Abstract. The family of \( V \)-variable fractals provides a means of interpolating between two families of random fractals previously considered in the literature; scale irregular fractals (\( V = 1 \)) and random recursive fractals (\( V = \infty \)). We consider a class of \( V \)-variable affine nested fractals based on the Sierpinski gasket with a general class of measures. We calculate the spectral exponent for a general measure and find the spectral dimension for these fractals. We show that the spectral properties and on-diagonal heat kernel estimates for \( V \)-variable fractals are closer to those of scale irregular fractals, in that it is the fluctuations in scale that determine their behaviour but that there are also effects of the spatial variability.

Résumé. La famille des fractales \( V \)-variables donne un moyen d’interpolation entre deux familles de fractales aléatoires étudiées dans la littérature : les fractales à échelle irrégulière (\( V = 1 \)) et les fractales récursives aléatoires (\( V = \infty \)). Nous considérons une classe de fractales \( V \)-variables affines emboîtées, construites à partir du tamis de Sierpinski muni d’une classe générale de mesures. Nous calculons l’exposant spectral d’une mesure générale, et déterminons la dimension spectrale de ces fractales. Nous montrons que les propriétés spectrales, de même que les estimées de noyau de la chaleur sur la diagonale, sont plus proches de celles des fractales à échelle irrégulière, du fait que ce sont les fluctuations d’échelle qui déterminent leurs comportements. Néanmoins, la variabilité spatiale a aussi une influence.

1. Introduction

The field of analysis on fractals has been primarily concerned with the construction and analysis of Laplace operators on self-similar sets. This has yielded a well developed theory for post critically finite (or p.c.f.) self-similar sets, a class of finitely ramified fractals [29]. One motivation for the development of such a theory, aside from its intrinsic mathematical interest, has come from the study of transport in disordered media. However, in this setting the fractals arise naturally in models from statistical physics at or near a phase transition and are therefore random objects without exact self-similarity but with some statistical self-similarity.

In order to develop the mathematical tools to tackle analysis on such random fractals one approach has been to work with simple models based on self-similar sets but exhibiting randomness. The first case to be treated was that of scale irregular fractals [2,16,23] and [10], which have spatial homogeneity but randomness in their scaling. A more natural setting is provided by random recursive fractals, initially constructed by [11,15,36], where the fractal can be decomposed into a random number of independent scaled copies. The study of some analytic properties of classes of random recursive Sierpinski gasket can be found in [17,19,21] and [32].
More recently there has been work tackling random sets arising from critical phenomena directly, with a particular focus on the percolation model. Substantial progress has been made in the study of random walk on critical percolation clusters in the high dimensional case, see [3] and [34]. A bridge between these two approaches can be found in work on the continuum random tree \cite{8,9} or on critical percolation clusters on hierarchical lattices \cite{22}, both of which have random self-similar decompositions and hence have descriptions as random recursive fractals.

In this paper we consider $V$-variable fractals recently introduced in \cite{5,6}. This class of random fractals is defined via a family of iterated function systems and a positive integer parameter $V$. It interpolates between the class of homogeneous (scale irregular) random fractals, corresponding to $V = 1$, and the class of random recursive fractals, corresponding to $V = \infty$. As for the random recursive fractals we can regard these $V$-variable fractals as determined by a probability measure on the set of labelled trees. In this case the measure is not a product measure, but is defined in a natural (if not completely obvious) manner which allows for at most $V$ distinct subtrees rooted at each level.

Our aim in this paper is to investigate the analytic properties of the class of $V$-variable Sierpinski gaskets and to compare their behaviour to the scale irregular and random recursive cases. We show their Hausdorff dimension in the resistance metric is the zero of a certain pressure function and their spectral dimension, the exponent for the growth of the eigenvalue counting function, is the zero of another pressure function. The connection between these two dimensions is established. We develop and extend standard methodology to examine more detailed properties of the eigenvalue counting function and the on-diagonal heat kernel. These results show that the $V$-variable fractals are closer to the scale irregular case, in that their fine properties are generally determined by fluctuations in scale rather than fluctuations which occur spatially across the fractal.

\section*{Model problems}

We consider two model problems. Recall from \cite{24} the description of a self-similar set as an iterated function system (or IFS) at each node of a tree generated by the address space.

\subsection*{Homogeneous and random recursive fractals}

For the first model problem we consider the two IFSs generating the Sierpinski gasket fractal SG(2) and the fractal SG(3) defined in \cite{16}. The scale factors for SG(2) are mass $m_2 = 3$, length $l_2 = 2$ and time $s_2 = 5$. For SG(3) we have mass $m_3 = 6$, length $l_3 = 3$ and time $s_3 = 90/7$. The conductance scale factors can be computed directly, or from the Einstein relation $\rho = s/m$, giving $\rho_2 = 5/3$, $\rho_3 = 15/7$. Let $(M, S, L)$ be a triple of random variables taking each of the values $(m_i, s_i, l_i)$ where $i = 2, 3$ with probabilities $p, 1 - p$ respectively.

Then, for the $V = 1$ (homogeneous) case, we construct a random fractal using a sequence taking its values in \{2, 3\} and applying the corresponding IFS to all sets at a given level of construction. A realization of the first few stages can be seen in Figure 2. Then a simple scaling analysis shows that the Hausdorff dimension is given by $d_f = \mathbb{E} \log M/\mathbb{E} \log L$ where $\mathbb{E}$ denotes the expectation with respect to the probability measure generating the sequence. For the spectral dimension with respect to the natural “flat measure” one can extend the idea from \cite{14} and \cite{33} in the case of a single IFS fractal and apply a scaling argument to the Dirichlet form together with a Dirichlet–Neumann bracketing argument, see \cite{18}. This gives the spectral dimension $d_s = 2\mathbb{E} \log M/\mathbb{E} \log S$. For the $V = \infty$ (random recursive) case, each IFS is chosen independently for each node at each level. In this case we have $d_s = 2d_f/(d_f + 1)$ where $d_f$ is the Hausdorff dimension in the resistance metric, that is $d_f$ is such that $\mathbb{E}(M(S/M)^{-d_f}) = \mathbb{E}M^{1+d_f}S^{-d_f} = 1$. The argument again uses scaling properties of the Dirichlet form and a Dirichlet–Neumann bracketing argument, see \cite{18,19}. An alternative approach to computing the spectral dimension for random $V = 1, \infty$ fractals is via heat kernel estimates, see \cite{2} and \cite{16–19}.

The second model problem is drawn from the class of affine nested fractals considered in \cite{13}. This model interpolates between the slit triangle (which is not itself an affine nested fractal) and SG(3). Consider 7 triangles in the configuration shown in Figure 1 and take $\ell$ as the side length of the three triangles at the corners of the original triangle. The side lengths of the other triangles are given as $1 - 2\ell$ for the three triangles on the centre of each side and $3\ell - 1$ for the downward pointing central triangle, where $1/3 < \ell < 1/2$. As $\ell \to 1/2$ we have the slit triangle and at $\ell = 1/3$ we have SG(3). We construct a homogeneous random or random recursive fractal by taking a suitable distribution for $\ell$ on $[1/3, 1/2)$ and either using a sequence, applying the same IFS at each node in the construction tree for the $V = 1$ case, or independently choosing an IFS for each node in the $V = \infty$ case.
Fig. 1. A member of the family of Sierpinski gaskets interpolating SG(3) and the slit triangle, where $1/3 < \ell < 1/2$.

Fig. 2. The level 3 approximation to a 1-variable tree, and the prefractal approximation to the associated 1-variable, or scale irregular, fractal. Here the family of IFSs is $F = \{F(2), F(3)\}$ with members generating the sets SG(2) and SG(3) respectively.

We note that even scale irregular ($V = 1$) affine nested gaskets of this type have not been treated before and as a consequence of our results we will be able to calculate the Hausdorff and spectral dimension for the random homogeneous version ($V = 1$). By the triangle-star transform, if we assume that the resistance of each piece is proportional to its length, then the resistance scale factor is $(2\ell + 1)/(\ell + 2)$ in that if we take resistances on the three different types of triangle to be $(\ell + 2)/(2\ell + 1)(\ell, 1 - 2\ell, 3\ell - 1)$ then this is electrically equivalent to the triangle with unit resistance on each edge.

In Section 2 we recall from [7] the Hausdorff dimension result for $V$-variable fractals, and we derive the spectral dimension from our calculations in Sections 4 and 5.

$V$-variable fractals

To understand the $V$-variable versions of our model problems, first consider the $V = 1$ (spatially homogeneous, scale irregular) case of a $V$-variable labelled tree in a manner parallel to the approach taken in the general setting. See Figure 2. For $V = 1$ all subtrees rooted at each fixed level are the same, as are the corresponding subfractals at each fixed level, hence the terminology “homogeneous.” The subfractals at one level are typically not the same as the subtrees at another level, hence the terminology “scale irregular.”

For a general $V$-variable tree and for the corresponding $V$-variable fractal, there are at most $V$ distinct subtrees up to isomorphism rooted at each fixed level, and correspondingly at most $V$ distinct subfractals up to rescaling at each fixed level of refinement. See Figure 3 for a level 2 approximation to a $V$-variable tree with $V \geq 2$. In Section 2 we discuss this in some detail and see that there is a natural probability distribution on the class of $V$-variable fractals for each fixed $V$.

The construction of $V$-variable trees and hence $V$-variable fractals will require an assignment of a type chosen from $\{1, \ldots, V\}$, as well as an IFS, to each node of the tree. Nodes with the same type and at the same level will have identical subtrees rooted at those nodes. The subfractals corresponding to those nodes will be identical up to scaling. See Figure 4. We choose the IFSs according to a probability measure and will write $P_V$ for the probability measure on the space of trees or $V$-variable fractals and $E_V$ for expectation with respect to $P_V$.

Let $n(1)$ be a random variable denoting the first level after level 0 at which all nodes are assigned the same type, see (13). Since the number of types is finite and we will assume a uniform upper bound on the branching number, $E_V n(1) < \infty$. Note that $n(1) = 1$ if $V = 1$, and clearly $E_V n(1)$ increases with $V$. 
Spectral asymptotics for $V$-variable Sierpinski gaskets

Fig. 3. Level 2 approximations to an IFS tree and to the associated fractal. Here $F = (F(2), F(3))$ contains the IFSs generating SG(2) and SG(3) respectively. Edges of the tree with a given initial node are enumerated from left to right; they correspond to subcells enumerated anticlockwise from the bottom left corner of the cell corresponding to the given node.

