle, \langle w,1\rangle, \langle f,2\rangle$ or $\langle e,2\rangle$.

However, the configuration is unreachable by a real execution of the PN, started in the initial configuration that marks $\langle f,i\rangle$ and $\langle w,i\rangle$, for all $i = 0, 1, 2$. An intuitive reason is that, in any reachable configuration, each fork is in state $f$(ree) only if none of its neighboring philosophers is in state $e$(ating). In order to prove deadlock freedom, one must learn this and other similar constraints. Next, we present a heuristic method for strengthening the trap invariant, that infers such universal constraints, involving a fixed set of components.

4.1 One Invariants

As shown by the example above, trap constraints do sometimes fail to prove interesting properties. Hence, it is desirable to refine the overapproximation of viable markings to exclude more spurious counterexamples. In order to do so, we consider a special class of linear invariants, called 1-invariants in the following. Although linear invariants are not structural and rely on the set of reachable markings of a marked Petri Net, the set of 1-invariants can be sufficiently under-approximated by structural conditions.

Definition 1. Given a marked PN $\mathcal{N} = (\langle S, T, E \rangle, m_0)$, with $S = \{s_1, \ldots, s_n\}$, a vector $a = (a_1, \ldots, a_n) \in \{0, 1\}^n$ is a 1-invariant of $\mathcal{N}$ if and only if, for each reachable marking $m \in \mathcal{R}(\mathcal{N})$, we have $\sum_{i=1}^n a_i \cdot m(s_i) = 1$.

The following lemma states the structural properties that sufficiently define 1-invariants. However, the opposite is not true: the are 1-invariants not captured by these conditions. Taking the intersection of this set of 1-invariants defines a weaker invariant, for the net, which is sound for our verification purposes.

Lemma 3. Given a marked PN $\mathcal{N} = (\langle S, T, E \rangle, m_0)$, a set of places $\subseteq S$ is a 1-invariant if the following hold:
We devote the rest of this section to describe \( WSxS \) formulae which capture the structural properties necessary to define 1-invariants as laid down by Lemma 3 (2). As demonstrated in Section 3 the pre- and postset of transitions, as well as general sets of places in a PN describing the execution semantics can be defined in \( WSxS \). Hence, we present the definitions of the following formulae only in the appendix and just give the intuitions here.

As before, we fix two tuples of set variables \( \overline{X} \) and \( \overline{X}' \), with one variable \( X_i \) for each state \( s \in \bigcup_{i=1}^{N} S^i \) and we define the formulae:

1. \( \sum_{s \in S^i} m_i(s) = 1 \),
2. either \( ||\overline{X} \cap t || = ||\overline{X} \cap t^* || = k \) with \( k \in \{0, 1\} \) or \( ||\overline{X} \cap t || > 1 \) for every \( t \in T \).

We may now define the 1-pred \( S \) which consists of a conjunction of unique-init \( S \) and the formulae:

\[
\forall x_1, \ldots, \forall x_r, (\text{Tr}(\varphi) \rightarrow [\neg \text{intersects-pre}_S^\xi \land \neg \text{intersects-post}_S^\xi \\
\lor \text{unique-pre}_S^\xi \land \text{unique-post}_S^\xi \\
\lor \text{intersects-pre}_S^\xi \land \neg \text{unique-pre}_S^\xi])
\]

one for each clause \( \xi \) in \( \Gamma \). We show the soundness of this definition, by the following:

**Lemma 4.** Given a component-based system \( S = (C^1, \ldots, C^N, \Gamma) \) and a tuple of set variables \( \overline{X} \), one for each state in a component of \( S \). Then, for any structure \((\mathcal{U}, t)\), such that \( t \) interprets the variables in \( \overline{X} \), the set \( P = \{(s, u) \in \bigcup_{i=1}^{N} S^i \times \mathcal{U} | u \in t(X_i)\} \) is a 1-invariant of \( N^U_S \) if \((\mathcal{U}, t) \models_{WS} 1\text{-pred}_S(\overline{X})\).

We may now define the 1-invariant analogously to the trap-invariant before:

\[
1\text{-invariant}_S(\overline{X}) = \forall \overline{X}' \cdot 1\text{-pred}_S(\overline{X}') \rightarrow \text{unique-intersection}_S(\overline{X}, \overline{X}').
\]

And by analogously reasoning we obtain a refinement of Theorem 1 since every reachable marking has to satisfy both invariants.

**Theorem 2.** Given a component-based system \( S \) and a \( WSxS \) formula \( \varphi(\overline{X}) \), if the formula:

\[
\exists \overline{X} \cdot \text{marking}_S(\overline{X}) \land 1\text{-invariant}_S(\overline{X}) \land \text{trap-invariant}_S(\overline{X}) \land \neg \varphi(\overline{X})
\]

is unsatisfiable, then for every universe \( \mathcal{U} \), the property defined by the formula \( \varphi(\overline{X}) \) holds in every reachable marking of \( N^U_S \).
5 Experiments

We have implemented a prototype (called ostrich) of this verification procedure to evaluate the viability of our approach. All the files and scripts used can be found online\(^6\). The current version of the prototype can only handle token-ring and pipeline topologies, but not trees; for these topologies the verification reduces to checking satisfiability of a formula of WS1S. We have also considered one example with tree-topology (see below), for which the formula was constructed manually. Satisfiability of WS1S and WS\(\kappa\)S formulae was checked using version 1.4/17 of Mona \cite{Mona}. We consider various examples separated in categories:

**Cache Coherence:** Following \cite{Bos} we formalized and checked the described safety properties and deadlock-freedom of the following cache coherence protocols: Illinois, Berkeley, Synapse, Firefly, MESI, MOESI, and Dragon.

