Definition of whole person care in general practice in the English language literature: a systematic review

Hayley Thomas,1 Geoffrey Mitchell,1 Justin Rich,1 Megan Best2

ABSTRACT

Objectives The importance of ‘whole person’ or ‘holistic’ care is widely recognised, particularly with an increasing prevalence of chronic multimorbidity internationally. This approach to care is a defining feature of general practice. However, its precise meaning remains ambiguous. We aimed to determine how the term ‘whole person’ care is understood by general practitioners (GPs), and whether it is synonymous with ‘[w]holistic’ and ‘biopsychosocial’ care.

Design Systematic literature review.

Methods MEDLINE, PubMed, EMBASE, CINAHL, PsycINFO, Web of Science, Proquest Dissertations and Theses, Science.gov (Health and Medicine database), Google Scholar and included studies’ reference lists were searched with an unlimited date range. Systematic or literature reviews, original research, theoretical articles or books/book chapters; specific to general practice; relevant to the research question; and published in English were included. Included literature was critically appraised, and data were extracted and analysed using thematic synthesis.

Results Fifty publications were included from 4297 non-duplicate records retrieved. Six themes were identified: a multidimensional, integrated approach; the importance of the therapeutic relationship; acknowledging doctors’ humanity; recognising patients’ individual personhood; viewing health as more than absence of disease; and employing a range of treatment modalities. Whole person, biopsychosocial and holistic terminology were often used interchangeably, but were not synonymous.

Conclusions Whole person, holistic and biopsychosocial terminology are primarily characterised by a multidimensional approach to care and incorporate additional elements described above. Whole person care probably represents the closest representation of the basis for general practice. Health systems aiming to incorporate both general and family practice throughout this report. A whole person or holistic approach characterises the self-definition of general practice, with its importance recognised by GPs from diverse cultural contexts and by patients.4–10 Historically, attention to WPC in western medicine developed in critique of the biomedical model’s reductionist framework.11 12 In 1977, Engel proposed the ‘biopsychosocial’ model, a paradigm shift that recognised psychological and social along with biological contributors to disease.13 The terms ‘holistic’ and ‘whole person’ care have been used to denote a similar approach.14–16 However, a series on the research agenda for general practice in Europe identified that chronic multimorbidity. Provision of ‘whole person care’ (WPC) is particularly important in meeting the needs of these patients and has been an objective of recent healthcare reforms in several nations.1–3

Societies worldwide are currently facing an increasing prevalence of patients with

Strengths and limitations of this study

To the best of our knowledge, this is the first systematic review of general practitioners’ understandings of ‘whole person’, ‘holistic’ and ‘biopsychosocial’ care and the relationships between these terms.

We used a comprehensive search strategy and included a broad range of literature types, to provide a sound understanding of these terms in English language general practice literature.

This study was limited to English language literature, so does not provide insight into the use of these or related terms in other languages.

Related terms such as ‘patient-centred’ care, ‘generalism’ and ‘comprehensiveness’ were not specifically studied, and additional work is required to determine their relationship to our findings.

There was considerable heterogeneity in included publications, and it is possible that other researchers may identify different themes from the same data.

despite the ‘implicit consensus about [the importance of an holistic approach] as an essential element for GP’;\textsuperscript{17} this lacked a clear practical definition, and little research had been conducted in the area. Indeed, ‘many different definitions of holism, and holistic, are being used in health and the healthcare literature, and no one is quite sure what anyone else means when they use these terms’\textsuperscript{18} While the terms ‘whole person’, ‘[w]holistic’ and ‘biopsychosocial’ care are sometimes used interchangeably, it is unclear whether they are synonymous, with differences between definitions proposed by general practice organisations.\textsuperscript{4, 7, 9} Additionally, it has been suggested that a commitment to WPC in general practice may be more rhetorical than practical.\textsuperscript{17, 19} Given the core commitment of general practice to providing whole person, or holistic, care, as expressed in statements such as the World Organisation of Family Doctors’ definition of general practice, this issue deserves attention.\textsuperscript{4} While studies have previously defined ‘holistic care’, ‘wholistic healthcare’ and ‘holistic practice’, these have either focused primarily on the context of nursing or been conducted in a limited geographical location, and it is unclear whether their findings are transferable to the general practice context.\textsuperscript{20–23} In order to evaluate the current concept of WPC within general practice and to design health system practices to provide WPC in a changing health climate effectively, it is first necessary to clarify how this term is defined. We conducted a systematic literature review and thematic analysis aiming to define how the term WPC is understood in general practice and whether it is synonymous with [w]holistic and biopsychosocial care.

