SHIFTED SUPER YANGIANS AND FINITE W-SUPERALGEBRAS

YUNG-NING PENG

Abstract. We study the finite W-superalgebra $W_e$ associated to a nilpotent element $e$ in a general linear Lie superalgebra. Under certain restriction on the Jordan type of $e$, we give a realization of $W_e$ in terms of a quotient of a shifted super Yangian.

1. Introduction

A finite $W$-algebra is an associative algebra constructed from a pair $(\mathfrak{g}, e)$, where $\mathfrak{g}$ is a finite dimensional semisimple or reductive Lie algebra and $e$ is a nilpotent element of $\mathfrak{g}$. In the extreme case where $e = 0$, the corresponding finite $W$-algebra is isomorphic to $U(\mathfrak{g})$, the universal enveloping algebra. In the other extreme case where $e$ is the principal nilpotent element $e_p$, Kostant proved that the associated finite $W$-algebra is isomorphic to the center of the universal enveloping algebra $U(\mathfrak{g})$ (cf. [Ko]). In recent decades, there are many new development on $W$-algebras; we refer to the survey papers [Lo] and [Wa] for the details.

On the other hand, the Yangians, defined by Drinfeld in 1983, are certain non-commutative Hopf algebras that are important examples of quantum groups. They were used to generate the rational solutions of the Yang-Baxter equations; see the book [Mo] for more details and further applications of Yangians.

The connection between Yangians and finite $W$-algebras of type A associated to a rectangular nilpotent element $e$ was first noticed by Ragoucy and Sorba in [RS]. The term “rectangular” means that the Jordan blocks of $e$ are all of the same size.
Brundan and Kleshchev in [BK2] generalized the result to an arbitrary nilpotent $e$ by a different approach. As a consequence, a realization of finite $W$-algebra of type $A$ as a quotient of a so-called shifted Yangian is obtained, and this provides a powerful tool for the study of finite $W$-algebras.

In this article, we establish such a connection between finite $W$-superalgebras and super Yangians explicitly in type $A$ where the Jordan type of $e$ satisfies certain condition (7.7). Let $Y_{m|n}$ denote the super Yangian of the general linear Lie superalgebra $\mathfrak{gl}_{m|n}$. In fact, such a connection was firstly obtained in [BR] when $e \in \mathfrak{gl}_{M|N}$ is rectangular; see also [Pe2]. Their result shows that the finite $W$-superalgebra associated to a rectangular $e \in \mathfrak{gl}_{M|N}$ is isomorphic to the truncated super Yangian $Y^\ell_{m|n}$, which is a certain quotient of the super Yangian $Y_{m|n}$. Here the indices $m$ and $n$ are determined by the number of Jordan blocks of the rectangular $e$ and $\ell$ is the size of the Jordan block.

In a more recent paper [BBG], the connection between the finite $W$-superalgebra associated to an $e \in \mathfrak{gl}_{M|N}$ and $Y_{1|1}$ is developed. It corresponds to the case when the nilpotent element $e \in \mathfrak{gl}_{M|N}$ is principal. Our main result (Theorem 9.1) is to establish an isomorphism of superalgebras between the truncated shifted super Yangian for $\mathfrak{gl}_{1|n}$ and a finite $W$-superalgebra.

Let us explain our approach, which is roughly generalizing the argument in [BK2] to the general linear Lie superalgebras. Firstly we give a presentation of the shifted super Yangian, denoted by $Y_{1|n}(\sigma)$, which is a subalgebra of $Y_{1|n}$ associated to a matrix $\sigma$. The set of generators is a certain subset, determined by $\sigma$, of the generators of $Y_{1|n}$. The defining relations are modified from the defining relations of $Y_{1|n}$ according to $\sigma$ as well. Then we quotient out a certain ideal to obtain the truncated super Yangian $Y^\ell_{1|n}(\sigma)$. One may naively think that those generators with degree higher than $\ell$ vanish in $Y^\ell_{1|n}(\sigma)$.

Next we introduce the combinatorial objects called pyramids; see [EK], [Ho]. This gives a nice way to record the necessary information (that is, $\sigma$ and $\ell$) to define $Y^\ell_{1|n}(\sigma)$ by a diagram. For example,

$$\ell = 4, \quad \sigma = \begin{pmatrix} 0 & 1 & 1 \\ 0 & 0 & 0 \\ 1 & 1 & 0 \end{pmatrix} \quad \longleftrightarrow \quad \pi = \begin{pmatrix} + & + \\ - & - \\ - & - \end{pmatrix}$$

The merit of using a pyramid is that one may obtain a nilpotent element $e$ and a semisimple element $h$ that determine a finite $W$-superalgebra. In our example above,

$$e = e_{\pi\pi} + e_{24} + e_{46} + e_{13} + e_{35} + e_{57},$$

$$h = \text{diag}(1, -1, 3, 1, 1, -1, -1, -3, -3),$$

where $e_{ij}$ means the elementary matrix in $\mathfrak{gl}_{2|7}$; see §7 for detail.

Therefore, given a pyramid $\pi$, we simultaneously obtain a truncated super Yangian $Y^\ell_{\pi}$ and a finite $W$-superalgebra $W_{\pi}$. In §8, we introduce the notion of super height so that one may explicitly write down certain distinguished elements in $W_{\pi}$.
from the diagram $\pi$. Finally, we prove that the map sending the generators of $Y_\pi$ into these distinguished elements is an isomorphism of filtered superalgebras by induction on $\ell$, the number of boxes of the base of $\pi$.

The general case, which means the even nilpotent $e \in gl_{|N}$ could be arbitrary, is highly challenging and requires new presentations of the super Yangian that are unknown yet.

This article is organized as follows. In §2, we define the shifted Yangian $Y_{1|n}(\sigma)$ and prove a PBW theorem for it. In §3, we introduce the notion of parabolic presentations for $Y_{1|n}(\sigma)$ as in [Pe1]. An important consequence is that we may write down an explicit formula for the so-called baby comultiplications in §4. In §5, we introduce the canonical filtration of $Y_{1|n}(\sigma)$. In the end it corresponds to the Kazhdan filtration of finite $W$-superalgebras. Then we define the truncated shifted Yangian $Y_{1|n}(\sigma)$ in §6 as a quotient of $Y_{1|n}(\sigma)$, and prove that $Y_{1|n}(\sigma)$ shares many nice properties of $Y_{1|n}(\sigma)$ such as PBW basis and baby comultiplications. Next we switch our attention to finite $W$-superalgebra. In §7 we give the definition of $W$-superalgebra with respect to an even good $Z$-grading. Then we use pyramids as a tool to encode the information needed to define the $W$-superalgebra. Moreover, we also explain how to read off a truncated shifted Yangian $Y_{1|n}(\sigma)$ from a given pyramid $\pi$. §8 is the most crucial section, in which we give explicitly the formulae for some elements in $U(p)$ that eventually can be identified as generators of our $W$-superalgebra. Our main theorem is stated and proved by induction in §9.

**Notation:** In this article the underlying field is always $\mathbb{C}$. A superalgebra means an associative $\mathbb{Z}_2$-graded algebra. The parity of a homogeneous element $x$ is denoted by $|x|$. For homogeneous elements $x$ and $y$ in a superalgebra $A = A_{\mathbb{E}} \oplus A_{\mathbb{T}}$, their supercommutator is $[x, y] := xy - (-1)^{|x||y|}yx$. We say $x$ and $y$ supercommute if $[x, y] = 0$. For homogeneous $x_1, \ldots, x_t \in A$, an ordered supermonomial in $x_1, \ldots, x_t$ means a monomial of the form $x_1^{i_1} \cdots x_t^{i_t}$ for some $i_1, \ldots, i_t \in \mathbb{Z}_{\geq 0}$ and $i_j \leq 1$ if $x_j$ is odd.

### 2. Shifted super Yangian of $gl_{1|n}$

In this section, we recall the definition of the super Yangian $Y_{1|n}$. Moreover, we define a certain superalgebra called the shifted super Yangian, which turns out to be a subalgebra of $Y_{1|n}$.

The super Yangian $Y_{1|n}$, which was introduced in [Na], is the associative $\mathbb{Z}_2$-graded algebra (i.e., superalgebra) over $\mathbb{C}$ with the RTT generators

$$\left\{ t^{(r)}_{ij} \mid 1 \leq i, j \leq n + 1; r \geq 0 \right\},$$

where $t^{(0)}_{ij} := \delta_{ij}$ and defining relations

$$[t^{(r)}_{ij}, t^{(s)}_{hk}] = (-1)^{ij+ih+jh} \sum_{t=0}^{\min(r,s)-1} \left( t^{(t)}_{hj} t^{(r+s-1-t)}_{ik} - t^{(r+s-1-t)}_{hj} t^{(t)}_{ik} \right),$$

(2.1)
where \( \overline{t} = 0 \) if \( i = 1 \) and \( \overline{t} = 1 \) otherwise. The bracket in (2.1) is understood as a supercommutator. For \( r > 0 \), the element \( t_{ij}^{(r)} \) is defined to be an odd element if \( \overline{i} + \overline{j} \equiv 1 \) (mod 2) and an even element if \( \overline{i} + \overline{j} \equiv 0 \) (mod 2).

The elements \( \{t_{ij}^{(r)}\} \) are called the RTT generators while the defining relations (2.1) are called the RTT relations. Next we use an alternate presentation of \( Y_{1|n} \) to define shifted Yangians that are not easily obtained from the classical definition.

Let \( \sigma \) be an \((n + 1) \times (n + 1)\) matrix \( (s_{i,j})_{1 \leq i,j \leq n+1} \) where the entries are non-negative integers satisfying that
\[
s_{i,j} + s_{j,k} = s_{i,k},
\]
whenever \( |i-j| + |j-k| = |i-k| \). Immediately, we have \( s_{1,1} = s_{2,2} = \cdots = s_{n+1,n+1} = 0 \), and \( \sigma \) is determined by the upper diagonal entries \( s_{1,2}, s_{2,3}, \ldots, s_{n,n+1} \) and the lower diagonal entries \( s_{2,1}, s_{3,2}, \ldots, s_{n+1,n} \). In addition, we will add lines to emphasize the parities. Such a matrix will be called a shift matrix. For example, the following matrix is a shift matrix:
\[
\sigma = \begin{pmatrix}
0 & 0 & 1 & 1 & 2 \\
0 & 0 & 1 & 1 & 2 \\
1 & 1 & 0 & 0 & 1 \\
3 & 3 & 2 & 0 & 1 \\
4 & 4 & 3 & 1 & 0 \\
\end{pmatrix}
\]

**Definition 2.1.** The shifted Yangian of \( \mathfrak{gl}_{1|n} \) associated to \( \sigma \), denoted by \( Y_{1|n}(\sigma) \), is the superalgebra over \( \mathbb{C} \) generated by the following elements
\[
\{D_i^{(r)}| 1 \leq i \leq n+1, r \geq 0\},
\]
\[
\{E_i^{(r)}| 1 \leq i \leq n, r > s_{i,i+1}\},
\]
\[
\{F_i^{(r)}| 1 \leq i \leq n, r > s_{i+1,i}\},
\]
subject to the following defining relations:
\[
D_i^{(0)} = 1
\]
\[
\sum_{t=0}^{r} D_i^{(t)} D_i^{(r-t)} = \delta_{r0}
\]
\[
[D_i^{(r)}, D_j^{(s)}] = \delta_{ij} \sum_{t=0}^{\min(r,s)-1} (D_i^{(t)} D_i^{(r+s-1-t)} - D_i^{(r+s-1-t)} D_i^{(t)})
\]
\[ [D_i^{(r)}, E_j^{(s)}] = \begin{cases} 
-\delta_{i,j} \sum_{t=0}^{r-1} D_i^{(t)} E_j^{(r+s-1-t)} + \delta_{i,j+1} \sum_{t=0}^{r-1} D_i^{(t)} E_j^{(r+s-1-t)}, & j \neq 1, \\
\delta_{i,j} \sum_{t=0}^{r-1} D_i^{(t)} E_j^{(r+s-1-t)} + \delta_{i,j+1} \sum_{t=0}^{r-1} D_i^{(t)} E_j^{(r+s-1-t)}), & j = 1, 
\end{cases} \]

(2.6)

\[ [D_i^{(r)}, F_j^{(s)}] = \begin{cases} 
\delta_{i,j} \sum_{t=0}^{r-1} F_j^{(r+s-1-t)} D_i^{(t)} - \delta_{i,j+1} \sum_{t=0}^{r-1} F_j^{(r+s-1-t)} D_i^{(t)}, & j \neq 1, \\
-\delta_{i,j} \sum_{t=0}^{r-1} F_j^{(r+s-1-t)} D_i^{(t)} - \delta_{i,j+1} \sum_{t=0}^{r-1} F_j^{(r+s-1-t)} D_i^{(t)}, & j = 1, 
\end{cases} \]

(2.7)

\[ [E_i^{(r)}, E_i^{(s)}] = \begin{cases} 
-\sum_{t=1}^{s-1} E_i^{(t)} E_i^{(r+s-1-t)} + \sum_{t=1}^{r-1} E_i^{(t)} E_i^{(r+s-1-t)}, & i \neq 1, \\
0, & i = 1, 
\end{cases} \]

(2.8)

\[ [F_i^{(r)}, F_i^{(s)}] = \begin{cases} 
-\sum_{t=1}^{r-1} F_i^{(r+s-1-t)} F_i^{(t)} + \sum_{t=1}^{s-1} F_i^{(r+s-1-t)} F_i^{(t)}, & i \neq 1, \\
0, & i = 1, 
\end{cases} \]

(2.9)

\[ [E_i^{(r+1)}, E_{i+1}^{(s)}] - [E_i^{(r)}, E_{i+1}^{(s+1)}] = -E_i^{(r)} E_{i+1}^{(s)}, \]

(2.10)

\[ [E_i^{(r+1)}, F_{i+1}^{(s)}] - [F_i^{(r)}, F_{i+1}^{(s+1)}] = F_i^{(s)} F_{i+1}^{(r)}, \]

(2.11)

\[ [E_i^{(r)}, E_j^{(s)}] = 0, \quad \text{if } |i-j| \geq 1, \]

(2.12)

\[ [F_i^{(r)}, F_j^{(s)}] = 0, \quad \text{if } |i-j| \geq 1, \]

(2.13)

\[ [E_i^{(r)}, [E_s^{(s)}, E_j^{(k)}]] + [E_s^{(s)}, [E_i^{(r)}, E_j^{(k)}]] = 0, \quad |i-j| \geq 1, \]

(2.14)

\[ [F_i^{(r)}, [F_s^{(s)}, F_j^{(k)}]] + [F_s^{(s)}, [F_i^{(r)}, F_j^{(k)}]] = 0, \quad |i-j| \geq 1, \]

(2.15)

for all "admissible" \(i, j, k, r, s\). For example, the relation (2.11) should be understood to hold for all \(1 \leq i \leq n-1, r > s_{i+1,i}\) and \(s > s_{i+2,i+1}\). The elements \(\{E_i^{(r)}|r > s_{1,2}\} \cup \{F_i^{(r)}|r > s_{2,1}\}\) are the only odd generators.

**Remark 2.2.** Note that the lower degree terms in (2.8) and (2.9) cancel each other so it is well-defined.
Remark 2.3. In the special case where $\sigma$ is the zero matrix, $Y_{1|n}(\sigma) = Y_{1|n}$ and the above presentation is exactly the presentation of $Y_{1|n}$ given in [Go], which is a generalization of Drinfeld’s presentation.

Let $\Gamma$ be the map sending the generators of $Y_{1|n}(\sigma)$ to the elements with the same name in $Y_{1|n}$. We now prove that the map $\Gamma : Y_{1|n}(\sigma) \longrightarrow Y_{1|n}$ is an injective algebra homomorphism and hence $Y_{1|n}(\sigma)$ is canonically a subalgebra of $Y_{1|n}$. As a corollary, a PBW basis for $Y_{1|n}(\sigma)$ is obtained.

Define the loop filtration on $Y_{1|n}(\sigma)$
$$L_0 Y_{1|n}(\sigma) \subseteq L_1 Y_{1|n}(\sigma) \subseteq L_2 Y_{1|n}(\sigma) \subseteq \cdots$$
by setting the degree of the generators $D_i^{(r)}$, $E_i^{(r)}$, and $F_i^{(r)}$ to be $(r - 1)$ and $L_k Y_{1|n}(\sigma)$ to be the span of all supermonomials in the generators of total degree $\leq k$ and denote the associated graded algebra by $gr^L Y_{1|n}(\sigma)$.

Next, for all $1 \leq i < j \leq n + 1$ and $r > s_{i,j}$, we define the elements $E_{i,j}^{(r)} \in Y_{1|n}(\sigma)$ recursively by
$$E_{i,i+1}^{(r)} := E_i^{(r)}, \quad E_{i,j}^{(r)} := -[E_{i,j-1}^{(r-s_{j,j-1})}, E_{j-1,j}^{(s_{j,j-1}+1)}]. \quad (2.16)$$
Similarly, for $1 \leq i < j \leq n + 1$ and $r > s_{j,i}$, we may define the elements $F_{j,i}^{(r)} \in Y_{1|n}(\sigma)$ by
$$F_{i+1,j}^{(r)} := F_i^{(r)}, \quad F_{j,i}^{(r)} := -[F_{j-1,j}^{(s_{j,j-1}+1)}, F_{j-1,i}^{(r-s_{j,j-1})}]. \quad (2.17)$$
For all $1 \leq i, j \leq n + 1$ and $r \geq s_{i,j}$, define
$$e_{i,j} := \begin{cases} 
gr^L D_i^{(r+1)} & \text{if } i = j, \\
gr^L E_i^{(r+1)} & \text{if } i < j, \\
gr^L F_i^{(r+1)} & \text{if } i > j,
\end{cases}$$
where the elements on the right-hand side are in $gr^L Y_{1|n}(\sigma)$ of degree $r$.