**Mutual Exclusion:** We modelled and checked for deadlock-freedom and mutual exclusion Burns’ \cite{Burns}, Dijkstra’s and Szymanski’s \cite{Szymanski} algorithms as well as a formulation of Dijkstra’s algorithm on a ring structure with token passing \cite{DijkstraRing}. Furthermore, we check synchronization via a semaphore which is atomically acquired and by broadcasting to ensure everyone else is not in the critical section.

**Dining Philosophers:** This is the classical problem of dining philosophers which all take first the right fork and then the left fork. We consider the following “flavors” of this problem:

- there is one philosopher who takes first her left and then her right fork,
- as above but the forks remember whom took them, and
- there are two global forks everyone grabs in the same order.

**Preemptive Tasks:** There are tasks which can be either waiting, ready, executing or preempted. Initially one task is executing while all others are waiting. At any point a task may become ready and any ready task may preempt the currently executing task. Upon finishing the executing task re-enables one preempted task. Here, we have additionally two alternatives: Firstly, we consider the case where always the agent with highest index resumes execution. Secondly, we let the processes establish the initial condition from a position where everyone is waiting.

**Dijkstra-Scholten:** This is an algorithm that is used to detect termination of distributed systems by message passing along a tree \cite{DijkstraTree}. Since the prototype only supports linear topologies we can generate the necessary formula automatically only for this case.

**Herman:** This algorithm implements self-stabilizing token passing in rings. The formulation as well as all following follow \cite{Herman}.

**Israeli-Jalfon:** This is another self-stabilizing token passing algorithm in rings.

**Lehmann-Rabin:** This is a randomized solution to the dining philosophers problem.

**Dining Cryptographers:** This time a group of cryptographers want to determine if one of them paid for a meal or a stranger.

The results are shown in Table 1. The first column reports which properties could (✓) and could not be verified (×) because the conjunction of trap and one-invariant

\(^6\) https://gitlab.lrz.de/i7/ostrich
was not strong enough to prove the given property. For the consistency properties of cache-coherence protocols we give \((x/y)\) which reads: “from \(y\) properties \(x\) could be established”. The following column reports the time (in second) it takes to prove all considered properties. To understand the next four columns, recall that Mona constructs for a given formula \(\phi(X)\) a finite automaton recognizing all the sets \(X\) for which \(\phi\) holds. Since the automata can have very large alphabets, the transition relation of the automaton is encoded as a binary decision diagram (BDD). The columns report the sizes of the automata (in the format: number of states / number of nodes of the BDD) for different formulas. More precisely, the columns trap, trap-inv, flow and flow-inv give the sizes of the automata for \(\text{trap-pred}_S \land \text{initially-marked}_S\), \(\text{trap-invariant}_S\), \(\text{l-pred}_S\) and \(\text{l-invariant}_S\) respectively. We write “n.a.” (for “not available”) to indicate that Mona timed out before the automaton was computed.

The first observation is that the satisfiability checks often can be done in very short time. This is surprising, because the formulas to be checked, namely (8) and (11), exhibit one quantifier alternation (recall that \(\text{trap-invariant}_S\) and \(\text{l-invariant}_S\) contain universal quantifiers). More specifically, since \(\text{trap-invariant}_S\) is obtained by universally quantifying over \(\text{trap-pred}_S \land \text{initially-marked}_S\), one would expect the automaton for the former to be much larger than the one for the latter, at least in some cases. But this does not happen: In fact, the automaton for \(\text{trap-invariant}_S\) is almost always smaller. Similarly, there is no blowup between \(\text{l-pred}_S\) and \(\text{l-invariant}_S\). A possible explanation could be that the exponential blowup caused by universal quantification in \(\text{WS}\text{x}\text{S}\) manifests only on theoretical corner cases, which do not occur in our examples.

6 Conclusions

We have shown that the trap technique used in [11,26,13] for the verification of single systems can be extended to parameterized systems with sophisticated communication structures, like pipelines, token rings and trees. Our extension constructs a parameterized trap invariant, a formula of \(\text{WS}\text{x}\text{S}\) satisfied by the reachable global states of all instances of the system. The core of the approach is a purely syntactic, automatic derivation of the trap invariant from the interaction formula describing the possible transitions of the system. When the set of safe global states can also be expressed in \(\text{WS}\text{x}\text{S}\), which is usually the case, we check using the Mona tool whether the trap invariant implies the safety formula. The technique proves correctness of systems that do not produce well-structured transition systems in the sense of [1,27], and of systems with broadcast communication, for which, to the best of our knowledge, cut-off results have not been obtained yet.

Our experiments demonstrate that trap invariants can be very effective in finding proofs of correctness (inductive invariants) of common benchmark examples. In practice, the technique is very cheap, since it avoids costly fixpoint computations. This suggests incorporating it into other verifiers as a cheap preprocessing step.

Table 1: Experimental results of a prototype implementation.
7 Proofs from Section 3.1

Lemma 1. Given an \(Lk\) formula \(\phi\), for any structure \(I = (\lambda, i)\), we have \(I \models L \phi \iff I \models ws_6 Tr(\phi)\).

Proof: By induction on the structure of \(\phi\). Since \(Tr(.)\) is homomorphic w.r.t the first-order connectives, the only interesting case is when \(\phi\) is \(\text{succ}(x) = y\).

\((\Rightarrow)\) If \((\lambda, i) \models ws_6 \text{succ}(x) = y\) then \(\sigma_I(t(x)) = \tau(y)\) and we distinguish two cases:

- If \(t(x)\) is not a maximal element of \(\lambda\), then \(\sigma_I(t(x)) = \xi_I(t(x))\), hence \((\lambda, i) \models ws_6 \neg \text{max}(x) \land \text{succ}(x) = y\).
- If \(t(x)\) is a maximal element of \(\lambda\), then \(\xi_I(t(x)) = e\), hence \((\lambda, i) \models ws_6 \text{max}(x) \land y = \mathcal{F}_\lambda\).

