DUAL GRAPHS FROM NONCOMMUTATIVE AND QUASISYMMETRIC SCHUR FUNCTIONS

S. VAN WILLIGENBURG

(Communicated by Patricia L. Hersh)

Abstract. By establishing relations between operators on compositions, we show that the posets of compositions arising from the right and left Pieri rules for noncommutative Schur functions can each be endowed with both the structure of dual graded graphs and dual filtered graphs when paired with the poset of compositions arising from the Pieri rules for quasisymmetric Schur functions and its deformation.

1. Introduction

Differential posets [19] and dual graded graphs [5,6] were first developed in order to better understand the Robinson-Schensted-Knuth algorithm. However, since then they have developed into a research area in their own right, for example [16,21], including rank variants [20] and signed analogues [13]. They also arise in the study of representations of towers of algebras [2,8], have been generalized to planar binary trees [17], Kac-Moody algebras [1,15], quantized versions [14], and most recently related to K-theory via dual filtered graphs [18]. The classic example of dual graded graphs is Young’s lattice paired with itself. Young’s lattice appears in a variety of areas, such as being used to describe the Pieri rules for Schur functions. From this perspective, natural generalizations of Young’s lattice exist arising from Pieri rules for the Schur function generalizations known as quasisymmetric Schur functions, and noncommutative Schur functions. In particular, quasisymmetric Schur functions [11] are a nonsymmetric generalization of Schur functions that form a basis for the increasingly ubiquitous Hopf algebra of quasisymmetric functions, for example [3,10,12]. Their Pieri rules [11, Theorem 6.3] give rise to the generalization of Young’s lattice known as the quasisymmetric composition poset. Dual to this Hopf algebra is the Hopf algebra of noncommutative symmetric functions [9], whose basis dual to that of quasisymmetric Schur functions is the basis of noncommutative Schur functions [3], a noncommutative analogue of Schur functions. Due to noncommutativity, two sets of Pieri rules arise, one arising from multiplication on the right [22, Theorem 9.3] and one from multiplication on the left [3, Corollary 3.8]. These two sets of Pieri rules give rise to two generalizations of Young’s lattice known as the right composition poset and the left composition poset. Therefore the question arises: Are these posets dual graded and dual filtered graphs? In this paper we answer this question in the affirmative.

More precisely, this paper is structured as follows. In Section 2 we review necessary notions on compositions in order to define operators on them. These operators are used to define three partially ordered sets in Subsection 2.1, \( \mathcal{R}_c \) and \( \mathcal{L}_c \) that arise in the right and left Pieri rules for noncommutative Schur functions, and \( \mathcal{Q}_c \) that arises in the Pieri rules for quasisymmetric Schur functions. We then establish useful relations satisfied by these operators in Subsections 2.2 and 2.3. In Section 3 we show that \( \mathcal{R}_c \) and \( \mathcal{Q}_c \), plus \( \mathcal{L}_c \) and \( \mathcal{Q}_c \), are each a pair of dual graded graphs in Theorems 3.3 and 3.15. We define a strong filtered graph \( \tilde{\mathcal{Q}}_c \) on the set of compositions using the operators arising in the Pieri rules for quasisymmetric Schur functions in Definition 3.5, and establish that \( \mathcal{R}_c \) and \( \tilde{\mathcal{Q}}_c \), plus \( \mathcal{L}_c \) and \( \tilde{\mathcal{Q}}_c \), are each a pair of dual filtered graphs in Theorems 3.8 and 3.17.

2. Compositions and operators

A finite list of integers \( \alpha = (\alpha_1, \ldots, \alpha_\ell) \) is called a weak composition if \( \alpha_1, \ldots, \alpha_\ell \) are nonnegative, and is called a composition if \( \alpha_1, \ldots, \alpha_\ell \) are positive. Note that every weak composition has an underlying composition, obtained by removing all 0s. Given \( \alpha = (\alpha_1, \ldots, \alpha_\ell) \) we call the \( \alpha_i \) the parts of \( \alpha \), and the sum of the parts of \( \alpha \) the size of \( \alpha \).

Now we will recall four families of operators, each of which are indexed by positive integers, and have already contributed to the theory of quasisymmetric and noncommutative Schur functions. Although originally defined on compositions, we will define them in the natural way on weak compositions to simplify our proofs. Our first operator is the box removing operator \( \text{d} \), which first appeared in the Pieri rules for quasisymmetric Schur functions [11]. Our second operator is the appending operator \( a \). Together these give our third operator, the jeu de taquin or jdt operator \( u \). This operator arises in jeu de taquin slides on semistandard reverse composition tableaux and in the right Pieri rules for noncommutative Schur functions [22]. Our fourth operator is the box adding operator \( t \), which plays the same role in the left Pieri rules for noncommutative Schur functions [3] as \( u \) does in the right Pieri rules. Each of these operators is defined on weak compositions for every integer \( i \geq 0 \) and we note that

\[
\text{d}_0 = a_0 = u_0 = t_0 = \text{Id}
\]

namely, the identity map, which fixes the weak composition it is acting on. We now define the remaining operators for \( i \geq 1 \), after establishing some set notation. Let \( \mathbb{N} \) be the set of positive integers. Anytime we refer to a set \( I \subset \mathbb{N} \), we implicitly assume that \( I \) is finite. Also, if we are given such a set \( I \), then \( I - 1 \) is the set obtained by subtracting 1 from all the elements in \( I \) and removing any 0s that might arise in so doing.

Example 2.1. If \( I = \{1, 2, 4\} \), then \( I - 1 = \{1, 3\} \).

By \([i]\) where \( i \geq 1 \), we mean the set \( \{1, 2, \ldots, i\} \). We furthermore define \([0]\) to be the empty set. We will denote the maximum element of a set \( A \) by \( \text{max}(A) \). If \( A \) is the empty set, by convention we have that \( \text{max}(A) = 0 \).