We write $i = i_1 \cdots i_k$ for a node in the tree and denote its height or length by $|i| = k$. The root node is denoted by $\emptyset$ and $|\emptyset| = 0$. The Hausdorff dimension $d_f$ of the $V$-variable gasket formed from SG(2) and SG(3) is given $P_V$ almost surely by the zero of a pressure function in that ($P_V$ almost surely) it is the unique $d_f$ such that $E_V \log \sum_{|i|=n(1)} (\ell_{i_1} \cdots \ell_{i_n})^{d_f} = 0$, where $\ell_{i_k}$ is the length contraction factor $1/2$ or $1/3$ according to which of SG(2) or SG(3) is chosen. See Theorem 2.18, also Theorem 2.19 for the general statement.

Results

For further detail see the Overview at the beginning of the following Sections 2–5.

Our main results first establish an expression for the spectral exponent over a general class of measures and determine the spectral dimension for these fractals. We then provide finer results of two types. We consider the eigenvalue counting function and the on-diagonal heat kernel and obtain upper and lower bounds on these quantities which hold for a large set of $V$-variable trees. Under the probability measure $P_V$ on the trees we obtain $P_V$ almost sure results capturing more explicitly their fluctuations. In the model problems the expectation is either over a discrete measure on $\{2, 3\}$ or over a suitable distribution on $[1/3, 1/2]$.

We show in Theorem 4.13 that the spectral exponent can also be expressed as the zero of a pressure function. In Theorems 4.15 and 4.17 we see that the spectral dimension, the maximum value of the spectral exponent over all measures $\mu$ defined using a product of weights, satisfies the equation $d_f / 2 = d'_f / (d'_f + 1)$ where $d'_f$ is the Hausdorff dimension in the resistance metric. This dimension in turn is the zero of another pressure function, see Theorem 3.12.

We establish upper and lower estimates for the eigenvalue counting function and on-diagonal heat kernel for a general class of measures. We show that the observed fluctuations arise from two different effects. The first is due to global scaling fluctuations as observed for scale irregular nested Sierpinski gaskets [2]. The second effect, which arises in the $V$-variable setting for $V > 1$ or $V = 1$ when the contraction factors are not all the same, gives additional, though much smaller, fluctuations due to the spatial variability of these fractals.

We first establish from Lemma 4.6 the non-probabilistic result that for a large set of all possible $V$-variable trees, if $\mathcal{N}(\lambda)$ denotes the number of eigenvalues less than $\lambda$ (for the Dirichlet or Neumann Laplacian), then there is a time scale factor $T_k$, a mass scale factor $M_k$ and a correction factor $A_k$, such that there are constants $c_1, c_2$ with

$$c_1 M_k \leq \mathcal{N}(A_k T_k) \quad \text{and} \quad \mathcal{N}(T_k) \leq c_2 M_k \quad \forall k.$$ 

In the scale irregular gaskets of [2], and the $V = 1$ case here, this result is true for all realizations. By construction the scale factors $M_k, T_k$ grow exponentially in $k$ but we will be able to show that $P_V$ almost surely we have $A_k \leq c k^\beta$, for some constants $c, \beta$. The spectral exponent for any measure $\mu$ defined by a set of weights associated with a given IFS is

$$\frac{d_s(\mu)}{2} := \lim_{\lambda \to \infty} \frac{\log \mathcal{N}(\lambda)}{\log \lambda},$$

and we give a formula for this quantity as the zero of a suitable pressure function. In the case where the weights are “flat” in the resistance metric we can show that there is a function $\phi(\lambda) = \exp(\sqrt{\log \lambda} \log \log \log \lambda)$ such that
Fig. 4. Approximations to a 4-variable tree and the prefractal approximations to the corresponding 4-variable fractal. The IFSs are $F(2)$ and $F(3)$ generating SG(2) and SG(3). The environment at each level is applied to the approximation at the previous level. The IFS labels are not shown since in this case they are determined by the branching number.

For large $\lambda$, where $d_s = 2d_f^r/(d_f^r + 1)$ and $d_f^r$ is the Hausdorff dimension in the resistance metric.

$$P_V\text{-almost surely}$$

$$c_1 \lambda^{d_s/2} \phi(\lambda)^{-c_2} \leq \mathcal{N}(\lambda) \leq c_3 \lambda^{d_s/2} \phi(\lambda)^{-c_4},$$

(1)
To compare our results with previous work we note that in the $V = 1$ case for nested Sierpinski gaskets it is shown in [2] that the Weyl limit for the normalized counting function does not exist in general and we have for all realizations that
\[ c_1 M_k \leq \mathcal{N}(T_k) \leq c_2 M_k. \]
This leads to the same size scale fluctuations as for the $V$-variable case given in (1). For the random recursive case of [19], the averaging leads to a Weyl limit in that
\[ \lim_{\lambda \to \infty} \frac{\mathcal{N}(\lambda)}{\lambda^d/2} \exists P_\infty \text{ a.s.,} \]
where $d_\epsilon = 2d_f/(d_f + 1)$ and $d_f$ is the Hausdorff dimension in the resistance metric.

We will also be able to obtain bounds on the on-diagonal heat kernel. We note that the measures we work with in this setting do not have the volume doubling property and hence it is harder work to produce good heat kernel estimates. In the setting considered here we can extend the arguments of [2] and [4] to get fluctuation results for the heat kernel. In Theorems 5.5 and 5.8 we show that the on-diagonal heat kernel estimate is determined by the local environment. In the case where the measure is the “flat” measure in the resistance metric we can describe the small time global fluctuations in that, $P_V$ almost surely for any point $x$ in the fractal,
\[ c_1 t^{-d_\epsilon/2} \phi(1/t)^{-c_2} \leq p_t(x, x) \leq c_3 t^{-d_\epsilon/2} \phi(1/t)^{c_4}, \quad 0 < t \leq c_5, \]
for suitable deterministic constants $c_1, c_2, c_3, c_4$, and for all $t \leq c_5$, a random constant independent of the point $x$. These are of the same order as the $V = 1$ case obtained in [2] and much larger than those in the random recursive case, [21].

In the case of general measures we will see that $P_V$-almost surely, $\mu$-almost every $x$ in the fractal does not have the same spectral exponent as the counting function (except when we choose the flat measure) and thus there will be a multifractal structure to the local heat kernel estimates in the same way as observed in [4,20].

We restrict ourselves to affine nested fractals based on the Sierpinski gasket in $\mathbb{R}^d$ where $d \geq 2$. The problem of the existence of a limiting Dirichlet form is not solved more generally, even for the case of homogeneous random fractals. If this problem were solved, then the techniques used here would enable more general results to be obtained concerning $V$-variable fractals constructed from more general p.c.f. self-similar sets.

The structure of the paper is as follows. We give the construction of $V$-variable affine nested fractals in Section 2. We show that by using the structure of $V$-variability there is a natural decomposition of the fractals at “necks”; a level at which all subtrees are the same. This idea was first used by Scealy in [37]. In Section 3 we focus on $V$-variable affine nested Sierpinski gaskets and we construct the Dirichlet form, compute the resistance dimension, and determine other properties which will facilitate analysis on these sets. In Section 4 we treat their spectral asymptotics. The heat kernel is dealt with in Section 5.

2. Geometry of $V$-variable fractals

2.1. Overview

Random $V$-variable fractals are generated from a possibly uncountable family $F$ of IFSs. Each individual IFS $F \in F$ generates an affine nested fractal. We also impose various probability distributions on $F$.

For motivation, consider the two model problems in the Introduction. Namely, $F = \{F_2, F_3\} =$ the pair of IFSs generating $\text{SG}(2)$ and $\text{SG}(3)$, or $F$ is the family of affine nested fractals $F_\ell$ generating the prefractal in Figure 1 for $\ell \in [1/3, 1/2]$.

A $V$-variable tree corresponding to $F$ is a tree with an IFS from $F$ associated to each node, a type from the set $\{1, \ldots, V\}$ associated to each node, and such that if two nodes at the same level have the same type, then the corresponding (labelled) subtrees rooted at those two nodes are isomorphic. This last requirement is achieved by using a sequence of environments, one at each level, to construct a $V$-variable tree. Each $V$-variable tree generates a $V$-variable fractal set in the natural way. We define a natural probability measure $P_V$ on the space of $V$-variable trees.
(and fractals). The case $V = 1$ corresponds to homogeneous fractals and $V \rightarrow \infty$ corresponds to random recursive fractals.

If all nodes at some level have the same type, the level is called a neck. Under $P_V$, neck levels are given by a sequence of independent geometric random variables. In Lemma 2.16 we record some useful results for such random variables. In Section 2.7 we recall the Hausdorff dimension result from [7] but in the framework of necks as used in this paper, and then give a refinement by using the law of the iterated logarithm. This provides motivation for some of the spectral results.

2.2. Families of affine nested fractals

Let $F$ be a possibly uncountable class of IFSs $F$, each generating a compact fractal $K_F$, and each defined via a set of similitudes $\{\psi_i^F\}_{i \in SF}$ acting on $\mathbb{R}^d$, $d \geq 2$, with contraction factors $\{\ell_i^F\}_{i \in SF}$ and $SF = \{1, \ldots, N^F\}$. If it is clear from the context we write $K$, $\psi_i$, $N$ and $S$ for $K_F$, $\psi_i^F$, $N^F$ and $SF$ respectively, and similarly for other notation.

We will have

\[ 3 \leq d + 1 \leq N_{\inf} := \inf \{N^F : F \in F\} \leq \sup \{N^F : F \in F\} =: N_{\sup} < \infty, \]

\[ 0 < \ell_{\inf} := \inf \{\ell^F_i : 1 \leq i \leq N_F, F \in F\} \leq \sup \{\ell^F_i : 1 \leq i \leq N_F, F \in F\} =: \ell_{\sup} < 1. \]

The first inequality follows from our later constructions, see (12). The other inequalities are for technical reasons arising in the proof of Lemma 2.9 and in the study of the heat kernel and spectral asymptotics. See also the comments after Definition 2.14, from which it is clear that weaker conditions will suffice to construct $V$-variable fractals and establish their Hausdorff dimension.

Let $\Psi^F$ denote the set of fixed points of the $\{\psi_i^F\}_{i \in SF}$. Then $x \in \Psi^F$ is an essential fixed point if there exists $y \in \Psi^F$ and $i \neq j$ such that $\psi_i^F(x) = \psi_j^F(y)$. Let $V_0$ denote the set of essential fixed points.

We always assume that $V_0$ does not depend on $F$ and is non-empty.

Assume the uniform open set condition for the $\{\psi_i^F\}$. That is, there is a non-empty, bounded open set $O$, independent of $F$, such that $\{\psi_i^F(O)\}_{i \in SF}$ are disjoint and $\bigcup_{i \in SF} \psi_i^F(O) \subset O$.