Denote the Lie superalgebra $\mathfrak{gl}_{1|n} \otimes \mathbb{C}[t]$ with basis elements $\{e_{i,j} t^r\}_{1 \leq i, j \leq n + 1, r \geq 0}$ by $\mathfrak{gl}_{1|n}[t]$, which can be viewed as a graded Lie superalgebra by setting the degree of $e_{i,j} t^r$ to be $r$.

By assumption (2.2), the elements $\{e_{i,j} t^r \mid 1 \leq i, j \leq n + 1, r \geq s_{i,j}\}$ generate a subalgebra of $\mathfrak{gl}_{1|n}[t]$ which we denote by $\mathfrak{gl}_{1|n}[t](\sigma)$. The grading on $\mathfrak{gl}_{1|n}[t](\sigma)$ induces a grading on $U(\mathfrak{gl}_{1|n}[t](\sigma))$, the universal enveloping algebra.

Theorem 2.4. The map $\gamma : U(\mathfrak{gl}_{1|n}[t](\sigma)) \longrightarrow gr^L Y_{1|n}(\sigma)$ such that
$$e_{i,j} t^r \longmapsto e_{i,j}$$
for each $1 \leq i, j \leq n + 1$ and $r \geq s_{i,j}$ is an isomorphism of graded superalgebras.

Proof. The map $\gamma$ is clearly well-defined and surjective. To prove the injectivity, the key step is showing that for all $1 \leq i, j, h, k \leq n + 1$ and $r \geq s_{i,j}$, $s \geq s_{h,k}$, we have
$$[e_{i,j} t^r, e_{h,k} s] = (-1)^{\delta_{i,j} e_{i,k} t^{r+s}} - (-1)^{\delta_{j} \delta_{i} e_{h,j} t^{r+s}} \quad (2.18)$$
where the identity is in $gr^L Y_{1|n}$; see [Go, Theorem 3] for its proof.
In the special case when \( \sigma \) is the zero matrix, (2.18) and PBW theorem of \( Y_{1|n} \) imply that the ordered supermonomials in \( \{ e_{i,j;r} \}_{1 \leq i,j \leq n+1, r \geq 0} \) are linearly independent in \( \text{gr}^L Y_{1|n} \) and \( \gamma \) is an isomorphism in this special case.

In general, the map \( \Gamma : Y_{1|n}(\sigma) \rightarrow Y_{1|n} \) is a homomorphism of filtered superalgebras, which induces a map \( \text{gr}^L Y_{1|n}(\sigma) \rightarrow \text{gr}^L Y_{1|n} \) sending \( e_{i,j;r} \in \text{gr}^L Y_{1|n}(\sigma) \) to \( e_{i,j;r} \in \text{gr}^L Y_{1|n} \). The previous paragraph implies that the ordered supermonomials in the elements \( \{ e_{i,j;r} \mid 1 \leq i,j \leq n+1, r \geq s_{i,j} \} \) are linearly independent in \( \text{gr}^L Y_{1|n}(\sigma) \) and hence \( \gamma \) is an isomorphism in general. \( \square \)

**Remark 2.5.** \( \Gamma \) does not send the general parabolic elements \( E_{i,j}^{(r+1)}, F_{j,i}^{(r+1)} \) in \( Y_{1|n}(\sigma) \) to \( E_{i,j}^{(r+1)}, F_{j,i}^{(r+1)} \) of \( Y_{1|n} \) if \( j-i > 1 \).

**Corollary 2.6.** The canonical map \( \Gamma : Y_{1|n}(\sigma) \rightarrow Y_{1|n} \) is injective.

**Proof.** The map \( \Gamma : Y_{1|n}(\sigma) \rightarrow Y_{1|n} \) is a filtered map and the induced map \( \text{gr}^L Y_{1|n}(\sigma) \rightarrow \text{gr}^L Y_{1|n} \) is injective. The corollary follows from induction argument on degree. \( \square \)

We denote the subalgebra of \( Y_{1|n}(\sigma) \) generated by all the \( D_i^{(r)} \)'s by \( Y_{1|n}^0 \), the subalgebra generated by all the \( E_i^{(r)} \)'s by \( Y_{1|n}^+ \) and the subalgebra generated by all the \( F_i^{(r)} \)'s by \( Y_{1|n}^- \), respectively.

**Corollary 2.7.** (i) The monomials in the elements \( \{ D_i^{(r)} \}_{1 \leq i \leq n+1, r > 0} \) taken in some fixed order form a basis for \( Y_{1|n}^0 \).

(ii) The supermonomials in the elements \( \{ E_{i,j}^{(r)} \}_{1 \leq i,j \leq n+1, r > s_{i,j}} \) taken in some fixed order form a basis for \( Y_{1|n}^+ \).

(iii) The supermonomials in the elements \( \{ F_{j,i}^{(r)} \}_{1 \leq j,i \leq n+1, r > s_{j,i}} \) taken in some fixed order form a basis for \( Y_{1|n}^- \).

(iv) The supermonomials in the union of the elements listed in (i)–(iii) taken in some fixed order form a basis for \( Y_{1|n}(\sigma) \).

**Proof.** (iv) follows from Theorem 2.4 and PBW theorem for \( U(\mathfrak{gl}_{1|n}[t](\sigma)) \). The others can be proved similarly using (2.18). \( \square \)

**Corollary 2.8.** The multiplicative map

\[
Y_{1|n}^-(\sigma) \otimes Y_{1|n}^0 \otimes Y_{1|n}^+(\sigma) \rightarrow Y_{1|n}(\sigma)
\]

is an isomorphism of vector spaces.

By the defining relations of \( Y_{1|n} \), the map \( \tau : Y_{1|n} \rightarrow Y_{1|n} \) defined by

\[
\tau(D_i^{(r)}) = D_i^{(r)}, \quad \tau(E_i^{(r)}) = F_i^{(r)}, \quad \tau(F_i^{(r)}) = E_i^{(r)}
\]

is an anti-automorphism of order 2 and its restriction on \( Y_{1|n}(\sigma) \) gives an anti-isomorphism \( \tau : Y_{1|n}(\sigma) \rightarrow Y_{1|n}(\sigma^t) \), where \( \sigma^t \) is the transpose of the matrix \( \sigma \).
Suppose instead that $\hat{\sigma} = (\hat{s}_{i,j})_{1 \leq i,j \leq n+1}$ is another shift matrix satisfying (2.2) and in addition $\hat{s}_{i,i+1} + \hat{s}_{i+1,i} = s_{i,i+1} + s_{i+1,i}$ for all $i = 1, \ldots, n$. Another check of relations shows that the map $\iota : Y_{1|n}(\sigma) \to Y_{1|n}(\hat{\sigma})$ defined by

$$\iota(D^{(r)}_i) = \hat{D}^{(r)}_i, \quad \iota(E^{(r)}_i) = \hat{E}^{(r)}_i, \quad \iota(F^{(r)}_i) = \hat{F}^{(r)}_i$$

(2.20)
is a superalgebra isomorphism. Here and later on we denote the generators $D^{(r)}_i, E^{(r)}_i$ and $F^{(r)}_i$ of $Y_{1|n}(\sigma)$ instead by $\hat{D}^{(r)}_i, \hat{E}^{(r)}_i$ and $\hat{F}^{(r)}_i$ to avoid possible confusion.

3. Parabolic presentations

In this section, we introduce the notion of parabolic presentation to the shifted super Yangian $Y_{1|n}(\sigma)$. We start with a brief review of about the parabolic presentations of $Y_{1|n}$ from [Pe1] in §3.1, and then we extend the notion to $Y_{1|n}(\sigma)$ in §3.2.

3.1. Parabolic presentations of $Y_{1|n}$. Recall that $Y_{1|n}$ is generated by the elements $t^{(r)}_{i,j}$ with defining relation (2.1). We define the formal power series

$$t_{ij}(u) = \delta_{ij} + t^{(1)}_{ij} u^{-1} + t^{(2)}_{ij} u^{-2} + t^{(3)}_{ij} u^{-3} + \ldots$$

and the matrix $T(u) := (t_{ij}(u))_{1 \leq i,j \leq n+1}$.

Let $\nu$ be a composition of $n$ with length $m$. For notational reason, we set

$$\mu_1 = 1 \quad \text{and} \quad \mu_j = \nu_{j-1} \quad \text{for all} \quad 2 \leq j \leq m+1,$$

and $\mu = (\mu_1, \mu_2, \mu_3, \ldots, \mu_{m+1})$ denotes the composition of $(1|n)$.

By definition, the leading minors of the matrix $T(u)$ are invertible. Depending on the given composition $\mu$, $T(u)$ possesses a Gauss decomposition

$$T(u) = F(u)D(u)E(u)$$

for unique block matrices $D(u)$, $E(u)$ and $F(u)$ of the form

$$D(u) = \begin{pmatrix}
D_1(u) & 0 & \cdots & 0 \\
0 & D_2(u) & \cdots & 0 \\
\vdots & \vdots & \ddots & \vdots \\
0 & 0 & \cdots & D_{m+1}(u)
\end{pmatrix},$$

$$E(u) = \begin{pmatrix}
I_{\mu_1} & E_{1,2}(u) & \cdots & E_{1,m+1}(u) \\
0 & I_{\mu_2} & \cdots & E_{2,m+1}(u) \\
\vdots & \vdots & \ddots & \vdots \\
0 & 0 & \cdots & I_{\mu_{m+1}}
\end{pmatrix},$$

$$F(u) = \begin{pmatrix}
I_{\mu_1} & 0 & \cdots & 0 \\
F_{2,1}(u) & I_{\mu_2} & \cdots & 0 \\
\vdots & \vdots & \ddots & \vdots \\
F_{m+1,1}(u) & F_{m+1,2}(u) & \cdots & I_{\mu_{m+1}}
\end{pmatrix},$$
where

\[ D_a(u) = (D_{a;i,j}(u))_{1 \leq i,j \leq \mu_a}, \quad \text{(3.1)} \]
\[ E_{a,b}(u) = (E_{a,b;i,j}(u))_{1 \leq i \leq \mu_a, 1 \leq j \leq \mu_b}, \quad \text{(3.2)} \]
\[ F_{b,a}(u) = (F_{b,a;i,j}(u))_{1 \leq i \leq \mu_b, 1 \leq j \leq \mu_a}, \quad \text{(3.3)} \]

are \( \mu_a \times \mu_a, \mu_a \times \mu_b \) and \( \mu_b \times \mu_a \) matrices, respectively, for all \( 1 \leq a \leq m + 1 \) in (3.1) and all \( 1 \leq a < b \leq m + 1 \) in (3.2) and (3.3).

For all \( 1 \leq a \leq m + 1 \), define the \( \mu_a \times \mu_a \) matrix \( D'_a(u) = (D'_{a;i,j}(u))_{1 \leq i,j \leq \mu_a} \) by

\[ D'_a(u) := (D_a(u))^{-1}. \]

The entries of these matrices are expanded into power series

\[ D_{a;i,j}(u) = \sum_{r \geq 0} D^{(r)}_{a;i,j} u^{-r}, \quad E_{a,b;i,j}(u) = \sum_{r \geq 1} E^{(r)}_{a,b;i,j} u^{-r}, \]
\[ D'_{a;i,j}(u) = \sum_{r \geq 0} D'^{(r)}_{a;i,j} u^{-r}, \quad F_{b,a;i,j}(u) = \sum_{r \geq 1} F^{(r)}_{b,a;i,j} u^{-r}. \]

Moreover, for \( 1 \leq a \leq n \), we set

\[ E_{a;i,j}(u) := E_{a,a+1;i,j}(u) = \sum_{r \geq 1} E^{(r)}_{a;i,j} u^{-r}, \]
\[ F_{a;i,j}(u) := F_{a+1,a;i,j}(u) = \sum_{r \geq 1} F^{(r)}_{a;i,j} u^{-r}. \]

**Proposition 3.1.** [Pe1, Theorem 4] The super Yangian \( Y_{1|n} \) is generated by the elements

\[ \{ D^{(r)}_{a;i,j}, D'^{(r)}_{a;i,j} \mid 1 \leq a \leq n+1, 1 \leq i,j \leq \mu_a, r \geq 0 \}, \]
\[ \{ E^{(r)}_{a;i,j} \mid 1 \leq a \leq n, 1 \leq i \leq \mu_a, 1 \leq j \leq \mu_{a+1}, r \geq 1 \}, \]
\[ \{ F^{(r)}_{a;i,j} \mid 1 \leq a \leq n, 1 \leq i \leq \mu_{a+1}, 1 \leq j \leq \mu_a, r \geq 1 \}, \]

subject to certain relations depending on \( \mu \).

Since the defining relations are exactly the relations (3.5)-(3.18) below when all \( s_{ij} = 0 \), we omit the relations here.

For example, the presentation of \( Y_{1|n} \) introduced in §2 is the special case when \( \mu = (1^{n+1}) \), where \( D^{(r)}_{a;1,1} = D^{(r)}_a, E^{(r)}_{a;1,1} = E^{(r)}_a \) and \( F^{(r)}_{a;1,1} = F^{(r)}_a \). The presentation depends on the composition \( \mu \) and hence we will use the notation \( Y_\mu = Y_{1|n} \) to emphasize the composition which we are using.

### 3.2. Parabolic presentation of \( Y_{1|n}(\sigma) \)

Throughout this subsection, we fix a shift matrix \( \sigma = (s_{i,j})_{1 \leq i,j \leq n+1} \). Also recall that we set \( \mu_1 = 1 \) for notational reason.

**Definition 3.2.** A composition \( \mu = (\mu_1, \mu_2, \ldots, \mu_{m+1}) \) of \( (1|n) \) is said to be admissible for \( \sigma \) if \( s_{i,j} = 0 \) for all \( \mu_1 + \ldots + \mu_{a-1} + 1 \leq i, j \leq \mu_1 + \ldots + \mu_a \), for each \( 1 \leq a \leq m + 1 \).
For example, the composition $\mu = (1^{n+1})$ is admissible for any shift matrix $\sigma$. We will use a shorthand notation from now on
\[ s_{a,b}^\mu := s_{\mu_1+\ldots+\mu_a,a+1}^{n+1}. \] (3.4)
Note that one can recover the original matrix $\sigma$ and an admissible shape $\mu$ if the admissible shape $\mu$ and the numbers $\{s_{a,b}^\mu | 1 \leq a, b \leq m+1\}$ are given. Assume from now on that a shift matrix $\sigma$ and an admissible shape $\mu$ for $\sigma$ are given.

**Definition 3.3.** The shifted Yangian of $\mathfrak{gl}_{1|n}$ associated to $\sigma$ and $\mu$, denoted by $Y_{\mu}(\sigma)$, is the superalgebra over $\mathbb{C}$ generated by the following elements
\[
\{D_{a,i,j}^{(r)} | 1 \leq a \leq m+1, 1 \leq i, j \leq \mu_a, r \geq 0\},
\{E_{a,i,j}^{(r)} | 1 \leq a \leq m, 1 \leq i \leq \mu_a, 1 \leq j \leq \mu_{a+1}, r > s_{a,a+1}^\mu\},
\{F_{a,i,j}^{(r)} | 1 \leq a \leq m, 1 \leq i \leq \mu_{a+1}, 1 \leq j \leq \mu_a, r > s_{a,a+1}^\mu\},
\]
subject to the following defining relations:
\[
D_{a,i,j}^{(0)} = \delta_{ij},
\]
\[
\sum_{t=0}^r D_{a,i,j}^{(t)} D_{a,p,j}^{(r-t)} = \delta_{r0} \delta_{ij},
\]
\[
[D_{a,i,j}^{(r)}, D_{b,h,k}^{(s)}] = \delta_{ab} \sum_{t=0}^{\min(r,s)-1} (D_{a,h,j}^{(t)} D_{a,i,k}^{(r+s-1-t)} - D_{a,i,j}^{(t)} D_{a,b,k}^{(r+s-1-t)}),
\]
\[
[D_{a,i,j}^{(r)}, E_{b,h,k}^{(s)}] =
\begin{cases}
-\delta_{a,b} \delta_{h,j} \sum_{t=0}^{r-1} D_{a,i,p}^{(t)} F_{a,p,k}^{(r+s-1-t)} + \delta_{a,b+1} \sum_{t=0}^{r-1} D_{a,i,k}^{(t)} E_{b,h,j}^{(r+s-1-t)}, b \neq 1, \\
\delta_{a,b} \delta_{h,j} \sum_{t=0}^{r-1} D_{a,i,p}^{(t)} E_{a,p,k}^{(r+s-1-t)} + \delta_{a,b+1} \sum_{t=0}^{r-1} D_{a,i,k}^{(t)} E_{b,h,j}^{(r+s-1-t)}, b = 1,
\end{cases}
\]
\[
[D_{a,i,j}^{(r)}, F_{b,h,k}^{(s)}] =
\begin{cases}
\delta_{a,b} \delta_{k,i} \sum_{t=0}^{r-1} E_{b,h,p}^{(r+s-1-t)} D_{a,p,j}^{(t)} - \delta_{a,b+1} \sum_{t=0}^{r-1} E_{b,i,k}^{(r+s-1-t)} D_{a,h,j}^{(t)}, b \neq 1, \\
-\delta_{a,b} \delta_{k,i} \sum_{t=0}^{r-1} E_{b,h,p}^{(r+s-1-t)} D_{a,p,j}^{(t)} - \delta_{a,b+1} \sum_{t=0}^{r-1} E_{b,i,k}^{(r+s-1-t)} D_{a,h,j}^{(t)}, b = 1,
\end{cases}
\]
\[
[E_{a,i,j}^{(r)}, E_{a,h,k}^{(s)}] =
\begin{cases}
-\sum_{t=1}^{s-1} E_{a,i,k}^{(t)} E_{a,j,h}^{(r+s-1-t)} + \sum_{t=1}^{r-1} E_{a,i,k}^{(t)} E_{a,h,j}^{(r+s-1-t)}, a \neq 1, \\
\sum_{t=1}^{r-1} E_{a,i,k}^{(t)} E_{a,j,h}^{(r+s-1-t)} - \sum_{t=1}^{s-1} E_{a,i,k}^{(t)} E_{a,h,j}^{(r+s-1-t)}, a = 1,
\end{cases}
\]
\[ [F^{(r)}_{a;i,j}, F^{(s)}_{a:h,k}] = \begin{cases} 
- \sum_{t=1}^{r-1} F^{(r+s-1-t)}_{a:i,k} F^{(t)}_{a:h,j} + \sum_{t=1}^{s-1} F^{(r+s-1-t)}_{a:i,k} F^{(t)}_{a:h,j}, & a \neq 1, \\
\sum_{t=1}^{r-1} F^{(r+s-1-t)}_{a:i,k} F^{(t)}_{a:h,j} - \sum_{t=1}^{s-1} F^{(r+s-1-t)}_{a:i,k} F^{(t)}_{a:h,j}, & a = 1, 
\end{cases} \] (3.11)