The first box removing operator on weak compositions, \( \text{d}_i \) for \( i \geq 1 \), is defined as follows. Let \( \alpha \) be a weak composition. Then

\[
\text{d}_i(\alpha) = \alpha',
\]
where $\alpha'$ is the weak composition obtained by subtracting 1 from the rightmost part equaling $i$ in $\alpha$. If there is no such part, then we define $\mathfrak{d}_i(\alpha) = 0$.

**Example 2.2.** Let $\alpha = (2,1,3)$. Then $\mathfrak{d}_1(\alpha) = (2,0,3)$, $\mathfrak{d}_2(\alpha) = (1,1,3)$, $\mathfrak{d}_3(\alpha) = (2,1,2)$, and $\mathfrak{d}_4(\alpha) = 0$. In fact, $\mathfrak{d}_i(\alpha) = 0$ for all $i \geq 4$.

Given a finite set $I = \{i_1 < \cdots < i_k\}$ of positive integers, we define

$$\mathfrak{d}_I = \mathfrak{d}_{i_1} \mathfrak{d}_{i_2} \cdots \mathfrak{d}_{i_k}.$$ 

For convenience, we define $\mathfrak{d}_\emptyset = \mathfrak{d}_0$. The empty product of box removing operators is also defined to be $\mathfrak{d}_0$.

**Example 2.3.**

$$\mathfrak{d}_{[3]}((3,1,4,2,1)) = \mathfrak{d}_1 \mathfrak{d}_2 \mathfrak{d}_3((3,1,4,2,1))$$

$$= \mathfrak{d}_1 \mathfrak{d}_2((2,1,4,2,1))$$

$$= \mathfrak{d}_1((2,1,4,1,1))$$

$$= (2,1,4,1,0).$$

The second *appending operator* on weak compositions, $a_i$ for $i \geq 1$, is defined as follows. Let $\alpha = (\alpha_1, \ldots, \alpha_\ell)$ be a weak composition. Then

$$a_i(\alpha) = (\alpha_1, \ldots, \alpha_\ell, i)$$

namely, the weak composition obtained by appending a part $i$ to the end of $\alpha$. To simplify proofs later, we will abuse notation and also think of $a_0$ as adding 0 to the end of $\alpha$ that we will eventually remove.

**Example 2.4.** Let $\alpha = (2,1,3)$. Then $a_2(\alpha) = (2,1,3,2)$. However, $a_2 \mathfrak{d}_4(\alpha) = 0$ since $\mathfrak{d}_4(\alpha) = 0$ by Example 2.2.

The third *jeu de taquin* or *jdt operator* on weak compositions, $u_i$ for $i \geq 1$, is defined as follows. Considering the box removing and appending operators,

$$u_i = a_i \mathfrak{d}_{[i-1]}.$$ 

**Example 2.5.** Let us compute

$$u_4((3,1,4,2,1)) = a_4 \mathfrak{d}_{[3]}((3,1,4,2,1)).$$

By Example 2.3

$$\mathfrak{d}_{[3]}((3,1,4,2,1)) = (2,1,4,1,0),$$

and hence $u_4(3,1,4,2,1) = (2,1,4,1,0,4)$.

For any set of finite positive integers $I = \{i_1 < \cdots < i_k\}$, we define

$$u_I = u_{i_k} \cdots u_{i_1}.$$ 

For convenience, we define $u_\emptyset = u_0$. The empty product of jdt operators is also defined to be $u_0$. Note further that the order of indices in $u_I$ is the reverse of that in $u_I$.

Lastly, the fourth *box adding operator* on weak compositions, $t_i$ for $i \geq 1$, is defined as follows. Let $\alpha = (\alpha_1, \ldots, \alpha_\ell)$ be a weak composition. Then

$$t_1(\alpha) = (1, \alpha_1, \ldots, \alpha_\ell)$$

and for $i \geq 2$

$$t_i(\alpha) = (\alpha_1, \ldots, \alpha_j + 1, \ldots, \alpha_\ell),$$
where $\alpha_j$ is the leftmost part equaling $i - 1$ in $\alpha$. If there is no such part, then we define $t_i(\alpha) = 0$.

**Example 2.6.** Let $\alpha = (3, 1, 4, 2, 1)$. Then $t_1(\alpha) = (1, 3, 1, 4, 2, 1)$, $t_2(\alpha) = (3, 2, 4, 2, 1)$, $t_3(\alpha) = (3, 1, 4, 3, 1)$, $t_4(\alpha) = (4, 1, 4, 2, 1)$, $t_5(\alpha) = (3, 1, 5, 2, 1)$, and $t_i(\alpha) = 0$ for all $i \geq 6$.

2.1. **Composition posets.** With our operators we will now define three partial orders on compositions noting that *if any parts of size 0 arise during computation, then they are ignored*. The adjectives right and left in the first two are not only used to distinguish between the posets, but also to refer to their roles in the right and left Pieri rules for noncommutative Schur functions in [22, Theorem 9.3] and [3, Corollary 3.8], respectively, and whose notation we follow now.

**Definition 2.7.** The *right composition poset*, denoted by $R_c$, is the poset consisting of all compositions with cover relation $\preceq_r$ such that for compositions $\alpha, \beta$

$$\beta \preceq_r \alpha \text{ if and only if } \alpha = u_i(\beta)$$

for some $i \geq 1$. Meanwhile the *left composition poset*, denoted by $L_c$, is the poset consisting of all compositions with cover relation $\preceq_c$ such that for compositions $\alpha, \beta$

$$\beta \preceq_c \alpha \text{ if and only if } \alpha = t_i(\beta)$$

for some $i \geq 1$.

The order relation $\preceq_r$ in $R_c$ (respectively, $\preceq_c$ in $L_c$) is obtained by taking the transitive closure of the cover relation $\preceq_r$ (respectively, $\preceq_c$).