Let $\psi_{i_1 \ldots i_n} = \psi_{i_1} \circ \cdots \circ \psi_{i_n}$ and let

\[ V_n^F = \bigcup_{i_1, \ldots, i_n \in SF} \psi_{i_1 \ldots i_n}(V_0), \quad V_n^* = \bigcup_{n \geq 0} V_n^F. \]

Then $K_F = cl(V_0^F)$, the closure of $V_0^F$.

For $i_1, \ldots, i_n \in SF$, we call $\psi_{i_1 \ldots i_n}(V_0)$ an n-cell and $\psi_{i_1 \ldots i_n}(K_F)$ an n-complex.

For $x, y \in \mathbb{R}^d (x \neq y)$, set $H_{xy} = \{z \in \mathbb{R}^d : |z - x| = |z - y|\}$ and let $U_{xy} : \mathbb{R}^d \rightarrow \mathbb{R}^d$ be the reflection transformation with respect to $H_{xy}$.

When we discuss analysis on $V$-variable fractals we further assume each $K_F$ is an affine nested fractal. That is, the open set condition holds, $|V_0| \geq 2$, and:

(1) $K_F$ is connected;
(2) (Nesting) If $(i_1, \ldots, i_n)$ and $(j_1, \ldots, j_n)$ are distinct n-tuples of elements from $SF$, then
\[ \psi_{i_1 \ldots i_n}(K_F) \cap \psi_{j_1 \ldots j_n}(K_F) = \psi_{i_1 \ldots i_n}(V_0) \cap \psi_{j_1 \ldots j_n}(V_0); \]
(3) (Symmetry) For $x, y \in V_0(x \neq y)$, $U_{xy}$ maps n-cells to n-cells, and it maps any n-cell which contains elements in both sides of $H_{xy}$ to itself for each $n \geq 0$.

We also make the technical assumption that $|\psi_i^F(V_0) \cap \psi_j^F(V_0)| \leq 1$ for all $1 \leq i < j \leq N_F$.

2.3. Trees and recursive fractals

Fix a family $F$ of IFSs as before. For our initial purposes it is sufficient only that the IFSs consist of uniformly contractive maps on $\mathbb{R}^d$. 
Each realisation of a random fractal is built by means of an **IFS construction tree**, or **tree** for short, defined as follows.

**Definition 2.1 (See Figure 3).** An (**IFS construction**) tree $T$ corresponding to $F$ is a tree with the following properties:

1. There is a single, level 0, root node $\emptyset$; 
2. The branching number $N^i$ at each node $i$ has $2 \leq N^i < \infty$ $(N^i \geq 3$ later$)$ ;
3. The edges with initial node $i$ are numbered (“left to right”) by $1, \ldots, N^i$; where $i = i_1 \cdots i_k$ in the usual manner and $|i| := k \geq 1$ is the level of $i$, or $i = \emptyset$ in which case $|i| := 0$ is the level;
4. There is an **IFS** $F^i \in F$ associated with each node $i$, $N^i = |F^i|$ (the cardinality of $F^i$), and the $k$th edge with initial node $i$ is associated with the $k$th function in the **IFS** $F^i$.

The unique compact set $K = K(T)$ associated with $T$ in the usual manner is called a **recursive fractal**.

**Notation 2.2.** The **boundary** $\partial T$ of a tree $T$ is the set of infinite paths through $T$ beginning at $\emptyset$.

For $i \in T$ the cylinder set $[i] \subset \partial T$ is the set of all infinite paths $w \in \partial T$ such that $i$ is an initial segment of $w$, written $i \prec w$, with the same notation also for $i, w \in T$.

The concatenation of two sequences $i$ and $j$, where $i$ is of finite length, is denoted by the juxtaposition $ij$.

The truncation of $i$ to the first $n$ places is defined by $i|n = i_1 \cdots i_n$.

A **cut** for the tree $T$ is a finite set $\Lambda \subset T$ with the property that for every $w \in \partial T$ there is exactly one $i \in \Lambda$ such that $i \prec w$. Equivalently, $\{i|n : i \in \Lambda\}$ is a partition of $\partial T$.

For a tree $T$ and a node $i \in T$, there will usually be associated quantities such as an **IFS** $F^i$, a type $\tau^i \in \{1, \ldots, V\}$ (see Definition 2.4) or a branching number $N^i$. In this case $i$ is shown as a **superscript**.

In particular, the **transfer operator** $\sigma^i$ acts on $T$ to produce the tree $\sigma^iT$, where, writing $T^j$ for the address of node $j$,

$$(\sigma^iT)^j := T^ij. \tag{4}$$

That is, $\sigma^iT$ is the subtree of $T$ which has its base (or root) node at $i$.

We frequently need to multiply a sequence of quantities, or compose a sequence of functions, along a finite branch corresponding to a node $i = i_1 \cdots i_n$ of $T$. In this case, $i$ is shown as a **subscript**. For example, if $i = i_1 \cdots i_n$ then, with some abuse of notation for the second term,

$$\ell_i := \ell_{i_1} \cdots \ell_{i_n} := \ell^{F_{i_1}}_{i_1} \cdot \ell^{F_{i_1i_2}}_{i_2} \cdot \ell^{F_{i_1i_2i_3}}_{i_3} \cdots \ell^{F_{i_1i_2\cdots i_n-i_{n-1}}}_{i_n} \tag{5}$$

is the product of scaling factors corresponding to the edges along the branch $i_1 \cdots i_n$, and analogously for other scaling factors. Similarly,

$$\psi_i := \psi_{i_1} \circ \cdots \circ \psi_{i_n} := \psi^{F_{i_1}}_{i_1} \circ \psi^{F_{i_1i_2}}_{i_2} \circ \psi^{F_{i_1i_2i_3}}_{i_3} \circ \cdots \circ \psi^{F_{i_1i_2i_3\cdots i_{n-1}}}_{i_n} \tag{6}$$

is the composition of functions along the same branch.

**Notation 2.3 (Cells and complexes).** The recursive fractal $K = K(T)$ generated by $T$ satisfies

$$K(T) = \bigcup_{i=1}^{N^\emptyset} \psi_i^{F^i}(K(\sigma^iT)) = \bigcup_{|i|=n} \psi_i(K(\sigma^iT)), \tag{7}$$

where the second equality comes from iterating the first.

For $|i| = n$ the $n$-**complex** and $n$-**cell** with address $i$ are respectively

$$K_i = \psi_i(K(\sigma^iT)), \quad \Delta_i := \psi_i(V_0), \tag{8}$$

recalling that $V_0$ is the set of essential fixed points of $F \in F$ and is the same for all $F$.
We will need various sequences of graph approximations \( \{G_n\}_{n=0}^{\infty} \) to the fractal \( K(T) \). In particular we use the notation \( G_n = (V_n, E_n) \), where \( G_0 = (V_0, E_0) \) is the complete graph on \( V_0 \) and

\[
V_n := \bigcup_{|i|=n} \psi_i(V_0) = \bigcup_{|i|=n} \Delta_i, \quad E_n := \bigcup_{|i|=n} \psi_i(E_0).
\]

We can recover the fractal itself as \( K(T) = cl(\bigcup_n V_n) \), where \( cl \) denotes closure.

We will write \( x \sim_n y \) for \( x, y \in V_n \) if \( x, y \) are connected by an edge in \( E_n \).

### 2.4. V-Variable trees and V-variable fractals

Fix a natural number \( V \). For motivation see Figure 4.

The following definition of a \( V \)-variable tree and \( V \)-variable fractal is equivalent to that in [6] and [7], but avoids working with \( V \)-tuples of trees and fractals.

**Definition 2.4.** A \( V \)-variable tree corresponding to \( F \) is an IFS construction tree \( T \) corresponding to \( F \), with a type \( \tau^i \in \{1, \ldots, V\} \) associated to each node \( i \). Moreover, if two nodes \( i \) and \( j \) at the same level \( |i| = |j| \) have the same type \( \tau^i = \tau^j \), then:

1. \( i \) and \( j \) have the same associated IFS \( F^i = F^j \) and hence the same branching number \( N^i = N^j \);
2. comparable successor nodes \( i_1 \) and \( j_1 \), where \( 1 \leq p \leq N^i = N^j \), have the same type \( \tau^{i_1} = \tau^{j_1} \).

The recursive fractal \( K = K(T) \) associated to a \( V \)-variable tree \( T \) as above is called a \( V \)-variable fractal corresponding to \( F \).

The class of \( V \)-variable trees and class of \( V \)-variable fractals corresponding to \( F \) are denoted by \( \Omega_V = \Omega^F_V \) and \( K_V = K^F_V \) respectively.

**Remark 2.5.** A \( V \)-variable tree has at most \( V \) distinct IFSs associated to the nodes at each fixed level. If two nodes at the same level of a \( V \)-variable tree have the same type then the subtrees rooted at these two nodes are identical, i.e.

\[
|i| = |j| \quad \text{and} \quad \tau^i = \tau^j \implies \sigma^i T = \sigma^j T.
\]

In particular, for each level, there are at most \( V \) distinct subtrees rooted at that level.

A 1-variable tree is essentially the same as an IFS tree which generates a scale irregular or homogeneous fractal as in [16,18] and [2].

The following is used in the construction and analysis of \( V \)-variable fractals.

**Definition 2.6.** An environment \( E \) assigns to each type \( v \in \{1, \ldots, V\} \) both an IFS \( F_v \in F \) and a sequence of types \( (\tau_v,i)_{i=1}^{F_v} \), where \( |F_v| \) is the number of functions in \( F_v \). We write

\[
E = (E(1), \ldots, E(V)), \quad E(v) = (F_v, \tau_v, E_v(1), \ldots, (E_v)_{E_v(1)}).
\]

For a pictorial example see Figure 4. For the following consider the case \( n = 2 \) in Figure 4.

**Construction 2.7.** A \( V \)-variable tree is constructed from a sequence of environments \( (E^k)_{k \geq 1} \) in the natural way as follows:

- **Stage 0:** Begin with the root node \( \emptyset \) and an initial type \( \tau^\emptyset \) assigned to this node.
- **Stage 1:** Use \( E^1 \) and the type \( \tau^\emptyset \) in the natural way to assign an IFS to the level 0 node, construct the level 1 nodes and assign a type to each of them.