\[ [E^{(r)}_{a;i,j}, F^{(s)}_{b:h,k}] = \delta_{a,b} \sum_{t=0}^{r+s-1} D^{(r+s-1-t)}_{a+1:h,j} D^{(t)}_{a:i,k}. \] (3.12)

\[ [E^{(r+1)}_{a;i,j}, E^{(s)}_{a+1:h,k}] - [E^{(r)}_{a;i,j}, E^{(s+1)}_{a+1:h,k}] = -\delta_{h,j} E^{(r)}_{a+1:i,q} E^{(s)}_{a+1:q,k}, \] (3.13)

\[ [F^{(r+1)}_{a;i,j}, F^{(s)}_{a+1:h,k}] - [F^{(r)}_{a;i,j}, F^{(s+1)}_{a+1:h,k}] = \delta_{i,k} F^{(s)}_{a+1:h,q} F^{(r)}_{a+1:q,j}, \] (3.14)

\[ [E^{(r)}_{a;i,j}, F^{(s)}_{b:h,k}] = 0 \quad \text{if} \ b > a + 1 \quad \text{or} \quad \text{if} \ b = a + 1 \text{ and } h \neq j, \] (3.15)

\[ [F^{(r)}_{a;i,j}, F^{(s)}_{b:h,k}] = 0 \quad \text{if} \ b > a + 1 \quad \text{or} \quad \text{if} \ b = a + 1 \text{ and } i \neq k, \] (3.16)

\[ [E^{(r)}_{a;i,j}, F^{(s)}_{a:h,k}] + [F^{(s)}_{a;i,j}, E^{(r)}_{a:h,k}] = 0, \quad |a-b| \geq 1, \] (3.17)

\[ [F^{(r)}_{a;i,j}, F^{(s)}_{a:h,k}] + [F^{(s)}_{a;i,j}, F^{(r)}_{a:h,k}] = 0, \quad |a-b| \geq 1, \] (3.18)

for all admissible \( a, b, f, g, h, i, j, k, l, r, s, t \), where the index \( p \) (resp. \( q \)) is summed over \( 1, \ldots, \mu_a \) (resp. \( 1, \ldots, \mu_{a+1} \)). Similarly, the only odd generators are

\[ \{ E^{(r)}_{1;i,j} | 1 \leq i \leq \mu_1, 1 \leq j \leq \mu_2, r > s_{1,2}^\mu \} \cup \{ F^{(r)}_{1;i,j} | 1 \leq i \leq \mu_2, 1 \leq j \leq \mu_1, r > s_{2,1}^\mu \}. \]

Let \( \Gamma \) denote the homomorphism \( Y_\mu(\sigma) \rightarrow Y_\mu \) sending the generators \( D^{(r)}_{a;i,j}, D^{(r)}_{a:i,j} \) and \( F^{(r)}_{a;i,j} \) in \( Y_\mu(\sigma) \) to those in \( Y_\mu \) with the same notations obtained by Gauss decomposition. We now prove that the map \( \Gamma \) is injective and its image is independent of the choice of the admissible shape \( \mu \). In particular, \( Y_\mu(\sigma) \) can be identified with \( Y_{1|n}(\sigma) \) introduced in \( \S \) which is the special case when \( \mu = (1^{n+1}) \) of our current definition.

For \( 1 \leq a < b \leq m + 1, 1 \leq i \leq \mu_a, 1 \leq j \leq \mu_b \) and \( r > s_{a,b}^\mu \), we define the elements \( E^{(r)}_{a;b;i,j} \) recursively by

\[ E^{(r)}_{a+1;i,j} := E^{(r)}_{a;i,j}, \quad E^{(r)}_{a;b;i,j} := -[E^{(r-s_{b,b-1}^\mu)}_{a;b-1;i,k}, E^{(s_{b,b-1}^\mu+1)}_{b-1;k,j}] \], \quad (3.19)\]

where \( 1 \leq k \leq \mu_{b-1} \).

Similarly, for \( 1 \leq a < b \leq m + 1, 1 \leq i \leq \mu_b, 1 \leq j \leq \mu_a \) and \( r > s_{b,a}^\mu \), we define the elements \( F^{(r)}_{b;a;i,j} \) in \( Y_{1|n}(\sigma) \) by

\[ F^{(r)}_{a+1;i,j} := F^{(r)}_{a;i,j}, \quad F^{(r)}_{b;a;i,j} := -[F^{(r-s_{b,b-1}^\mu)}_{b-1;i,k}, F^{(s_{b,b-1}^\mu+1)}_{b-1;k,j}], \] (3.20)

where \( 1 \leq k \leq \mu_{b-1} \). The above definitions are independent of the choice of \( k \); see [BK1, (6.9)] for the detail.
Similar to §2, we introduce the loop filtration on $Y_\mu(\sigma)$

$$L_0 Y_\mu(\sigma) \subseteq L_1 Y_\mu(\sigma) \subseteq L_2 Y_\mu(\sigma) \subseteq \cdots$$

by setting the degree of the generators $D^{(r)}_{a;i,j}$, $E^{(r)}_{a;i,j}$, and $F^{(r)}_{a;i,j}$ to be $(r - 1)$ and $L_k Y_\mu(\sigma)$ to be the span of all supermonomials in the generators of total degree $\leq k$ and denote the associated graded algebra by $\text{gr}^L Y_\mu(\sigma)$.

Define elements $\{e_{i,j;r}\}_{1 \leq i,j \leq n+1,r \geq s_{i,j}}$ in $\text{gr}^L Y_\mu(\sigma)$ by

$$e_{\mu_1+\cdots+\mu_a-1+i,\mu_1+\cdots+\mu_a-1+j;r} = \text{gr}^L D^{(r+1)}_{a;i,j}, \quad (3.21)$$

$$e_{\mu_1+\cdots+\mu_a-1+i,\mu_1+\cdots+\mu_a-1+j;r} = \text{gr}^L E^{(r+1)}_{a,b;i,j}, \quad (3.22)$$

$$e_{\mu_1+\cdots+\mu_b-1+i,\mu_1+\cdots+\mu_b-1+j;r} = \text{gr}^L F^{(r+1)}_{b,a;i,j}. \quad (3.23)$$

One can prove that these elements satisfy relation (2.18) as well. As a result, there exists a surjective superalgebra homomorphism $\gamma : U(\mathfrak{gl}_{1\mid n}[t](\sigma)) \to \text{gr}^L Y_\mu(\sigma)$ such that $\gamma(e_{i,j;r}) = e_{i,j;r}$. By PBW theorem for $\mathfrak{gl}_{1\mid n}[t](\sigma)$, $\gamma$ is also injective and hence an isomorphism.

Let $Y^0_\mu$ denote the subalgebra of $Y_{1\mid n}(\sigma)$ generated by all the $D^{(r)}_{a;i,j}$’s, $Y^\pm_\mu(\sigma)$ denote the subalgebra generated by all the $E^{(r)}_{a;i,j}$’s and $Y^-_\mu(\sigma)$ denote the subalgebra generated by all the $F^{(r)}_{a;i,j}$’s. The following corollaries are parallel to Corollary 2.7 and Corollary 2.8.

**Corollary 3.4.** (i) The monomials in the elements $\{D^{(r)}_{a;i,j}\}_{a=1,\ldots,m+1,1 \leq i,j \leq \mu_a, r \geq 0}$ taken in some fixed order form a basis for $Y^0_\mu$.

(ii) The supermonomials in the elements $\{E^{(r)}_{a,b;i,j}\}_{1 \leq a < b \leq m+1,1 \leq i \leq \mu_a, 1 \leq j \leq \mu_b, r \geq s_{a,b}^\mu}$ taken in some fixed order form a basis for $Y^\pm_\mu(\sigma)$.

(iii) The supermonomials in the elements $\{F^{(r)}_{b,a;i,j}\}_{1 \leq a < b \leq m+1,1 \leq \mu_a, 1 \leq j \leq \mu_b, r \geq s_{b,a}^\mu}$ taken in some fixed order form a basis for $Y^-_\mu(\sigma)$.

(iv) The supermonomials in the union of the elements listed in (i)-(iii) taken in some fixed order form a basis for $Y_\mu(\sigma)$.

**Corollary 3.5.** The multiplicative map $Y^-_\mu(\sigma) \otimes Y^0_\mu \otimes Y^+_\mu(\sigma) \to Y_{1\mid n}(\sigma)$ is an isomorphism of vector spaces.

Now we prove that the definition of $Y_\mu(\sigma)$ is independent of the choice of the admissible shape $\mu$. If $\mu_i = 1$ for all $i$, then $Y_\mu(\sigma)$ is defined as in §2. Suppose that $\mu_b > 1$ for some $2 \leq b \leq m+1$. We may further assume that $\mu_b = \alpha + \beta$ for some $\alpha, \beta \geq 1$. Define a finer composition $\nu$ of $(1\mid n)$ by

$$\nu = (\mu_1, \mu_2, \ldots, \mu_{b-1}, \alpha, \beta, \mu_{b+1}, \ldots, \mu_{m+1}).$$

Note that $\nu$ is also an admissible shape for $\sigma$. As a result, the matrix $T(u)$ has a Gauss decomposition with respect to $\nu$ as well; that is,

$$T(u) = ^\mu E(u)^\mu D(u)^\mu F(u) = ^\nu E(u)^\nu D(u)^\nu F(u),$$

where the matrices are block matrices as introduced in the beginning of this section.
We will denote by $\mu D_a$ and $\nu D_a$ to be the $a$-th diagonal matrices in $\mu D(u)$ and $\nu D(u)$ with respect to the compositions $\mu$ and $\nu$, respectively. Similarly, $\mu E_a$ and $\mu F_a$ are defined to be the matrices in the $a$-th upper and lower-diagonal of $\mu E(u)$ and $\mu F(u)$ respectively; $\nu E_a$ and $\nu F_a$ are defined to be the matrices in the $a$-th upper and lower-diagonal of $\nu E(u)$ and $\nu F(u)$ respectively.

**Lemma 3.6.** In the notation above, define an admissible shape $\alpha$. Then, one obtains the maps $\tau$ in terms of parabolic generators. The anti-isomorphism $\iota$ is defined in terms of the RTT generators.

**Proof.** Multiply matrices.

To show the definition of $Y_\mu(\sigma)$ is independent the choice of $\mu$, it suffices to show that $Y_\nu(\sigma) = Y_\mu(\sigma)$. By Lemma 3.6, one has that $Y_\nu(\sigma) \subseteq Y_\mu(\sigma)$. Now the equality follows from the fact that the isomorphism $U(\mathfrak{gl}_n[t]([\sigma])) \cong gr^L Y_\mu(\sigma)$ is independent of $\mu$.

**Proposition 3.7.** The superalgebra $Y_\mu(\sigma)$ is independent of the choices of the admissible shape $\mu$.

Using Lemma 3.6 and induction on the length of the composition, one can describe the maps $\tau$ and $\iota$ in terms of parabolic generators. The anti-isomorphism $\iota$ satisfies

$$
\tau(D_{a,i,j}^{(r)}) = D_{a,i,j}^{(r)}, \quad \tau(E_{a,i,j}^{(r)}) = E_{a,i,j}^{(r)}, \quad \tau(F_{a,i,j}^{(r)}) = F_{a,i,j}^{(r)}.
$$

Also, in terms of the notation of (2.20), suppose that $\mu$ is an admissible shape for $\sigma$ and $\hat{\sigma}$ simultaneously, then the isomorphism $\iota : Y_\mu(\sigma) \to Y_\mu(\tilde{\sigma})$ satisfies

$$
\iota(D_{a,i,j}^{(r)}) = D_{a,i,j}^{(r)}, \quad \iota(E_{a,i,j}^{(r)}) = E_{a,i,j}^{(r)-s_{a,a+1}^\mu+s_{a,a+1}^\nu}, \quad \iota(F_{a,i,j}^{(r)}) = F_{a,i,j}^{(r)-s_{a+1,a+1}^\mu+s_{a+1,a+1}^\nu}.
$$

**4. Baby comultiplications**

In this section, we define some comultiplication-like maps on $Y_\mu(\sigma)$ that are crucial in later sections.

We first consider the special case where $\sigma = 0$, i.e., the usual super Yangian $Y_{1|n}$. It is well-known (cf. [Go]) that $Y_{1|n}$ is a Hopf superalgebra where the comultiplication $\Delta : Y_{1|n} \to Y_{1|n} \otimes Y_{1|n}$ is defined in terms of the RTT generators $\{t_{i,j}^{(r)}\}$ by
the formula
\[ \Delta(t_{i,j}^{(r)}) = \sum_{r=0}^{n+1} \sum_{k=1}^{n+1} t_{i,k}^{(s)} \otimes t_{k,j}^{(r-s)}. \] (4.1)

Moreover, the evaluation homomorphism \( \text{ev} : Y_{1|n} \to U(\mathfrak{gl}_{1|n}) \) defined by
\[ \text{ev}(t_{i,j}^{(r)}) = \delta_{r,0} \delta_{i,j} + \delta_{r,1} (-1)^{i} e_{i,j}, \] (4.2)

where \( e_{i,j} \) is the elementary matrices in \( \mathfrak{gl}_{1|n} \), is surjective.

Define \( \tilde{\Delta}_{R} := (\text{id} \otimes \text{ev}) \circ \Delta \) and \( \tilde{\Delta}_{L} := (\text{ev} \otimes \text{id}) \circ \Delta \), where they are both algebra homomorphisms. Thus we have
\[ \tilde{\Delta}_{R} : Y_{1|n} \to Y_{1|n} \otimes U(\mathfrak{gl}_{1|n}), \quad t_{i,j}^{(r)} \mapsto t_{i,j}^{(r)} \otimes 1 + \sum_{k=1}^{n+1} (-1)^{r-1} t_{i,k}^{(r-1)} \otimes e_{k,j} \] (4.3)
\[ \tilde{\Delta}_{L} : Y_{1|n} \to U(\mathfrak{gl}_{1|n}) \otimes Y_{1|n}, \quad t_{i,j}^{(r)} \mapsto 1 \otimes t_{i,j}^{(r)} + \sum_{k=1}^{n+1} (-1)^{r} e_{i,k} \otimes t_{k,j}^{(r-1)}. \] (4.4)

In general, if \( \sigma \) is not the zero matrix, then \( Y_{\mu}(\sigma) \) does not have a comultiplication. But we may define some nice homomorphisms called the 'baby comultiplications as in [BK2], suggested from the maps \( \tilde{\Delta}_{R} \) and \( \tilde{\Delta}_{L} \) above.

**Definition 4.1.** An admissible composition \( \mu \) of \( (1|n) \) for \( \sigma \) is called **minimal admissible** if the length of \( \mu \) is minimal.

For example, \( \mu = (1,2,1,1) \) is a minimal admissible shape of \( (1|4) \) for the shift matrix
\[
\sigma = \begin{bmatrix}
0 & 0 & 0 & 1 & 1 \\
0 & 0 & 0 & 1 & 2 \\
0 & 0 & 0 & 1 & 2 \\
2 & 2 & 2 & 0 & 1 \\
4 & 4 & 4 & 2 & 0
\end{bmatrix}.
\]

Note that the minimal admissible shape denotes the "sizes" of largest zero square matrices in the diagonal of \( \sigma \), *respecting the parity* (so we use \((1,2)\) rather than \((3)\) in the north-western corner). Throughout this section, we fix a shift matrix \( \sigma \) and a minimal admissible shape \( \mu \) of \((1|n)\) for \( \sigma \).

For convenience, we let \( \beta = \mu_{m+1} \). Since \( \mu \) is a minimal admissible shape for \( \sigma \), we have that \( 1 \leq \beta \leq n \) and either \( s_{n+1-\beta,n+2-\beta} \neq 0 \) or \( s_{n+2-\beta,n+1-\beta} \neq 0 \).

**Theorem 4.2.** Let \( \mu = (\mu_{1}, \mu_{2}, \ldots, \mu_{m+1}) \) be a minimal admissible shape of \((1|n)\) for the shift matrix \( \sigma \). For \( 1 \leq i,j \leq \beta \), let
\[ \tilde{e}_{i,j} := e_{i,j} + \delta_{i,j} (n - 1 - \beta) \in U(\mathfrak{gl}_{\beta}). \]

(1) Suppose that \( s_{n+1-\beta,n+2-\beta} \neq 0 \). Define \( \hat{\sigma} = (\hat{s}_{i,j})_{1 \leq i,j \leq n+1} \) by
\[ \hat{s}_{i,j} = \begin{cases} s_{i,j} - 1 & \text{if } i \leq n + 1 - \beta < j, \\ s_{i,j} & \text{otherwise.} \end{cases} \] (4.5)
Then the map $\Delta_R : Y_{1|n}(\sigma) \to Y_{1|n}(\hat{\sigma}) \otimes U(\mathfrak{gl}_\beta)$ defined by

\[ D_{a;i,j}^{(r)} \mapsto \hat{D}_{a;i,j}^{(r)} \otimes 1 - \delta_{a,m+1} \sum_{k=1}^{\beta} \hat{D}_{a;i,k}^{(r-1)} \otimes \hat{e}_{k,j}, \]

\[ E_{a;i,j}^{(r)} \mapsto \hat{E}_{a;i,j}^{(r)} \otimes 1 - \delta_{a,m} \sum_{k=1}^{\beta} \hat{E}_{a;i,k}^{(r-1)} \otimes \hat{e}_{k,j}, \]

\[ F_{a;i,j}^{(r)} \mapsto \hat{F}_{a;i,j}^{(r)} \otimes 1, \]

is a superalgebra homomorphism.