**Example 2.8.** Let $\beta = (3, 1, 4, 2, 1)$, $\alpha^R = (2, 1, 4, 1, 4)$, and $\alpha^L = (4, 1, 4, 2, 1)$. Then $\beta \preceq_r \alpha^R = u_i(\beta)$ and $\beta \preceq_c \alpha^L = t_i(\beta)$ by Examples 2.5 and 2.6, respectively.

Our third poset, meanwhile, stems from the Pieri rules for quasisymmetric Schur functions [11, Theorem 6.3], hence its name.

**Definition 2.9.** The *quasisymmetric composition poset*, denoted by $Q_c$, is the poset consisting of all compositions with cover relation $\preceq_q$ such that for compositions $\alpha, \beta$

$$\beta \preceq_q \alpha \text{ if and only if } \delta_i(\alpha) = \beta$$

for some $i \geq 1$.

Again, the order relation $\preceq_q$ in $Q_c$ is obtained by taking the transitive closure of the cover relation $\preceq_q$.

**Example 2.10.** Let $\beta = (4, 1, 3, 2, 1)$ and $\alpha = (4, 1, 4, 2, 1)$. Then $\delta_4(\alpha) = \beta \preceq_q \alpha$.

2.2. **Relations satisfied by operators of type $u$ and $\delta$.** We will now give a variety of lemmas regarding the jdt operators and box removing operators, which will be useful in proving our main theorems later. Hence this subsection can be safely skipped for now and referred to later. In all the proofs we assume that $\alpha$ is a weak composition.

**Lemma 2.11.** For $i \geq 0$ we have that $a_i = \delta_{i+1} a_{i+1}$.

**Proof.** Let $\alpha = (\alpha_1, \ldots, \alpha_\ell)$. Then $a_{i+1}(\alpha) = (\alpha_1, \ldots, \alpha_\ell, i + 1)$. This implies by definition that $\delta_{i+1} a_{i+1}(\alpha) = (\alpha_1, \ldots, \alpha_\ell, i) = a_i(\alpha)$. \qed

As a corollary we obtain the following relationship between any two appending operators.
Corollary 2.12. For positive integers $i$ and $j$ satisfying $i \geq j$, we have that
$$d_j d_{j+1} \cdots d_{i-1} a_i = a_{j-1}.$$

Lemma 2.13. Let $i \neq j$ be positive integers. Then
$$d_i a_j = a_j d_i.$$

Proof. Let $\alpha = (\alpha_1, \ldots, \alpha_\ell)$. Let $\beta = a_j(\alpha) = (\alpha_1, \ldots, \alpha_\ell, j)$. If $\alpha$ does not have a part equaling $i$, then neither does $\beta$, as $i \neq j$. Thus in this case we have that $d_i a_j(\alpha) = d_i(\beta) = 0 = a_j d_i(\alpha)$. Now, assume that $\alpha_r$ is the rightmost part equaling $i$ in $\alpha$. Then $a_j d_i(\alpha) = (\alpha_1, \ldots, \alpha_{r-1}, \alpha_r - 1, \ldots, \alpha_\ell, j)$. Since $i \neq j$, we are guaranteed that $d_i(\beta) = (\alpha_1, \ldots, \alpha_{r-1}, \alpha_r - 1, \ldots, \alpha_\ell, j)$. Thus we have that $d_i a_j(\alpha) = a_j d_i(\alpha)$ in this case as well, and we are done. \hfill \square

The proofs of the next three lemmas consist of case analyses that are similar in style to the proof of Lemma 2.13 however, they are more technical and hence we omit them for brevity.

Lemma 2.14. Let $i$ and $j$ be distinct positive integers such that $|i - j| \geq 2$. Then
$$d_i d_j = d_j d_i.$$

Lemma 2.15. Let $i \geq 1$. Then $d_i d_{i+1} = d_{i+1} d_i$.

Lemma 2.16. Let $i \geq 1$. Then $d_i d_{i+1} = d_{i+1} d_i$.

Lemma 2.17. Let $i \neq j$ be positive integers. Then
$$u_i d_j = d_j u_i.$$

Proof. Let us first consider the case $1 \leq i \leq j - 1$. Then by Lemmas 2.13 and 2.14 we have that $d_i$ commutes with $a_i, d_1, \ldots, d_{i-1}$. Hence $u_i d_j = d_j u_i$ in this case.

Now consider the case where $i > j \geq 1$. Then $d_j u_i = d_j a_i d_1 d_2 \cdots d_{i-1}$. Again, using Lemmas 2.13 and 2.14 we can write this as
$$a_i d_1 \cdots d_{j-2} d_j d_{j-1} d_j d_{j+1} \cdots d_{i-1}.$$

Using Lemma 2.16 we can write the above as
$$a_i d_1 \cdots d_{j-2} d_{j-1} d_j d_j d_{j+1} \cdots d_{i-1}.$$

Notice at this stage, if we assume $j = i - 1$, then we have shown that $u_i d_j = d_j u_i$. So let us assume $i - j \geq 2$. Using Lemma 2.15 we can transform the above expression to
$$a_i d_1 \cdots d_{j-2} d_{j-1} d_j d_j d_j d_{j+2} \cdots d_{i-1}.$$

Now Lemma 2.14 easily establishes that the above expression equals
$$a_i d_1 \cdots d_{j-2} d_{j-1} d_j d_j d_{j+2} \cdots d_{i-1} d_j$$
and we are done. \hfill \square

Lemma 2.18. Let $i \geq 1$. Then $u_i d_i = d_{i+1} u_{i+1}$.

Proof. Notice that $u_i d_i = a_i d_{[i]}$. Furthermore, Lemma 2.11 states that $a_i = d_{i+1} a_{i+1}$, and hence $u_i d_i = d_{i+1} a_{i+1} d_{[i]}$. Since $u_{i+1} = a_{i+1} d_{[i]}$, by definition, the claim follows. \hfill \square
2.3. Relations satisfied by operators of type \( t \) and \( d \). We now give two useful lemmas, but this time regarding the box adding and box removing operators. Again, if desired, this subsection can be safely skipped for now and referred to later. In all the proofs we assume that \( \alpha \) is a weak composition.