More precisely, use \( E^1(v) \) where

\[
v := \tau^\emptyset, \quad E^1(v) = (F_v, \tau_v, E_v(1), \ldots, (E_v)_{E_v(1)}).
\]
to assign the IFS $F^\emptyset := F^E_\emptyset$ to the node $\emptyset$ and in particular determine the branching number $N^\emptyset := |F^E_\emptyset|$ at $\emptyset$, and to assign the type $\tau^j := \tau^E_{v,j}$ to each level 1 node $j$

Stage $n$: (By the completion of stage $n - 1$ for $n \geq 2$, an IFS $F^i$ will have been assigned to each node $i$ of level $|i| \leq n - 2$, all nodes $j$ of level $|j| \leq n - 1$ will have been constructed and a type $\tau^j$ will have been assigned to each.)

Use $E^n_i$ in the natural way to assign an IFS to each level $n - 1$ node according to its type, to construct the level $n$ nodes and to assign a type to them.

More precisely, use $E^n(v)$ for $1 \leq v \leq V$ where 

$$E^n(v) = (F^E_{v,n}, \tau^E_{v,1}, \ldots, \tau^E_{v,|F^E_n|,})$$

to assign the IFS $F^i := F^E_\emptyset$ to each level $n - 1$ node $i$ of type $v$ and in particular to determine the branching number $N^i := |F^E_{v,n}|$ at the node $i$, and to assign the type $\tau^{i,j} := \tau^E_{v,i,j}$ to the level $n$ node $i,j$.

It follows by an easy induction that the properties in Definition 2.4 hold at all nodes.

Assumption 2.8. In the following lemma, and in Section 3 and subsequently, we assume

$$V_0 \text{ is the set of vertices of an equilateral tetrahedron in } \mathbb{R}^d \text{ for some } d \geq 2,$$

$$E_0 \text{ is the set of edges such that } G_0 = (V_0, E_0) \text{ is the complete graph on } V_0.$$

To emphasise this we often write “$V$-variable gasket” for “$V$-variable fractal,” “gasket” for “fractal” etc.

Moreover, we take the open set $O$ in the open set condition to be the interior of the tetrahedron with vertex set $V_0$ and assume the uniform nesting condition; that is condition (2) of the definition of affine nested fractal in Section 2.2 with $K^F$ replaced by $\overline{O}$.

We note that under our assumption that $\ell_{\sup} < 1$ we have that $\{K_i\}_{i \in \mathbb{N}}$ is a decreasing sequence of closed sets and thus has a non-empty limit. Thus, for any $V$-variable fractal $K$, there is a well defined address map $\pi : \partial T \rightarrow K$ with $\{\pi(i)\} = \bigcap_{n=1}^{\infty} K_{i,n}$. Under the open set condition we know that for $x \in K$ we have $\pi^{-1}(x)$ is a finite set, see Falconer [12], Lemma 9.2.

Lemma 2.9. Let $K$ be a $V$-variable gasket. Then

1. $K$ is pathwise connected and hence connected;
2. $K$ is nested: For all $i, j \in T$, if $[i] \cap [j] = \emptyset$, then $\psi_i(\overline{O}) \cap \psi_j(\overline{O}) = \psi_i(V_0) \cap \psi_j(V_0)$ and hence $K_i \cap K_j = \psi_i(V_0) \cap \psi_j(V_0)$.

Proof. (1) Fix a vertex $x_0 \in V_0$. Suppose $\pi(i), \pi(j) \in K$. For each $n$ there is a polygonal path in $K$ joining $\psi_{i,n}(x_0)$ to $\psi_{j,n}(x_0)$, given by a continuous function $f_n : [0,1] \rightarrow K$. Moreover, using the uniform bounds $N_{\sup} < \infty$ and $\ell_{\sup} < 1$, these paths can clearly be constructed so they converge uniformly to a continuous function $f : [0,1] \rightarrow K$. (See the proof of Theorem 1.6.2 in [29].) This establishes pathwise connectedness.

(2) In our setting this is straightforward to see as if $[i] \cap [j] = \emptyset$, there exists a $k$ of maximal length with $k \prec i$ and $k \prec j$, such that $\psi_k(\overline{O}) \subset \psi_k(\overline{O})$ and $\psi_k(\overline{O}) \subset \psi_k(\overline{O})$. If we write $i = k_{i_1} \cdots$ and $j = k_{j_1} \cdots$, then $i_1 \neq j_1$ and by the uniform nesting condition in Assumption 2.8 we have $\psi_{k_{i_1}}(\overline{O}) \cap \psi_{k_{j_1}}(\overline{O}) = \psi_{k_{i_1}}(V_0) \cap V_{k_{j_1}}(V_0)$. If the intersection is empty we are done. Otherwise, by our technical assumption on affine nested fractals (at the end of Section 2.2) that $|\psi_{k_{i_1}}^E(V_0) \cap \psi_{k_{j_1}}^E(V_0)| \leq 1$, there is a single intersection point which is the image of a fixed point in $V_0$. If $\psi_k(\overline{O}) \cap \psi_k(\overline{O}) \neq \emptyset$, this is the intersection point of $\psi_k(\overline{O}) \cap \psi_k(\overline{O})$ and therefore of $\psi_k(V_0) \cap \psi_k(V_0)$ as required. If $\psi_k(\overline{O}) \cap \psi_k(\overline{O}) = \emptyset$ we are done. \qed
2.5. Random $V$-variable trees and random $V$-variable fractals

Definition 2.10. Fix a probability distribution $P$ on $F$. This induces a probability distribution $P_V$ on the set of environments as follows. Choose the IFSs $F^E_v$ for $v \in \{1, \ldots, V\}$ in an i.i.d. manner according to $P$. Choose types $\tau^E_{v,j}$ for $1 \leq j \leq |F^E_v|$ in an i.i.d. manner according to the uniform distribution on $\{1, \ldots, V\}$ and otherwise independently of the $F^E_w$.

Definition 2.11. The probability distribution on the set $\Omega_V$ of $V$-variable trees is obtained by choosing $\tau^\emptyset \in \{1, \ldots, V\}$ according to the uniform distribution and independently choosing the environments at each stage in an i.i.d. manner according to $P_V$. This probability distribution on $V$-variable trees induces a probability distribution on the set $K_V$ of $V$-variable fractals. Both the probability distribution on trees and that on fractals are denoted by $P_V$. We will write $E_V$ for expectation with respect to $P_V$.

Random $V$-variable trees and random $V$-variable fractals are random labelled trees and random compact subsets of $\mathbb{R}^d$ respectively, having the distribution $P_V$. Later, when we add additional scale factors for resistance and weights associated with each $F \in F$, we will assume they are measurable with respect to $F \in F$.

Although the distribution $P_V$ on environments is a product measure, this is far from the case for the corresponding distribution $P_V$ on $\Omega_V$ and $K_V$. There is a high degree of dependency between the types (and hence the IFSs) assigned to different nodes at the same level.

Remark 2.12. The classes $K_V$ interpolate between the class of homogeneous fractals in the case $V = 1$ and the class of recursive fractals as $V \to \infty$. The probability spaces $(K_V, P_V)$ interpolate between the natural probability distribution on homogeneous fractals in the case $V = 1$ and the natural probability distribution on the class of recursive fractals as $V \to \infty$. See [5] and [6].

Notation 2.13. It will often be convenient to identify the sample space for random quantities such as trees, fractals, functions associated to a branch of a tree, etc., with the set $\Omega_V$ of $V$-variable trees. We use $\omega$ to denote a generic element of $\Omega_V$ and combine this with other notations in the natural manner. Thus we may write $T^\omega$, $K^\omega$, $\psi^\omega_i$, etc.

In particular, $\sigma^t \omega$ is the transfer operator defined in Notation 2.2 for a tree $T$. See for example the first equality in (27). However, we usually suppress $\omega$ as in the second equation in (27).

2.6. Necks

The notion of a neck is critical for the analysis that follows.

Definition 2.14. The environment $E$ in Definition 2.6 is a neck if all $\tau^E_{v,i}$ are equal.

A neck for a $V$-variable tree $\omega$ is a natural number $n$ such that the environment $E$ applied at stage $n$ in the construction of $\omega$ is a neck environment. In this case we say a neck occurs at level $n$. If $i$ is a node in $\omega$ and $|i| = n$, then $i$ is called a level $n$ neck node.

If a neck occurs at level $n$ then the type assigned to every node at that level is the same. See Figure 5. It follows from Remark 2.5 that all subtrees rooted at level $n$ will be the same. Note that the subtrees themselves are only constructed at later stages, and even the common value of the IFS at a level $n$ neck node is not determined until stage $n + 1$.

There is however no restriction on the IFSs occurring in a neck environment $E$. For a level $n$ neck these IFSs are applied at level $n - 1$.

Because there is an upper bound on the number of functions $N^F$ in any IFS $F \in F$, there is only a finite number of type choices to be made in selecting an environment. It follows that necks occur infinitely often almost surely with respect to the probability $P_V$ defined in Definition 2.11. The sequence of neck levels in the construction of a $V$-variable tree or fractal is denoted by

$$0 = n(0) < n(1) < \cdots < n(k) < \cdots.$$  

(13)
Under $P_V$ the sequence $\{n(k) - n(k - 1)\}_{k=1}^{\infty}$ of times between necks is a sequence of independent and identically distributed geometric random variables, and in particular the expected first neck satisfies

$$E_V n(1) < \infty.$$  \hfill (14)

Many of our future estimates rely on various a.s. properties of necks. However, some estimates just require that there be an infinite sequence of necks satisfying a certain condition. For this reason we make the definition:

**Definition 2.15.** For $0 < a \leq 1$ let $\Omega_{V,a} \subset \Omega_V$ be the set of $V$-variable trees with an infinite sequence of necks satisfying

$$\sum_{j} a^{n(j) - n(j-1)} = \infty.$$

We next give an elementary result on the asymptotic behaviour of a sequence of geometric random variables $(Y_k)_{k \geq 1}$. It follows that $Y_k$ grows at most logarithmically in $k$, and powers of $Y_k$ grow at most geometrically, with similar results for the maximum and the empirical mean of $\{Y_1, \ldots, Y_k\}$.

The following is standard but included for completeness. Note that the $Y_k$ need not actually be geometric random variables.
Lemma 2.16. Suppose \( \{ Y_k \}_{k=1}^{\infty} \) is a sequence of not necessarily independent random variables with \( P(Y_k > x) \leq A p^x \), for all \( x > 0 \), where \( A > 0 \) and \( 0 < p < 1 \) are constants. Suppose \( n \geq 1 \) is a natural number. Then a.s.

\[
\begin{align*}
\limsup_{k \to \infty} & \frac{Y_{nk}}{\log k} \leq \frac{1}{\log 1/p}, \\
\limsup_{k \to \infty} & \frac{\max_{1 \leq i \leq nk} Y_i}{\log k} \leq \frac{1}{\log 1/p}, \\
\limsup_{k \to \infty} & \frac{\sum_{i=1}^{nk} Y_i}{k \log k} \leq \frac{2n}{\log 1/p}.
\end{align*}
\]

(15) (16)

Proof. The case \( n > 1 \) is a direct consequence of the case \( n = 1 \), which we establish.

