Giant backscattering peak in angle-resolved Andreev reflection

C. W. J. Beenakker, J. A. Melsen, and P. W. Brouwer

Instituut-Lorentz, University of Leiden, P.O. Box 9506, 2300 RA Leiden, The Netherlands

It is shown analytically and by numerical simulation that the angular distribution of Andreev reflection by a disordered normal-metal-superconductor junction has a narrow peak at the angle of incidence. The peak is higher than the well-known coherent backscattering peak in the normal state, by a large factor $G/G_0$ (where $G$ is the conductance of the junction and $G_0 = 2e^2/h$). The enhanced backscattering can be detected by means of ballistic point contacts.

PACS numbers: 74.80.Fp, 72.15.Rn, 73.50.Jt, 74.50.+r — cond-mat/9501003

Coherent backscattering is a fundamental effect of time-reversal symmetry on the reflection of electrons by a disordered metal \[ 2 \]. The angular reflection distribution has a narrow peak at the angle of incidence, due to the constructive interference of time-reversed sequences of multiple scattering events. At zero temperature, the peak is twice as high as the background. Coherent backscattering manifests itself in a transport experiment as a small negative correction of order $G_0 = 2e^2/h$ to the average conductance $G$ of the metal (weak localization \[ 3 \]). Here we report the theoretical prediction, supported by numerical simulations, of a giant enhancement of the backscattering peak if the normal metal (N) is in contact with a superconductor (S). At the NS interface an electron incident from N is reflected either as an electron (normal reflection) or as a hole (Andreev reflection). Both scattering processes contribute to the backscattering peak. Normal reflection contributes a factor of two. In contrast, we find that Andreev reflection contributes a factor $G/G_0$, which is $\geq 1$.

If the backscattering peak in an NS junction is so large, why has it not been noticed before in a transport experiment? The reason is a cancellation in the integrated angular reflection distribution which effectively eliminates the contribution from enhanced backscattering to the conductance of the NS junction. However, this cancellation does not occur if one uses a ballistic point contact to inject the current into the junction. We discuss two configurations, both of which show an excess conductance due to enhanced backscattering which is a factor $G/G_0$ greater than the weak-localization correction.

We consider a disordered normal-metal conductor (length $L$, width $W$, mean free path $l$, with $N$ propagating transverse modes at the Fermi energy $E_F$) which is connected at one end to a superconductor (see inset of Fig. 1). An electron (energy $E_F$) incident from the opposite end in mode $m$ is reflected into some other mode $n$, either as an electron or as a hole, with probability amplitudes $r_{nm}$ and $r_{nm}^\ast$, respectively. The $N \times N$ matrices $r_{nm}$ and $r_{nm}^\ast$ are given by

\[
\begin{align*}
    r_{nm} &= s_{11} - s_{12}s_{22}^* (1 + s_{22}s_{22}^*)^{-1} s_{21}, \\
    r_{nm}^\ast &= -i s_{12}^* (1 + s_{22}s_{22}^*)^{-1} s_{21}.
\end{align*}
\]

The $s_{ij}$’s are submatrices of the scattering matrix $S$ of the disordered normal region,

\[
S = \begin{pmatrix} s_{11} & s_{12} \\ s_{21} & s_{22} \end{pmatrix} = \begin{pmatrix} u & 0 \\ 0 & v \end{pmatrix} \begin{pmatrix} -\sqrt{R} & \sqrt{T} \\ \sqrt{T} & \sqrt{R} \end{pmatrix} \begin{pmatrix} u' & 0 \\ 0 & v' \end{pmatrix},
\]

where $u, v, u', v'$ are $N \times N$ unitary matrices, $R = 1 - T$, and $T$ is a diagonal matrix with the transmission eigenvalues $T_1, T_2, \ldots, T_N$ on the diagonal.

We first consider zero magnetic field ($B = 0$). Time-reversal symmetry then requires that $S$ is a symmetric matrix, hence $u' = u^T$, $v' = v^T$. Eq. (1) simplifies to

\[
r_{nm} = -2u \sqrt{1 - T} u^T, \quad r_{nm}^\ast = -iu^* \frac{T}{2} u^T. \tag{2}
\]

We seek the average reflection probabilities $\langle |r_{nm}|^2 \rangle$, where $\langle \cdots \rangle$ denotes an average over impurity configurations. Following Mello, Akkermans, and Shapiro \[ 4 \], we assume that $u$ is uniformly distributed over the unitary group. This “isotropy assumption” is an approximation which ignores the finite time scale of transverse diffusion. The reflection probabilities contain a product of four $u$’s, which can be averaged by means of the formula

\[
\langle u_{nl}^* u_{ml} u_{kn} u_{nm}^* \rangle = (N^2 - 1)^{-1} (\delta_{kl} \delta_{ij} + \delta_{nm} \delta_{il} \delta_{jk}) - (N^2 - N)^{-1} (\delta_{ij} \delta_{kl} + \delta_{nm} \delta_{ik} \delta_{jl}). \tag{3}
\]