**Lemma 2.19.** Let \( i \neq j \) be positive integers. Then

\[
 t_i d_j = d_j t_i.
\]

**Proof.** Let \( \alpha = (\alpha_1, \ldots, \alpha_\ell) \). First consider the case \( i = 1 \). If \( \alpha \) does not have a part equaling \( j \), then \( t_1 d_j(\alpha) = 0 \). Note now that, since \( j \neq 1 \), we have that \( d_j t_1(\alpha) = d_j((1, \alpha_1, \ldots, \alpha_\ell)) = 0 \) as well.

Hence we can assume that \( i \geq 2 \). If \( \alpha \) does not have a part equaling \( i - 1 \), then using the fact that \( i \neq j \), we get that \( d_j(\alpha) \) does not have a part equaling \( i - 1 \) either (assuming it does not equal 0 already). This implies that \( t_i d_j(\alpha) = 0 \). Our assumption that \( \alpha \) has no part equaling \( i - 1 \) also implies that \( d_j t_i(\alpha) = 0 \).

Finally assume that \( \alpha \) does have a part equaling \( i - 1 \), and let \( \alpha_r \) denote the leftmost such part. Then

\[
 t_i(\alpha) = (\alpha_1, \ldots, \alpha_r + 1, \ldots, \alpha_\ell).
\]

If \( \alpha \) does not have a part equaling \( j \), then neither does \( t_i(\alpha) \). This follows from the fact that \( i \neq j \). This immediately implies that \( t_i d_j(\alpha) = d_j t_i(\alpha) = 0 \) in this case.

If \( \alpha \) does have a part equaling \( j \), then let \( \alpha_s \) denote the rightmost such part. Note that \( \alpha_s \) continues to be the rightmost part equaling \( j \) in \( t_i(\alpha) \) as well (unless there is a single part equaling \( j = i - 1 \), in which case \( t_i d_j(\alpha) = d_j t_i(\alpha) = 0 \)). Again, this follows since \( i \neq j \). Thus we get that

\[
 t_i d_j(\alpha) = d_j t_i(\alpha) = (\alpha_1, \ldots, \alpha_r + 1, \ldots, \alpha_{s-1}, \ldots, \alpha_\ell)
\]

if \( r < s \) and

\[
 t_i d_j(\alpha) = d_j t_i(\alpha) = (\alpha_1, \ldots, \alpha_{s-1}, \ldots, \alpha_r + 1, \ldots, \alpha_\ell)
\]

if \( s < r \). \( \square \)

The proof of the next lemma consists of a number of small case analyses that are similar in style to the above proof, and hence we omit them for brevity.

**Lemma 2.20.** Let \( i \) be a positive integer. When \( i = 1 \) we have the following:

1. If \( \alpha \) has parts equaling 1, then \( d_1 t_1(\alpha) = t_1 d_1(\alpha) \neq 0 \).
2. If \( \alpha \) has no parts equaling 1, then \( d_1 t_1(\alpha) = 0 \) and \( t_1 d_1(\alpha) = 0 \).

When \( i \geq 2 \) we have the following:

1. If \( \alpha \) has parts equaling both \( i \) and \( i - 1 \), then \( d_i t_i(\alpha) = t_i d_i(\alpha) \neq 0 \).
2. If \( \alpha \) has parts equaling \( i \) and no parts equaling \( i - 1 \), then \( d_i t_i(\alpha) = 0 \) and \( t_i d_i(\alpha) = \alpha \).
3. If \( \alpha \) has no parts equaling \( i \) and parts equaling \( i - 1 \), then \( d_i t_i(\alpha) = \alpha \) and \( t_i d_i(\alpha) = 0 \).
4. If \( \alpha \) has parts equaling neither \( i \) nor \( i - 1 \), then \( d_i t_i(\alpha) = t_i d_i(\alpha) = 0 \).

In particular, if \( d_i t_i(\alpha) \) and \( t_i d_i(\alpha) \) are nonzero, then \( d_i t_i(\alpha) = t_i d_i(\alpha) \).
3. Dual graphs from composition posets

We now recall terminology pertaining to graded graphs and filtered graphs, and follow the notation of [18]. Let \( G \) be a graph consisting of a set of vertices \( P \) endowed with a rank function \( \rho : P \to \mathbb{Z} \) with vertices \( x, y \in P \) and \( y \) is of rank weakly greater than \( x \). Then \( G \) is called a graded graph when the edge set \( E \) satisfies if \( (x, y) \in E \), then \( \rho(y) = \rho(x) + 1 \). The graph \( G \) is called a weak filtered graph when the edge set \( E \) satisfies if \( (x, y) \in E \), then \( \rho(y) \geq \rho(x) \), and a strong filtered graph when the edge set \( E \) satisfies if \( (x, y) \in E \), then \( \rho(y) > \rho(x) \). Now given a field \( K \) of characteristic 0, the vector space \( KP \) is the space consisting of all formal linear combinations of vertices of \( G \). Then we define the up and down operators \( U, D \in \text{End}(KP) \) associated with \( G \) to be

\[
U(x) = \sum_{y} m(x, y) y, \\
D(y) = \sum_{x} m(x, y) x,
\]

where \( x \) and \( y \) are vertices of \( G \), \( y \) is of weakly greater rank than \( x \), and \( m(x, y) \) is the number of edges connecting \( x \) and \( y \). With this in mind, let \( G_1 \) be a graded graph with up operator \( U \) and let \( G_2 \) be a graded graph with down operator \( D \) such that \( G_1 \) and \( G_2 \) have a common vertex set \( P \) and rank function \( \rho \). Then \( G_1 \) and \( G_2 \) are dual graded graphs if and only if on \( KP \)

\[
DU - UD = \text{Id},
\]

where \( \text{Id} \) is the identity operator on \( KP \). Similarly let \( \widetilde{G}_1 \) be a weak filtered graph with up operator \( \widetilde{U} \) and let \( \widetilde{G}_2 \) be a strong filtered graph with down operator \( \widetilde{D} \) such that \( \widetilde{G}_1 \) and \( \widetilde{G}_2 \) have a common vertex set \( P \) and rank function \( \rho \). Then \( \widetilde{G}_1 \) and \( \widetilde{G}_2 \) are dual filtered graphs if and only if on \( KP \)

\[
\widetilde{D}\widetilde{U} - \widetilde{U}\widetilde{D} = \widetilde{D} + \text{Id}.
\]