**METHODS**

**Search strategy**

We searched the MEDLINE, PubMed, EMBASE, CINAHL, PsycINFO and Web of Science databases for published literature, and Proquest Dissertations and Theses, Science.gov (Health and Medicine database) and Google Scholar for grey literature, until April 2017. These databases were chosen to provide broad coverage of relevant subject areas. Results from Science.gov were limited to the ‘top results’ reported (maximum 500) and Google Scholar searches to the first 50 hits for each search string. We hand-searched the reference lists of included studies.

We developed search terms iteratively, then performed a preplanned search. The final strategy combined search terms for holistic, whole person or biopsychosocial with terms for general practice. The MEDLINE search strategy is shown in box 1 and was modified for other databases. Shorter search strings combining key search terms were used for Science.gov and Google Scholar due to functional limitations.

**Inclusion criteria**

Peer-reviewed systematic or literature reviews, original research (qualitative studies, quantitative studies with findings expressed as descriptive statements for inclusion in qualitative analysis), theoretical articles or books/book chapters; literature specific to general practice (studies with a majority of GP or GP registrar participants or separate reporting of their views; text/opinion authored exclusively by GPs or PG registrars, or with at least one GP/GP registrar author and a focus on the general practice context); relevant to the research question (included descriptions, definitions or theoretical models of the terms ‘whole person’, ‘holistic’ or ‘biopsychosocial’ (care/medicine, etc)); and published in English.

**Exclusion criteria**

Non-English articles, articles not specific to general practice and literature authored by general practice professional organisations. The latter was excluded to achieve an understanding of WPC within academic general practice literature, which was likely to be the basis of general practice organisations’ literature.

All eligible citations were uploaded into Endnote X8 and duplicates removed. Two independent reviewers (HT and JR) screened titles and abstracts. Studies that did not meet inclusion criteria were excluded, with disagreements resolved by discussion. A single reviewer (HT) assessed full text of remaining literature against inclusion criteria. Studies that this reviewer considered borderline or suitable for inclusion were reviewed by at least one other author (GM and/or MB), with disagreements resolved by discussion.

**Quality appraisal**

Qualitative studies’ conduct and reporting were critically appraised using Kmet et al’s Standard Quality Assessment Criteria.\textsuperscript{24} An additional question, ‘Have ethical issues been taken into consideration?’ was added, to give a total possible score of 22. Validity and authenticity of book chapters and opinion pieces were appraised using Joanna Briggs Institute’s Critical Appraisal Checklist for Text and Opinion.\textsuperscript{25} Initially, two reviewers (HT and MB) independently appraised five pieces of literature with disagreements resolved by discussion. Subsequent quality assessment was performed by a single reviewer (HT). No studies were excluded due to quality.
Data extraction
Details including author, year, country, type of literature, population focus (for qualitative studies), key term (holistic, whole person, biopsychosocial) and descriptions of key terms were extracted by two reviewers (HT and MB) for an initial five pieces of literature, and consensus was achieved. A single reviewer (HT) extracted data from remaining literature.

Data analysis
Full text of included studies was uploaded into NVivo 11. Original data relevant to the research question (including relevant results and original statements in discussion of qualitative studies, and original statements in books and theoretical pieces) were thematically coded. Two independent reviewers (HT and MB) performed coding inductively on an initial sample of five pieces of literature to search for concepts, with disagreements resolved by discussion. Following this, a single reviewer (HT) coded remaining literature. Subsequent studies were coded into pre-existing concepts, and new concepts were created when deemed necessary.