(2) Suppose that $s_{n+2-\beta,n+1-\beta} \neq 0$. Define $\hat{\sigma} = (\hat{s}_{i,j})_{1 \leq i,j \leq n+1}$ by

\[ \hat{s}_{i,j} = \begin{cases} 
 s_{i,j} - 1 & \text{if } j \leq n + 1 - \beta < i, \\
 s_{i,j} & \text{otherwise.} 
 \end{cases} \quad (4.6) \]

Then the map $\Delta_L : Y_{1|n}(\sigma) \to U(\mathfrak{gl}_\beta) \otimes Y_{1|n}(\hat{\sigma})$ defined by

\[ D_{a;i,j}^{(r)} \mapsto 1 \otimes \hat{D}_{a;i,j}^{(r)} - \delta_{a,m+1} \sum_{k=1}^{\beta} \hat{e}_{i,k} \otimes \hat{D}_{a;k,j}^{(r-1)}, \]

\[ E_{a;i,j}^{(r)} \mapsto 1 \otimes \hat{E}_{a;i,j}^{(r)}, \]

\[ F_{a;i,j}^{(r)} \mapsto 1 \otimes \hat{F}_{a;i,j}^{(r)} - \delta_{a,m} \sum_{k=1}^{\beta} \hat{e}_{i,k} \otimes \hat{F}_{a;k,j}^{(r-1)} \]

is a superalgebra homomorphism.

Proof. Check that $\Delta_R$ and $\Delta_L$ preserve the defining relations in Definition 3.3. Similar to [BK2, Theorem 4.2], to check (3.17) and (3.18), one needs to use (3.13), (3.14), (3.15) and (3.16) multiple times. \qed

Remark 4.3. In the above theorem and following lemma, the elements $\hat{D}_{a;i,j}^{(r)}$, $\hat{E}_{a;i,j}^{(r)}$, and $\hat{F}_{a;i,j}^{(r)}$ are in $Y_{1|n}(\hat{\sigma})$ where $\hat{\sigma}$ is defined by either (4.5) or (4.6).

The next lemma shows how to compute the baby comultiplications on the general parabolic elements $E_{a,b;i,j}^{(r)}$ and $F_{b,a;i,j}^{(r)}$ under the same minimal admissible shape.

Lemma 4.4. (i) Under the same assumption of Theorem 4.2(1), for all admissible $i, j, r$ and $1 \leq a < b - 1 < m + 1$, we have

\[ \Delta_R(F_{b,a;i,j}^{(r)}) = \hat{F}_{b,a;i,j}^{(r)} \otimes 1, \]

\[ \Delta_R(E_{a,b;i,j}^{(r)}) = \hat{E}_{a,b;i,j}^{(r)} \otimes 1, \quad \text{if } b \leq m + 1, \]

and

\[ \Delta_R(E_{a,m+1;i,j}^{(r)}) = - \left[ \hat{E}_{a,m;i,j}^{(r-s_{m,m+1})}, \hat{E}_{m,h;i,j}^{(s_{m,m+1})} \right] \otimes 1 \right) - \sum_{k=1}^{\beta} \hat{E}_{a,m+1;i,k}^{(r-1)} \otimes \hat{e}_{k,j}, \]

for any $1 \leq h \leq \mu_m$. 

(ii) Under the same assumption of Theorem 4.2(2), for all admissible $i, j, r$ and $1 \leq a < b - 1 < m + 1$, we have

$$
\Delta_L(E_{a,b;i,j}^{(r)}) = 1 \otimes \hat{E}_{a,b;i,j}^{(r)},
$$

$$
\Delta_L(F_{b,a;i,j}^{(r)}) = 1 \otimes \hat{F}_{b,a;i,j}^{(r)}, \quad \text{if } b < m + 1,
$$

and

$$
\Delta_L(F_{m+1,a;i,j}^{(r)}) = -\left(1 \otimes \left[\hat{F}_{m+1;i,h}^{(s_{m+1,m}^1)}; \hat{F}_{m+1;a,h,j}^{(r-s_{m+1,m}^1)}\right]\right) - \sum_{k=1}^{\beta} \tilde{e}_{k,j} \otimes \hat{F}_{m+1,a;k,j}^{(r-1)},
$$

for any $1 \leq h \leq \mu_m$.

\textbf{Proof.} We compute $\Delta_R(E_{a,m+1;i,j}^{(r)})$ for $1 \leq a \leq m$ in detail here, while others are similar. By definition,

$$
E_{a,m+1;i,j}^{(r)} = -[E_{a,m;i,h}^{(r-s_{m,m+1}^1)}; E_{m,h;j}^{(s_{m,m+1}^1)}],
$$

for any $1 \leq h \leq \mu_m$. Also, $\Delta_R(E_{a,m;i,h}^{(r-s_{m,m+1}^1)}) = \hat{E}_{a,m;i,h}^{(r-s_{m,m+1}^1)} \otimes 1$. Hence

$$
\Delta_R(E_{a,m+1;i,j}^{(r)}) = -\left[\hat{E}_{a,m;i,h}^{(r-s_{m,m+1}^1)} \otimes 1; \hat{E}_{m,h;j}^{(s_{m,m+1}^1)} \otimes 1\right]
$$

$$
+ \left[\hat{E}_{a,m;i,h}^{(r-s_{m,m+1}^1)} \otimes 1, \sum_{k=1}^{\beta} \hat{E}_{m,h;k}^{(s_{m,m+1}^1)} \otimes \tilde{e}_{k,j}\right]
$$

$$
= -\left[\hat{E}_{a,m;i,h}^{(r-s_{m,m+1}^1)}; \hat{E}_{m,h;j}^{(s_{m,m+1}^1)}\right] \otimes 1 - \sum_{k=1}^{\beta} \hat{E}_{a,m+1;i,k}^{(r-1)} \otimes \tilde{e}_{k,j},
$$

as claimed. $\square$

\textbf{Proposition 4.5.} The maps $\Delta_R$ and $\Delta_L$ are injective, whenever they are defined.

\textbf{Proof.} Let $\beta$ be defined as in Theorem 4.2 and let $\epsilon : U(\mathfrak{gl}_\beta) \to \mathbb{C}$ be the homomorphism such that $\epsilon(e_{i,j}) = 0$ for $1 \leq i, j \leq \beta$. By definition, $Y_{1|n}(\sigma)$ and $Y_{1|n}(\bar{\sigma})$ are subalgebras of $Y_{1|n}$ with $Y_{1|n}(\sigma) \subseteq Y_{1|n}(\bar{\sigma})$. One may check that the compositions $m \circ (\text{id} \otimes \epsilon) \circ \Delta_R$ and $m \circ (\epsilon \otimes \text{id}) \circ \Delta_L$ coincide with the natural embedding $Y_{1|n}(\sigma) \hookrightarrow Y_{1|n}(\bar{\sigma})$, where $m(a \otimes b) := ab$ (the usual multiplication). $\square$

5. Canonical filtration

Recall that the canonical filtration of $Y_{1|n}$

$$
F_0Y_{1|n} \subseteq F_1Y_{1|n} \subseteq F_2Y_{1|n} \subseteq \cdots
$$

defined by $\deg t_{ij}^{(r)} := r$, i.e., $F_dY_{1|n}$ is the span of all supermonomials in the generators $t_{ij}^{(r)}$ of total degree $\leq d$. It is clear from (2.1) that the associated graded superalgebra $\text{gr} Y_{1|n}$ is supercommutative.
Now we describe the canonical filtration by parabolic presentation. Let \( \mu = (\mu_1, \ldots, \mu_{m+1}) \) be a composition of \((1|n)\). By [P1, Proposition 3.1], the parabolic generators \( D_{a;i,j}^{(r)} \), \( E_{a;i,j}^{(r)} \), and \( F_{b;\alpha;i,j}^{(r)} \) of \( Y_\mu = Y_{1|n} \) are linear combinations of supermonomials in the \( t_{ij}^{(r)} \) of total degree \( r \).

On the other hand, if we set \( D_{a;i,j}^{(r)} \), \( E_{a;i,j}^{(r)} \), and \( F_{b;\alpha;i,j}^{(r)} \) all to be of degree \( r \), by multiplying out the matrix equation \( T(u) = F(u)D(u)E(u) \), each \( t_{ij}^{(r)} \) is a linear combination of supermonomials in the parabolic generators of total degree \( r \). Hence we may describe \( F_d Y_{1|n} \) as the span of all supermonomials in the parabolic generators \( D_{a;i,j}^{(r)} \), \( E_{a;i,j}^{(r)} \), and \( F_{b;\alpha;i,j}^{(r)} \) of total degree \( \leq d \).

For \( 1 \leq a, b \leq n+1, 1 \leq i \leq \mu_a, 1 \leq j \leq \mu_b \) and \( r > 0 \), define the following elements in \( \text{gr} Y_{1|n} \) by

\[
e_{a,b;i,j}^{(r)} := \begin{cases} 
\text{gr} D_{a;i,j}^{(r)} & \text{if } a = b, \\
\text{gr} E_{a;i,j}^{(r)} & \text{if } a < b, \\
\text{gr} F_{a,b;i,j}^{(r)} & \text{if } a > b.
\end{cases}
\]

(5.1)

Note that the notation depends on the shape \( \mu \) implicitly. Since \( \text{gr} Y_{1|n} \) is supercommutative, together with Corollary 3.4 \((iv)\) in the case \( \sigma = 0 \), we have the following:

**Proposition 5.1.** For any shape \( \mu = (\mu_1, \ldots, \mu_{m+1}) \), \( \text{gr} Y_{1|n} \) is the free commutative superalgebra on generators \( \{e_{a,b;i,j}^{(r)}\}_{1 \leq a,b \leq m+1, 1 \leq i \leq \mu_a, 1 \leq j \leq \mu_b, r > 0} \).

Next we show that the shifted Yangian adapts the canonical filtration as well. Let \( \mu = (\mu_1, \ldots, \mu_{m+1}) \) be a given admissible shape for a fixed shift matrix \( \sigma \). Here we use the notations \( Y_\mu \) for \( Y_{1|n} \) and \( Y_\mu(\sigma) \) for \( Y_{1|n}(\sigma) \) to emphasize the shape \( \mu \).

Since \( Y_\mu(\sigma) \) is a subalgebra of \( Y_\mu \) we may induce the canonical filtration of \( Y_\mu \) to \( Y_\mu(\sigma) \) by defining \( F_d Y_\mu(\sigma) := F_d Y_\mu \cap Y_\mu(\sigma) \). Therefore, the inclusion map \( Y_\mu(\sigma) \hookrightarrow Y_\mu \) is a filtered map and the induced map \( \text{gr} Y_\mu(\sigma) \to \text{gr} Y_\mu \) is injective as well. Hence we may identify \( \text{gr} Y_\mu(\sigma) \) with a subalgebra of the supercommutative superalgebra \( \text{gr} Y_\mu \). The next theorem describes this subalgebra explicitly.

**Theorem 5.2.** For an admissible shape \( \mu = (\mu_1, \ldots, \mu_{m+1}) \), \( \text{gr} Y_\mu(\sigma) \) is the subalgebra of \( \text{gr} Y_\mu \) generated by the elements \( \{e_{a,b;i,j}^{(r)}\}_{1 \leq a,b \leq m+1, 1 \leq i \leq \mu_a, 1 \leq j \leq \mu_b, r > 0} \).

**Proof.** By relations (3.13) and (3.14), the element \( e_{a,b;i,j}^{(r)} \) of \( \text{gr} Y_\mu(\sigma) \) is identified with the element of the same notation in \( \text{gr} Y_\mu \). The theorem follows from Corollary 3.4 \((iv)\) and Proposition 5.1. \( \square \)

**Remark 5.3.** One consequence of Theorem 5.2 is that we may define the canonical filtration on \( Y_\mu(\sigma) \) intrinsically by setting the elements \( D_{a;i,j}^{(r)}, E_{a;i,j}^{(r)}, \) and \( F_{a,b;i,j}^{(r)} \) of \( Y_\mu(\sigma) \) all to be degree \( r \). This definition is independent of the choice of admissible shape \( \mu \) by Proposition 3.7.

**Remark 5.4.** By definition, the comultiplication \( \Delta : Y_{1|n} \to Y_{1|n} \otimes Y_{1|n} \) is a filtered map with respect to the canonical filtration. If we extend the canonical filtration
of $Y_{1|n}(\sigma)$ to $Y_{1|n}(\hat{\sigma}) \otimes U(\mathfrak{gl}_\beta)$ by declaring the degree of the matrix unit $e_{ij} \in \mathfrak{gl}_\beta$ to be 1, then the baby comultiplications $\Delta_R$ and $\Delta_L$ in Theorem 4.2 are filtered maps as well, provided that they are defined. Moreover, following the argument in Proposition 4.5, we have that the associated graded maps $\text{gr} \Delta_L$ and $\text{gr} \Delta_R$ are injective.

6. Truncation

Fix a shift matrix $\sigma = (s_{i,j})_{1 \leq i,j \leq n+1}$. Choose an integer $\ell \geq s_{1,n+1} + s_{n+1,1}$, which will be called the “level” later. For each $1 \leq i \leq n+1$, set
$$p_i := \ell - s_{i,n+1} - s_{n+1,i}. \tag{6.1}$$

This defines a tuple $(p_1, \ldots, p_{n+1})$ of integers such that $0 \leq p_1 \leq \cdots \leq p_{n+1} = \ell$.

Let $\mu = (\mu_1, \ldots, \mu_{m+1})$ be an admissible shape for $\sigma$. For each $1 \leq a \leq m+1$, set
$$p^\mu_a := p_{\mu_1 + \cdots + \mu_a}. \tag{6.2}$$

It is clear form the definition that for each $1 \leq a \leq m+1$, we have $p_i = p^\mu_a$ for all $\mu_1 + \cdots + \mu_{a-1} + 1 \leq i \leq \mu_1 + \cdots + \mu_a$.

**Definition 6.1.** The *truncated shifted super Yangian of level* $\ell$, denoted by $Y^\ell_{1|n}(\sigma)$, is the quotient of $Y_{1|n}(\sigma)$ by the two-side ideal generated by the elements $(D^{(r)}_1)_{r > p_1}$.

When $\sigma = 0$, since $t^{(r)}_{11} = D^{(r)}_1$ for all $r$ and $p_1 = \ell$, the above definition is exactly the super analogy of Yangian of level $\ell$ due to Cherednik or the truncated Yangian as in [BK1].

It should be clear from the context that we are dealing with $Y_{1|n}(\sigma)$ or $Y^\ell_{1|n}(\sigma)$ and hence we will use the same symbols $D^{(r)}_{a,i,j}$, $E^{(r)}_{a,b;i,j}$ and $F^{(r)}_{a,b;i,j}$ to denote the generators of $Y_{1|n}(\sigma)$ and their images in the quotient $Y^\ell_{1|n}(\sigma)$, by abusing notations.

It is clear that the anti-isomorphism $\tau$ defined in (2.19) factors through the quotient and induces an anti-isomorphism
$$\tau: Y^\ell_{1|n}(\sigma) \to Y^\ell_{1|n}(\sigma'). \tag{6.3}$$

Similarly, let $\hat{\sigma}$ be another shift matrix satisfying that $\hat{s}_{i,i+1} = s_{i,i+1} + s_{i+1,i}$ for all $1 \leq i \leq n+1$. Then the isomorphism $\iota$ defined by (2.20) also induces an isomorphism
$$\iota: Y^\ell_{1|n}(\sigma) \to Y^\ell_{1|n}(\hat{\sigma}). \tag{6.4}$$

Consider the canonical filtration defined in §5. We obtain a filtration
$$F_0 Y^\ell_{1|n}(\sigma) \subseteq F_1 Y^\ell_{1|n}(\sigma) \subseteq \cdots$$

induced from the quotient map $Y_{1|n}(\sigma) \to Y^\ell_{1|n}(\sigma)$. By Remark 5.3, we may define directly that for a given admissible shape $\mu$ for $\sigma$, the elements $D^{(r)}_{a,i,j}$, $E^{(r)}_{a,b;i,j}$ and $F^{(r)}_{a,b;i,j}$ of $Y^\ell_{1|n}(\sigma)$ are all of degree $r$ and then $F_d Y^\ell_{1|n}(\sigma)$ is the span of all supermonomials in these elements of total degree $\leq d$. 
For $1 \leq a, b \leq m + 1$, $1 \leq i \leq \mu_a$, $1 \leq j \leq \mu_b$ and $r > s^{\mu}_{a,b}$, define element $e_{a,b,i,j}^{(r)}$ in the associative graded superalgebra $gr Y^\ell_{1|n} (\sigma)$ by formula (5.1). Since $gr Y^\ell_{1|n} (\sigma)$ is a quotient of $gr Y_{1|n} (\sigma)$, by Theorem 5.2, it is also supercommutative and is generated by the elements $\{e_{a,b,i,j}^{(r)}\}_{1 \leq a \leq m+1, 1 \leq i \leq \mu_a, 1 \leq j \leq \mu_b, r > s^{\mu}_{a,b} \}$. In fact, we don’t need all of them to generate $gr Y^\ell_{1|n} (\sigma)$, as suggested by the following lemma.

**Lemma 6.2.** For any admissible shape $\mu = (\mu_1, \ldots, \mu_{m+1})$, $gr Y^\ell_{1|n} (\sigma)$ is generated only by the elements $\{e_{a,b,i,j}^{(r)}\}_{1 \leq a, b \leq m+1, 1 \leq i \leq \mu_a, 1 \leq j \leq \mu_b, s^{\mu}_{a,b} < r \leq s^{\mu}_{a,b} + \nu_{min(a,b)}^{\mu} \}$.

**Proof.** It can be proved by using the same argument as in [BK2, Lemma 6.1], except that we start the induction in the case where $\mu = (1, n)$ and our notations are slightly different. \hfill \Box

Suppose that the shift matrix $\sigma$ is nonzero and the level $\ell > 0$. Let $\beta$ be the size of the maximal zero square matrix in the east-southern corner of $\sigma$. Hence we have $1 \leq \beta \leq n$ and either $s_{n+1-\beta, n+2-\beta} \neq 0$ or $s_{n+2-\beta, n+1-\beta} \neq 0$.