3.1. Dual graphs and the right composition poset. Observe that our composition posets \( \mathcal{R}_c \) and \( \mathcal{Q}_c \) defined in Subsection 2.1 with the vertex set being the set of all compositions, whose rank function is given by the size of a composition and whose edge sets are the respective cover relations, are both clear examples of graded graphs. By the definition of the cover relation \( \prec_r \) it follows that the up operator associated with \( \mathcal{R}_c \) is given by

\[
U = \sum_{i \geq 1} u_i.
\]

Example 3.1. Let \( \alpha \) be the composition \( (2, 1, 3) \). Then

\[
U((2, 1, 3)) = (2, 1, 3, 1) + (2, 0, 3, 2) + (1, 0, 3, 3) + (2, 1, 0, 4) \\
= (2, 1, 3, 1) + (2, 3, 2) + (1, 3, 3) + (2, 1, 4).
\]

Similarly, by the definition of the cover relation \( \prec_q \) it follows that the down operator associated with \( \mathcal{Q}_c \) is given by

\[
D = \sum_{i \geq 1} d_i.
\]
Example 3.2. Let \( \alpha \) be the composition \((2, 1, 3)\). Then by Example 2.2

\[
D((2, 1, 3)) = (2, 0, 3) + (1, 1, 3) + (2, 1, 2) = (2, 3) + (1, 1, 3) + (2, 1, 2).
\]

Moreover we have the following.

Theorem 3.3. \( R_c \) and \( Q_c \) are dual graded graphs, that is, on compositions

\[
DU - UD = \text{Id}.
\]

Proof. Notice that

\[
DU = \sum_{i \neq j, i, j \geq 1} d_j u_i + \sum_{k \geq 1} d_k u_k
\]

and

\[
UD = \sum_{i \neq j, i, j \geq 1} u_i d_j + \sum_{k \geq 1} u_k d_k.
\]

Using Lemmas 2.17 and 2.18 we reach the conclusion that

\[
DU - UD = d_1 u_1.
\]

By Lemma 2.11 \( d_1 u_1 = a_0 = \text{Id} \). This finishes the proof.

Example 3.4. Let \( \alpha = (2, 1, 3) \). Then suppressing commas and parentheses for ease of comprehension, we have by Examples 3.1 and 3.2 that

\[
DU(\alpha) = D(2131 + 2032 + 1033 + 2104) = 2130 + 1131 + 2121 + 2031 + 2022 + 0033 + 1032 + 2004 + 1104 + 2103
\]

and

\[
UD(\alpha) = U(203 + 1131 + 2121 + 2031 + 2022 + 0033 + 1032 + 2004 + 1104 + 2103) = 2031 + 0033 + 2004 + 1131 + 1032 + 1104 + 2121 + 2022 + 2103.
\]

Thus \( (DU - UD)(\alpha) = 213 = \text{Id}(\alpha) \).

To describe our results in the context of dual filtered graphs, we need the following.

Definition 3.5. Let \( \tilde{Q}_c \) be the graded graph whose vertex set is the set of all compositions, whose rank function is given by the size of a composition, and whose edge set is as follows. Given compositions \( \alpha \) and \( \beta \) such that the size of \( \alpha \) is strictly greater than \( \beta \), we have the edge

\[
(\beta, \alpha) \text{ if and only if } d_I(\alpha) = \beta
\]

for some finite \( \emptyset \neq I \subset \mathbb{N} \).

As before, when computing \( d_I(\alpha) \) in Definition 3.5 we ignore all parts that equal 0.

Example 3.6. We have an edge between \( \beta = (4, 1, 3, 1, 1) \) and \( \alpha = (4, 1, 4, 2, 1) \) in \( \tilde{Q}_c \) since \( d_{\{2,4\}}(\alpha) = \beta \).

Remark 3.7. Observe that the relation \( <_{\tilde{q}} \) on compositions defined by \( \beta <_{\tilde{q}} \alpha \) if and only if \( \beta = d_I(\alpha) \) does not give rise to a poset structure, since transitivity is not satisfied. For example, \( d_{\{1,4\}}((4, 1, 4, 1)) = (4, 1, 3) \) and \( d_{\{1,4\}}((4, 1, 3)) = (3, 3) \), but no \( I \) exists such that \( d_I((4, 1, 4, 1)) = (3, 3) \).
Clearly, we have that \( \tilde{Q}_c \) is an example of a strong filtered graph by definition. The associated down operator is given by

\[
\tilde{D} = \sum_{I \subseteq \mathbb{N}} d_I,
\]

where the sum is over all finite but nonempty subsets of \( \mathbb{N} \). Hence we can relate \( R_c \) and \( \tilde{Q}_c \) as follows, since any graded graph, such as \( R_c \), is also a weak filtered graph.