Thematic synthesis was performed by a single reviewer (HT) and discussed with another two reviewers (GM and MB) for consensus.26 Thematic synthesis was chosen as it allows development of interpretive theories while remaining close to the primary data. The terms ‘whole person’, ‘holistic’ and ‘biopsychosocial’ were then compared by exploring similarities and differences between the themes represented within each term, assisted by NVivo query functions. It was identified during analysis that variations of ‘holistic’ terminology (eg, holistic care, medicine, etc) may have different connotations, and these were subsequently compared. Temporal and geographical variations in usage were found to be absent.

Patient and public involvement
This research was done without patient involvement, due to its primary focus being on the understanding of WPC among GPs, and its nature as a systematic review.

RESULTS
Searches retrieved 4297 non-duplicate publications. Following title/abstract screen, 587 publications were selected for full text retrieval. We were unable to access eight of these despite conducting a library search. Of the remaining publications, 50 met inclusion criteria (figure 1). These originated from 12 countries, and comprised 5 qualitative studies, 40 theoretical articles, 4 book chapters and 1 thesis. The primary terms of interest were ‘holistic’ in 24 sources, ‘whole person’ in 9 sources, ‘biopsychosocial’ in 14 sources, both whole person/holistic in 2 sources and both whole person/biopsychosocial in 1 source. None of the papers using whole person and only one paper using biopsychosocial terminology specifically aimed to define these terms, whereas multiple papers specifically defined holistic terminology.16 18 22 27–33

The characteristics of included literature and results of quality assessment are shown in online supplementary appendix 1. We believe theoretical saturation was reached.

Thematic synthesis
There was substantial heterogeneity in the literature. However, six overarching themes were identified, each with between one and four subthemes. These are shown in table 1 and discussed below. Few sources specifically drew a distinction between whole person, holistic and biopsychosocial terminology, with several using these terms interchangeably.29 31–38 However, on overall analysis, we identified differences in emphasis, as discussed below and illustrated in figure 2. Subthemes that are relevant to more than one of the three terms overlap in the diagram.

A multidimensional, integrated approach
Employing a multidimensional, integrated approach, rather than a biomedical reductionist model, was the dominant theme throughout the literature.

The literature emphasised that biopsychosocial, holistic and whole-person approaches must address multiple aspects of the person and their context, rather than being strictly biomedical.16 18 22 27 31 33 34 36 39–54 In a paper discussing the definition of holism, Freeman stated that:

An approach to health and medicine that is not reductionist is an implicit part of the comprehensive care provided by GPs. We are not doctors for particular diseases, or particular organs, or particular stages in the life cycle—we are doctors for people.18

Similarly, in a study on the perceived meaning of a (w) holistic view among GPs and district nurses in Sweden, Stranderg et al found that:

Biomedical attitude is not enough. There is a need for a multidimensional viewpoint including a bio-psychosocial attitude towards the patients.22

Which important aspects of the ‘whole’ to include in care varied. Biological, psychological and social factors were commonly identified.27 29 34 37 39 40 42 44 48 50 54 57 58 Some GPs argued for the importance of additional factors. Spirituality was prominent among these.14 29 33 34 37 39 40 42 44 48 50 54 57 58

Murray et al concluded from their study on GPs’ views on their role in providing spiritual care that:

The whole-person approach to medicine may be incomplete if it lacks consideration of the spiritual dimension.37

The patient’s ecological/environmental context was also emphasised by some GPs.11 14 30

The literature also emphasised that aspects of the person must be viewed in an integrated fashion.16 18 27–29 31–33 36 39 40 42–47 52 53 55 56 58 60 In their study
on the meaning of an (w)holistic view, Strandberg et al found that:

The participants discussed the concepts ‘the whole’ versus ‘parts of the whole’. Many meant that the whole actually is greater than the sum of all the parts. \(^{22}\)

Similarly, Pietroni stated that a key principle of holistic medicine is that:

The human organism is a multidimensional being, possessing body, mind and spirit, all inextricably connected, each part affecting the and whole and the whole being greater than the sum of the parts. \(^{29}\)

Sturmberg identified ‘understanding the interconnectedness of various illness aspects’ \(^{53}\) as the second step in an approach to teaching holistic care.