In each case, we obtain \((\lambda, i) \models ws_6 Tr(\text{succ}(x) = y)\).

\((\Leftarrow)\) Since \((\lambda, i) \models ws_6 Tr(\text{succ}(x) = y)\), we have two cases:

- If \((\lambda, i) \models ws_6 \neg \text{max}(x) \land \text{succ}(x) = y\) then \(t(x)\) is not a maximal element of \(\lambda\) and \(\xi_I(t(x)) = \tau(y)\), thus \(\sigma_I(t(x)) = \tau(y)\) and \((\lambda, i) \models ws_6 \text{succ}(x) = y\).
- If \((\lambda, i) \models ws_6 \text{max}(x) \land y = \mathcal{F}_\lambda\) and \(t(x)\) is a maximal element of \(\lambda\). In this case we have \(\sigma_I(t(x)) = e = \tau(y)\), hence \((\lambda, i) \models L \text{succ}(x) = y\). \(\square\)

8 Proofs from Section 3.2

Lemma 2. Given a component-based system \(S = \langle C', \ldots, C^n, \Gamma \rangle\) and a structure \(I = (\lambda, i)\), where \(i\) is an interpretation of the set variables \(X\), the set \(P = \{(s, u) \in \bigcup_{s=1}^N \lambda^s \times S | u \in i(x_s)\}\) is a trap of \(N^S\) if and only if \((\lambda, i) \models ws_6 \text{trap-pred}_S(\lambda, X)\).

Proof: Central to our analysis of \(N^S = (S, T, E)\) is the following fact:

Fact 1 For any transition \(t \in T\) exists a clause
\[C(x_1, \ldots, x_t) = \exists \cdot \varphi \land \bigwedge_{j=1}^{\ell} p_j(x_j) \land \bigwedge_{j=\ell+1}^{\ell+m} \forall x_j \cdot \psi_j \rightarrow p_j(x_j)\]
in \(\Gamma\) and values \(u_1, \ldots, u_t \in \lambda\) such that:
\[
(\langle \lambda, i[x_1 \leftarrow u_1, \ldots, x_t \leftarrow u_t \rangle \rangle \models \varphi, \\ 
* \ i = \{(s, u) | u \in \psi_j \land s = \ast p_j \text{ for some } \ell + 1 \leq j \leq \ell + m \cup \{(\ast p_1, u_1), \ldots, (\ast p_t, u_t)\}\}
\ast \ i = \{(s, u) | u \in \psi_j \ land s = p_j^\ast \text{ for some } \ell + 1 \leq j \leq \ell + m \cup \{(p_1^\ast, u_1), \ldots, (p_t^\ast, u_t)\}\}
\]
where \(\psi_j \models \{u \in U | \langle \lambda, [y_j \leftarrow u]_\lambda, 0 \rangle \models \varphi \}\) for \(\ell + 1 \leq j \leq \ell + m\). Dually, for a fixed clause \(\varphi\) in \(\Gamma\) and a tuple of values \(\bar{u} = (u_1, \ldots, u_t)\) such that \((\langle \lambda, i[x_1 \leftarrow u_1, \ldots, x_t \leftarrow u_t \rangle \rangle \models \varphi\) there exists a unique transition \(t \in T\) with \(*i\) and \(*i\) as above, denoted \((\varphi, \bar{u})\).

Proof: By the definition of \(N^S\), for any \(t \in T\) there exists a clause \(C\) of \(\Gamma\) of the form (5)

and a minimal model \(I = (\lambda, i)\) of \(C\). Hence, there are values \(u_1 \in \iota(p_1), \ldots, u_t \in \iota(p_t)\) such that \((\langle \lambda, i[x_1 \leftarrow u_1, \ldots, x_t \leftarrow u_t \rangle \rangle \models \varphi\). By the minimality of \(I\), \(u_1, \ldots, u_t\) are the only elements of \(\iota(p_1), \ldots, \iota(p_t)\), respectively. Moreover, for every \(\ell + 1 \leq j \leq \ell + m\) and \(u \in \psi_j\), we have \(u \in \iota(p_j)\) and nothing else is \(\iota(p_j)\). By the definition of \(N^S\), we obtain \(*i\) and \(*i\) as stated above.
For the dual direction, we fix $\mathcal{C}$ in $F$ and $u_1, \ldots, u_\ell$ such that $\langle \Delta, i(x_1 \leftarrow u_1, \ldots, x_\ell \leftarrow u_\ell \rangle \models_\Delta \varphi$. The structure $\mathcal{T} = (\Delta, \pi)$, where:
\[
\pi(x_j) = u_j \text{ and } \pi(p_j) = \{u_j\}, \text{ for all } 1 \leq j \leq \ell \\
\pi(p_j) = \emptyset, \text{ for all } \ell + 1 \leq j \leq \ell + m
\]
is a minimal model of $\mathcal{C}$ and uniquely determines $t \in T$ with the above properties.