If $s_{n+1-\beta, n+2-\beta} \neq 0$, then one may easily check that the baby comultiplication $\Delta_R$ defined in Theorem 4.2 factors through the quotients to induce a map

$$\Delta_R : Y^\ell_{1|n} (\sigma) \rightarrow Y^{\ell-1}_{1|n} (\hat{\sigma} \otimes U(\mathfrak{gl}_\beta)),$$

(6.5)

where $\hat{\sigma}$ is defined by (4.5). Similarly, if $s_{n+2-\beta, n+1-\beta} \neq 0$, then the baby comultiplication $\Delta_L$ defined in Theorem 4.2 induces a map

$$\Delta_L : Y^\ell_{1|n} (\sigma) \rightarrow U(\mathfrak{gl}_\beta) \otimes Y^{\ell-1}_{1|n} (\hat{\sigma}),$$

(6.6)

where $\hat{\sigma}$ is defined by (4.6). By Remark 5.4, $\Delta_R$ and $\Delta_L$ are filtered maps so they induce the following homomorphisms of graded superalgebras

$$gr \Delta_R : gr Y^\ell_{1|n} (\sigma) \rightarrow gr (Y^{\ell-1}_{1|n} (\hat{\sigma} \otimes U(\mathfrak{gl}_\beta))),$$

(6.7)

$$gr \Delta_L : gr Y^\ell_{1|n} (\sigma) \rightarrow gr (U(\mathfrak{gl}_\beta) \otimes Y^{\ell-1}_{1|n} (\hat{\sigma})).$$

(6.8)

**Theorem 6.3.** For any admissible shape $\mu = (\mu_1, \ldots, \mu_{m+1})$, $gr Y^\ell_{1|n} (\sigma)$ is the free supercommutative superalgebra on generators

$$\{e_{a,b,i,j}^{(r)}\}_{1 \leq a, b \leq m+1, 1 \leq i \leq \mu_a, 1 \leq j \leq \mu_b, s^{\mu}_{a,b} < r \leq s^{\mu}_{a,b} + \nu_{min(a,b)}^{\mu} \}.$$

Also, the maps $gr \Delta_R$ and $gr \Delta_L$ in (6.7) and (6.8) are injective whenever they are defined, and so are the maps $\Delta_R$ and $\Delta_L$ in (6.5) and (6.6).

**Proof.** We prove by induction on $\ell$, where the case $\ell = 0$ is trivial. Assume $\ell > 0$ and the first statement holds for any smaller $\ell$. It suffices to prove the induction step in the special case where $\mu = (\mu_1, \ldots, \mu_{m+1})$ is the minimal admissible shape for $\sigma$. Thus, at least one of $\Delta_R$ or $\Delta_L$ is defined. We assume without loss of generality that $\Delta_R$ is defined, where the other case can be derived from this by applying the anti-isomorphism $\tau$ defined in (2.19).
Define the following elements in $\text{gr} \left( Y_{1\ln}^\ell(\hat{\sigma}) \otimes U(\mathfrak{gl}_\beta) \right)$:

$$
\hat{e}_{a,b,i,j}^{(r)} := \begin{cases} 
\text{gr}_r \hat{D}_{a,i,j}^{(r)} \otimes 1 & \text{if } a = b, \\
\text{gr}_r \hat{E}_{a,b,i,j}^{(r)} \otimes 1 & \text{if } a < b, \\
\text{gr}_r \hat{F}_{a,b,i,j}^{(r)} \otimes 1 & \text{if } a > b,
\end{cases}
$$

and $x_{i,j} := \text{gr}_1 1 \otimes e_{ij}$ for all $1 \leq i, j \leq \beta$.

By Theorem 4.2 (1), Lemma 4.4 (i) and Lemma 6.2, there exists some polynomials $f_{a;i,j}^{(r)}$ all in the variables $\hat{e}_{a,b,i,j}^{(s)}$ such that

$$
\text{gr} \Delta_R(\hat{e}_{a,b,i,j}^{(r)}) = \hat{e}_{a,b,i,j}^{(r)},
$$

for all $1 \leq a \leq m + 1, 1 \leq b \leq m, 1 \leq i \leq \mu_a, 1 \leq j \leq \mu_b, s_{a,b}^\mu < r \leq s_{a,b}^\mu + p_{\min(a,b)}^\mu$, and

$$
\text{gr} \Delta_R(\hat{e}_{a,m+1;i,j}^{(r)}) = \sum_{k=1}^\beta \hat{e}_{a,m+1;i,k}^{(r-1)} x_{k,j} + f_{a;i,j}^{(r)},
$$

for all $1 \leq a \leq m + 1, 1 \leq i \leq \mu_a, 1 \leq j \leq \mu_{m+1}, s_{a,m+1}^\mu < r \leq s_{a,m+1}^\mu + p_{\mu}^\mu$, where $\hat{e}_{a,m+1;i,j}^{(0)} := \delta_{ij}$.

By the induction hypothesis and the PBW theorem for $U(\mathfrak{gl}_\beta)$, the elements

$$
\{x_{i,j} \}^{1 \leq i,j \leq \beta},
\{\hat{e}_{a,b,i,j}^{(r)} \}^{1 \leq a \leq m+1, 1 \leq b \leq m, 1 \leq i \leq \mu_a, 1 \leq j \leq \mu_b, s_{a,b}^\mu < r \leq s_{a,b}^\mu + p_{\min(a,b)}^\mu},
\{\hat{e}_{a,m+1;i,j}^{(r)} \}^{1 \leq a \leq m+1, 1 \leq i \leq \mu_a, 1 \leq j \leq \mu_{m+1}, s_{a,m+1}^\mu + p_{a}^\mu - 1 < r \leq s_{a,m+1}^\mu + p_{a}^\mu - 1}
$$

are algebraically independent in $\text{gr} \left( Y_{1\ln}^\ell(\sigma) \otimes U(\mathfrak{gl}_\beta) \right)$. By this and (6.9) – (6.10), we directly check that the images of the generators of $\text{gr} Y_{1\ln}^\ell(\sigma)$ from Lemma 6.2 under the map $\text{gr} \Delta_R$ are algebraically independent in $\text{gr} Y_{1\ln}^\ell(\hat{\sigma}) \otimes U(\mathfrak{gl}_\beta)$, hence $\text{gr} \Delta_R$ is injective and these generators must be algebraically independent in $\text{gr} Y_{1\ln}^\ell(\sigma)$. This completes the proof of the induction step.

As a corollary, we obtain a PBW theorem for $Y_{1\ln}^\ell(\sigma)$ in terms of parabolic generators.

**Corollary 6.4.** For any admissible shape $\mu = (\mu_1, \ldots, \mu_{m+1})$, the supermonomials in the elements

$$
\{D_{a;i,j}^{(r)} \}^{1 \leq a \leq m + 1, 1 \leq i, j \leq \mu_a, 0 < r \leq p_{a}^\mu},
\{E_{a,b;i,j}^{(r)} \}^{1 \leq a < b \leq m + 1, 1 \leq i \leq \mu_a, 1 \leq j \leq \mu_b, s_{a,b}^\mu < r \leq s_{a,b}^\mu + p_{a}^\mu},
\{F_{b,a;i,j}^{(r)} \}^{1 \leq a < b \leq m + 1, 1 \leq i \leq \mu_b, 1 \leq j \leq \mu_a, s_{b,a}^\mu < r \leq s_{b,a}^\mu + p_{a}^\mu},
$$

taken in any fixed order form a basis for $Y_{1\ln}^\ell(\sigma)$. 

□
7. Finite $W$-superalgebras and pyramids

Throughout this section, $\mathfrak{g} = \mathfrak{gl}_{M|N}$ and $(\cdot, \cdot)$ denotes the non-degenerate even supersymmetric invariant bilinear form on $\mathfrak{g}$ defined by $(x, y) := \text{str}(xy)$ for all $x, y \in \mathfrak{g}$, where $\text{str}$ means the super trace form and $xy$ stands for the usual composition. Every element of $\mathfrak{g}$ in our description is considered $\mathbb{Z}_2$-homogeneous unless mentioned specifically.

In §7.1, we recall the definition of finite $W$-superalgebras, which is determined by an nilpotent $e$ and a semisimple $h$ of $\mathfrak{gl}_{M|N}$. In §7.2, we use the combinatorial object called pyramid to encode the $e$ and $h$ by a diagram $\pi$. Finally, in §7.3, when $\pi$ satisfies certain restriction, we explain how to associate such a $\pi$ to $Y^\ell_{1|n}(\sigma)$, a shifted Yangian of level $\ell$.

7.1. Finite $W$-superalgebras of $\mathfrak{gl}_{M|N}$. Let $e$ be an even nilpotent element in $\mathfrak{g}$. It can be shown (cf. [Ho], [Wa]) that there exists (not uniquely) a semisimple element $h \in \mathfrak{g}$ such that $\text{ad} h : \mathfrak{g} \to \mathfrak{g}$ gives a good $\mathbb{Z}$-grading of $\mathfrak{g}$ for $e$, which means the following:

1. $\text{ad} h(e) = 2e$,
2. $\mathfrak{g} = \bigoplus_{j \in \mathbb{Z}} \mathfrak{g}(j)$, where $\mathfrak{g}(j) := \{ x \in \mathfrak{g} | \text{ad} h(x) = jx \}$,
3. the center of $\mathfrak{g}$ in contained in $\mathfrak{g}(0)$,
4. $\text{ad} e : \mathfrak{g}(j) \to \mathfrak{g}(j+2)$ is injective for all $j \leq -1$,
5. $\text{ad} e : \mathfrak{g}(j) \to \mathfrak{g}(j+2)$ is surjective for all $j \geq -1$.

Example 7.1. Let $e$ be an even nilpotent element. By Jacobson-Morozov Theorem, there exist $h \in \mathfrak{g}$ and $f \in \mathfrak{g}$ such that $\{e, h, f\}$ forms an $\mathfrak{sl}_2$-triple. One may check by $\mathfrak{sl}_2$-theory that $\text{ad} h$ gives a good $\mathbb{Z}$-grading of $\mathfrak{g}$ for $e$, called the Dynkin grading.

Assume that a good $\mathbb{Z}$-grading for $e$ is given. To simplify the definition of $W$-superalgebra, throughout this article, we assume the grading is even; that is, $\mathfrak{g}(i) = 0$ for all $i \notin 2\mathbb{Z}$. Note that, in general, the Dynkin grading in the example above may not be even.

Define the nilpotent subalgebras of $\mathfrak{g}$ as follows:

$$\mathfrak{p} := \bigoplus_{j \geq 0} \mathfrak{g}(j), \quad \mathfrak{m} := \bigoplus_{j < 0} \mathfrak{g}(j).$$

Let $\chi \in \mathfrak{g}^*$ be defined by $\chi(y) := (y, e)$, for all $y \in \mathfrak{g}$. Then the restriction of $\chi$ on $\mathfrak{m}$ gives a one dimensional $U(\mathfrak{m})$-module. Let $I_\chi$ denote the left ideal of $U(\mathfrak{g})$ generated by $\{a - \chi(a) | a \in \mathfrak{m}\}$.

By PBW theorem of $U(\mathfrak{g})$, we have $U(\mathfrak{g}) = U(\mathfrak{p}) \oplus I_\chi$. Let $\text{pr}_\chi : U(\mathfrak{g}) \to U(\mathfrak{p})$ be the natural projection and we can identify $U(\mathfrak{g})/I_\chi \cong U(\mathfrak{p})$. Next we define the $\chi$-twisted action of $\mathfrak{m}$ on $U(\mathfrak{p})$ by $a \cdot y := \text{pr}_\chi([a, y])$ for all $a \in \mathfrak{m}$ and $y \in U(\mathfrak{p})$.

The finite $W$-superalgebra (which we will usually omit the term “finite” from now on) is defined to be the $\mathfrak{m}$-invariant space of $U(\mathfrak{p})$ under the $\chi$-twisted action;
that is,

\[ W_{e,h} := U(p)^m = \{ y \in U(p) | \text{pr}_\chi([a,y]) = 0, \forall a \in m \} = \{ y \in U(p) | (a - \chi(a))y \in I_\chi, \forall a \in m \}. \]

**Example 7.2.** If we take the nilpotent element \( e = 0 \), then \( \chi = 0 \), \( g = g(0) = p \), \( m = 0 \), \( W_{e,h} = U(p) = U(g) \).

At this point, the definition of \( W \)-superalgebra depends on the nilpotent element \( e \) and a semisimple element \( h \) which gives a good \( \mathbb{Z} \)-grading for \( e \).

### 7.2. Pyramids and \( W \)-superalgebras.

Suppose that we are given a tuple of positive integers \( (q_1, \ldots, q_\ell) \). We associate a diagram \( \pi \) consisting of \( q_1 \) boxes stacked in the first (leftmost) column, \( q_2 \) boxes stacked in the second column, \ldots , \( q_\ell \) boxes stacked in the \( \ell \)-th (rightmost) column.

We call a diagram obtained in this way a *pyramid* if each row of the diagram is a connected horizontal strip. For example, the left diagram is a pyramid but the right one is not:

Moreover, we color the boxes of a given pyramid by + and − such that the boxes in the same row have the same color. Such a pyramid will called *colored*. For example,

\[ \pi = \begin{array}{cccc}
+ & + & - & - \\
- & - & - & -
\end{array} \]

Let \( M \) (respectively, \( N \)) be the number of boxes colored with + (respectively, −) in a colored pyramid \( \pi \). We now explain how to obtain an even nilpotent \( e(\pi) \) and a semisimple \( h(\pi) \) in \( \mathfrak{gl}_{M,N} \) which gives a good \( \mathbb{Z} \)-grading for \( e \) from a given colored pyramid \( \pi \).

First we enumerate the “+”-colored boxes by the numbers \( \overline{1}, \ldots, \overline{M} \) down columns from left to right, and enumerate the “−”-colored boxes by the numbers \( 1, \ldots, N \) in the same way. Moreover, we image that each box of \( \pi \) is of size \( 2 \times 2 \) and our pyramid is built on the \( x \)-axis where the center of \( \pi \) is exactly on the origin as shown in the example below.

\[ \pi = \begin{array}{cccc}
\overline{1} & \overline{2} & 2 & 4 \\
1 & 3 & 5 & 6
\end{array} \]

(7.2)
Let $I = \{\overline{1} < \ldots < \overline{M} < 1 < \ldots < N\}$ be an ordered index set and let \(\{e_i | i \in I\}\) be a basis of \(\mathbb{C}^{M|N}\). We identify \(\mathfrak{gl}_{M|N} \cong \text{End}(\mathbb{C}^{M|N})\) with the \((M+N) \times (M+N)\) matrices over \(\mathbb{C}\) by this basis of \(\mathbb{C}^{M|N}\) with respect to the following order

\[e_i < e_j\text{ if }i < j\text{ in }I.\]

Define the element

\[e(\pi) := \sum_{i,j \in I} e_{i,j} \in \mathfrak{gl}_{M|N},\]

summing over all adjacent pairs \([i \, \overline{j}]\) of boxes in \(\pi\). It is clear that such an element \(e(\pi)\) is even nilpotent.

Let \(\text{col}(i)\) denote the \(x\)-coordinate of the box numbered with \(i\) in \(\pi\). Then we define the following diagonal matrix

\[h(\pi) := -\text{diag}(\text{col}(\overline{1}), \ldots, \text{col}(\overline{M}), \text{col}(1), \ldots, \text{col}(N)) \in \mathfrak{gl}_{M|N}.\]  

(7.4)

For example, the elements \(e(\pi)\) and \(h(\pi)\) in \(\mathfrak{gl}_{2|7}\) associated to the \(\pi\) in (7.2) are

\[e(\pi) = e_{\overline{1}2} + e_{24} + e_{46} + e_{13} + e_{35} + e_{57},\]

\[h(\pi) = \text{diag}(1, -1, 3, 1, 1, -1, -1, -3, -3).\]

One may check directly that \(\text{ad } h(\pi)\) gives a good \(\mathbb{Z}\)-grading of \(\mathfrak{g}\) for \(e(\pi)\).

Observe that if we shift the rows of \(\pi\) to obtain another pyramid \(\pi'\), then \(e(\pi) = e(\pi')\) but \(h(\pi) \neq h(\pi')\). The following theorem assures that every good \(\mathbb{Z}\)-gradings for \(e(\pi)\) is obtained by shifting the rows of \(\pi\). In fact, it still holds if we drop the term “even”.

**Theorem 7.3.** [Ho, Theorem 7.2] Let \(\pi\) be a given colored pyramid, \(e = e(\pi)\) and \(h = h(\pi)\) be the elements in \(\mathfrak{gl}_{M|N}\) defined by (7.3) and (7.4), respectively. Then \(\text{ad } h\) defines an even good \(\mathbb{Z}\)-grading for \(e\). Moreover, any even good \(\mathbb{Z}\)-grading for \(e\) is defined by \(\text{ad } h(\pi')\) where \(\pi'\) is some colored pyramid obtained by shifting rows of \(\pi\) horizontally.

Now we characterize those \(e\) which is of the form \(e(\pi)\) for some \(\pi\). Let \(e \in \mathfrak{gl}_{M|N}\) be even nilpotent. Consider

\[e = e_M \oplus e_N \in \text{End } \mathbb{C}^{M|N},\]

(7.5)

where \(e_M\) and \(e_N\) are the restriction of \(e\) to \(\mathbb{C}^{M|0}\) and \(\mathbb{C}^{0|N}\), respectively. Let \(\mu = (\mu_1, \mu_2, \ldots)\) and \(\nu = (\nu_1, \nu_2, \ldots)\) be the partitions representing the Jordan type of \(e_M\) and \(e_N\), respectively. We define a new partition \(\lambda\) by collecting all parts of \(\mu\) and \(\nu\) together and reorder them by the usual decreasing order, except that if \(\mu_i = \nu_j\) for some \(i, j\), then we let \(\mu_i\) appear first.