One exception to this emphasis on a multidimensional, integrated approach was identified in O’Brien et al’s study. \(^{38}\) GPs in one practice in this study understood holism as caring for a patient’s multiple comorbidities and placed boundaries between ‘the medical’ and ‘the social’.

Some authors also proposed a ‘split biopsychosocial model’ in which different components of care are selectively addressed depending on the patient’s presentation, though the utility of this approach was debated. \(^{45-62}\)

Employing a multidimensional, integrated approach to care was the key theme characterising each of the biopsychosocial, holistic and whole person terminologies. \(^{16, 18, 22, 27, 29, 31-34, 36, 39-56}\)

Biopsychosocial terminology was the most specific of the terms in defining the aspects of care that it addressed (biological, psychological, social). \(^{36, 41, 43, 46}\) Some GPs suggested the biopsychosocial approach was too narrow and should be expanded to a ‘biopsychosociospiritual’, \(^{34, 39}\), ‘ecobiopsychosocial’ \(^{59}\) or ‘psychosomatosemiotic’ model. \(^{53, 63}\) Occasionally, the term biopsychosocial was used to incorporate these broader aspects. \(^{35}\) There was some debate regarding whether the biopsychosocial model employed an integrated approach, with some arguing that it remained dualistic. \(^{49, 55, 64}\)

Whole person and holistic terminology were less specific than biopsychosocial in defining their domains
of care, encompassing a varied and broad range of biological, psychological, social, spiritual and environmental/ecological aspects.16 18 27–29 31 32 34 37 38 40 42 43 45 46 47 48 50 51 52 53 54

Some models of WPC specifically distinguished between care of the person (body, soul, spirit) and external factors (social, environmental). However, these still addressed external factors in their overall approach to care. Emphasis on an integrated approach was strongest in holistic terminology, and also present in whole person terminology.16 18 27–29 31 32 34 35 39 40 42 43 45 46 48 50 51 52 53 54

**Importance of the therapeutic relationship**

The importance of the therapeutic relationship, a collaborative approach and characteristics of the doctor that fostered this relationship was emphasised.12 14 16 22 27–30 32 33 35 38 39 42 43 45 46 48 50 52 54 55 57 65–69

The therapeutic doctor–patient relationship was valued.12 28 29 50 Risdon and Edey stated that:

> True healing and mending of brokenness is possible only within an authentic human relationship. 50

O’Brien et al included relationship as a suggested component in a whole person intervention.38 One GP in their study:

> describ[ed] how she felt the essence of the GP (relationship, intuition, support and continuity) had been lost with the medical nuts & bolts of monitoring…, a view supported by her colleagues.

Personal qualities of the doctor that fostered the therapeutic relationship were emphasised.18 27 29 32 38 39 46 52 55 57 60 63 65 67 69 These included characteristics such as being fully present, attentive to and interested in the patient, supportive (compassionate, empathetic, respectful, non-judgemental, etc) and possessing knowledge and understanding of the patient in addition to technical competence. Participants in Strandberg et al’s study identified that an important component of a holistic view was:

> finding the patient’s hidden agenda and listening to what the patient is actually saying.22

Multiple sources emphasised a collaborative approach, with patients taking responsibility for their