Next, we prove the following points:

1. $P \cap *\langle \mathcal{C}, i(x_1), \ldots, i(x_\ell) \rangle \neq \emptyset \iff (\Delta, i) \models_{\mathcal{WS}_S} \text{intersects-pre}_{\mathcal{S}}(\bar{X}, x_1, \ldots, x_\ell)$:
   
   "⇒" If $P \cap *\langle \mathcal{C}, i(x_1), \ldots, i(x_\ell) \rangle \neq \emptyset$, then we have two cases:
   - if $(*p_j, i(x_j)) \in P$, for some $1 \leq j \leq \ell$, then by the definition of $P$, we obtain $i(x_j) \in i(X_{p_j})$ and thus $\mathcal{T} \models_{\mathcal{WS}_S} \text{pre}_{\mathcal{S}}(x_j)$, by Lemma 1. Since also $\mathcal{T} \models_{\mathcal{WS}_S} X_{p_j}(x_j)$, by a similar argument as before, we obtain $(\Delta, i) \models_{\mathcal{WS}_S} \exists x_j. \text{pre}(x_j) \land X_{p_j}(x_j)$.
   - else $(p_j, u) \in \ell$ for some $1 \leq j \leq \ell$, leading to $u \in \mathcal{P}_j$. But then $\mathcal{T} \models_{\mathcal{WS}_S} \text{pre}(\ell)$, by Lemma 1, and therefore $(\Delta, i) \models_{\mathcal{WS}_S} \exists x_{\ell}. \text{pre}(x_{\ell}) \land X_{p_j}(x_j)$, by a similar argument as before, we obtain $(\Delta, i) \models_{\mathcal{WS}_S} \exists x_j. \text{pre}(x_j) \land X_{p_j}(x_j)$.

   "⇐" If $(\Delta, i) \models_{\mathcal{WS}_S} \text{intersects-pre}_{\mathcal{S}}(\bar{X}, x_1, \ldots, x_\ell)$ then one of the following holds:
   - if $(\mathcal{C}, i(x_1), \ldots, i(x_\ell)) \neq \emptyset$, then by the definition of $P$ and Fact 1, we obtain $(*p_j, i(x_j)) \in P \cap *\langle \mathcal{C}, i(x_1), \ldots, i(x_\ell) \rangle$.
   - else $(\mathcal{C}, i(x_1), \ldots, i(x_\ell)) \neq \emptyset$. From 1 and 2, we conclude that $P \cap *\langle \mathcal{C}, i(x_1), \ldots, i(x_\ell) \rangle \neq \emptyset$, whereas $P \cap \langle \mathcal{C}, i(x_1), \ldots, i(x_\ell) \rangle^* \neq \emptyset$. But then, $P$ is not a trap of $N_{\mathcal{S}}^\square$, because $t \in P$, whereas $t \notin P^*$.

2. $P \cap *\langle \mathcal{C}, i(x_1), \ldots, i(x_\ell) \rangle \neq \emptyset \iff (\Delta, i) \models_{\mathcal{WS}_S} \text{trap-pre}_{\mathcal{S}}(\bar{X})$.

   This case is proved using a similar argument as (1) above.

Back to the main proof, we need to show that $P$ is a trap in $N_{\mathcal{S}}^\square \iff (\Delta, i) \models_{\mathcal{WS}_S} \text{trap-pre}_{\mathcal{S}}(\bar{X})$.

"⇒" Consider the case where $(\Delta, i) \models_{\mathcal{WS}_S} \text{trap-pre}_{\mathcal{S}}$. Hence, there is a clause $\mathcal{C}$ and nodes $u_1, \ldots, u_\ell \in \mathcal{U}$ such that $(\mathcal{C}, i(x_1 \leftarrow u_1, \ldots, x_\ell \leftarrow u_\ell) \models_{\mathcal{WS}_S} \text{pre}(\varphi)$, thus, by Lemma 1, $(\mathcal{C}, i(x_1 \leftarrow u_1, \ldots, x_\ell \leftarrow u_\ell) \models_{\mathcal{WS}_S} \text{pre}(\varphi) \land X_{p_j}(x_j)$, which is a trap $\mathcal{T} \models_{\mathcal{WS}_S} \exists x_j. \text{pre}(x_j) \land X_{p_j}(x_j)$. This in turn leads to $u_j \in \mathcal{P}_j$, and therefore $(*p_j, u_j) \in P \cap *\langle \mathcal{C}, i(x_1), \ldots, i(x_\ell) \rangle$.

"⇐" Assume that $(\Delta, i) \models_{\mathcal{WS}_S} \text{trap-pre}_{\mathcal{S}}$ and let $t \in P^*$ be a transition. By Fact 1, there is a clause $\mathcal{C}$ and nodes $\pi = (u_1, \ldots, u_\ell) \in \mathcal{U}$ such that $t \in \mathcal{C}(\pi)$. Then, we have $(\mathcal{C}, i(x_1 \leftarrow u_1, \ldots, x_\ell \leftarrow u_\ell) \models_{\mathcal{WS}_S} \text{pre}(\varphi)$, by Lemma 1, and since $t \in P^*$, we have $P \cap t^* \neq \emptyset$, thus $P \models_{\mathcal{WS}_S} \text{pre}(\varphi)$, by (1). Because $(\Delta, i) \models_{\mathcal{WS}_S} \text{trap-pre}_{\mathcal{S}}$, we also obtain that $P \cap \langle \mathcal{C}, i(x_1 \leftarrow u_1, \ldots, x_\ell \leftarrow u_\ell \rangle \models_{\mathcal{WS}_S} \text{pre}(\varphi)$, by (2). This leads to $t \in P^*$, and since the choice of $t$ was arbitrary, we obtain $P^* \subseteq P$, as required.

Theorem 1. Given a component-based system $S$ and a WS$\mathcal{S}$ formula $\varphi(\bar{X})$, if the formula
\[
\exists \bar{X}. \text{marking}(\bar{X}) \land \text{trap-invariant}_S(\bar{X}) \land \neg \varphi(\bar{X})
\]
is unsatisfiable, then for every universe $\Delta$, the property defined by the formula $\varphi(\bar{X})$ holds in every reachable marking of $N_{\mathcal{S}}^\square$.