**Theorem 3.8.** \( R_c \) and \( \tilde{Q}_c \) are dual filtered graphs, that is, on compositions

\[
\tilde{D}U - U\tilde{D} = \tilde{D} + I_d.
\]

**Proof.** First note that the operator \( \tilde{D}U \) has the following expansion:

\[
\tilde{D}U = \sum_{i \geq 1} \sum_{I \subseteq \mathbb{N}} u_i d_I,
\]

\[
= \sum_{I \subseteq \mathbb{N}} d_I u_i + \sum_{i \geq 1, i \not\in I} \sum_{I \subseteq \mathbb{N}} u_i d_I.
\]

In a similar manner, we obtain the following expansion for \( U\tilde{D} \):

\[
U\tilde{D} = \sum_{i \geq 1} \sum_{I \subseteq \mathbb{N}} u_i d_I,
\]

\[
= \sum_{I \subseteq \mathbb{N}} d_I u_i + \sum_{i \geq 1, i \not\in I} \sum_{I \subseteq \mathbb{N}} u_i d_I.
\]

Using Lemma 2.17, we obtain that

\[
\tilde{D}U - U\tilde{D} = \sum_{I \subseteq \mathbb{N}} d_I u_i - \sum_{I \subseteq \mathbb{N}} u_i d_I.
\]

Now consider a fixed set \( I \subseteq \mathbb{N} \) and \( i \in I \). We will next show that the operator \( d_I u_i \) corresponds to either a unique operator \( u_i d_{I'} \) where \( i' \in I' \), or an operator \( a_0 d_{I'} \) where \( I' \) might be the empty set.

Let \( j \in I \) be the smallest positive integer such that \( j - 1 \notin I \) but every integer \( k \) satisfying \( j \leq k \leq i \) belongs to \( I \). Consider the following sets:

\[
A = \{k \mid k \in I, k < j\},
\]

\[
B = \{k \mid j \leq k \leq i\},
\]

\[
C = \{k \mid k \in I, k > i\}.
\]

Clearly, we have that \( I = A \mathop{\cup} B \mathop{\cup} C \) where \( \mathop{\cup} \) denotes disjoint union. Define the set \( I' \) to be \( A \mathop{\cup} (B - 1) \mathop{\cup} C \). Notice that \( I' \) can be the empty set (precisely in the case where \( A \) and \( C \) are empty, while \( B = \{1\} \)). Now we have the following sequence of
equalities using Lemmas \ref{lem:2.17} and \ref{lem:2.18}:
\[
\partial_i u_i = \partial_A \partial_B \partial_C u_i = \partial_A \partial_B u_i \partial_C = \partial_A u_{j-1} \partial_B \partial_C = u_{j-1} \partial_A \partial_B \partial_C = u_{j-1} \partial_{I'}.
\]

Given the invertibility of our computation, it is clear how to recover \(\partial_I u_i\) starting from \(u_{j-1} \partial_I'\). Furthermore, if \(j \neq 1\), then we clearly have that \(j - 1 \in I'\). The above thus implies that
\[
\sum_{I \subset \mathbb{N}} \partial_I u_i - \sum_{i \in I} \partial_i d_I = a_0 + a_0 \tilde{D}
\]
thereby finishing the proof.

\[\square\]

**Example 3.9.** Let \(\alpha = (1, 2)\). Then suppressing commas and parentheses as before, we have that
\[
\tilde{D}(\alpha) = (02 + 11 + 10).
\]

Therefore
\[
\tilde{D} U(\alpha) = \tilde{D}(121 + 022 + 103) = 120 + 111 + 110 + 021 + 020 + 003 + 102 + 002 + 101 + 100
\]
and
\[
U \tilde{D}(\alpha) = U(02 + 11 + 10) = 021 + 003 + 111 + 102 + 101 + 002.
\]

Thus \((\tilde{D} U - U \tilde{D})(\alpha) = 2 + 11 + 1 + 12 = (\tilde{D} + \text{Id})(\alpha)\).

**Remark 3.10.** It is worth noting the connection between our results here and Fomin’s work in \cite{Fomin1992}. In particular, note that the relations \cite[Equation 1.9]{Fomin1992} satisfied by his box adding and box removing operators on partitions (denoted therein by \(u\) and \(d\), respectively) are the same as those satisfied by the jdt operators and box removing operators on compositions. The relations are easy to establish in the case of partitions, but as we have seen, deriving the same relations in the case of compositions is more delicate.

Fomin then uses these operators to define generating functions \(A(x)\) and \(B(y)\) that add or remove horizontal strips in all possible ways, respectively, and then uses \cite[Equation 1.9]{Fomin1992} to prove the following commutation relation \cite[Theorem 1.2]{Fomin1992}:
\[
A(x)B(y) = B(y)A(x)(1 - xy)^{-1}.
\]

He later notes that the dual graded graph nature of Young’s lattice is encoded in the aforementioned identity. More precisely it follows from comparing the coefficient of \(xy\) on either side \cite[Equation 1.13]{Fomin1992}. In fact, one can obtain various identities by comparing coefficients and one can verify that the relations describing dual filtered graphs can be obtained by setting \(y = 1\) and then subsequently comparing the coefficient of \(x\) on either side. Thus, in a sense, the relations uniformly establish both the dual graded graph and the dual filtered graph structures on Young’s lattice and \(R_c\).
We now proceed to discuss \( L_c \) defined using box adding operators. We will establish that this poset can also be endowed with a structure of a dual graded graph and a dual filtered graph. But the relations satisfied in this case are different from the ones we have encountered, and we cannot use Fomin’s commutation relation in this setting. In fact, as we will see, the cancellations in the case of \( L_c \) are more subtle despite the simplicity of the action of \( t \) compared to the action of \( u \).

### 3.2. Dual graphs and the left composition poset

Our composition poset \( L_c \) with the vertex set being the set of all compositions, whose rank function is given by the size of a composition and whose edge set is the cover relations is clearly a graded graph and hence also a weak filtered graph. By the definition of the cover relation \( \prec_c \) it follows that the up operator associated with \( L_c \) is given by

\[
U_t = \sum_{i \geq 1} t_i.
\]

**Example 3.11.** Let \( \alpha \) be the composition \( (2, 1, 3) \). Then

\[
U_t((2, 1, 3)) = (1, 2, 1, 3) + (2, 2, 3) + (3, 1, 3) + (2, 1, 4).
\]

Again \( Q_c \) and \( \bar{Q}_c \) are, respectively, a graded graph and a strong filtered graph with respective down operators \( D \) and \( \bar{D} \).