| Table 1 Themes and subthemes | Terms characterised by this theme |
|-----------------------------|----------------------------------|
| **Theme**                  | **Subthemes**                     |                                |
| Employs a multidimensional, | - Considers multiple aspects of the person and their context. | Biopsychosocial (multidimensional= integrated) |
| integrated approach        | - Integrates these aspects such that the whole is seen as greater than the sum of the parts. | Whole person |
|                            |                                  | Holistic                      |
| Importance of the          | - Values the therapeutic relationship. | Biopsychosocial (variable)   |
| therapeutic relationship   | - Places importance on personal attributes of the doctor that foster the therapeutic relationship. | Whole person |
|                            | - Employs a collaborative approach that emphasises patient responsibility. | Holistic                  |
|                            | - Values continuity of care.       |                               |
| Acknowledges the           | - Places importance on doctors’ self-awareness. | Biopsychosocial (self-awareness) |
| humanity of the doctor     | - Adopts a ‘physician heal thyself’ philosophy. | Whole person |
|                            | - Identifies potential for personal growth of the doctor through treating the patient. | Holistic                  |
| Recognises the individual  | - Views patients as individual, unique persons. | Biopsychosocial (minor theme) |
| personhood of each patient | - Focuses on the person rather than on the disease. | Whole person |
|                            | - Distinguishes between disease (a pathological derangement) and illness (a broader term encompassing the effect of disease on the patient’s life). | Holistic                  |
| Health as more than        | - Health is viewed as more than the absence of disease. | Biopsychosocial (minor theme) |
| absence of disease         | - Disease is viewed as a state of imbalance and healing as restoring the balance of health. | Whole person |
|                            | - Emphasises preventive health measures. | Holistic                  |
| Employs a range of          | - Use of a range of treatment modalities. | Biopsychosocial |
| treatment modalities       | - May include (but is not synonymous with) CAM. | Whole person |
|                            |                                  | Holistic (specific focus on CAM) |

CAM, complementary and alternative medicine.
van Velden expressed this succinctly, stating that:

[in the] holistic bio-psychological model...the doctor–patient relationship changes from one of monologue to one of dialogue, with the doctor no longer instructing the patient but rather involved in negotiating with the latter. People start taking responsibility for personal choices rather than deferring to the rules of institutions.

Illness may be viewed as an opportunity for personal growth. Borins stated that:

sometimes illness can be a creative opportunity for the patient to learn more about himself and the direction he is taking...Sometimes physical or emotional pain can inform a person that he must change his life and grow.

Finally, some sources identified continuity as an important aspect of the doctor–patient relationship. One author specifically distinguished between holistic and WPC on the basis that continuity was a feature of whole person but not of holistic care. However, this distinction was not found elsewhere in the literature.

Emphasis on the doctor–patient relationship was prominent within whole person and holistic literature. Literature on the biopsychosocial approach was mixed, with the doctor–patient relationship emphasised in papers that specifically focused on the practical application of a biopsychosocial approach. An alternative view also existed, that considered the biopsychosocial model an ethically neutral scientific theory rather than an approach to care.

Acknowledges the humanity of the doctor
The literature placed importance on acknowledgement of the doctor’s humanity. This encompasses self-awareness, a ‘physician heal thyself’ philosophy and the potential for personal growth of the doctor through the clinical interaction.

Several sources argued for the importance of doctors’ self-awareness. Stewart stated that:

holistic care implied a set of values as well as behaviours on the part of the physician; this set would include...awareness of his own person...

Figure 2  The Inter-relationship between biopsychosocial, whole person and holistic terminology. Features of each approach are included within their respective circles in the diagram. Features placed on the circles’ boundaries are a minor feature of the inner circle term, but more pronounced in the outer circle’s term. The diagram illustrates that biopsychosocial was the narrowest but most well defined of the terms, encompassing multidimensional-integrated care, and the use of a range of treatment modalities. Minor themes of the biopsychosocial approach include recognising the individual personhood of each patient, and viewing health as more than absence of disease. Some sources that specifically discuss the practical application of the biopsychosocial approach also emphasise the importance of the therapeutic relationship and of acknowledging the humanity of the doctor. Holistic and whole person terminology were broader than biopsychosocial. These terms included a stronger emphasis than biopsychosocial care on the therapeutic relationship, recognition of the patients’ individual personhood and the humanity of the doctor, and a view of health as a state of wholeness and balance. Whole person and holistic care were essentially synonymous. ‘Holistic medicine’/‘holistic health’ were related broader terms that sometimes incorporated complementary and alternative medicine.
Epstein also implied the importance of self-reflection when discussing how to apply the biopsychosocial vision, suggesting that doctors ask themselves:

What parts of your self are you engaging in the care of this patient, right now? and then, ‘Does it have to be that way?’

A ‘physician heal thyself’ philosophy was emphasised. Holistic care means practitioners matter too. We need to look after ourselves, not only to be an example to our patients, but for our own well-being and that of our families.