Proof: Let $(\Delta, i)$ be a structure, such that $i$ interprets $\bar{X}$ and $\bar{X'}$ and let $m$ be a marking of $N_{\mathcal{S}}^\square$. We define the sets:
\[
G_i = \bigcup_{j=1}^K S \times \mathcal{U} \mid u \in i(X_j) \} \quad \text{and} \quad G_i' = \bigcup_{j=1}^K S \times \mathcal{U} \mid u \in i(X_j') \}
\]
\[
G_m = \bigcup_{S \subseteq \mathcal{U}} \{ s \times \bar{G}_m \} \quad \text{where} \quad \bar{G}_m = \{ u \in \mathcal{U} \mid m((s,u)) = 1 \}
\]
and note the following points (the proofs of which are easy checks left to the reader):

(a) for any marking \( m \) of \( N_S^\| \) if \( \ell(X_1) = G_m^\| \) then \( (\mathcal{U}, t) \models_{\text{WS}^S} \text{marking}_S(X) \).  
(b) \( (\mathcal{U}, t) \models_{\text{WS}^S} \text{intersection}_S(X, \overline{X}) \iff G_t \cap G_t^\| \neq \emptyset \), and  
(c) if \( m_0 \) is the initial marking of \( N_S^\| \), then

\[
(\mathcal{U}, t) \models_{\text{WS}^S} \text{initial-marked}_S(X) \iff G_t \cap G_{m_0} \neq \emptyset.
\]

With (c) and Lemma 2 we conclude that \( (\mathcal{U}, t) \models_{\text{WS}^S} \text{trap-pred}_S(X, \overline{X}) \wedge \text{initial-marked}_S(X) \) if and only if \( G_t^\| \) is an IMT. Which yields using (b) that \( (\mathcal{U}, t) \models_{\text{WS}^S} \text{trap-invariant}_S(X) \) if and only if \( G_t \) intersects all IMTs. Hence, if there is a marking \( m \in \mathcal{R}(N_S^\|) \) such that \( (\mathcal{U}, t[X_1 \leftarrow G_m^\|]_{|\ell(X_1) \leq k} \mathcal{S}) \models_{\text{WS}^S} \neg \phi \), i.e. \( G_m \) “violates” \( \phi \), then by (a), we obtain:

\[
(\mathcal{U}, t[X_1 \leftarrow G_m^\|]_{|\ell(X_1) \leq k} \mathcal{S}) \models_{\text{WS}^S} \text{marking}_S(X) \wedge \text{trap-invariant}_S(X) \wedge \neg \phi(X).
\]

The proof follows by contraposition. \( \square \)

9 Proofs from Section 4

Proposition 1. Consider an instance of the alternating dining philosophers system in Fig. 3, consisting of components \( \text{Fork}(0) \), \( \text{Philosopher}_{\ell}(0) \), \( \text{Fork}(1) \), \( \text{Philosopher}_{\ell}(1) \), \( \text{Fork}(2) \) and \( \text{Philosopher}_{\ell}(2) \) placed in a ring, in this order. Then each nonempty trap of this system contains one of the places \( \langle b, 0 \rangle, \langle h, 0 \rangle, \langle b, 1 \rangle, \langle w, 1 \rangle, \langle f, 2 \rangle \) or \( \langle e, 2 \rangle \).  

Proof: Let \( C = \{ \langle b, 0 \rangle, \langle h, 0 \rangle, \langle b, 1 \rangle, \langle w, 1 \rangle, \langle f, 2 \rangle, \langle e, 2 \rangle \} \) in the following. We shall try to build a nonempty trap \( T \) that avoids every state in \( C \). If such a trap can be found, the counterexample is shown to be spurious (unreachable). Below is the list of states allowed in \( T \), indexed by component (using other states that the ones listed below would result in a trap that is satisfied by the counterexample \( C \), which is exactly the opposite of what we want):

| Component | States |
|-----------|--------|
| Fork(0)   | \langle f, 0 \rangle, \langle w, 0 \rangle, \langle e, 0 \rangle |
| Philosopher_{\ell}(0) | \langle f, 1 \rangle, \langle e, 1 \rangle |
| Fork(1)   | \langle h, 1 \rangle, \langle h, 1 \rangle |
| Philosopher_{\ell}(1) | \langle b, 2 \rangle, \langle w, 2 \rangle, \langle h, 2 \rangle |
| Fork(2)   | \langle f, 2 \rangle, \langle b, 2 \rangle |
| Philosopher_{\ell}(2) | \langle e, 2 \rangle |

Assume that \( \langle f, 0 \rangle \in T \). Then \( T \) must contain \( \langle b, 0 \rangle \) or \( \langle e, 2 \rangle \) (constraint \( \text{gr}(2) \wedge \neg \text{gr}(0) \)). However neither is allowed, thus \( \langle f, 0 \rangle \notin T \). Assume that \( \langle f, 1 \rangle \in T \). Then \( T \) must contain \( \langle b, 1 \rangle \) or \( \langle h, 0 \rangle \) (constraint \( \text{gr}(0) \wedge \neg \text{gr}(1) \)), contradiction, thus \( \langle f, 1 \rangle \notin T \). Assume that \( \langle b, 2 \rangle \in T \). Then \( T \) must contain \( \langle f, 1 \rangle, \langle w, 1 \rangle \) or \( \langle f, 2 \rangle \) (constraint \( \text{gr}(2) \wedge \neg \text{gr}(1) \wedge \neg \text{gr}(1) \)), contradiction, thus \( \langle b, 2 \rangle \notin T \). Then \( T \) contains only philosopher states, except for \( \langle h, 0 \rangle, \langle w, 1 \rangle \) and \( \langle e, 2 \rangle \). One can prove that there is no such trap, for instance, for \( \text{Philosopher}_{\ell}(1) \) we have:

\[
\langle h, 1 \rangle \in T \Rightarrow \langle e, 1 \rangle \in T \\
\langle e, 1 \rangle \in T \Rightarrow \langle w, 1 \rangle \in T
\]

since \( \langle f, 1 \rangle, \langle b, 1 \rangle, \langle f, 2 \rangle, \langle b, 2 \rangle \notin T \). Since \( \langle w, 1 \rangle \notin T \), we obtain that \( \langle h, 1 \rangle, \langle e, 1 \rangle \notin T \). Then the only possibility is \( T = \emptyset \). \( \square \)
10 Missing Material from Section 4.1