For example, consider \(\mathfrak{gl}_{6|4}\), \(\mu = (\overline{3, 2, 1})\) and \(\nu = (3, 1)\). Then the resulting \(\lambda\) is given by \(\lambda = (\overline{3, 3, 2, 1, 1})\), where we use \(\overline{t}\) to indicate the numbers form \(\mu\).

In particular, the Young diagram \(\lambda\) in French style is itself a colored pyramid if we color the boxes of a row by “+” when that row corresponds to a part of \(\mu\) and by “−” otherwise (so we do need to distinguish the numbers from \(\mu\) and \(\nu\)).
As a consequence, the good \( \mathbb{Z} \)-gradings of \( \mathfrak{gl}_{M|N} \) for any nilpotent \( e \) are classified by Theorem 7.3. Therefore, for a given colored pyramid \( \pi \), we let \( \mathcal{W}_\pi := \mathcal{W}_{e(\pi), h(\pi)} \) denote the \( W \)-superalgebra associated to \( e(\pi) \) and \( h(\pi) \).

Let \( \mathfrak{g} = \mathfrak{gl}_{M|N} \). Now we label the columns of \( \pi \) from left to right by \( 1, \ldots, \ell \), and for any \( i \in I \) we let \( \text{col}(i) \) denote the column where \( i \) appear. Define the Kazhdan filtration of \( U(\mathfrak{g}) \)

\[
\cdots \subseteq F_d U(\mathfrak{g}) \subseteq F_{d+1} U(\mathfrak{g}) \subseteq \cdots
\]

by declaring

\[
\deg(e_{i,j}) := \text{col}(j) - \text{col}(i) + 1
\]

for each \( i, j \in I \) and \( F_d U(\mathfrak{g}) \) is the span of all supermonomials \( e_{i_1,j_1} \cdots e_{i_s,j_s} \) for \( s \geq 0 \) and \( \sum_{k=1}^s \deg(e_{i_k,j_k}) \leq d \). Let \( \text{gr} U(\mathfrak{g}) \) denote the associated graded superalgebra. The natural projection \( \mathfrak{g} \to \mathfrak{p} \) induces a grading on \( \mathcal{W}_\pi \).

On the other hand, let \( \mathfrak{g}^e \) denote the centralizer of \( e \) in \( \mathfrak{g} \) and let \( S(\mathfrak{g}^e) \) denote the associated supersymmetric superalgebra. We define the Kazhdan filtration on \( S(\mathfrak{g}^e) \) by the same setting (7.6). The following proposition was observed in [Zh], where the mild assumption there is satisfied when the good \( \mathbb{Z} \)-grading for \( e \) is even.

**Proposition 7.4.** [Zh, Remark 3.9] \( \text{gr} \mathcal{W}_\pi \cong S(\mathfrak{g}^e) \) as Kazhdan graded superalgebras.

### 7.3. Pyramids and shifted super Yangians.

From now on and the remainder of this article, we will assume that our colored pyramids satisfy the following property:

\[
\text{The top row of } \pi \text{ is the only row colored by } +. \tag{7.7}
\]

In terms of the notations in (7.5), it means that \( e(\pi) = e = e_M \oplus e_N \), where \( e_M \) is principal nilpotent in \( \mathfrak{gl}_{M|0} \) and the sizes of the Jordan blocks of \( e_N \) are all greater or equal to \( M \).

Let \( \pi \) be a fixed colored pyramid satisfying (7.7). We explain how to associate \( \pi \) with a truncated shifted super Yangian. Firstly, let \( \ell \) be the length of the bottom row of \( \pi \), and we label the columns of \( \pi \) by \( 1, \ldots, \ell \) from left to right. Next we let \( |q_i| \) denote the number of boxes in the \( i \)-th column of \( \pi \) for \( 1 \leq i \leq \ell \) and let \( n+1 \) be the maximal number in \( \{|q_i| | 1 \leq i \leq \ell \} \). Also, we label the rows of \( \pi \) by \( 1, \ldots, n+1 \) from top to bottom.

Define the shift matrix \( \sigma := (s_{i,j})_{1 \leq i,j \leq n+1} \) by setting

\[
s_{i,j} := \text{the number of bricks the } i \text{-th row is indented from the } j \text{-th row}
\]

at the left (respectively, right) edge of

the diagram if \( i \geq j \) (respectively, if \( i \leq j \)).

It is not hard to check that such a definition gives a shift matrix satisfying (2.2). With this shift matrix and the integer \( \ell \), we know precisely the generators and defining relations for \( Y_{1|n}(\sigma) \) and hence \( Y_{1|n}^\ell(\sigma) \) as its quotient.

This process can be reversed as follows. Let \( \sigma = (s_{ij})_{1 \leq i,j \leq n+1} \) be a shift matrix and let the level \( \ell \geq s_{1,n+1} + s_{n+1,1} \) be given. We define the tuple \( (p_1, \ldots, p_{n+1}) \) from \( p_i := \ell - s_{i,n+1} - s_{n+1,i} \) as in (6.1). Now draw a pyramid \( \pi \) with \( p_i \) bricks
on the $i$th row indented $s_{n+1,i}$ columns from the left-hand edge and $s_i,n+1$ columns from the right-hand edge, for each $i = 1, \ldots , n+1$. Finally we color the top row of $\pi$ by $+$ and the remaining boxes by $-$. 

As a summary, given a colored pyramid $\pi$, we obtain $Y^n_1(\sigma)$, a shifted Yangian of level $\ell$ and vice versa. For example, $\ell = 6$, $\sigma = \begin{pmatrix} 0 & 1 & 1 & 2 \\ 0 & 0 & 0 & 1 \\ 1 & 1 & 0 & 1 \\ 2 & 2 & 1 & 0 \end{pmatrix} \quad \iff \quad \pi = \begin{array}{cccc} + & + \\ - & - & - \\ - & - \\ - & - & - & - \end{array}$

The following proposition is a well-known result about $\mathfrak{g}^e$. As remarked in [BBG], the result is similar to the Lie algebra case $\mathfrak{gl}_{M+N}$ because $e$ is even.

**Proposition 7.5.** Let $\pi$ be a colored pyramid with row lengths $\{p_i|1 \leq i \leq n+1\}$, $\sigma = (s_{i,j})_{1 \leq i,j \leq n+1}$ be the associated shift matrix of $\pi$ and let $e$ be the nilpotent element defined by (7.3). For all $1 \leq i,j \leq n+1$ and $r > 0$, define 

$$c^{(r)}_{i,j} := \sum_{\substack{h,k \in I \\
row(h) = i, row(k) = j \\
col(k) - col(h) = r - 1}} e_{h,k} \in \mathfrak{g} = \mathfrak{gl}_{M|N}.$$ 

Then the set of vectors $\{c^{(r)}_{i,j}|1 \leq i,j \leq n+1, s_{i,j} < r \leq s_{i,j} + p_{\min(i,j)}\}$ forms a basis for $\mathfrak{g}^e$.

**Corollary 7.6.** Consider $Y^n_1(\sigma)$ with the canonical filtration and $S(\mathfrak{g}^e)$ with the Kazhdan filtration. Let $F_d Y^n_1(\sigma)$ and $F_d S(\mathfrak{g}^e)$ denote the associated filtered superalgebras, respectively. Then for each $d \geq 0$, we have $\dim F_d Y^n_1(\sigma) = \dim F_d S(\mathfrak{g}^e)$.

**Proof.** Follows from Theorem 6.3, Proposition 7.5 and induction on $d$. \qed

8. **Invariants**

Let $\pi$ be a given colored pyramid satisfying (7.7). We will define some elements in $U(\mathfrak{p})$. It turns out later that they are $\mathfrak{m}$-invariant, i.e., belong to $W_{\pi}$.

Let $(q_1, \ldots , q_\ell)$ denote the super column heights of $\pi$, where each $q_i$ is defined to be the number of boxes colored by “+” subtract the number of boxes colored by “−” in the $i$-th column of $\pi$. We also define the absolute height of $q_i$ by setting $|q_i| :=$ the number of total boxes (regardless the colors) in the $i$-th column. Let $h$ denote the super height of $\pi$, which is defined to be the number $q_j$ such that $|q_j|$ is maximal.

Define $\rho = (\rho_1, \ldots , \rho_\ell)$ by setting that 

$$\rho_r := h - q_r - q_{r+1} - \cdots - q_\ell$$ 

for each $r = 1, \ldots , \ell$.

Recall that the ordered index set $I := \{1 < \ldots < M < 1 < \ldots < N\}$, where $M$ and $N$ denote the number of boxes of $\pi$ colored by “+” and “−”, respectively. For
all $i, j \in I$, define
\[
\tilde{e}_{i,j} := (-1)^{\text{col}(j)-\text{col}(i)}(e_{i,j} + \delta_{i,j}(-1)^{\text{pa}(i)} \rho_{\text{col}(i)}),
\]
where $\text{pa}(i) := 0$ if $i \in \{1, \ldots, M\}$ and $\text{pa}(i) := 1$ otherwise. One may check that
\[
[e_{i,k}, \tilde{e}_{h,k}] = (\tilde{e}_{i,k} - \delta_{i,k}(-1)^{\text{pa}(i)} \rho_{\text{col}(i)}) \delta_{h,j} - (-1)^{(\text{pa}(i)+\text{pa}(j))} \delta_{i,k}(\tilde{e}_{h,j} - \delta_{h,j}(-1)^{\text{pa}(j)} \rho_{\text{col}(j)}).
\]

Let us also spell out the effect of the homomorphism $U(m) \rightarrow \mathbb{C}$ induced by the character $\chi$. For any $i, j \in I$, we have
\[
\chi(\tilde{e}_{i,j}) = \begin{cases} (-1)^{\text{pa}(i)+1} & \text{if } \text{row}(i) = \text{row}(j) \text{ and } \text{col}(i) = \text{col}(j) + 1; \\ 0 & \text{otherwise.} \end{cases}
\]

Now we give the most important definition of this article. For $1 \leq i, j \leq n+1$ and signs $\sigma_i \in \{\pm\}$, we let $T^{(0)}_{i,j;\sigma_1,\ldots,\sigma_{n+1}} := \delta_{i,j} \sigma_i$ and for $r \geq 1$ define
\[
T^{(r)}_{i,j;\sigma_1,\ldots,\sigma_{n+1}} := \sum_{s=1}^{r} \sum_{i_1,\ldots,i_s,j_1,\ldots,j_s} \sigma_{\text{row}(i_1)} \cdots \sigma_{\text{row}(i_{s-1})}(-1)^{\text{pa}(i_1)\cdots+\text{pa}(i_s)} \tilde{e}_{i_1,j_1} \cdots \tilde{e}_{i_s,j_s}
\]
where the second sum is over all $i_1, \ldots, i_s, j_1, \ldots, j_s \in I$ such that
\begin{align*}
&\text{(1) } \deg(e_{i_1,j_1}) + \cdots + \deg(e_{i_s,j_s}) = r \text{ (recall (7.6));} \\
&\text{(2) } \text{col}(i_t) \leq \text{col}(j_t) \text{ for each } t = 1, \ldots, s; \\
&\text{(3) } \text{if } \sigma_{\text{row}(i_t)} = + \text{ then } \text{col}(j_t) < \text{col}(i_{t+1}) \text{ for each } t = 1, \ldots, s-1; \\
&\text{(4) } \text{if } \sigma_{\text{row}(i_t)} = - \text{ then } \text{col}(j_t) \geq \text{col}(i_{t+1}) \text{ for each } t = 1, \ldots, s-1; \\
&\text{(5) } \text{row}(i_1) = i, \text{ row}(j_s) = j; \\
&\text{(6) } \text{row}(j_t) = \text{row}(i_{t+1}) \text{ for each } t = 1, \ldots, s-1. \\
\end{align*}

Note that the assumptions (1) and (2) imply that $T^{(r)}_{i,j;\sigma_1,\ldots,\sigma_{n+1}}$ belongs to $F_rU(p)$.

For $0 \leq x \leq n+1$, let $T^{(r)}_{i,j;x}$ denote $T^{(r)}_{i,j;\sigma_1,\ldots,\sigma_{n+1}}$ in the special case that $\sigma_i = -$ for all $i \leq x$ and $\sigma_j = +$ for all $j > x$. Define the following series for all $1 \leq i, j \leq n+1$:
\[
T_{i,j;x}(u) := \sum_{r \geq 0} T^{(r)}_{i,j;x} u^{-r} \in U(p)[[u^{-1}]].
\]

**Lemma 8.1.** Let $i, j, x, y$ be non-negative integers.

(i) If $x < i \leq y < j \leq n+1$ then
\[
T_{i,j;x}(u) = \sum_{k=x+1}^{y} T_{i,k;x}(u) T_{k,j;y}(u).
\]

(ii) If $x < j \leq y < i \leq n+1$ then
\[
T_{i,j;x}(u) = \sum_{k=x+1}^{y} T_{i,k;y}(u) T_{k,j;x}(u).
\]
(iii) If \( x < y < i \leq n + 1 \) and \( y < j \leq n + 1 \), then
\[
T_{i,j:x}(u) = T_{i,j:y}(u) + \sum_{k,l=x+1}^{y} T_{i,k:y}(u) T_{k,l:x}(u) T_{l,j:y}(u).
\]

(iv) If \( x < i \leq y \leq n + 1 \) and \( x < j \leq y \), then
\[
\sum_{k=x+1}^{y} T_{i,k:x}(u) T_{k,j:y}(u) = -\delta_{i,j}.
\]

Proof. All of the proofs are exactly the same as in [BK2, Lemma 9.2] and hence they are omitted. □

Define \( T(u) := (T_{i,j:0}(u) \otimes (-1)^{(i+j)} E_{i,j})_{1 \leq i,j \leq n+1} \), an invertible \((n+1) \times (n+1)\) matrix with entries in \( U(p)[[u^{-1}]]\). Also let \( \mu = (\mu_1, \mu_2, \ldots, \mu_{m+1}) \) be a fixed shape such that \( \mu_1 = 1 \). Consider the Gauss factorization \( T(u) = F(u) D(u) E(u) \) where \( D(u) \) is a block diagonal matrix, \( E(u) \) is a block upper unitriangular matrix, and \( F(u) \) is a block lower unitriangular matrix, all block matrices being of shape \( \mu \). The diagonal blocks of \( D(u) \) define matrices \( D_1(u), \ldots, D_{m+1}(u) \), the upper diagonal blocks of \( E(u) \) define matrices \( E_1(u), \ldots, E_m(u) \), and the lower diagonal matrices of \( F(u) \) define matrices \( F_1(u), \ldots, F_m(u) \). Also let \( D^\prime_a(u) := D_a(u)^{-1} \).

Thus \( D_a(u) = (D_{a;i,j}(u))_{1 \leq i,j \leq \mu_a} \) and \( D^\prime_a(u) = (D_{a;i,j}^\prime(u))_{1 \leq i,j \leq \mu_a} \) are matrices, \( E_a(u) = (E_{a;i,j}(u))_{1 \leq i \leq \mu_a, 1 \leq j \leq \mu_{a+1}} \) is a \( \mu_a \times \mu_{a+1} \) matrix, and \( F_a(u) = (F_{a;i,j}(u))_{1 \leq i \leq \mu_{a+1}, 1 \leq j \leq \mu_a} \) is a \( \mu_{a+1} \times \mu_a \) matrix. Write
\[
D_{a;i,j}(u) = \sum_{r \geq 0} D_{a;i,j}^{(r)} u^{-r}, \quad D_{a;i,j}^\prime(u) = \sum_{r \geq 0} D_{a;i,j}^{(r)} u^{-r},
\]
\[
E_{a;i,j}(u) = \sum_{r \geq 0} E_{a;i,j}^{(r)} u^{-r}, \quad F_{a;i,j}(u) = \sum_{r \geq 0} F_{a;i,j}^{(r)} u^{-r},
\]
thus defining elements \( D_{a;i,j}^{(r)}, E_{a;i,j}^{(r)} \) and \( F_{a;i,j}^{(r)} \) of \( U(p) \), all depend on the fixed choice of \( \mu \). All this parallels the definition of the elements of \( Y_{1|n} \) with the same names in section 3.

Theorem 8.2. With \( \mu = (\mu_1, \mu_2, \ldots, \mu_{m+1}) \) fixed as above and all admissible \( a, i, j \), we have that
\[
D_{a;i,j}(u) = T_{\mu_1 + \ldots + \mu_{a-1} + i, \mu_1 + \ldots + \mu_{a-1} + j},
\]
\[
D_{a;i,j}^\prime(u) = -T_{\mu_1 + \ldots + \mu_{a-1} + i, \mu_1 + \ldots + \mu_{a-1} + j},
\]
\[
E_{a;i,j}(u) = T_{\mu_1 + \ldots + \mu_{a-1} + i, \mu_1 + \ldots + \mu_{a-1} + j},
\]
\[
F_{a;i,j}(u) = T_{\mu_1 + \ldots + \mu_{a-1} + i, \mu_1 + \ldots + \mu_{a-1} + j},
\]

Proof. Note that it is enough to show the formulae for \( D, E \) and \( F \), since the one for \( D^\prime \) follows from the one for \( D \) and Lemma 8.1(iv). We prove this by induction on the length of \( \mu \). The initial case is when \( \mu = (1, n) \). By Gauss decomposition,
we have
\[ T(u) = \left( \begin{array}{cc} I_1 & 0 \\ F_1 & I_n \end{array} \right) \left( \begin{array}{cc} D_1 & 0 \\ 0 & D_2 \end{array} \right) \left( \begin{array}{cc} I_1 & E_1 \\ 0 & I_n \end{array} \right) = \left( \begin{array}{cc} D_1 & D_1 E_1 \\ F_1 D_1 & D_2 + F_1 D_1 E_1 \end{array} \right). \]
Comparing the corresponding blocks and using Lemma 8.1, we have proved the initial step of induction.