Suppose \( \varepsilon > 0 \). Since \( P(Y_k > x) \leq A p^x \) for \( x > 0 \),

\[
\sum_{k \geq 1} P\left( Y_k > \frac{(1 + \varepsilon) \log k}{\log 1/p} \right) \leq A \sum_{k \geq 1} p^{(1+\varepsilon) \log k/(\log 1/p)} = A \sum_{k \geq 1} k^{-(1+\varepsilon)} < \infty.
\]

Hence by the first Borel–Cantelli lemma,

\[
\limsup_{k \to \infty} \frac{Y_k}{\log k} \leq \frac{1 + \varepsilon}{\log 1/p} \text{ a.s.}
\]

Since \( \varepsilon > 0 \) is arbitrary, the first inequality in (15) follows.

The second inequality in (15) is now an elementary consequence. Suppose \( \delta > 0 \). Using the first inequality in (15) to get the second inequality below, \( P \) a.s. there exists \( k_0 = k_0(\omega, \delta) \) such that \( k \geq k_0 \) implies

\[
\max_{k_0 \leq i \leq k} Y_i \leq \max_{k_0 \leq i \leq k} \frac{Y_i}{\log i} \leq \frac{1}{\log 1/p} + \delta.
\]

Hence

\[
\limsup_{k \to \infty} \max_{k_0 \leq i \leq k} \frac{Y_i}{\log k} \leq \frac{1}{\log 1/p} + \delta \text{ a.s.}
\]

Replacing \( k_0 \) by 1 and letting \( \delta \to 0 \) in the above implies the second inequality in (15).

For (16) fix \( \gamma > 0 \). Then

\[
\sum_{k \geq 1} P\left( \sum_{i=1}^{k} Y_i > \frac{\gamma k \log k}{\log 1/p} \right) \leq \sum_{k \geq 1} \sum_{i=1}^{k} P\left( Y_i > \frac{\gamma \log k}{\log 1/p} \right)
\]

\[
\leq \sum_{k \geq 1} k A p^{\gamma \log k/(\log 1/p)} = A \sum_{k \geq 1} k^{1-\gamma} < \infty, \quad \text{if} \ \gamma > 2.
\]

By the first Borel–Cantelli lemma, if \( \gamma > 2 \),

\[
\limsup_{k \to \infty} \frac{\sum_{i=1}^{k} Y_i}{k \log k} \leq \frac{\gamma}{\log 1/p} \text{ a.s.}
\]

This gives (16). \( \square \)

We also include a decomposition of sums of products of scale factors.

It may help to note that the factors on the right side of (18) in the next Lemma are calculated by first choosing and fixing, for each \( j = 1 \cdots k \), an arbitrary node of \( T \) at level \( n(j - 1) \). For fixed \( j \) all subtrees of \( T \) rooted at this level are identical by the definition of a neck. The factor in (18) is the sum, of products of \( s^p_i \) type weights, along all paths in such a subtree starting from its root node and ending at a first neck level node. There is a one-one correspondence between the set of such paths in the subtree and the set of paths in the original tree starting from the chosen node at level \( n(j - 1) \) and ending at a level \( n(j) \) node.
Lemma 2.17. Let $s_i = s_i^F \in \mathbb{R}$ for $i = 1, \ldots, N^F$ be scaling factors associated with each family $F$, where

\[
0 < s_{\inf} := \inf \{ s_i^F : i = 1, \ldots, N^F, F \in F \},
\]

\[
s_{\sup} := \sup \{ s_i^F : i = 1, \ldots, N^F, F \in F \} < \infty.
\]

Then, writing $s_i = s_{i_1} \cdots s_{i_n}$ for $i = i_1 \cdots i_n \in T$, and with $s_i^{(j)}$ defined in the natural way in the body of the proof, we have

\[
\sum_{i \in T, |i| = n(k)} s_i = \prod_{j=1}^k \left( \sum_{|i| = n(j) - n(j-1)} s_i^{(j-1)} \right).
\]

Moreover,

\[
\lim_{k \to \infty} \frac{1}{k} \log \sum_{|i| = n(k)} s_i = E_V \log \sum_{|i| = n(1)} s_i, \quad P_V \text{ a.s.}
\]

Proof. Let $T^{(k)}$ denote the unique subgraph of $T$ rooted at the neck level $n(k)$, so that in particular $T^{(0)} = T$.

Then, as explained subsequently (and following the notation of (5) but with the $F$ there suppressed),

\[
\sum_{i \in T, |i| = n(k)} s_i = \sum_{i \in T, |i| = n(k)} s_{i_1}^{(0)} \cdots s_{i_n}^{(0)} i_{n(1)} \cdots i_{n(n(1)-1)}
\]

\[
= \sum_{i \in T^{(0)}, |i| = n(1)} \left\{ \left( s_{i_1}^{(0)} \cdots s_{i_n}^{(0)} \right) i_{n(1)} \cdots i_{n(n(1)-1)} \right\}
\]

\[
= \sum_{i \in T^{(0)}, |i| = n(1)} \left( s_{i_1}^{(0)} \cdots s_{i_n}^{(0)} \right) i_{n(1)} \cdots i_{n(n(1)-1)}
\]

\[
= \left( \sum_{|i| = n(1)} s_i^{(0)} \right) \left( \sum_{|i| = n(2)-n(1)} s_i^{(1)} \right) \cdots \left( \sum_{|i| = n(k)-n(k-1)} s_i^{(k-1)} \right).
\]

The first and last equality are immediate from the definitions. The second equality is just a bracketing of terms.

For the third equality note that each $n(j)$ is a neck. A term such as $s_{i_{n(1)+1}}^{(1)}$, which corresponds to the edge in $T$ from $i|n(1) = i_1 \cdots i_{n(1)}$ to $i_1 \cdot i_{n(1)+1}$, is independent of $i|n(1)$ and can also be regarded as corresponding to the level one edge from $\mathcal{O}$ to $i_{n(1)+1}$ of the unique tree $T^{(1)}$ rooted at every level $n(1)$ node. Thus we rewrite $s_{i_{n(1)+1}}^{(1)}$ as $s_{i_1}^{(1)}$, with an abuse of notation in that $i$ and $i_{n(1)+1}$ in the first term refer to words from $T = T^{(0)}$ whereas $i_1$ in the second term is the first element of a word from $T^{(1)}$. Similarly, $s_{i_{n(1)+2}}^{(1)}$ is also independent of $i|n(1)$ and can also be regarded as corresponding to a level two edge from $T^{(1)}$, etc. Now use simple algebra to put the summations inside the parentheses.

The final equality is a rewriting of the previous line and provides the definition of $s_i^{(j)}$. 
For the $P_V$ almost sure convergence in (19) let

$$X_k = \log \sum_{|i|=n(k)-n(k-1)} s_i^{(k-1)}, \quad k \geq 1.$$  

By construction the $X_k$ are i.i.d. and in particular $X_1 = \log \sum_{|i|=n(1)} s_i$. By the bounds on $s_i$ we have

$$E_V |X_1| \leq \sum_{n \geq 1} P(n(1) = n) \max \left\{ |\log (N^\sup n s^\sup)|, |\log (N^\inf n s^\inf)| \right\}$$

$$= \max \left\{ |\log (N^\sup s^\sup)|, |\log (N^\inf s^\inf)| \right\} E_V n(1) < \infty.$$  

Hence, using (18), the $P_V$ almost sure convergence follows from the strong law of large numbers for the sequence $\{X_k\}$. \hfill $\square$

### 2.7. Hausdorff and box dimensions

Assume that the family of IFSs $F$ satisfies the open set condition as in Section 2.2. We do not here require the affine nested condition. Recall the notation from Section 2.2 and from Notation 2.2.

Splitting up and treating the necks in the manner here was done first by Scealy in his Ph.D. thesis [37].

**Theorem 2.18.** Suppose $K$ is the random $V$-variable fractal generated from $F$. Then the Hausdorff and box dimension of $K$ is $P_V$ a.s. given by the unique $\alpha$ such that

$$E_V \log \sum_{|i|=n(1)} \ell_i^\alpha = 0.$$  

**Proof.** See the Main Theorem in Section 4.4 of [7]. The expression there for the pressure function is equal to the simpler expression here. This in turn leads to a simpler proof of that theorem, still along the lines of Lemma 5.7 in [7] but working with a single neck as in the (somewhat more complicated) proofs of Theorems 3.12 and 4.13. \hfill $\square$

We give a slight refinement of this result.

**Theorem 2.19.** There exists a constant $C$ such that

$$\limsup_{k \to \infty} \frac{1}{\sqrt{k \log \log k}} \log \sum_{|i|=n(k)} \ell_i^\alpha = C, \quad P_V \text{ a.s.}$$  

**Proof.** We can apply Lemma 2.17 with $s_i = \ell_i^\alpha$.

Since $E_V \log \sum_{|i|=n(1)} \ell_i^\alpha = 0$, \lim$_{k \to \infty} \frac{1}{k} \log \sum_{|i|=n(k)} \ell_i^\alpha = 0$, $P_V$ a.s. Using the bounds (2) on $N^F$ and $\ell^F$ it is easy to check that $E_V (\log \sum_{|i|=n(1)} \ell_i^\alpha)^2 < \infty$. The law of the iterated logarithm for the sequence of random variables $\{X_k\}_{k=1}^\infty$, where $X_k$ is as in the proof of Lemma 2.17 with $s_i = \ell_i^\alpha$, now implies the result. \hfill $\square$

### 3. Analysis on $V$-variable Sierpinski gaskets

#### 3.1. Overview

Recall Assumption 2.8. Our $V$-variable affine nested gaskets are connected and nested by Lemma 2.9 but they need not have spatial symmetry, in contrast to the scale irregular nested gaskets considered in [2].

In order to study analysis on these $V$-variable affine nested fractals we define in Section 3.2 their Dirichlet forms and show that these are resistance forms. We also show that the resistance metric between points is comparable to an appropriate product of resistance factors. In Section 3.3 we introduce general families of weights and measures and
prove a few basic properties. We introduce in Section 3.4 the notion of the cut set \( \Lambda_k \), where each cut is at a neck level and the crossing time for the corresponding neck cell is of order \( e^{-k} \). Asymptotic properties of various quantities associated with these neck cells are established. In Section 3.5 we show the Hausdorff dimension in the resistance metric is given by the zero of an appropriate pressure function.

3.2. Dirichlet and resistance form

The construction of the Dirichlet form follows [29] and is very close to [32], Section 22.