Lemma 3. Given a marked PN $N = ((S, T, E), m_0)$, a set of places $\overline{\gamma} \subseteq S$ is a $1$-invariant if the following hold:
1. $\sum_{s \in \overline{\gamma}} n_0(s) = 1$,
2. either $\|\overline{\gamma} \cap t\| = \|\overline{\gamma} \cap \bullet\| = k$ with $k \in \{0, 1\}$ or $\|\overline{\gamma} \cap t\| > 1$ for every $t \in T$.

Proof: A simple inductive argument allows to prove the invariant $\sum_{s \in \overline{\gamma}} m(s) = 1$ for every marking $m \in \mathcal{R}(N)$ while additionally maintaining that any transition $t$ such that $\|W \cap t\| > 1$ cannot be fired.

In the following we give the missing formulae and auxiliaries from Section 4.1 for the case that the preset of a transition is considered. The case of a postset is completely analogous. We let $x$ denote a vector $x := (x_1, \ldots, x_t)$.

$$\text{unique-init}_S(\overline{X}) = \exists x . \bigvee_{1 \leq k \leq K} (X_{s_k}(x) \land \bigwedge_{1 \leq l \leq K} \neg X_{s_l}(y)) \land \forall y . \bigvee_{1 \leq k \leq K} X_{s_k}(y) \rightarrow x = y$$

$$\text{unique-intersection}_S(\overline{X}, \overline{Y}) = \exists x . \bigvee_{p \in \overline{U} \cup \overline{X}} \left( (X_q(x) \land X_s(x)) \land \bigwedge_{p \in \overline{U} \cup \overline{X} \setminus \{q\}} \neg (X_q(x) \land X_s(x)) \right) \land \forall y . \bigvee_{p \in \overline{U} \cup \overline{X}} X_q(y) \land X_s(y) \rightarrow x = y$$

$$\text{unique-pre-ex}_S(\overline{X}, x) = \bigvee_{1 \leq f \leq m} (X_{p_1}(x_1) \land \bigwedge_{1 \leq l \leq f} \neg X_{p_l}(x_0) \land X_{p_l}(x_0) \rightarrow x_1 = x_0)$$

$$\text{disjoint-pre-broadcast}_S(\overline{X}, x) = \forall y . \bigwedge_{f + 1 \leq l \leq m} \left[ \psi(x, y) \rightarrow \neg X_p(y) \right]$$

$$\text{disjoint-pre-ex}_S(\overline{X}, x) = \bigwedge_{1 \leq f \leq m} \neg X_p(x_1)$$

$$\text{unique-pre-broadcast}_S(\overline{X}, x) = \bigvee_{f + 1 \leq l \leq m} \left[ \exists x . \left( \psi(x, x_1) \land X_{p_1}(x_j) \land \bigwedge_{1 \leq l \leq f} \neg X_{p_l}(x_0) \land X_{p_l}(x_0) \rightarrow x_1 = x_0 \right) \land \forall y . \left[ \psi(x, y) \land X_{p_1}(y) \rightarrow y = x_1 \right] \land \bigwedge_{1 \leq l \leq f} \neg X_{p_l}(y) \right]$$

$$\text{unique-pre-ex}_S(\overline{X}, x) = \left( \text{unique-pre-ex}_S(\overline{X}, x) \land \text{disjoint-pre-broadcast}_S(\overline{X}, x) \right) \lor \left( \text{unique-pre-broadcast}_S(\overline{X}, x) \land \text{disjoint-pre-ex}_S(\overline{X}, x) \right)$$

Lemma 4. Given a component-based system $S = (C^1, \ldots, C^n, \Gamma)$ and a tuple of set variables $\overline{X}$, one for each state in a component of $S$. Then, for any structure $\langle \mathcal{U}, t \rangle$, such that $t$ interprets the variables in $\overline{X}$, the set $P = \{(x, u) \in \bigcup_{i=1}^N \mathcal{S} \times \mathcal{U} | u \in i(X_i)\}$ is a $1$-invariant of $N^\mathcal{U}_S$ if $\langle \mathcal{U}, t \rangle \models_{\mathcal{U}, S} l$-pred$_S(\overline{X})$.

Proof: We begin by formulating some auxiliary statements. For this we fix a clause $C(x_1, \ldots, x_t)$ in $\Gamma$ and values $u_1, \ldots, u_t$ such that $\langle \mathcal{U}, t \rangle(x_1 \leftarrow u_1, \ldots, x_t \leftarrow u_t) \models_{\mathcal{U}} \varphi$ and by Fact 1 we get a corresponding transition $t$. We separate $\bullet t$ and $t^\bullet$ into its existential and universal part, i.e.

$$\bullet t = \bullet^3 \cup t^\bullet$$

with $\bullet^3 = \{ \bullet p_1, c_1 \}, \ldots, (\bullet p_t, c_t) \}$ and $t^\bullet = \{ l + 1 \leq j \leq \ell + m \}$. 