The result is (with the definition $\tau_k \equiv T_k (2 - T_k)^{-1}$)

\[
\langle |r_{nm}^{ee} |^2 \rangle = \frac{\delta_{nm} + 1}{N^2 + N} (N - \langle \sum_k \tau_k^2 \rangle), \tag{4a}
\]

\[
\langle |r_{nm}^{he} |^2 \rangle = \frac{\delta_{nm} + 1}{N^2 + N} (\langle \sum_k \tau_k^2 \rangle + \frac{N \delta_{nm} - 1}{N^2 - N} \langle \sum_{k \neq k'} \tau_k \tau_{k'} \rangle). \tag{4b}
\]

In the metallic regime $N \gg L/l \gg 1$. In this large-$N$ limit we may factorize $\langle \sum_k \tau_k^2 \rangle$ into $\langle \sum_k \tau_k^2 \rangle^2$, which can be evaluated using

\[
\langle \sum_k f(T_k) \rangle = \langle N l / L \rangle f_0^\infty dx f(1/\cosh^2 x). \tag{5}
\]

The result for normal reflection is

\[
\langle |r_{nm}^{no} |^2 \rangle = (1 + \delta_{nm}) N^{-1} (1 - \frac{l}{L}). \tag{6}
\]

Off-diagonal ($n \neq m$) and diagonal ($n = m$) reflection differ by precisely a factor of two, just as in the normal state \[ 5 \]. In contrast, for Andreev reflection we find

\[
\langle |r_{nm}^{ai} |^2 \rangle = \frac{1}{2} (1 + \delta_{nm}) N^{-1} (1 - \frac{l}{L}). \tag{7}
\]

The result for Andreev reflection is

\[
\langle |r_{nm}^{ai} |^2 \rangle = \frac{1}{2} (1 + \delta_{nm}) N^{-1} (1 - \frac{l}{L}). \tag{8}
\]
\[ \langle |r_{nm}^{\text{he}}|^2 \rangle = \frac{1}{2} l/N L \ (n \neq m), \ \langle |r_{nm}^{\text{re}}|^2 \rangle = \left( \pi l/4 L \right)^2. \] (7)

Off-diagonal and diagonal reflection now differ by an order of magnitude \( NL \sim G/G_0 \gg 1 \).

Eqs. (3) and (4) hold for \( B = 0 \). If time-reversal symmetry is broken (by a magnetic field \( B \geq B_c \equiv h/eLW \)), then the matrices \( u, u', v, v' \) are all independent [4]. Carrying out the average in the large-\( N \) limit, we find

\[ \langle |r_{nm}^{\text{re}}|^2 \rangle = N^{-1} (1 - \frac{1}{2L}/L), \ \langle |r_{nm}^{\text{he}}|^2 \rangle = \frac{1}{2} l/N L. \] (8)

Diagonal and off-diagonal reflection now occur with the same probability.

We have checked this theoretical prediction of a giant backscattering peak by a numerical simulation along the lines of Ref. [4]. The disordered normal region was modeled by a tight-binding Hamiltonian on a two-dimensional square lattice (dimensions 300 × 300, \( N = 126 \)), with a random impurity potential at each site (\( L/l = 9.5 \)). The scattering matrix \( S \) was computed numerically and then substituted into Eq. (1) to yield \( r^{\text{re}} \) and \( r^{\text{he}} \). Results are shown in Fig. 1. This is raw data from a single sample. For normal reflection (bottom panel) the backscattering peak is not visible due to statistical fluctuations in the reflection probabilities (speckle noise). The backscattering peak for Andreev reflection is much larger than the fluctuations and is clearly visible (top panel). A magnetic flux of 10\( h/e \) through the disordered region completely destroys the peak (middle panel). The arrow in the top panel indicates the ensemble-averaged peak height from Eq. (7), consistent with the simulation within the statistical fluctuations. The peak is just one mode wide, as predicted by Eq. (5). If \( W > L \) the isotropy assumption breaks down [5] and we expect the peak to broaden over \( W/L \) modes. Fig. 1 tells us that for \( L = W \) the isotropy assumption is still reasonably accurate in this problem.