Similarly, Borins stated that:

An important concept of holistic medicine is that of ‘Physician, heal thyself’. The more complete we are in our own spiritual, psychological and physical development, the easier it will be to help someone else on the path of positive growth.

A minor subtheme is the potential for personal growth of the doctor through treating the patient. In reference to spiritual care, Anandarajah stated that:

physicians have the potential to heal and be healed through their clinical interactions, as clearly illustrated by numerous physician stories.

Sawa stated that:

The practice of whole-person medicine increases the practitioner’s personal growth and develops his or her analytic skill and ability to think in terms of a complex web of contributing factors, rather than in terms of single chains of causal relationships.

Recognising doctors’ humanity is a feature of biopsychosocial, holistic and whole person terminology, however the specific subthemes represented in these terminologies differed. Doctors’ self-awareness featured in literature describing all three terms. A ‘physician heal thyself’ philosophy primarily characterised holistic, and to a lesser extent WPC. Potential for personal growth of the doctor was a minor theme of some sources on holistic and WPC.

Recognises the individual personhood of each patient

Recognition of the unique personhood of each patient within their individual context also characterised the literature. McWhinney stated that:

Understanding and treating illness in its context is what holistic medicine means to me….The natural (holistic) diagnostician tends to notice what is unique in each patient. He is reluctant to classify and label, and he does not separate the disease from the man or the man from his environment.

Focus was placed on the person rather than the disease. In a study exploring how GPs who practised complementary therapies understood the term ‘holism’, Adams identified that they viewed:

holism in terms of treating a person rather than simply a patient. These doctors suggest that treating an individual as a patient leads to ‘unhealthy’ focus upon disease and a failure to acknowledge what they see as the complex and multilayered nature of illness.

Some papers distinguished between disease and illness. Strandberg et al’s study identified that to have a holistic view:

GP’s and nurses have to deal with the gap between ‘illness’ and ‘disease’, that is, what the patient experiences and what is the medical problem.

Recognising patients’ individual personhood primarily characterised whole person and holistic terminology. Variations on this theme were occasionally present in biopsychosocial literature.

Health as more than absence of disease

Papers incorporating this theme viewed health as more than absence of disease. van Velden stated that:

Optimal health is therefore much more than the absence of disease or infirmity. It is the conscious pursuit of the highest qualities of the spiritual, mental, emotional, physical, environmental, occupational and social aspects of the human experience, as illustrated in the bio-psycho-social model.

Some sources conceptualised disease as a state of ‘imbalance’ and healing as restoring the balance of health. Pietroni, for example, stated that:

Disease or ill-health arises as a result of a state of imbalance, either from within the human being or because of some external force in the environment.

Preventive health measures were also emphasised.

Aspects of this theme were included in whole person, holistic and biopsychosocial care. However, it was most pronounced in the holistic literature.

Employs a range of treatment modalities

Using a wide range of treatment modalities was the final theme identified.

Examples include Anandarajah’s suggestion of treatment modalities in her body, mind, spirit, environment, social, transcendent model of WPC. These ranged from medication, surgery and physical therapy, to counselling and cognitive therapy, spiritual counselling, compassion, presence and connection. Margalit et al’s study on the practical application of the biopsychosocial model identified that offering not only medication, but also advice on health promotion and managing emotions characterised a biopsychosocial doctor–patient encounter.
A subset of literature using holistic terminology specifically included the use of complementary and alternative medicine (CAM). Pietroni stated that:

An holistic approach…involves a willingness to use a wide range of interventions—traditional medical interventions, alternative approaches and self-help measures.48

However, the literature consistently emphasized that CAM is not holistic if used in isolation.14 16 18 22 27–31 35 48 Pietroni stated that:

Holism is more than a pot-pourri of therapies. It is an approach to health and disease that transcends any particular therapy…Holism should not be confused with the positive-health movement nor with the complementary medicine movement. Many complementary practitioners do not have an holistic approach and use their therapies in the traditional reductive manner. Conversely, many doctors who know nothing of homeopathy or acupuncture adopt a whole-person approach to their work and have done even before the word holistic became current.50