Assume as given a harmonic structure \( (D, \rho_F) \) for each IFS \( F \) in the family \( F \). Since all our affine nested fractals are based on the same triangle or \( d \)-dimensional tetrahedron with vertices \( V_0 \), the matrix \( D \) will be independent of \( F \) and is given by

\[
D(x, y) = \begin{cases} 
1 & \forall x, y \in V_0 \text{ with } x \neq y, \\
-1 & \forall x \in V_0.
\end{cases}
\]

Vectors \( \rho_F = (\rho_1^F, \ldots, \rho_{N_F}^F) \), specifying the conductance scaling factors to be applied to each cell, will be chosen to respect the symmetries of the limiting fractal.

Assume

\[
1 < \rho_{\inf} := \inf \{ \rho_i^F : 1 \leq i \leq N^F, F \in F \},
\rho_{\sup} := \sup \{ \rho_i^F : 1 \leq i \leq N^F, F \in F \} < \infty.
\]

The associated renormalization map for each \( F \in F \) is assumed to have the usual fixed point property. We now state this more formally.

Let

\[
E_0(f, g) = \frac{1}{2} \sum_{x, y \in V_0} (f(x) - f(y))(g(x) - g(y))
\]

be the Dirichlet form on the graph \( G_0 = (V_0, E_0) \) with conductances determined by the matrix \( D \). Each edge is summed over twice, and hence the factor 1/2.

Consider the choice of \( \rho^F \) is such that

\[
E_0(f, f) = \inf \left\{ \sum_{i=1}^{N^F} \rho_i^F E_0(h \circ \psi_i^F, h \circ \psi_i^F) \left| h : V_1 \to \mathbb{R}, h|_{V_0} = f \right. \right\}.
\]

One can also regard this as placing conductors \( \rho_i^F \) on each edge of the 1-cell with address \( i \), which ensure that the effective resistance between any two vertices of \( G_0 \) in the graph \( G_1 \) is the same as the effective resistance between the vertices in the graph \( G_0 \) itself – see Notation 2.3 and (31).

Define \( \mathcal{F}_n := \{ f | f : V_n \to \mathbb{R} \} \). Use recursion on \( n \geq 1 \) to define

\[
E_n(f, g) = \sum_{|i|=n} \rho_i \circ \sigma_i E_{n-1}^\sigma(f \circ \psi_i, g \circ \psi_i) \quad \forall f, g \in \mathcal{F}_n,
\]

i.e.

\[
E_n(f, g) = \sum_{i=1}^{N^\sigma} \rho_i^\sigma E_{n-1}^\sigma(f \circ \psi_i^\sigma, g \circ \psi_i^\sigma) \quad \forall f, g \in \mathcal{F}_n.
\]

It follows that

\[
E_n(f, g) = \sum_{|i|=n} \rho_i E_0(f \circ \psi_i, g \circ \psi_i),
\]

where \( \rho_i \) and \( \psi_i \) are as in Notation 2.2.
The sequence of forms \((\mathcal{E}_n, \mathcal{F}_n)\) can be thought of as corresponding to conductances \(\rho_i\) on the edges of the cell \(\Delta_i\) in the graph \(G_n\), where \(|i| = n\).

One next defines a resistance form first on \(V_o := \bigcup_{n \geq 0} V_n\) and then on its closure \(\overline{K}\) in the standard manner as follows. Firstly, as in [29], Section 2.2, by the definition of the conductance scale factors \(K\), one can now define a limit form on \(\overline{K}\). Namely, for continuous \(f\) on \(\overline{K}\), one can define a limit form on \(\overline{K}\). Notation 2.2. Namely, for continuous \(f\) and \(g\) on \(\overline{K}\),

\[
\mathcal{F}^{*0}(f, g) = \lim_{n \to \infty} \mathcal{E}_n(f, g) \quad \forall f, g \in \mathcal{F}^{*0}.
\]

Using the definition of the effective resistance \(R\) in (31) with \(K\) replaced by \(V_o\), one shows that \(R\) is a metric on \(V_o\) as in Theorem 2.1.14 and Proposition 2.2.4 of [29]. We then need to show that we can extend the form on \(V_o\) to a form on \(K\). To do this we follow [29], Section 3.3 and show \((V_o, R)\) is uniformly homeomorphic to \((V_o, |\cdot|)\), so that completing \(V_o\) in the resistance metric induces the Euclidean topology on \(K\).

It is straightforward to establish, noting definition (32), the natural analogue of Lemma 3.3 and Corollary 3.4 for \(V_o\), without utilising Theorem 3.2. It is also possible to see that

\[
\inf_{x \in K_j \cap V_o, y \in K_j \cap V_o} R(x, y) > 0,
\]

for any \(i, j \in T\) with \(|i| = |j|\) and \(K_i \cap K_j = \emptyset\). The proof is a minor modification of that of [32] Lemma 22.6.

Thus we have that \(f \in \mathcal{F}^{*0}\) is uniformly continuous with respect to \(|\cdot|\) and hence can be canonically identified with its unique continuous extension to \(K\) so that \(\mathcal{F}^{*0}\) can be identified with

\[
\mathcal{F}^{0} = \left\{ f : K \to \mathbb{R}, f \text{ is continuous, } \lim_{n \to \infty} \mathcal{E}_n^0(f, f) < \infty \right\}.
\]

One can now define a limit form on \(K\) by

\[
\mathcal{E}^0(f, g) = \lim_{n \to \infty} \mathcal{E}_n^0(f, f) \quad \forall f, g \in \mathcal{F}^0,
\]

where \(f : K \to \mathbb{R}\).

**Remark 3.1.** The construction of the Dirichlet form \((\mathcal{E}^0, \mathcal{F}^0)\) is carried out in detail for the case of all realizations of a certain class of random recursive Sierpinski gaskets in [32], Section 22. Although there are differences in the underlying class of Sierpinski gaskets, the realizations of our \(V\)-variable fractals built from the same gaskets will be possible realizations of these random recursive gaskets (for example the first model problem mentioned in the Introduction).

It follows from the definitions that there is a decomposition of the limit form for any cut \(\Lambda\) of the tree \(T^\omega\), see Notation 2.2. Namely, for continuous \(f : K \to \mathbb{R}\) we have \(f \in \mathcal{F}^0\) if and only if \(f \circ \psi_i \in \mathcal{F}^{0\psi_i}\) for any \(i \in \Lambda\), and

\[
\mathcal{E}^0(f, g) = \sum_{i \in \Lambda} \rho_i \mathcal{E}^{0\psi_i}(f \circ \psi_i, g \circ \psi_i) \quad \forall f, g \in \mathcal{F}^0. \tag{30}
\]

Note the case \(\Lambda = \{i : |i| = k\}\) for some \(k\) and the case \(\Lambda = \Lambda_k\) as in (51). The result (30) in the first of these cases with \(k = 1\) is essentially just a consequence of the scaling property (27) and letting \(n \to \infty\). The general result follows from iterating this down the various levels corresponding to the partition \(\Lambda\).

The effective resistance metric between any pair of points \(x, y \in K\) is defined by

\[
R(x, y)^{-1} = \inf \left\{ \mathcal{E}(f, f) : f(x) = 0, f(y) = 1 \right\}
\]

\[
= \inf \left\{ \frac{\mathcal{E}(f, f)}{|f(x) - f(y)|^2} : f(x) \neq f(y) \right\}. \tag{31}
\]
The proof this is a metric is essentially in Theorem 2.1.14, Section 2.2 and Lemma 2.3.9 of [29].

Recall that \((\mathcal{E}, \mathcal{F})\) is a local regular Dirichlet form on \(L^2(K, \mu)\) if it has the following properties:

1. \textit{Closed}: \(\mathcal{F}\) is a Hilbert space under the inner product \(\langle f, g \rangle \mapsto \mathcal{E}(f, g) + \int f g \, d\mu\);
2. \textit{Markov or Dirichlet}: \(\mathcal{E}(f, f) \leq \mathcal{E}(f, f)\) if \(\mathcal{F}\) is obtained by truncating \(f\) above by 1 and below by 0;
3. \textit{Core or regular}: if \(C(K)\) is the space of continuous functions on \(K\) then \(C(K) \cap \mathcal{F}\) is dense in \(\mathcal{F}\) in the Hilbert space sense and dense in \(C(K)\) in the sup norm;
4. \textit{Local}: \(\mathcal{E}(f, g) = 0\) if \(f\) and \(g\) have disjoint supports.

For \((\mathcal{E}, \mathcal{F})\) to be a resistance form it is sufficient that in addition \(R\) defines a metric, and in particular that \(R(x, y)\) is finite and non zero if \(x \neq y\).

\textbf{Theorem 3.2.} For each \(\omega \in \Omega\) and each finite Borel regular measure \(\mu^\omega\) on \(K^\omega\) with full topological support, \((\mathcal{E}^\omega, \mathcal{F}^\omega)\) defines a local regular Dirichlet form on \(L^2(K^\omega, \mu^\omega)\). The Dirichlet form is a resistance form with resistance metric \(R\).

\textbf{Proof.} The existence of the Dirichlet form \((\mathcal{E}, \mathcal{F})\) as the limit of an increasing sequence of Dirichlet forms is essentially as summarised in the first paragraph of Section 3.4 of [29]. See [29] Appendix B3 for a discussion of Dirichlet forms. The proof that the Dirichlet form is a resistance form is essentially as in Section 2.3 of [29].

It will be convenient here and subsequently to work with resistance scaling factors which are just the inverse of the conductance scaling factors introduced in Section 3.2. Thus we define

\[ r_i^F = \left(\rho_i^F\right)^{-1}, \quad r_i = \rho_i^{-1}. \tag{32} \]

We also note that for the resistance scale factors we have

\[ 0 < r_{\inf} := \inf\{r_i^F : i \in 1, \ldots, N^F, F \in F\} = \rho_{\sup}^{-1}, \]

\[ r_{\sup} := \sup\{r_i^F : i \in 1, \ldots, N^F, F \in F\} = \rho_{\inf}^{-1} < 1. \tag{33} \]

Next we see that the resistance metric distance between two vertices in a cell \(\Delta_i\) (see (8)) is comparable to the resistance scaling factor \(r_i\) for that cell.

\textbf{Lemma 3.3.} There is a non-random constant \(c_1 > 0\) such that if \(x, y \in \Delta_i\) and \(x \neq y\) then

\[ c_1 r_i \leq R(x, y) \leq r_i. \tag{34} \]

\textbf{Proof.} Fix \(x, y\) and \(i\) as in the statement of the lemma.