For the remainder of this section, we will fix a composition \( \alpha \). This given, we will define a function \( \Phi : Y \to X \), where the sets \( X \) and \( Y \) are defined as follows:

\[
X = \{ \partial_I t_i \mid I \subset \mathbb{N}, i \in I, \partial_I t_i(\alpha) \neq 0 \},
\]

\[
Y = \{ t_i \partial_I \mid I \subset \mathbb{N}, i \in I, t_i \partial_I(\alpha) \neq 0 \}.
\]

Consider \( w = t_i \partial_I \in Y \). Decompose \( I = A \amalg \{i\} \amalg B \) where

\[
A = \{ j \in I \mid j < i \},
\]

\[
B = \{ j \in I \mid j > i \}.
\]

By Lemma 2.19 we have that \( w = \partial_A t_i \partial_B \). Let \( k \) denote the largest part of \( \alpha \) that is strictly less than \( i \). Then \( k \geq \max(A) \) as follows.

Decompose \( A = A' \amalg \{m\} \) with \( m = \max(A) \). Then we have \( \partial_A \partial_m t_i \partial_B(\alpha) = w(\alpha) \neq 0 \) and it follows that \( m \) is a part in the composition \( t_i \partial_m \partial_B(\alpha) \) (otherwise, \( \partial_m (t_i \partial_m \partial_B(\alpha)) = 0 \), which implies that \( w(\alpha) = 0 \) contradicting \( w(\alpha) \neq 0 \)). Hence the largest part of \( \alpha \) strictly less than \( i \) is at least \( m = \max(A) \).

If such a part does not exist, we define \( k \) to be 0. Let \( i' = k + 1 \). Now let \( I' = A \amalg \{i'\} \amalg B \) and

\[
\Phi(w) = \partial_I' t_i' = \partial_A \partial_B t_i' \partial_B.
\]

Then the following can be proved using Lemmas 2.19 and 2.20:

**Lemma 3.12.** Let \( w = t_i \partial_I \in Y \) and let \( w' = \Phi(w) \). Then the following statements hold:

1. \( w'(\alpha) = w(\alpha) \) if \( i = 1 \).
2. \( w'(\alpha) = w(\alpha) \) if \( i \geq 2 \) and \( i \) is not the smallest part of \( \partial_B(\alpha) \).
3. \( w'(\alpha) = (0, w(\alpha)) \) if \( i \geq 2 \) and \( i \) is the smallest part of \( \partial_B(\alpha) \).

In particular, \( \Phi : Y \to X \) and, at the level of compositions, we have that \( \Phi(w)(\alpha) = w(\alpha) \) for all \( w \in Y \).
The next step for us is to identify the image of $Y$ under the map $\Phi$. The image of $Y$ is a very special subset of $X$, which has the following explicit description. Let the largest part of $\alpha$ be $m$. Define $Z$ as follows:

$$Z = \{ \partial_i t_i \in X \mid i \leq m \}.$$ 

Thus in other words, $Z$ is the subset comprising of words that never add a box to the largest part. Note that by the definition of $\Phi$ we have that $\Phi(Y) \subseteq Z$ since if $w \in Y$ and $\Phi(w)$ has rightmost operator $t_j$, then $j \leq m$. Our next aim is to find the inverse of $\Phi$.

Consider $w = \partial_I t_i \in Z$. Writing $I = A \Pi \{i\} \Pi B$ in the usual way, and using Lemma 2.19 allows us to write $w$ as shown below

$$w = \partial_A \partial_i \partial_B.$$

Let $i''$ be the smallest part of $\partial_B(\alpha)$ weakly greater than $i$. This always exists by our hypothesis that $w \in Z$. We define $\Psi(w)$ to be

$$\Psi(w) = \partial_A t_i' \partial_i'' \partial_B = t_i' \partial I'',$$

where $I'' = A \Pi \{i''\} \Pi B$. It is straightforward to see that if $k$ is the largest part of $\alpha$ strictly less than $i$, $i' = k + 1$, and $i''$ is the smallest part of $\partial_B(\alpha)$ weakly greater than $i'$, then $i'' = i$ and hence

$$\Psi(\Phi(w)) = \partial_A \partial_i \partial_B = w$$

so $\Psi$ is the inverse of $\Phi$. Hence we have the bijection

$$(3.7) \quad \Phi(Y) = Z.$$

**Example 3.13.** Consider the composition $\alpha = (2, 6, 1, 4)$ and let $w = t_4 \partial_\{1, 4, 5, 6\}$. Then $w(\alpha) = (2, 4, 0, 4)$ so $w \in Y$. We have the following decomposition for $w$:

$$w = \partial_\{1\} t_4 \partial_4 \partial_\{5, 6\}.$$

Then the corresponding $A$, $B$, and $i$ are $\{1\}$, $\{5, 6\}$, and 4, respectively. Our method for constructing $\Phi(w)$ requires that first we find the largest part $k$ strictly less than $i$ in $\alpha$. So it follows that $k = 2$. This implies that

$$\Phi(w) = \partial_\{1, 3, 5, 6\} t_3 = \partial_\{1\} \partial_3 t_3 \partial_\{5, 6\}$$

and hence $\Phi(w)(\alpha) = (2, 4, 0, 4) = w(\alpha)$ and $\Phi(w) \in Z$. Lastly note that since $\partial_B(\alpha) = (2, 4, 1, 4)$ we have for $\Phi(w)$ that its $i'' = 4$ and

$$\Psi(\Phi(w)) = \Psi(\partial_\{1\} \partial_3 t_3 \partial_\{5, 6\}) = \partial_\{1\} t_4 \partial_4 \partial_\{5, 6\} = w,$$

as desired.

Since $\Psi$ is the inverse of $\Phi$ we also have the following.