Coherent backscattering in the normal state is intimately related to the weak-localization correction to the average conductance. We have found that the backscattering peak for Andreev reflection is increased by a factor \( G/G_0 \). However, the weak-localization correction in an NS junction remains of order \( G_0 \) [6]. The reason is that the conductance

\[ G = 2G_0 \sum_{n,m} |r_{nm}^{\text{he}}|^2 \] (9)

contains the sum over all Andreev reflection probabilities [10], so that the backscattering peak is averaged out. Indeed, Eqs. (3) and (4) give the same \( G \), up to corrections smaller by factors \( 1/N \) and \( 1/L \). In order to observe the enhanced backscattering in a transport experiment one has to increase the sensitivity to Andreev reflection at the angle of incidence. This can be done by injecting the electrons through a ballistic [6] point contact (width \( l \), number of transmitted modes \( N_0 \)). For \( B = 0 \), one can compute the average conductance from [6]

\[ \langle G \rangle = 2G_0 \int_0^1 dT \rho(T) T^2 (2 - T)^{-2}. \] (10)

The density of transmission eigenvalues \( \rho(T) \) is known [10,13], in the regime \( N_0 \gg 1, \ N \gg L/l \). One finds

\[ \langle G \rangle = G_0 \frac{1}{2} (1 + \sin \vartheta)/N_0 + L/[N L]^{-1}, \] (11a)

\[ \frac{1}{2} \vartheta (1 + \sin \vartheta) = (N_0 L/N l) \cos \vartheta, \ \vartheta \in (0, \pi/2). \] (11b)

In the absence of time-reversal symmetry (\( B \geq B_c \)) we find from the large-\( N \) limit of Eqs. (1) and (2) that

\[ \langle G \rangle = G_0 (1/N_0 + L/N l)^{-1}. \] (12)

This is just the classical addition in series of the Sharvin conductance \( N_0 G_0 \) of the point contact and the Drude conductance \( (N l/N)/G_0 \) of the disordered region.

In Fig. 2 we have plotted the difference \( \Delta G = \langle G(B = 0) \rangle - \langle G(B \geq B_c) \rangle \) of Eqs. (11) and (12). If \( N_0/N \ll l/L \ll 1 \) the conductance drops from \( 2 N_0 G_0 \) to \( N_0 G_0 \) upon breaking time-reversal symmetry. A doubling of the conductance remains of order \( N_0 \), with amplitude of order \( NL/N_0 \) the backscattering as the origin of this increase.

As a second example we discuss how enhanced backscattering manifests itself when electrons are injected into a Josephson junction. The system considered is shown schematically in Fig. 3. A disordered metal grain is contacted by four ballistic point contacts (with \( N_i \) modes transmitted through contact \( i = 1, 2, 3, 4 \)). The scattering matrix \( S \) has submatrices \( s_{ij} \), the matrix elements \( s_{ij,nm} \) being the scattering amplitude from mode \( m \) in contact \( j \) to mode \( n \) in contact \( i \). The grain forms a Josephson junction in a superconducting ring. Coupling to the two superconducting banks is via point contacts 3 and 4 (phase difference \( \phi \), same electrostatic potential). Contacts 1 and 2 are connected to normal metals (potential difference \( V \)). A current \( I \) is passed between contacts 1 and 2 and one measures the conductance \( G = I/V \) as a function of \( \varphi \). Spivak and Khmel'nitskii computed \( \langle G(\varphi) \rangle \) at temperatures higher than the Thouless energy [11]. They found a periodic modulation of the weak-localization correction, with amplitude of order \( G_0 \). Zaitsev and Kadigrobov et al. have discovered that at lower temperatures the amplitude increases to become much greater than \( G_0 \) [12,17]. Here we identify enhanced backscattering as the origin of this increase.

The reflection matrices \( r^{\text{re}} \) and \( r^{\text{he}} \) (with elements \( r_{ij,nm} \)) contain the combined effect of scattering in the normal grain (described by the matrix \( S \)) and Andreev reflection at the two contacts with the superconductor. By summing a series of multiple Andreev reflections we obtain expressions analogous to Eq. (1),

\[ r^{\text{re}} = a - b \Omega e^{i \varphi} (1 + c \Omega e^{i \varphi})^{-1} d, \] (13a)

\[ r^{\text{he}} = -ib \Omega e^{i \varphi} (1 + c \Omega e^{i \varphi})^{-1} d. \] (13b)
where we have abbreviated
\[
\begin{align*}
  a &= \left( \begin{array}{cc} s_{11} & s_{12} \\ s_{21} & s_{22} \end{array} \right), \\
  b &= \left( \begin{array}{cc} s_{13} & s_{14} \\ s_{23} & s_{24} \end{array} \right), \\
  c &= \left( \begin{array}{cc} s_{33} & s_{34} \\ s_{43} & s_{44} \end{array} \right), \\
  d &= \left( \begin{array}{cc} s_{31} & s_{32} \\ s_{41} & s_{42} \end{array} \right), \\
  \Omega &= \left( \begin{array}{cc} e^{i\phi/2} & 0 \\ 0 & e^{-i\phi/2} \end{array} \right).
\end{align*}
\]