If \(f(x) = 0\) and \(f(y) = 1\), then using (30), (25), monotonicity of the limit in (29), and (12),

\[ \mathcal{E}(f, f) \geq \rho_i \mathcal{E}_0(f \circ \psi_i, f \circ \psi_i) \geq \frac{d + 1}{2} \rho_i. \]

This gives the upper bound for \(R\) in (34).

For the lower bound, following Notation 2.2, consider a cut \(\Lambda\) of the underlying tree such that \(j = j_1 \cdots j_n \in \Lambda\) if \(r_j\) is comparable to \(r_i\). More precisely, \(j \in \Lambda\) if

\[ r_j \leq r_i < r_{j_1} \cdots r_{j_n-1}. \tag{35} \]

Let \(\tilde{V} = \bigcup_{j \in \Lambda} \psi_j(V_0)\) be the set of vertices corresponding to cells \(\Delta_j\) for \(j \in \Lambda\) (analogous to (9)). Note that \(i \in \Lambda\) and so \(x, y \in \tilde{V}\). Consider the function \(f\) such that \(f(x) = 1\) and \(f(z) = 0\) for all other \(z \in \tilde{V}\), and harmonically interpolate. Then

\[ \mathcal{E}(f, f) = \sum_{j \in \Lambda, \psi_j} \rho_j \mathcal{E}_0(f \circ \psi_j, f \circ \psi_j) = d \sum_{j \in \Lambda, \psi_j} \rho_j \leq \frac{d M}{r_{\inf}} \rho_i, \tag{36} \]
using (35), taking $d$ as in (12), and $M$ the maximum number of regular tetrahedra in $\mathbb{R}^d$ with disjoint interiors that can have a common vertex.

This gives the lower bound in (34).

**Corollary 3.4.** There is an upper bound on the diameter of the set $K$ in the resistance metric, in that there exists a non-random constant $C$ such that

$$\text{diam}_R K := \sup_{x,y \in K} R(x,y) \leq C. \quad (37)$$

More generally, for all $i \in T$,

$$\text{diam}_R K_i := \sup_{x,y \in K_i} R(x,y) \leq C r_i. \quad (38)$$

**Proof.** First consider points $x, y \in V_n$ (see (9)) and suppose $x \in \Delta_i \subset V_n, y \in \Delta_j \subset V_n$, with $|i| = |j| = n$.

Let $x_0 = y_0, x_k \in \Delta_i | k \subset V_n, y_k \in \Delta_j | k \subset V_n$, for $k = 1, \ldots, n$, with $x_n = x$ and $y_n = y$. By the triangle inequality for the metric $R$,

$$R(x,y) \leq \sum_{k=1}^{n} R(x_{k-1},x_k) + \sum_{k=1}^{n} R(y_{k-1},y_k).$$

Since $x_{k-1}, x_k \in V_k$ and all cells are triangles or tetrahedra, if a path from $x_{k-1}$ to $x_k$ consisting of edges from $V_k \cap K_{|i|k-1}$ contains two edges from the same $k$-cell then it can be replaced by a shorter path from $x_{k-1}$ to $x_k$ also consisting of edges from $V_k$.

It follows there is a path from $x_{k-1}$ to $x_k$ consisting of at most $N^{\text{sup}}$ edges from $V_k$. Hence

$$R(x_{k-1},x_k) \leq N^{\text{sup}} r^{k}.$$ 

from (34). Hence

$$R(x,y) \leq \frac{2N^{\text{sup}}}{(1 - r^{\text{sup}})}.$$ 

Using the density of the vertices $\bigcup_n V_n$ in $K$ we have the result.

The second statement follows in the same way. \[\square\]

Note that the result holds for all $\omega \in \Omega_V$.

### 3.3. Weights and measures

We next introduce a general family of measures on $\partial T$ (see Notation 2.2) and on the corresponding fractal set $K$, by using a set of weights $(w_i^F, \ldots, w_i^{N_F})$ defined for each $F \in F$ with $w_i^F > 0$. We do not require $\sum_i w_i^F = 1$.

Assume and/or define

\begin{align*}
0 < w_{\text{inf}} &:= \inf \{w_i^F : 1 \leq i \leq N^F, F \in F\}, \\
 w_{\text{sup}} &:= \sup \{w_i^F : 1 \leq i \leq N^F, F \in F\} < \infty, \quad (39) \\
 \zeta &:= w_{\text{inf}} / w_{\text{sup}} \leq 1.
\end{align*}

Following Notation 2.2 let the weight $w_i$ of the cell $\Delta_i$ (corresponding complex, or corresponding cylinder) be the natural product of weights along the branch given by the node $i$. That is, if $|i| = n$, then

$$w_i := w_i^{F_0} \cdot w_i^{F_1} \cdots w_i^{F_{|i|-1} n-1}. \quad (40)$$
Of particular interest are weights of the form \( w_i^F = (r_F^i)^\alpha \) for all \( F \in F \) and some fixed \( \alpha > 0 \), in which case \( w_i = r_i^\alpha \). This example is the reason we do not require \( \sum_i w_i^F = 1 \), since it would not be possible to achieve the normalisation simultaneously for all \( F \in F \).

The following construction is basic, and is special to the case of \( V \)-variable fractals.

**Definition 3.5.** Let \( (w_1^F, \ldots, w_{|F|}^F) \) for \( F \in F \) be a set of weights as before. For \( |i| \) a neck let

\[
\mu_i := \mu([i]) := \frac{w_i}{\sum_{|j|=|i|} w_j}.
\]

The corresponding unit mass measure \( \mu \) on \( \partial T \) is called the **unit mass measure with weights** \( w_i^F \).

The pushforward measure on \( K \) under the address map \( \pi : \partial T \rightarrow K \) given by \( \bigcap_{n=1}^\infty K_{i,n} = \{ \pi(i) \} \) is also denoted by \( \mu \).

Note that from the definition of a neck, (41) is consistent via finite additivity from one level of neck to the next, it extends by addition to any complex or cylinder, and so by standard consistency conditions it extends to a unit mass (probability) measure \( \mu \) on \( \partial T \).

We note the following simple estimates for use in the rest of this subsection and in Lemmas 4.3, 4.4 and 5.11.

**Lemma 3.6.** Suppose \( i \) and \( j \) are two nodes of the same type with \( |i| = |j| = n \). Then

\[
\zeta_n \mu_j \leq \mu_i \leq \zeta_n^{-1} \mu_j.
\]

If \( i \) is a neck node then

\[
\zeta_n N_{\sup}^{-n} \leq \mu_i < (1 + \zeta_n)^{-1} < 1.
\]

**Proof.** Suppose \( N \) is the first neck \( \geq n \). Then

\[
\mu_i = \frac{\sum_{|k|=N, k \in T^{vi}} w_{ik}}{\sum_{|p|=N, p \in T} w_p} = \frac{w_i}{\sum_{|p|=N, p \in T} w_p} \leq \frac{w_i}{\sum_{|p|=n, p \in T} w_p} \leq \frac{w_i}{w_{\sup}}.
\]

where \( w_{\sup} \) is the product of weights along any branch of \( T^{vi} \) of length \( N - n \) beginning at \( \emptyset \), or equivalently any branch of \( T \) of length \( N - n \) beginning at \( i \). A similar expression is obtained for \( \mu_j \) since \( i \) and \( j \) are of the same type and level, the trees \( T^{vi} \) and \( T^{vj} \) are identical, and so \( \mu_i/w_i = \mu_j/w_j \).

Then (42) follows from \( w_{\inf}^n \leq w_i \leq w_{\sup}^n \).

If \( n \) is a neck then

\[
\mu_i = \frac{w_i}{\sum_{|p|=n} w_p} \geq \zeta_n N_{\sup}^{-n}.
\]

Also we have that

\[
\mu_i = \frac{w_i}{\sum_{|p|=n} w_p} \leq \left( 1 + \sum_{|p|=n, p \neq i} \frac{w_p}{w_i} \right)^{-1} \leq \left( 1 + (N_{\sup}^n - 1) \zeta_n^{-1} \right)^{-1} < (1 + \zeta_n)^{-1} < 1,
\]

completing the proof of (43). \( \square \)

We show in Lemma 3.8 that the pushforward measure on \( K \) is given by a similar expression to that for \( \mu \) on \( \partial T \). For this we first show that the measure \( \mu \) on \( K \) is non-atomic provided our trees satisfy a certain condition.

Recall Definition 2.15.
Lemma 3.7. For all $\omega \in \Omega_{V,\zeta}$ and hence also $P_V$ a.s. for $i \in \partial T$

$$\mu(i) = 0.$$  

Proof. Since $[i;n]$ is a decreasing sequence of sets, from (41)

$$\mu(i) = \lim_{k \to \infty} \mu[i;n(k)].$$

By (43), and using the notation of Lemma 2.17, we can bound

$$\frac{\mu_i[n(j)]}{\mu_i[n(j-1)]} = \frac{\sum_{j=n(j)-n(j-1)} u_{j}^{(j-1)}}{\sum_{j=n(j)-n(j-1)} u_{j}^{(j-1)}} \leq \left(1 + \zeta^{n(j)-n(j-1)}\right)^{-1}.$$  

Taking logs

$$\log \mu(i) \leq \limsup_{k \to \infty} \log \mu[i;n(k)] \leq -\sum_{j=1}^{\infty} \log(1 + \zeta^{n(j)-n(j-1)}) \leq -\frac{1}{2} \sum_{j=1}^{\infty} \zeta^{n(j)-n(j-1)}.$$  

Thus we have $\lim_{k \to \infty} \mu[i;n(k)] = 0$ for all $\omega \in \Omega_{V,\zeta}$ as required. It is straightforward to check that $P_V$ a.s. we have $\sum_{j} \zeta^{n(j)-n(j-1)} = \infty$ as then $\{n(j) - n(j-1)\}_j$ is a sequence of i.i.d. geometric random variables.  

Note that by the law of large numbers we see, $P_V$ a.s., for all $i$,

$$\limsup_{k \to \infty} \frac{1}{k} \log \mu[i;n(k)] \leq -\lim_{k \to \infty} \frac{1}{k} \sum_{j=1}^{k} \log(1 + \zeta^{n(j)-n(j-1)}) = -E_V \log(1 + \zeta^{n(1)}).$$  

Now, using the fact that $n(1)$ is a geometric random variable, $\zeta \leq 1$ and $\log(1 + x) \geq x/2$ for $x \leq 1$, we conclude

$$-E_V \log(1 + \zeta^{n(1)}) \leq -\frac{1}{2} E_V \zeta^{n(1)} = -\frac{1}{2} \frac{\zeta}{E_V \log(1/\zeta)} < 0.$$  

In particular, $P_V$ almost surely, for all $i \in \partial T$, we have $\lim_{k \to \infty} \mu[i;n(k)] = 0$ exponentially fast.