**Corollary 3.14.** $\Phi$ is an injection from $Y$ to $X$.

Consider the sets $P$ and $Q$ defined as follows:

$$P = \{ \partial_i t_i \mid i \geq 1, \partial_i t_i(\alpha) \neq 0 \},$$

$$Q = \{ t_i \partial_i \mid i \geq 1, t_i \partial_i(\alpha) \neq 0 \}.$$
Clearly, $P \subset X$ and $Q \subset Y$. Furthermore, we have that $\Phi(Q)$ maps into $P$. In fact, a stronger claim holds from the discussion prior to this:

$$\Phi(Q) = P \setminus \{d_{m+1}t_{m+1}\},$$

where $m$ is the largest part of $\alpha$.

Then utilising all of the above we have the following two theorems.

**Theorem 3.15.** $\mathcal{L}_c$ and $\mathcal{Q}_c$ are dual graded graphs, that is, on compositions $DU_t - U_tD = \text{Id}$.

**Proof.** First note that $DU_t$ corresponds to the following expansion:

$$DU_t = \sum_{i,j \geq 1} d_it_j = \sum_{i,j \geq 1, i \neq j} d_it_j + \sum_{k \geq 1} d_kt_k.$$

Also the operator $U_tD$ corresponds to the expansion below,

$$U_tD = \sum_{i,j \geq 1} t_jd_i = \sum_{i,j \geq 1, i \neq j} t_jd_i + \sum_{k \geq 1} t_kd_k.$$

Then, on using Lemma 2.19, we obtain the following:

$$DU_t - U_tD = \sum_{k \geq 1} d_kt_k - \sum_{k \geq 1} t_kd_k.$$

Taking $\alpha$ into account we can rewrite the above equation as stating the following:

$$(DU_t - U_tD)(\alpha) = \sum_{w \in P} w(\alpha) - \sum_{w \in Q} w(\alpha) = d_{m+1}t_{m+1}(\alpha) + \sum_{w \in Q} (\Phi(w) - w)(\alpha).$$

Now at the level of compositions we have $\sum_{w \in Q} (\Phi(w) - w)(\alpha) = 0$ by Lemma 3.12 and $d_{m+1}t_{m+1}(\alpha) = \alpha$. This implies the claim. □

**Example 3.16.** Let $\alpha = (2,1,3)$. Then suppressing commas and parentheses as before, we have that

$$DU_t(\alpha) = D(1213 + 223 + 313 + 214)$$

$$= 1203 + 1113 + 1212 + 213 + 222 + 303 + 312 + 204 + 114 + 213$$

and

$$U_tD(\alpha) = U_t(203 + 113 + 212)$$

$$= 1203 + 303 + 204 + 1113 + 213 + 114 + 1212 + 222 + 312.$$

Thus $(DU_t - U_tD)(\alpha) = 213 = \text{Id}(\alpha)$.

**Theorem 3.17.** $\mathcal{L}_c$ and $\tilde{\mathcal{Q}}_c$ are dual filtered graphs, that is, on compositions $\tilde{D}U_t - U_t\tilde{D} = \tilde{D} + \text{Id}$.

**Proof.** The beginning of the proof is very similar to that in Theorem 3.8 but with $t_i$ instead of $u_i$. Using Lemma 2.19 we obtain the following equality:

$$\tilde{D}U_t - U_t\tilde{D} = \sum_{I \subseteq \mathbb{N}} \sum_{i \in I} d_it_i - \sum_{I \subseteq \mathbb{N}} t_i d_i.$$
Now for the fixed composition $\alpha$, we can rewrite the above equation as follows:

$$\left(\widetilde{D}U_t - U_t \widetilde{D}\right)(\alpha) = \sum_{w \in X} w(\alpha) - \sum_{w \in Y} w(\alpha)$$

$$= \sum_{w \in X \setminus Z} w(\alpha) + \sum_{w \in Z} w(\alpha) - \sum_{w \in Y} w(\alpha).$$

(3.9)

At the level of compositions, Lemma 3.12 implies that

$$\sum_{w \in Y} (\Phi(w)(\alpha) - w(\alpha)) = 0.$$

Using the above and equation (3.7) in equation (3.9) at the level of compositions gives

$$\left(\widetilde{D}U_t - U_t \widetilde{D}\right)(\alpha) = \sum_{w \in X \setminus Z} w(\alpha).$$

Observe now that every element of $X \setminus Z$ has the form $d_A d_{m+1} t_{m+1}$ where $A$ consists only of instances of $d_i$ where $i \leq m$ and $m$ is the largest part of $\alpha$. Furthermore we do have the possibility that $A$ is empty. Additionally, it is easy to see that $d_{m+1} t_{m+1}$ is the identity map. The preceding discussion allows us to conclude the following equality at the level of compositions, thereby finishing the proof:

$$\left(\widetilde{D}U_t - U_t \widetilde{D}\right)(\alpha) = (\widetilde{D} + \text{Id})(\alpha).$$

□

Example 3.18. Let $\alpha = (1, 2)$. Then suppressing commas and parentheses as before, we have that

$$\widetilde{D}(\alpha) = (02 + 11 + 10).$$

Therefore

$$\widetilde{D}U_t(\alpha) = \widetilde{D}(112 + 22 + 13) = 102 + 111 + 110 + 21 + 20 + 03 + 12 + 02 + 11 + 10$$

and

$$U_t \widetilde{D}(\alpha) = U_t(02 + 11 + 10) = 102 + 03 + 111 + 21 + 110 + 20.$$

Thus $(\widetilde{D}U_t - U_t \widetilde{D})(\alpha) = 2 + 11 + 1 + 12 = (\widetilde{D} + \text{Id})(\alpha)$.

Acknowledgments

The author would like to thank Vasu Tewari for many enjoyable and enlightening conversations. She is also most grateful to the referees for their deep and thoughtful feedback, which she implemented if journal space permitted and used for editing guidance if not.