Now assume the statement is true for some \( \nu = (\nu_1, \nu_2, \ldots, \nu_{m+1}) \) with length at least 2. For some \( 2 \leq b \leq m+1 \), write \( \nu_b = \alpha + \beta \) with \( \alpha, \beta \geq 1 \). Following exactly the same argument as in [BK2, Theorem 9.3], one may complete the induction argument.

\[ \square \]

In the extreme case that \( \mu = (1^{n+1}) \), we write simply \( D_i^{(r)}, D_i^{(r)}, E_i^{(r)} \) and \( F_i^{(r)} \) for the elements \( D_{i,i,1}^{(r)}, D_{i,i,1}^{(r)}, E_{i,i,1}^{(r)} \) and \( F_{i,i,1}^{(r)} \) of \( U(p) \), respectively.

**Corollary 8.3.** \( D_i^{(r)} = T_{i,i-1}^{(r)}, E_i^{(r)} = T_{i+1,i}^{(r)}, F_i^{(r)} = T_{i+1,i}^{(r)} \) and \( D_i^{(r)} = -T_{i,i+1}^{(r)} \).

9. **Main theorem**

Let \( \pi \) be a colored pyramid of base \( \ell \) satisfying (7.7) and let \( \sigma = (s_{i,j})_{1 \leq i,j \leq n+1} \) be the shift matrix associated to \( \pi \) as explained in §7. Let \( Y_{1|n}^\ell(\sigma) \) denote the truncated shifted Yangian associated to \( \pi \) equipped with the canonical filtration and let \( W_\pi \) denote the finite \( W \)-superalgebra associated to \( \pi \) equipped with the Kazhdan filtration.

Suppose also that \( \mu = (\mu_1, \mu_2, \ldots, \mu_{m+1}) \) with \( \mu_1 = 1 \) is an admissible shape for \( \sigma \), and recall the notation \( s^\mu_{a,b} \) and \( p^\mu_a \) from (3.4) and (6.2). We have the elements \( D_{a;i,j}^{(r)}, D_{a;i,j}^{(r)}, E_{a;i,j}^{(r)} \) and \( F_{a;i,j}^{(r)} \) of \( U(p) \) defined by Theorem 8.2 relative to this fixed shape. We also have the parabolic generators \( D_{a;i,j}^{(r)}, D_{a;i,j}^{(r)}, E_{a;i,j}^{(r)} \) and \( F_{a;i,j}^{(r)} \) of \( Y_{1|n}^\ell(\sigma) \) as defined in §3. The main result of the article is as follows.

**Theorem 9.1.** Let \( \pi \) be a colored pyramid satisfying (7.7). There is a unique isomorphism \( Y_{1|n}^\ell(\sigma) \cong W_\pi \) of filtered superalgebras such that for any admissible shape \( \mu = (\mu_1, \mu_2, \ldots, \mu_{m+1}) \) with \( \mu_1 = 1 \), the generators

\[
\begin{align*}
\{ D_{a;i,j}^{(r)} \}_{1 \leq a \leq m+1, 1 \leq i,j \leq \mu_a, r > 0}, \\
\{ E_{a;i,j}^{(r)} \}_{1 \leq a < m+1, 1 \leq i \leq \mu_a, 1 \leq j \leq \mu_a+1, r > 0} \cup \{ s^\mu_{a,b} \}, \\
\{ F_{a;i,j}^{(r)} \}_{1 \leq a < m+1, 1 \leq i \leq \mu_a+1, 1 \leq j \leq \mu_a, r > 0} \cup \{ p^\mu_a \}
\end{align*}
\]

of \( Y_{1|n}^\ell(\sigma) \) are mapped to the elements of \( U(p) \) with the same names. In particular, these elements of \( U(p) \) are \( m \)-invariants and they generate \( W_\pi \).

The rest of this article is devoted to prove Theorem 9.1. We shall prove it by induction on the number \( \ell - t \), where \( \ell \) is the length of the bottom row and \( t \) is the length of the top row of \( \pi \).

The initial step \( \ell = t \) was established in [BR]; see also [Pe2] for an approach similar to our setting here. In this case, the pyramid is of rectangular shape so
the associated shift matrix is the zero matrix. Hence the shifted super Yangian is the whole super Yangian $Y_{1|n}$ itself, and its quotient is exactly the truncated super Yangian $Y_{1|n}^t$.

By [Pe2, Theorem 4.3], the map $\gamma$ sending $t_{i,j}^{(r)} \in Y_{1|n}^t$ to $T_{i,j;0}^{(r)} \in \mathcal{W}_\pi$ defined by (8.5) is an isomorphism of filtered superalgebras. By Lemma 8.1 and Theorem 8.2, the images of the parabolic generators

$$\{D_1^{(r)}, D_{2;i,j}^{(r)}, E_{i;1,j}^{(s)}, F_{i;i,1}^{(s)} | 1 \leq i, j \leq n, r \geq 0, s \geq 1\}$$

in $Y_{1|n}^t$ under $\gamma$ are exactly the elements in $\mathcal{W}_\pi$ with the same name, which proves the initial step of the induction argument.

Now we assume that our colored pyramid $\pi$ is not a rectangle so $\ell - t > 0$ and $\ell \geq 2$ ($\ell = 1$ must be a rectangle). The first reduction is that it suffices to prove the case where $\mu$ is a minimal admissible shape for the shift matrix $\sigma$ associated to $\pi$, by induction on the length of the shape and Lemma 3.6. Therefore, we assume from now on that $\mu$ is a minimal admissible shape for $\sigma$ and we denote by $\beta$ the absolute column height of the shortest column of $\pi$. Since $\pi$ is a pyramid, we know that either $\beta = |q_1|$ or $\beta = |q_t|$, and we discuss them case-by-case.

- Case $R$: $|q_1| \geq |q_t| = \beta$.
- Case $L$: $|q_1| = \beta < |q_t|$.

We will explain Case $R$ in detail and sketch the proof of Case $L$, which can be obtained by a very similar argument. Our approach is similar to [BK2]. Recall that we numbered the boxes of $\pi$ using the index set $I := \{\overline{1} \ldots < \overline{M} \mid \overline{1} < \overline{2} < \ldots < \overline{N}\}$ in the standard way: down columns from left to right, where $\overline{1}$ (resp. $\overline{i}$) stands for the boxes colored with $-$ (resp. $+$).

Let $\tilde{\pi}$ be the pyramid obtained by removing the right-most column of $\pi$, i.e. removing the boxes numbered by $N - \beta + 1, N - \beta + 2, \ldots, N$ of $\pi$. Let $\tilde{\sigma} = (\tilde{s}_{i,j})_{1 \leq i, j \leq n+1}$ be the shift matrix defined by (4.5) where its associated pyramid is $\tilde{\pi}$. Define $\tilde{\mathfrak{p}}, \tilde{\mathfrak{m}}$ and $\tilde{e}$ in $\tilde{\mathfrak{g}} = \mathfrak{gl}_{M|N-\beta}$ according to (7.1) and (7.3) and let $\tilde{\chi} : \tilde{\mathfrak{m}} \to \mathbb{C}$ be the character $x \mapsto (x, \tilde{e})$.

Let $\tilde{D}_{a;i,j}^{(r)}, \tilde{D}_{a;i,j}^{(r)}$, $\tilde{E}_{a;i,j}$ and $\tilde{F}_{a;i,j}$ denote the elements of $U(\tilde{\mathfrak{p}})$ as defined in §8 associated to the shape $\mu$. Note that $\mu$ is an admissible shape for both $\sigma$ and $\tilde{\sigma}$.

By the induction hypothesis, Theorem 9.1 holds for $\tilde{\pi}$, so the following elements of $U(\tilde{\mathfrak{p}})$ are invariant under the twisted action of $\tilde{\mathfrak{m}}$, i.e. they belong to finite $\tilde{\mathcal{W}}$-superalgebra $\tilde{\mathcal{W}} = U(\tilde{\mathfrak{p}})^{\tilde{\mathfrak{m}}}$:

$$\{\tilde{D}_{a;i,j}^{(r)}, \tilde{D}_{a;i,j}^{(r)}\}$ for $1 \leq a \leq m + 1, 1 \leq i, j \leq \mu_a$ and $r > 0$;

$$\{\tilde{E}_{a;i,j}\}$$ for $1 \leq a \leq m, 1 \leq i \leq \mu_a, 1 \leq j \leq \mu_{a+1}$ and $r > s_{a,a+1}^\mu - \delta_{a,m};$

$$\{\tilde{F}_{a;i,j}\}$$ for $1 \leq a \leq m, 1 \leq i \leq \mu_{a+1}, 1 \leq j \leq \mu_a$ and $r > s_{a+1,a}^\mu.$

We embed $U(\tilde{\mathfrak{g}})$ into $U(\mathfrak{g})$ such that the generators $\tilde{e}_{ij}$ of $U(\tilde{\mathfrak{g}})$ defined from $\tilde{\pi}$ are mapped to the generators $\tilde{e}_{ij}$ of $U(\mathfrak{g})$ defined from $\pi$, for all $i, j$ in the index set $\tilde{I} := \{\overline{1}, \ldots, \overline{M}, 1, \ldots, N - \beta\}$. It also embeds $U(\tilde{\mathfrak{p}})$ into $U(\mathfrak{p})$ and $\tilde{\mathfrak{m}}$ into $\mathfrak{m}$. 
Moreover, the character $\hat{\chi}$ of $\hat{m}$ is the restriction of the character $\chi$ of $m$ and hence the twisted action of $\hat{m}$ on $U(\hat{p})$ is the restriction of the twist action of $m$ on $U(p)$.

The next crucial lemma gives the relations between the elements $D^{(r)}_{a;i,j}$, $E^{(r)}_{a;i,j}$, $F^{(r)}_{a;i,j}$ of $U(p)$ and the elements $\hat{D}^{(r)}_{a;i,j}$, $\hat{E}^{(r)}_{a;i,j}$, $\hat{F}^{(r)}_{a;i,j}$ of $U(\hat{p})$.

**Lemma 9.2.** The following equations hold for $r > 0$, all admissible $a, i, j$ and any fixed $1 \leq h \leq \beta$:

\[
D^{(r)}_{a;i,j} = \hat{D}^{(r)}_{a;i,j}
\]
\[
E^{(r)}_{a;i,j} = \hat{E}^{(r)}_{a;i,j} + \delta_{a,m+1}\left(-\sum_{k=1}^{\beta} \hat{E}_{a;i,k}^{(r-1)} \bar{e}_{N-\beta+k,N-\beta+j} + [\hat{D}_{a;i,h}^{(r-1)}, \bar{e}_{N-2\beta+h,N-\beta+j}]\right), \tag{9.1}
\]
\[
F^{(r)}_{a;i,j} = \hat{F}^{(r)}_{a;i,j}, \tag{9.2}
\]
where for (9.2) we are assuming that $r > s^{\mu}_{m,m+1}$ if $a = m$.

**Proof.** It follows from Theorem 8.2 and the explicit form of the elements $T^{(r)}_{i;j;x}$ from (8.5). \qed

In the following several lemmas we will use the above inductive descriptions and the induction hypothesis to show that the elements $D^{(r)}_{a;i,j}$, $E^{(r)}_{a;i,j}$ and $F^{(r)}_{a;i,j}$ of $U(p)$ are $m$-invariants for the appropriate $r$.

**Lemma 9.3.** The following elements of $U(p)$ are $m$-invariant:

(i) $D^{(r)}_{a;i,j}$ and $D^{(r)}_{a;i,j}$ for $1 \leq a \leq m$, $1 \leq i, j \leq \mu_a$ and $r > 0$;

(ii) $E^{(r)}_{a;i,j}$ for $1 \leq a \leq m$, $1 \leq i \leq \mu_a$, $1 \leq j \leq \mu_{a+1}$ and $r > s^{\mu}_{a,a+1}$;

(iii) $F^{(r)}_{a;i,j}$ for $1 \leq a \leq m$, $1 \leq i \leq \mu_{a+1}$, $1 \leq j \leq \mu_a$ and $r > s^{\mu}_{a+1,a}$.

**Proof.** By Lemma 9.2 and the definitions of $D^{(r)}_{a;i,j}$ and $\hat{D}^{(r)}_{a;i,j}$, all these elements of $U(p)$ coincide with the corresponding elements of $U(\hat{p})$. By the induction hypothesis, they are $\hat{m}$-invariant. Hence it is enough to show that they are invariant under the twisted action of all $\bar{e}_{f,g} \in m \setminus \hat{m}$, where one should note that $\bar{e}_{f,g} \in m \setminus \hat{m}$ if and only if $g \leq N - \beta < f \leq N$.

By Theorem 8.2 and the explicit form of (8.5), all these elements under our consideration are linear combinations of supermonomials of the form $\bar{e}_{i_1,j_1} \cdots \bar{e}_{i_r,j_r}$ in $U(\hat{p})$ with $i_s \in \hat{I}$ and $\bar{T} \leq j_s \leq N - 2\beta$ for all $s = 1, \ldots, r$.

By the fact that $\chi(e_{f,g}) = 0$ for all $g \leq N - 2\beta$ and $N - \beta < f \leq N$, one may prove that all such supermonomials are invariant under the twisted action of all $\bar{e}_{f,g} \in m \setminus \hat{m}$ and our assertion follows. \qed

**Lemma 9.4.** The following elements of $U(p)$ are $\hat{m}$-invariant under the twisted action:
Proof. (1) Let $x \in \mathfrak{m}$. By Lemma 9.2, we have

$$D^{(r)}_{m+1;i,j} = D^{(r)}_{m+1;i,j} - \sum_{k=1}^{\beta} D^{(r-1)}_{m+1;i,k} e_{N-\beta+k,N-\beta+j} - \left[ D^{(r-1)}_{m+1;i,h} \right].$$

Note that $[x, e_{N-\beta+k,N-\beta+j}] = 0 = [x, e_{N-2\beta+h,N-\beta+j}]$. Using this and the induction hypothesis, one can easily show that $pr_x([x, D^{(r)}_{m+1;i,j}]) = 0$. (2) can be derived in a similar way. \hfill \Box

Lemma 9.5. (1) $D^{(1)}_{m+1;i,j}$ is $\mathfrak{m}\setminus\mathfrak{m}$-invariant for $1 \leq i, j \leq \mu_{m+1}$.

(2) Suppose $s^{\mu}_{m,m+1} = 1$. Then $D^{(2)}_{m+1;i,j}$ is $\mathfrak{m}\setminus\mathfrak{m}$-invariant for $1 \leq i, j \leq \mu_{m+1}$.

(3) Suppose $s^{\mu}_{m,m+1} = 1$. Then $E^{(2)}_{m;i,j}$ is $\mathfrak{m}\setminus\mathfrak{m}$-invariant for $1 \leq i \leq \mu_m$ and $1 \leq j \leq \mu_{m+1}$.

Proof. (1) can be derived from the explicit expression of $D^{(1)}_{m+1;i,j}$ together with (8.3) and (8.4). (2) and (3) can be derived similarly, although the computations are complicated. \hfill \Box

Lemma 9.6. Suppose that $s^{\mu}_{m,m+1} = 1$. Then the following identities hold in $U(\mathfrak{p})$ for $r > 1$:

(1) $E^{(r+1)}_{m;i,j} = (-1)^{\beta} D^{(2)}_{m;i,g} E^{(r)}_{m;i,j} - \sum_{j=1}^{\mu_m} D^{(1)}_{m;i,j} E^{(r)}_{m;j,j}$,

(2) $D^{(r+1)}_{m+1;i,j} = (-1)^{\beta} F^{(2)}_{m;i,g} E^{(r)}_{m;i,j} - \sum_{t=1}^{r+1} D^{(r+1-t)}_{m+1;i,j} D^{(t)}_{m;i,g}$.

Proof. There are two possibilities here: either $m = 1$ and $\mu = (1, \beta)$, or $m > 1$ and $\mu = (1, \mu_2, \ldots, \mu_m, \beta)$. Assume that $m > 1$. We prove (2) in detail, where (1) can be proved using exactly the same method.

By the induction hypothesis and defining relation (3.12), we have

$$[F^{(2)}_{m;i,g}, E^{(r)}_{m;i,j}] = (-1)^{\beta} \sum_{t=0}^{r+1} D^{(r+1-t)}_{m+1;i,j} D^{(t)}_{m;i,g} = -\hat{D}^{(r+1)}_{m+1;i,j} - \sum_{t=1}^{r+1} D^{(r+1-t)}_{m+1;i,j} \hat{D}^{(t)}_{m;i,g}. \tag{9.4}$$

By Lemma 9.2, we have

$$E^{(r)}_{m;i,j} = \hat{E}^{(r)}_{m;i,j} - \sum_{k=1}^{\beta} \hat{E}^{(r-1)}_{m;i,k} e_{N-\beta+k,N-\beta+j} + \hat{E}^{(r-1)}_{m;i,h} e_{N-2\beta+h,N-\beta+j}. \tag{9.5}$$
Now bracket (9.5) with $F^{(2)}_{m,i,g} = F^{(2)}_{m,i,g}$. Note that no supermonomial in the expansion of $F^{(2)}_{m,i,g}$ contains any matrix unit of the forms $\tilde{e}_{N-\beta + h}$, $\tilde{e}_{N-\beta + h}$, or $\tilde{e}_{N-2\beta + h}$.

As a result, $[F^{(2)}_{m,i,g}, \tilde{e}_{N-\beta + k, N-\beta + j}] = [F^{(2)}_{m,i,g}, \tilde{e}_{N-2\beta + h, N-\beta + j}] = 0$.

Using (9.4) and (9.1) twice, we obtain

$$[F^{(2)}_{m,i,g}, D^{(r)}_{m+1;i,j}] = -\hat{D}^{(r+1)}_{m+1;i,j} - \sum_{t=1}^{r+1} \hat{D}^{(r+1-t)}_{m+1;i,j} \hat{D}^{(t)}_{m+1;i,j}$$

Thus $D^{(r+1)}_{m+1;i,j} = -[F^{(2)}_{m,i,g}, D^{(r)}_{m+1;i,j}] = -\sum_{t=1}^{r+1} D^{(r+1-t)}_{m+1;i,j} \hat{D}^{(t)}_{m+1;i,j}$ for $m > 1$.