Similarly, in his study on GPs who practise complementary therapies, Adams found that:

Many of the GPs are keen to stress that a holistic approach does not evolve simply with their development of complementary practice. They talk of always having been holistic and how holism is not confined to complementary medicines.27

Additionally, McWhinney wrote that:

There is nothing unorthodox about holistic medicine. Unfortunately, the term has been used so much by unorthodox groups of healers, that it is in danger of losing some of its meaning for us. I do not wish to suggest that we should ignore the contribution which unorthodox methods can make to healing. Let us remember, however, that the holistic approach has a long and distinguished history in orthodox medicine itself.28

The use of a wide range of treatment modalities characterised whole person, holistic and biopsychosocial care.14 16 18 27 31 33 35 48 58 However, the inclusion of CAM was a specific characteristic of holistic terminology.14 18 27 29 31 34 48 50 58 A distinction was found between various ‘holistic’ terms in this respect. Sources that discussed ‘holistic medicine’ or ‘holistic health’ frequently incorporated CAM, with the exception of McWhinney’s paper describing holistic medicine.14 16 27–29 31 58 Conversely, sources discussing ‘holistic care’ rarely referred to the use of CAM. This suggests that the term ‘holistic care’ does not necessarily imply incorporation of complementary approaches within the GP context. The terms ‘holism’, ‘holistic approach’ and ‘holistic view’ were more varied in this respect, making these terms somewhat more ambiguous.18 27 28 30 34 36 38 48 55 66

Specific distinctions between whole person, holistic and biopsychosocial terms

Whole person, holistic and biopsychosocial terminology were used interchangeably in several papers.29 31–38 Some papers did specifically differentiate these terms, but with no consistency among the literature.29 35 54 55 64 66 69 Davidsen et al implied that the biopsychosocial approach is not holistic due to a lack of integration between the components it addresses.55 Grantham differentiated the biopsychosocial approach from holistic medicine, arguing that the latter implied inclusion of CAM.55 Pietroni stated that the biopsychosocial approach comprised patient-centeredness in addition to holism.66 Sawa differentiated between whole person medicine and biopsychosocial therapy by the inclusion of systems theory in the latter.69 Wun distinguished between WPC and holistic care by an additional element of continuity of care in the former, stating that:

Whole person care is the accumulation of many incidences of holistic care throughout the lifetime.54

Pietroni stated that holistic care includes ‘more recent scientific discoveries’ (such as psychoneuroimmunology, physics and field forces) in addition to whole person medicine.29

On overall analysis of the literature, however, representation of themes discussed above differed between the terms, as illustrated in figure 2.

‘Technoscientific holism’

One alternative description of holism in the literature was ‘technoscientific holism’ described by Vogt et al.70 71 Vogt et al analysed whether P4 systems theory, a ‘predictive, preventive, personalised and participatory’ approach to medicine, was holistic. In doing so, they specifically differentiated between the ‘technoscientific holism’ of systems theory, and an approach more similar to that described above which they referred to as the ‘holism of humanistic medicine’.70 They described ‘technoscientific holism’ as:

…resulting from an altered, more all-encompassing technological gaze on human life and related changes in biomedicine’s methods and philosophy…the whole continuum of health and disease states…is defined as potentially quantifiable, predictable and actionable70 (author’s emphasis).

This concept is unique in the included literature.

DISCUSSION

Our analysis suggests that GPs understand WPC to be an approach that considers multiple dimensions of the patient and their context, including biological, psychological, social and possibly spiritual and ecological factors, and addresses these in an integrated fashion that keeps sight of the whole. It employs a range of
Vanderpool. He suggested that holistic terminology is one theory that may explain this has been suggested by features of this care, and consider expanding their definitions identified in our study to be important whether the GPs they represent consider the additional narrower definitions of holistic/WPC may wish to explore in preference to ‘holistic’ terminology seems advisable. Where both multidimensional/integrated care and relational elements of care (the doctor–patient relationship, recognising patients’ individuality) are in view, we would suggest WPC as the preferred term. If additional themes such as using CAM are in view, we would suggest that this should be stated specifically to avoid confusion.