The four-terminal generalization of Eq. (3) is
\[
\begin{align*}
  G/G_0 &= R_{11}^{ee} + R_{22}^{ee} + 2\langle R_{12}^{he}R_{21}^{he} - R_{12}^{he}R_{21}^{ee} \rangle \quad (14a) \\
  R_{ij}^{ee} &= \sum_{n,m} |r_{ij,n,m}|^2, \quad R_{ij}^{he} = \sum_{n,m} |r_{ij,n,m}|^2. \quad (14b)
\end{align*}
\]

Following Ref. [19], we evaluate \langle G \rangle by averaging \mathcal{S} over the circular ensemble. For \( B = 0 \) this means that \( \mathcal{S} = U U^\dagger \) with \( U \) uniformly distributed in the group \( U(M) \) of \( M \times M \) unitary matrices (\( M = \sum_{i=1}^N N_i \)). This is the circular orthogonal ensemble (COE). If time-reversal symmetry is broken, then \( S \) is itself uniformly distributed in \( U(M) \). This is the circular unitary ensemble (CUE). In the CUE we can do the average analytically for any \( N_i \) and \( \phi \). The result is
\[
\langle G \rangle_{\text{CUE}} = G_0 N_1 N_2 / (N_1 + N_2),
\]

independent of \( \phi \). In the COE we can do the average analytically for \( N_i \gg 1 \) and \( \phi = 0 \), and numerically [20] for any \( N_i \) and \( \phi \). We find that the difference \( \Delta G(\phi) = \langle G(\phi) \rangle_{\text{COE}} - \langle G \rangle_{\text{CUE}} \) is positive for \( \phi = 0 \),
\[
\frac{\Delta G(0)}{\langle G \rangle_{\text{CUE}}} = \rho + \frac{1}{2}(1 + \rho)^2 - (1 + \rho)\sqrt{\rho + \frac{1}{4}(1 + \rho)^2},
\]

with \( \rho \equiv (N_3 + N_4)/(N_1 + N_2) \). The excess conductance \([13]\) is a factor \( G/G_0 \) greater than the negative weak-localization correction, which is observable in Fig. 3 at \( \phi = \pi \). For \( N \gtrsim 10 \) the finite-\( N \) curves (solid) are close to the large-\( N \) limit [21] (dotted) which we have obtained using the Green’s function formulation of Refs. [13,14].

The excess conductance is a direct consequence of enhanced backscattering. This is easiest to see for the symmetric case \( N_1 = N_2 \equiv N \), when \( \langle R_{12}^{he} \rangle = \langle R_{21}^{he} \rangle \), \( \langle R_{12}^{he} \rangle = \langle R_{21}^{he} \rangle \). Current conservation requires \( R_{12}^{he} + R_{21}^{he} + R_{12}^{ee} + R_{21}^{ee} = N \). For \( N \gg 1 \) we may replace \( f(R_{ij}) \) by \( f(\langle R_{ij} \rangle) \). The average of Eq. (14) then becomes
\[
\langle G/G_0 \rangle = \frac{1}{2}N - \frac{1}{2}(R_{11}^{ee} - R_{22}^{ee}) + \frac{1}{2}(R_{11}^{he} - R_{22}^{he}).
\]

The first term \( \frac{1}{2}N \) is the classical series conductance. The second term is the weak-localization correction due to enhanced backscattering for normal reflection. Since \( R_{11}^{ee} - R_{22}^{ee} = O(1) \) this negative correction to \( \frac{1}{2}N \) can be neglected if \( N \gg 1 \). The third term gives the excess conductance due to enhanced backscattering for Andreev reflection. Since \( R_{11}^{he} - R_{22}^{he} = O(N) \) this positive contribution is a factor \( G/G_0 = O(N) \) greater than the negative weak-localization correction.

In conclusion, we have predicted (and verified by numerical simulation) an order \( G/G_0 \) enhancement of coherent backscattering by a disordered metal connected to a superconductor. The enhancement can be observed as an excess conductance which is a factor \( G/G_0 \) greater than the weak-localization correction, provided ballistic point contacts are used to inject the current into the junction. The junction should be sufficiently small that phase coherence is maintained throughout. Several recent experiments [22] are close to this size regime, and might well be equipped with ballistic point contacts.