The case for $m = 1$ is exactly the same, except that $E_1$’s and $F_1$’s are odd elements. □

**Lemma 9.7.** Suppose $s^\mu_{m,m+1} = 1$. Then

1. $D^{(r)}_{m+1;i,j}$ are $m$-invariant for all $r \geq 0$ and $1 \leq i, j \leq \mu_{m+1}$.
2. $E^{(r)}_{m;i,j}$ are $m$-invariant for all $r > 1$ and $1 \leq i \leq \mu_m$, $1 \leq j \leq \mu_{m+1}$.

*Proof.* These elements are known to be $\tilde{m}$-invariant by Lemma 9.4. Hence it suffices to show that they are $m\backslash\tilde{m}$-invariant. By Lemma 9.5, Lemma 9.6 and induction on $r$, the statement follows. □

**Lemma 9.8.** Suppose that $s^\mu_{m,m+1} > 1$. Then the following elements are invariant under the twisted action of $\tilde{e}_{N-\beta + f, N-2\beta + g}$ for all $1 \leq f, g \leq \beta$.

1. $D^{(r)}_{m+1;i,j}$ for all $r \geq 2$ and $1 \leq i, j \leq \mu_{m+1}$.
2. $E^{(r)}_{m;i,j}$ for all $r > s^\mu_{m,m+1}$ and $1 \leq i \leq \mu_m$, $1 \leq j \leq \mu_{m+1}$.
Proof. (1) Let $\tilde{\pi}$ be the pyramid obtained by deleting the rightmost two columns from $\pi$. Define $\tilde{p}$, $\tilde{m}$ and $\tilde{e} \in \mathfrak{gl}_{N-2\beta}$ as before, and embed $U(\hat{\mathfrak{g}})$ into $U(\hat{\mathfrak{g}})$ as we embed $U(\hat{\mathfrak{g}})$ into $U(\mathfrak{g})$. By the induction hypothesis, the elements $\tilde{D}^{(r)}_{m+1;i,j}$ in $W_{\tilde{\pi}}$ are $\tilde{m}$-invariant.

Assuming $r \geq 2$ and applying Lemma 9.1 to $\pi$, we have

$$D^{(r)}_{m+1;i,j} = \tilde{D}^{(r)}_{m+1;i,j} - \sum_{k=1}^{\beta} \tilde{D}^{(r-1)}_{m+1;i,k} \tilde{e}_{N-\beta+k,N-\beta+j} + [\tilde{D}^{(r-1)}_{m+1;i,h}, \tilde{e}_{N-2\beta+h,N-\beta+j}] \quad (9.6)$$

Applying Lemma 9.1 to $\pi$, we obtain

$$\dot{D}^{(r)}_{m+1;i,j} = \dot{\tilde{D}}^{(r)}_{m+1;i,j} - \sum_{k=1}^{\beta} \dot{\tilde{D}}^{(r-1)}_{m+1;i,k} \tilde{e}_{N-2\beta+k,N-2\beta+j} + [\dot{\tilde{D}}^{(r-1)}_{m+1;i,h}, \tilde{e}_{N-3\beta+h,N-2\beta+j}] \quad (9.7)$$

Substituting (9.7) into (9.6) and simplifying by (8.3), one deduces that for all $r \geq 2$, $D^{(r)}_{m+1;i,j} = A - B + C - D + E - F - G + H$, where

$$A = \dot{\tilde{D}}^{(r)}_{m+1;i,j}, \quad B = \sum_{k=1}^{\beta} \dot{\tilde{D}}^{(r-1)}_{m+1;i,k} \tilde{e}_{N-2\beta+k,N-2\beta+j},$$

$$C = [\dot{\tilde{D}}^{(r-1)}_{m+1;i,h}, \tilde{e}_{N-3\beta+h,N-2\beta+j}], \quad D = \sum_{k=1}^{\beta} \dot{\tilde{D}}^{(r-1)}_{m+1;i,k} \tilde{e}_{N-\beta+k,N-\beta+j},$$

$$E = \sum_{k,s=1}^{\beta} \dot{\tilde{D}}^{(r-2)}_{m+1;i,s} \tilde{e}_{N-2\beta+s,N-2\beta+k} \tilde{e}_{N-\beta+k,N-\beta+j}, \quad F = \sum_{k=1}^{\beta} \dot{\tilde{D}}^{(r-2)}_{m+1;i,k} \tilde{e}_{N-2\beta+k,N-\beta+j},$$

$$G = \sum_{k=1}^{\beta} [\dot{\tilde{D}}^{(r-2)}_{m+1;i,h}, \tilde{e}_{N-3\beta+h,N-2\beta+k}] \tilde{e}_{N-\beta+k,N-\beta+j}, \quad H = [\dot{\tilde{D}}^{(r-2)}_{m+1;i,g}, \tilde{e}_{N-3\beta+g,N-\beta+j}].$$

Let $x = \tilde{e}_{N-\beta+f,N-2\beta+g}$ for some $1 \leq f, g \leq \beta$. Note that $x$ commutes with all elements in $U(\tilde{\mathfrak{p}})$. Applying $\text{ad} \ x$ to the above elements and using (8.1), (8.3) and
Proof. The elements Proposition 9.9. The elements
\[ \left\{ F_{\alpha, i, j}^{(r)} \right\}_{1 \leq a < m+1, 1 \leq i \leq j \leq \mu_a, r > 0}, \]
\[ \left\{ F_{\alpha, i, j}^{(r)} \right\}_{1 \leq a < m+1, 1 \leq i \leq j \leq \mu_{a+1}, r > s_{a,b}^{(r)}}, \]
\[ \left\{ F_{\alpha, i, j}^{(r)} \right\}_{1 \leq a < m+1, 1 \leq i \leq j \leq \mu_a, r > s_{a,a}^{(r)}} \]
of \( U(\mathfrak{p}) \) are \( m \)-invariant.

Proof. By the induction hypothesis and Lemma 9.3–9.8.

A consequence of Proposition 9.9 is that the elements in the description of Theorem 9.1 are indeed elements of \( \mathcal{W}_\pi \). By the induction hypothesis, we may identify \( Y_{1|n}^{t-1}(\dot{\sigma}) \) with \( \mathcal{W}_\pi \subseteq U(\mathfrak{p}) \) and hence the generators \( \tilde{D}_{a,i,j}^{(r)}, \tilde{E}_{a,i,j}^{(r)} \) and \( \tilde{F}_{a,i,j}^{(r)} \) in \( Y_{1|n}^{t-1}(\dot{\sigma}) \) coincide with the elements of \( \mathcal{W}_\pi \) with the same name. Recall an injective superalgebra homomorphism \( \Delta_R : Y_{1|n}^t(\sigma) \rightarrow U(\mathfrak{p}) \otimes U(\mathfrak{g}_\beta) \) in Theorem 6.3.

By Corollary 7.6 we have for each \( d \geq 0 \),
\[ \dim \Delta_R(F_d Y_{1|n}^t(\sigma)) = \dim F_d Y_{1|n}^t(\sigma) = \dim F_d S(\mathfrak{g}^e), \tag{9.8} \]
where \( F_d S(\mathfrak{g}^e) \) is the sum of all the graded elements in \( S(\mathfrak{g}^e) \) of degree \( \leq d \) in the Kazhdan grading.

Define the general parabolic generators \( E_{a,b,i,j}^{(r)} \) and \( F_{a,b,i,j}^{(r)} \) in \( F_d U(\mathfrak{p}) \) by formulae (3.19) and (3.20) recursively, choosing an arbitrary integer \( k \) there. Let \( X_d \) denote
the subspace of $U(\mathfrak{p})$ spanned by all supermonomials in the elements
\[
\begin{aligned}
\{ D^{(r)}_{a, i, j} \} &_{1 \leq a \leq m + 1, 1 \leq i, j \leq n, 0 \leq r \leq s^\mu_{a, i},} \\
\{ F^{(r)}_{a, b, i, j} \} &_{1 \leq a < b \leq m + 1, 1 \leq i, j \leq n, s^\mu_{a, b} < r \leq s^\mu_{a, b} + p^\mu_{b},} \\
\{ F^{(r)}_{a, b, i} \} &_{1 \leq b < a \leq m + 1, 1 \leq i \leq n, s^\mu_{a, b} < r \leq s^\mu_{a, b} + p^\mu_{b},}
\end{aligned}
\]
taken in some fixed order and of total degree $\leq d$. By Proposition 9.9, $X_d$ is a subspace of $F_d \mathcal{W}_\pi$.

Define a superalgebra homomorphism $\psi_R : U(\mathfrak{p}) \to U(\hat{\mathfrak{p}}) \otimes U(\mathfrak{gl}_\beta)$ by
\[
\psi_R(\tilde{e}_{i, j}) := \begin{cases} \\
\tilde{e}_{i, j} \otimes 1 & \text{if } \text{col}(i) \leq \text{col}(j) \leq \ell - 1, \\
0 & \text{if } \text{col}(i) \leq \ell - 1, \text{col}(j) = \ell, \\
1 \otimes \tilde{e}_{i-N+\beta, j-N+\beta} & \text{if } \text{col}(i) = \text{col}(j) = \ell.
\end{cases}
\]
By Lemma 9.2, we have
\[
\psi_R(D^{(r)}_{a, i, j}) = \hat{D}^{(r)}_{a, i, j} \otimes 1 - \delta_{a, m+1} \sum_{k=1}^\beta \hat{D}^{(r-1)}_{a, i, k} \otimes \tilde{e}_{k, j},
\]
\[
\psi_R(E^{(r)}_{a, i, j}) = \hat{E}^{(r)}_{a, i, j} \otimes 1 - \delta_{a, m} \sum_{k=1}^\beta \hat{E}^{(r-1)}_{a, i, k} \otimes \tilde{e}_{k, j},
\]
\[
\psi_R(F^{(r)}_{a, i, j}) = F^{(r)}_{a, i, j} \otimes 1.
\]
Comparing this with Theorem 4.2(1) and recalling the PBW basis for $Y_{1|n}^\ell(\sigma)$ obtained from Corollary 6.4, we deduce that $\psi_R(X_d) = \Delta_R(F_d Y_{1|n}^\ell(\sigma))$. Combining this with (9.8) and Corollary 7.6, we obtain
\[
\dim F_d S(\mathfrak{g}^\ell) = \dim \psi_R(X_d) \leq \dim X_d \leq \dim F_d \mathcal{W}_\pi \leq \dim F_d S(\mathfrak{g}^\ell).
\]
Thus equality holds everywhere so we have $X_d = F_d \mathcal{W}_\pi$ for each $d \geq 0$, and in particular, the map $\psi_R : \mathcal{W}_\pi \to U(\hat{\mathfrak{p}}) \otimes \mathfrak{gl}_\beta$ is an injective homomorphism. Moreover, recall the map $\Delta_R : Y_{1|n}^\ell(\sigma) \to U(\hat{\mathfrak{p}}) \otimes \mathfrak{gl}_\beta$ defined in Theorem 4.2(1). Comparing the formulae, we have that $\psi_R(D^{(r)}_{a, i, j}) = \Delta_R(D^{(r)}_{a, i, j})$, where the element $D^{(r)}_{a, i, j}$ on the left-hand side is the element of $\mathcal{W}_\pi$, and the element $D^{(r)}_{a, i, j}$ on the right-hand side is the generator of $Y_{1|n}^\ell(\sigma)$. Similarly, $\psi_R(E^{(r)}_{a, i, j}) = \Delta_R(E^{(r)}_{a, i, j})$ and $\psi_R(F^{(r)}_{a, i, j}) = \Delta_R(F^{(r)}_{a, i, j})$ for all admissible $a, i, j, r$.

Therefore, the composition map $\psi_R^{-1} \circ \Delta_R : Y_{1|n}^\ell(\sigma) \to \mathcal{W}_\pi$ is exactly the filtered superalgebra isomorphism described in Theorem 9.1 and the elements listed in Theorem 9.1 indeed generate $\mathcal{W}_\pi$. This proves Theorem 9.1 in Case R.

Next we sketch how to complete the induction step in Case L. In this case, we enumerate the bricks of $\pi$ down columns from right to left. Note that different ways of enumerating are just choosing different bases to describe $\mathfrak{gl}_{M|N} \cong \text{End}(\mathbb{C}^M|N)$ so we may choose the best way to our current purpose.

Let $\tilde{\pi}$ denote the pyramid obtained from $\pi$ by deleting the left-most column of $\pi$; that is, deleting the bricks numbered with $N, N - 1, \ldots, N - \beta$. Let $\tilde{\sigma}$ be the
shift matrix obtained from (4.6), where the corresponding pyramid is exactly \( \hat{\pi} \), and define \( \hat{p}, \hat{m}, \hat{e} \in \hat{g} := \mathfrak{gl}_{M|N-\beta} \) via (7.1) and (7.3) with respect to \( \hat{\pi} \). Note that in this case we embed \( U(\hat{g}) \) into \( U(g) \) by the natural embedding, since it already sends the elements \( \hat{e}_{ij} \) of \( U(\hat{g}) \) to the elements \( e_{ij} \) of \( U(g) \) for all \( 1 \leq i, j \leq N-\beta \).

Under this embedding, the superalgebra \( W_\pi = U(\hat{p})^m \) is a subalgebra of \( U(\hat{p}) \subset U(p) \) and the twisted action of \( \hat{m} \) on \( U(\hat{p}) \) is exactly the restriction of the twisted action of \( m \) on \( U(p) \). Let \( \hat{D}^{(r)}_{a;i,j}, \hat{D}^{(r)}_{a;i,j}, \hat{E}^{(r)}_{a;i,j}, \hat{F}^{(r)}_{a;i,j} \) denote the elements of \( U(\hat{p}) \) as defined in section 8 associated to the shape \( \mu \) which is also admissible for \( \hat{\sigma} \). By the induction hypothesis, these elements are \( \hat{m} \)-invariant.

The idea is exactly the same. By the following crucial lemma, which is the analogue of Lemma 9.2, we may express the elements \( D^{(r)}_{a;i,j}, D^{(r)}_{a;i,j}, E^{(r)}_{a;i,j} \) and \( F^{(r)}_{a;i,j} \) in \( U(p) \) in terms of \( \hat{D}^{(r)}_{a;i,j}, \hat{D}^{(r)}_{a;i,j}, \hat{E}^{(r)}_{a;i,j} \) and \( \hat{F}^{(r)}_{a;i,j} \). Then by case-by-case discussions and computations, we can prove that \( D^{(r)}_{a;i,j}, D^{(r)}_{a;i,j}, E^{(r)}_{a;i,j} \) and \( F^{(r)}_{a;i,j} \) are indeed \( m \)-invariant. Since the arguments are almost identical, we will only provide the most crucial lemma below, where the proof is exactly the same.

**Lemma 9.10.** The following equations hold for \( r > 0 \), all admissible \( a, i, j \) and any fixed \( 1 \leq h \leq \beta \):

\[
D^{(r)}_{a;i,j} = \hat{D}^{(r)}_{a;i,j} + \delta_{a,m+1} \left( -\sum_{k=1}^{\beta} \hat{e}_{N-\beta+k,N-\beta+k} \hat{D}^{(r-1)}_{a;k,j} + \left[ \hat{e}_{N-\beta+i,N-\beta+h} \hat{D}^{(r-1)}_{a;h,j} \right] \right), \tag{9.9}
\]

\[
E^{(r)}_{a;i,j} = \hat{E}^{(r)}_{a;i,j}, \tag{9.10}
\]

\[
F^{(r)}_{a;i,j} = \hat{F}^{(r)}_{a;i,j} + \delta_{a,m} \left( -\sum_{k=1}^{\beta} \hat{e}_{N-\beta+i,N-\beta+k} \hat{E}^{(r-1)}_{a;k,j} + \left[ \hat{e}_{N-\beta+i,N-\beta+h} \hat{F}^{(r-1)}_{a;h,j} \right] \right), \tag{9.11}
\]

where for (9.11) we are assuming that \( r > s_{m+1,m}^\mu \) if \( a = m \).

With the help of Lemma 9.10, one can deduce that the statement of Proposition 9.9 still holds in Case L. Finally, define a superalgebra homomorphism \( \psi_L : U(p) \rightarrow U(\mathfrak{gl}_p) \otimes U(p) \) by

\[
\psi_L(\hat{e}_{i,j}) := \begin{cases} 
\hat{e}_{i-N+\beta,j-N+\beta} \otimes 1 & \text{if } \text{col}(i) = \text{col}(j) = 1, \\
0 & \text{if } \text{col}(i) = 1, \text{col}(j) \geq 2, \\
1 \otimes \hat{e}_{i,j} & \text{if } 2 \leq \text{col}(i) \leq \text{col}(j).
\end{cases}
\]
By Lemma 9.10, we have that
\[
\psi_L(D^{(r)}_{a;i,j}) = 1 \otimes \hat{D}^{(r)}_{a;i,j} - \delta_{a,m+1} \sum_{k=1}^{\beta} \tilde{e}_{i,k} \otimes \hat{D}^{(r-1)}_{a;k,j}
\]
\[
\psi_L(E^{(r)}_{a;i,j}) = 1 \otimes \hat{E}^{(r)}_{a;i,j},
\]
\[
\psi_L(F^{(r)}_{a,j;i,j}) = 1 \otimes \hat{F}^{(r)}_{a;j,i,j} - \delta_{a,m} \sum_{k=1}^{\beta} \tilde{e}_{i,k} \otimes \hat{F}^{(r-1)}_{a;k,j}.
\]

Same argument as in Case R shows that the map \( \psi_L \) is injective and the composition map \( \psi_L^{-1} \circ \Delta_L : Y^{\ell}_1(\sigma) \rightarrow \mathcal{W}_\pi \) gives the required isomorphism of filtered superalgebras. This completes the proof of Theorem 9.1.

**Corollary 9.11.** Let \( \pi \) be a colored pyramid satisfying (7.7). Then there exists a superalgebra isomorphism \( \iota : \mathcal{W}_\pi \rightarrow \mathcal{W}_\tilde{\pi} \) defined on parabolic generators with respect to an admissible shape \( \mu \) by (2.20).

**Proof.** Follows from Theorem 9.1 and (6.4). \( \square \)