Our findings raise several practical implications and questions for future research. First, our findings were consistent with previous observations that there is little primary research defining our terms of interest in general practice. Only six pieces of primary research, of variable quality, were identified. Opinion pieces may have reflected the views of GPs with a strong interest in biopsychosocial/whole person/holistic care, and primary research is required to determine the relevance of our findings to the broader GP context. Second, due to heterogeneity among included literature, with many pieces only including a selection of identified themes, it remains unclear whether GPs would share consensus that all of these features characterise the terms of interest, what relative weighting should be applied to each and which aspects of care in addition to biological, psychological and social factors are included. Previous studies have gone some way to addressing this issue, particularly regarding GPs’ role in addressing existential and spiritual factors, however work remains to be done.

Further research is also required to explore the facilitators, barriers and outcomes of WPC as described. Finally, our definition of WPC shares close similarities with the concepts of ‘patient-centred’ or ‘person-centred’ care, and of ‘generalism’. We limited our focus in this study to the terms ‘whole person’, ‘holistic’ and ‘biopsychosocial’ care, as these appeared to be used interchangeably in some literature, and frequently differentiated from the term ‘patient-centred’ or ‘person-centred’ care.

However, given their close similarities, future studies could explore the relationship between these terms.

Our findings have practical implications in the context of primary health system reforms that aim to provide WPC in response to the increasing prevalence of patients with chronic multimorbidity. They enable GPs to reflect on their individual practice with respect to WPC and could inform focused education and refinement of clinical approaches to provide WPC. They also suggest that WPC requires both multidimensionality and integration. Achieving both can be challenging, particularly where multiple providers are involved in care.
our findings suggest that to provide WPC, this is essential. Proposals for health system redesign have included strategies such as improved communication between providers and integration of healthcare systems which go some way towards addressing this issue.²³ Our findings suggest that such system changes need to embed an enduring, therapeutic patient–GP relationship which must not be overlooked in a quest to achieve efficiency and tangible outcomes. Previous health reforms have at times neglected this relational aspect of care.¹¹ Our findings highlight the danger that such an approach may fail to deliver the whole person approach that ideally characterises primary care. Finally, our work raises ethical questions regarding where the boundaries of the doctors’ role lie, and whether employing a multidimensional approach encourages the medicalisation of life. Some authors have argued that this approach in fact breaks the cycle of medicalisation and iatrogenesis through considering non-biomedical contributors to disease.²⁸⁻³⁰ Vogt et al, however, identifies ‘the medicalisation of health and life itself’ as a potential danger of ‘technoscientific holism’ which they differentiate from the more ‘humanistic holism’ discussed in most of the literature, as discussed previously.³⁰ He suggests a focus on ‘quaternary prevention’ (a concept also discussed by other authors that focusses on preventing overmedicalisation) to address this.³⁰ These aspects deserve consideration when applying a whole person approach.

Strengths of this study include its comprehensive search strategy and broad range of literature included, resulting in inclusion of a large number of publications from a broad geographical distribution. As a result, we can be confident that our results represent a comprehensive summary of the understanding of WPC in the English language general practice literature. We do note that most of the countries represented have western-style health systems, though the gatekeeper role of the GP within these systems varies. This may reflect an absence of literature from countries with other health system structures on this topic, or the unavailability of this literature on database searching. Limitations of this study include our decision not to include definitions from professional associations representing general practice, as these are considered to have been derived from existing work rather than introducing original concepts. Our study only included English language literature, so does not provide insight into the usage of similar terminology in other languages. Finally, there is considerable heterogeneity in the papers, and it is possible that other researchers may identify different themes from the same data.

CONCLUSION
Within general practice literature, the terms whole person, biopsychosocial and holistic care share an emphasis on a multidimensional, integrated approach to care and also incorporate additional themes which vary among the terms as discussed. These findings can inform GPs’ self-reflective practice and the design of health systems that foster true WPC. Further research is required to explore the transferability of our findings, together with the facilitators, barriers and outcomes of WPC as defined.