W.l.o.g. we assume that $\aleph^\ast \cap \aleph^{\ast'} = \emptyset$ and moreover $||p_j : \ell + 1 \leq j \leq \ell + m|| = m$. This is achieved by two steps. Namely, if there are two broadcasts

$$\forall x_j : \varphi_j(x_1, \ldots, x_{\ell}, x_j) \rightarrow p_j(x_j) \quad \text{and} \quad \forall x_j : \varphi_j(x_1, \ldots, x_{\ell}, x_j) \rightarrow p_j(x_j)$$

such that $p_j = p_j = p$ then we replace these by one broadcast\(^7\)

$$\forall x_j : (\varphi_j(x_1, \ldots, x_{\ell}, x_j) \lor \varphi_j(x_1, \ldots, x_{\ell}, x_j)) \rightarrow p(x_j).$$

Moreover, if there is $1 \leq i \leq \ell$ with an atom $p_i(x_i)$ in $C$ and a broadcast

$$\forall x_j : \varphi_j \rightarrow p_j(x_j)$$

such that $p_i = p_j$ then we replace the broadcast\(^8\) with

$$\forall x_j : (\varphi_j \land x_j \neq x_i) \rightarrow p_j(x_j).$$

This allows that there is for every port precisely one broadcast term and no broadcast “shadows” an atom of a free variable in $C$.

Our proof relies on the following observations:

(a) $||T_i \cap \{s_0\} \times U : 1 \leq k \leq K|| = 1 \iff (U, i) \models_{ws_S} unique-init_S$,

(b) $||T_i \cap \aleph^{\ast} || = 1 \iff (U, i) \models_{ws_S} unique-pre-ex_S$,

(c) $||T_i \cap \aleph^{\ast'} || = 1 \iff (U, i) \models_{ws_S} unique-pre-broadcast_S$,

(d) $||T_i \cap \aleph^{\ast} || = 0 \iff (U, i) \models_{ws_S} disjoint-pre-ex_S$ and

(e) $||T_i \cap \aleph^{\ast'} || = 0 \iff (U, i) \models_{ws_S} disjoint-broadcast_S$.

Since the line of reasoning can be easily adapted for the different cases we restrict our arguments to (c) since it is the most elaborate formula.

ad (c) **⇒**: Fix $j \in \{\ell + 1, \ldots, \ell + m\}$ such that $q = \ast p_j$ and $u_j \in P_j$ with $(q, u_j) = T_i \cap \aleph^{\ast'}$. Hence, by definition of $T_i$, $u_j \in X_q$ and therefore $(U, i) \models_{ws_S} X_q(x_j)$, while, by definition of $P_j$ and Lemma 1, $(U, i) \models_{ws_S} T \varphi(x_j, x_j, y) \rightarrow \exists x \psi(y)$.

For any fixed $u_0 \in U_{\ell+1 \leq l \leq \ell+m} \forall y$ we distinguish different cases:

If $u_0 = u_j$, we immediately have $(U, i) \models_{ws_S} \varphi(x_1, \ldots, x_{\ell}, x_j, y \leftarrow u_0) \models_{ws_S} \varphi(x_1, \ldots, x_{\ell}, x_j, y) \rightarrow \exists x \psi(y)$.

And, by pairwise disjointness of all $P_n$ for $\ell + 1 \leq n \leq \ell + m$, we get

$$(U, i) \models_{ws_S} \bigwedge_{\ell + 1 \leq s \leq \ell + m} \varphi(x_1, \ldots, x_{\ell}, x_j, y) \rightarrow \exists x \psi(y)$$

since $(U, i) \models_{ws_S} \varphi(x_1, \ldots, x_{\ell}, x_j, y \leftarrow u_0) \models_{ws_S} \psi(x_1, \ldots, x_{\ell}, x_j, y)$ for any $a \neq j$.

If on the other hand, $u_0 \in P_k$ for $k \neq j$ then we have by definition of $P_k$ that $(U, i) \models_{ws_S} Tr(\varphi_k)$, however by pairwise disjointness of all $P_n$ for $\ell + 1 \leq n \leq \ell + m$ we have $(U, i) \models_{ws_S} \varphi(x_1, \ldots, x_{\ell}, x_j, y \leftarrow u_0) \models_{ws_S} Tr(\varphi_k)$ for any $\ell + 1 \leq n \leq \ell + m$ different from $k$ and $(U, i) \models_{ws_S} \varphi(x_1, \ldots, x_{\ell}, x_j, y \leftarrow u_0) \models_{ws_S} \exists x \psi(y)$ because otherwise $(\ast p_j, u_j) \models T_i \cap \aleph^{\ast'}$. This gives in combination $(U, i) \models_{ws_S} \varphi(x_1, \ldots, x_{\ell}, x_j, y \leftarrow u_0) \models_{ws_S} \varphi(x_1, \ldots, x_{\ell}, x_j, y) \rightarrow \exists x \psi(y)$ which already implies

$$(U, i) \models_{ws_S} \bigwedge_{\ell + 1 \leq s \leq \ell + m} \varphi(x_1, \ldots, x_{\ell}, x_j, y) \rightarrow \exists x \psi(y)$$

\(^7\) Note that this is not a valid broadcast in the sense of clauses, however in the translation into WSes we can incorporate these changes.

\(^8\) This actually is a valid broadcast.
Thirdly, consider the case that \( u_\ell \in T_j \) but \( u_\ell \neq u_j \). Again by pairwise disjointness of all \( T_j \) for \( \ell + 1 \leq n \leq \ell + m \) we have \((\mathbb{U}, i(x_1 \leftarrow u_1, \ldots, x_\ell \leftarrow u_\ell, x_j \leftarrow u_j, y \leftarrow u_j)) \not\models_{\mathbb{W}\mathbb{S}} \, T(\phi_j) \) for any \( n \) different from \( j \). However, since \((q, c_j) \in ^* \Gamma \) it cannot be in \( T_j \) since it is in \( ^* \Gamma \). This gives \( u_j \not\models (X \cdot p_j) \) and therefore \((\mathbb{U}, i(x_1 \leftarrow u_1, \ldots, x_\ell \leftarrow u_\ell, x_j \leftarrow u_j, y \leftarrow u_j)) \not\models_{\mathbb{W}\mathbb{S}} \, \neg X_y(y) \).

Concludingly, we may use \( u_j \) as the witness for the existential quantification and get \((\mathbb{U}, i(x_1 \leftarrow u_1, \ldots, x_\ell \leftarrow u_\ell)) \not\models_{\mathbb{W}\mathbb{S}} \text{unique-pre-broadcast}^S \).

**ad (c) "**⇐": Consider the case that \( T_j \cap \Gamma \Gamma = \emptyset \), then for all \( u_j \in T_j \) holds \((\mathbb{U}, i(x_1 \leftarrow u_1, \ldots, x_\ell \leftarrow u_\ell)) \not\models_{\mathbb{W}\mathbb{S}} \, X_{p_j} \) since \( u_j \not\models \phi_j \). Moreover, \((\mathbb{U}, i(x_1 \leftarrow u_1, \ldots, x_\ell \leftarrow u_\ell, y \leftarrow u_j)) \not\models_{\mathbb{W}\mathbb{S}} \, \neg T(\phi_j) \) for all \( \ell + 1 \leq n \leq \ell + m \) different from \( j \) for all \( \ell + 1 \leq j \leq \ell + m \) (again by pairwise disjointness). This specifically yields \((\mathbb{U}, i(x_1 \leftarrow u_1, \ldots, x_\ell \leftarrow u_\ell, \mathbb{I}) \not\models_{\mathbb{W}\mathbb{S}} \neg \phi_j \).

If on the other hand \( ||T_j \cap \Gamma \Gamma|| > 1 \) then we can fix an arbitrary \((q_1, u_1) \in T_j \cap \Gamma \Gamma \) such that \( u_2 \in \mathbb{U} \). Hence, \((\mathbb{U}, i(x_1 \leftarrow u_1, \ldots, x_\ell \leftarrow u_\ell, x_j \leftarrow u_j)) \not\models_{\mathbb{W}\mathbb{S}} \, X_{p_j} \) and therefore \((\mathbb{U}, i(x_1 \leftarrow u_1, \ldots, x_\ell \leftarrow u_\ell, y \leftarrow u_2)) \not\models_{\mathbb{W}\mathbb{S}} \, T(\phi_j) \). Since \( u_1 \neq u_2 \) we have \((\mathbb{U}, i(x_1 \leftarrow u_1, \ldots, x_\ell \leftarrow u_\ell, x_j \leftarrow u_1)) \not\models_{\mathbb{W}\mathbb{S}} \, \phi_j \).

If on the other hand \( j_1 \neq j_2 \) then
\[
(\mathbb{U}, i(x_1 \leftarrow u_1, \ldots, x_\ell \leftarrow u_\ell, x_j \leftarrow u_j, y \leftarrow u_2)) \not\models_{\mathbb{W}\mathbb{S}} \phi_j (x_1, \ldots, x_\ell, y) \to \neg X_{p_{j_2}}(y)
\]
and consequently
\[
(\mathbb{U}, i(x_1 \leftarrow u_1, \ldots, x_\ell \leftarrow u_\ell, x_j \leftarrow u_j)) \not\models_{\mathbb{W}\mathbb{S}} \, \bigwedge_{\ell + 1 \leq n \leq \ell + m} \forall y. \phi_j (x_1, \ldots, x_\ell, y) \to \neg X_{p_{j_2}}(y).
\]

However, for any value \( u \in \mathbb{U} \) such that \((\mathbb{U}, i(x_1 \leftarrow u_1, \ldots, x_\ell \leftarrow u_\ell, x_j \leftarrow u_j)) \not\models_{\mathbb{W}\mathbb{S}} \phi_j (x_1, \ldots, x_\ell, x_j) \wedge X_{p_{j_2}}(x_j) \) for one \( \ell + 1 \leq j \leq \ell + m \) it is easy to see from the definitions of \( \Gamma \Gamma \cap T \) and \( T \) that \((i, j_1, 1) \in \Gamma \Gamma \cap T \). This concludes then that \((\mathbb{U}, i(x_1 \leftarrow c_1, \ldots, x_\ell \leftarrow c_\ell, x_j \leftarrow c_1)) \not\models_{\mathbb{W}\mathbb{S}} \text{unique-pre-broadcast}^S \).

Because any choice for the existential quantification of \( x \) does not allow for all values chosen for \( y \) to satisfy the formula as demonstrated above.

In consequence, the statements (a) - (c) show that the given formulae model the properties laid out in Lemma 3 and therefore the lemma follows. \( \Box \)

**Theorem 2.** Given a component-based system \( S \) and a \( \mathbb{W}\mathbb{S} \) formula \( \varphi(X) \), if the formula:
\[
\exists X. \, \text{marking}_{G}(X) \wedge 1\text{-invariant}_{G}(X) \wedge \text{trap-invariant}_{G}(X) \wedge \neg \varphi(X)
\]
is unsatisfiable, then for every universe \( \mathbb{U} \), the property defined by the formula \( \varphi(X) \) holds in every reachable marking of \( S \).

**Proof:** In the light of Theorem 1, it is sufficient to prove the theorem for the formula:
\[
\exists X. \, \text{marking}_{G}(X) \wedge 1\text{-invariant}_{G}(X) \wedge \neg \varphi(X)
\]
(12)
The proof goes along the lines of the proof of Theorem 1, with the additional observation:
\[
(\mathbb{U}, i) \models_{\mathbb{W}\mathbb{S}} \text{unique-intersection}^S(X, X') \iff ||G \cap G'|| = 1 \]
\( \Box \)