Lemma 3.8. The address map $\pi : \partial T \to K$ is one-one except on a countable set. For all $\omega \in \Omega_{V,\zeta}$ (and hence $P_V$ a.s.) the pushforward measure $\mu$ on $K$ is nonatomic and for $[i]$ a neck,

$$\mu_i = \mu(K_i) = \frac{u_i}{\sum_{j=|i|} w_j}.$$  

Proof. We note that as only a finite number of sets can meet at a point $\pi^{-1}(x)$ is a finite set for any $x \in K$. Suppose $a = \pi(i) = \pi(j)$ for some $i, j \in \partial T$ with $i \neq j$. Then for some $n$ we have $i_1 \cdots i_n = j_1 \cdots j_n$ and $i_{n+1} \neq j_{n+1}$. It follows that $a \in K_{i_1} \cdots i_{n+1} \cap K_{j_1} \cdots j_{n+1}$. From Lemma 2.9, $a \in \psi_{i_1 \cdots i_n} \cap (V_0)$. This establishes countability of the set of points in $K$ with more than one address. From Lemma 3.7 it follows this set has $\mu$-measure zero. The result (44) now follows from (41) and the definition of the pushforward measure.  

It follows from (44) that for all $\omega \in \Omega_{V,\zeta}$

$$\int_{K_i} f d \mu = \mu_i \int_{K^{\sigma_i}} f \circ \psi_i d \mu^{\sigma_i},$$  

where as usual $\mu = \mu^{\omega}$ is the measure on $K = K^\omega$ but here restricted to $K_i = K_i^\omega$, and $\mu^{\sigma_i} = \mu^{\omega,\sigma_i}$ is the measure on $K^{\sigma_i} = K^{\omega,\sigma_i}$ which is essentially just a scaled copy of the subfractal $K_i$. By construction, the left integral is a
multiple of the right integral, with constant independent of \( f \). Setting \( f = 1 \) gives the constant. Note that \(|i| = n\) need not be a neck.

The inner product (or any integral) can be decomposed as follows:

\[
(f, g)_\mu = \sum_{i \in \Lambda} \mu_i (f \circ \psi_i, g \circ \psi_i)_{\mu^i},
\]

for any cut \( \Lambda \), see Notation 2.2.

Note that (46) is analogous to the decomposition (30) for the Dirichlet form. The difference is that the scaling factors \( \rho_i \) in (30) are simply computed from the prescribed quantities \( \rho_{i}^F \), unlike the scaling factors \( \mu_i \) in (46) which are related to the prescribed quantities \( w_{i}^F \) in a simple manner only in the case where the \( i \) are all neck nodes.

We write

\[
\| f \|_2 = (f, f)_{\mu}^{1/2}
\]

for the natural norm on \( L^2(K, \mu) \).

### 3.4. Time and neck cuts

We now introduce the special cut sets which will be essential for our analysis. The idea is to cut at neck nodes in such a manner that crossing times are comparable.

Define

\[
t_i = \mu_i r_i.
\]

From the Einstein relation \( t_i \) can be thought of as a crossing time for the continuous time random walk on the cell \( \Delta_i \), with resistance given by \( r_i \) and expected jump time given by \( \mu_i \).

Note that whereas \( w_i \) defined in (40) is a simple product of factors, as are \( \ell_i, \rho_i \) and \( r_i \) following the notation of (5), this is not the case for \( \mu_i \) and hence not for \( t_i \).

Define

\[
\eta = \frac{r_{\text{inf}}} {\zeta},
\]

and note that \( 0 < \eta < 1 \). Then from (48) and (43),

\[
\eta^n \leq t_i \leq \frac{n}{\sup} \quad \text{if} \quad |i| = n \quad \text{is a neck}.
\]

The second inequality is clearly true for any \( i \), not necessarily at a neck.

Recalling from (13) the notation \( n(\ell) \) for the \( \ell \)th neck, define the cut sets of \( T \)

\[
\Lambda_0 = \{ \emptyset \}, \quad \Lambda_k = \{ i \in T : \exists \ell \left( |i| = n(\ell), t_i \leq e^{-k} < t_{i[n(\ell)-1]} \right) \} \quad \text{if} \quad k \geq 1,
\]

where \( \emptyset \) is the root node. Thus \( \Lambda_k \) is the set of neck nodes for which the crossing times of the corresponding cells are comparable to \( e^{-k} \).

For any \( i \) such that \(|i|\) is a neck, and in particular if \( i \in \Lambda_k \), then we define

\[
\ell(i) := \ell \quad \text{if} \quad |i| = n(\ell).
\]

That is, \( \ell(i) \) is the number of the neck corresponding to \( i \).

We introduce further notation to capture the scale factors

\[
M_k = |\Lambda_k|, \quad \bar{t}_k = M_k^{-1} \sum_{i \in \Lambda_k} t_i, \quad T_k = \bar{t}_k^{-1};
\]

\[
y_k(i) = n(\ell) - n(\ell - 1) \quad \text{if} \quad i \in \Lambda_k \quad \text{and} \quad |i| = n(\ell), \quad y_k = \max_{i \in \Lambda_k} y_k(i);
\]

\[
z_k = \max\{ |i| : i \in \Lambda_k \}.
\]
Thus $M_k$ is the cardinality of the cut set $\Lambda_k$, $\bar{t}_k$ is the average crossing time for cells $K_i$ with $i \in \Lambda_k$ or equivalently the average time scaling when passing from $K$ to $K_i$, conversely $T_k$ is the average time scaling when passing from $K_i$ to $K$ for $i \in \Lambda_k$; $y_k(i)$ is the number of generations between $\Delta_1 i$ and its most recent ancestor also at a neck level, and $y_k$ is the maximum such number of ancestral generations over $i \in \Lambda_k$; $z_k$ is the maximum branch length of nodes in $\Lambda_k$.

Trivially,

$$\min_{i \in \Lambda_k} t_i \leq \bar{t}_k \leq \max_{i \in \Lambda_k} t_i.$$  \hspace{1cm} (56)

For functions $f(k)$ and $g(k)$ we will use the notation

$$f(k) \preceq g(k) \iff \limsup_{k \to \infty} \frac{f(k)}{g(k)} \leq 1.$$  \hspace{1cm} (57)

That is, $f(k) \preceq g(k)$ means $f$ is asymptotically dominated by $g$.

In the next lemma we use Lemma 2.16 to estimate the asymptotic behaviour of $y_k$ and $z_k$, and of the fluctuations of $\ell(i)$ and $t_i$ for $i \in \Lambda_k$. Note that sharper estimates for the simple case $V = 1$ are given in Lemma 3.10.

**Lemma 3.9.** Suppose $\eta$ is as in (49).

(a) There exist $c_1, c_2 > 0$ such that $P_V$ a.s., if $i \in \Lambda_k$ then

$$c_1 k (\log k)^{-1} \leq \ell(i) \leq c_2 k.$$  \hspace{1cm}

(b) There exist $c_3, c_4 > 0$ such that $P_V$ a.s.

$$1 \leq y_k \leq c_3 \log k, \quad z_k \leq c_4 k.$$  \hspace{1cm}

(c) There exists $\beta' > 0$ such that $P_V$ a.s., if $i \in \Lambda_k$ then

$$k^{-\beta'} e^{-k} \leq \eta^y e^{-k} \leq t_i \leq e^{-k}.$$  \hspace{1cm}

**Proof.** (a) Suppose $i \in \Lambda_k$ and let $\ell = \ell(i)$. From (50) and the definition of $\Lambda_k$,

$$\eta^n(\ell) \leq t_i \leq e^{-k} < t_i | n(\ell - 1) | r_{sup}^{n(\ell - 1)}.$$  \hspace{1cm} (58)

In particular, $n(\ell - 1) \leq k / \log(1/r_{sup})$.

It follows that

$$\ell = 1 + (\ell - 1) \leq 1 + n(\ell - 1) \leq 1 + \frac{k}{\log 1/r_{sup}} \leq c_2 k.$$  \hspace{1cm}

On the other hand from (58), $n(\ell) \geq k / \log(1/\eta)$. Using also $\log k \geq \log \ell + \log 1/c_2$, it follows from Lemma 2.16 (16), since $n(\ell) = \sum_{i=1}^{\ell} (n(i) - n(i - 1))$ is a sum of geometric random variables, that a.s. (where $i \in \Lambda_k$)

$$\limsup_{k \to \infty} \frac{k}{\ell(i) \log k} \leq \limsup_{k \to \infty} \frac{n(\ell) \log 1/\eta}{\ell(\log \ell + \log 1/c_2)} \leq \frac{2 \log 1/\eta}{\log 1/p} =: 1/c_1.$$  \hspace{1cm}

Here $p$ is the constant probability of not obtaining a neck at any particular level $\geq 1$.

(b) Trivially, $y_k \geq 1$. By definition

$$y_k = \max_{i \in \Lambda_k} y_k(i) = \max_{i \in \Lambda_k} (n(\ell(i)) - n(\ell(i) - 1)) \leq \max_{1 \leq j \leq c_2 k} (n(j) - n(j - 1)),$$

where the inequality comes from (a).
By Lemma 2.16 (15) with $Y_j = n(j) - n(j - 1)$, $P_V$ a.s.

$$\limsup_{k \to \infty} \frac{y_k}{\log k} \leq \limsup_{k \to \infty} \max_{1 \leq j \leq c_2 k} \frac{Y_j}{\log c_2 k - \log c_1} \leq \frac{1}{\log 1/p} =: c_3,$$

where $p$ is as in (a).

It follows that with $i \in \Lambda_k$ and $\ell = \ell(i)$, $P_V$ a.s.

$$|i| = n(\ell) = n(\ell - 1) + n(\ell) - n(\ell - 1) \leq n(\ell - 1) + y_k$$

$$\leq k/\log(1/r_{sup}) + c_3 \log k \leq k/\log(1/r_{sup}).$$

This gives the last inequality in (b).

(c) The third inequality in (c) is immediate from the definition of $\Lambda_k$.

For the second inequality suppose $i \in \Lambda_k$ with $|i| = n(\ell)$. Then

$$t_i = r_i \mu_i \geq r_{i[n(\ell - 1)]} \mu_i[n(\ell - 1)] \eta^{n(\ell) - n(\ell - 1)}$$

by a similar argument to that for the first inequality in (50). More precisely, note that by definition $\mu_i$ is a product of $\mu_{i[n(\ell - 1)]}$ with factors that depend only on weights $w$ defined along edges in the subtree rooted at $i[n(\ell - 1)]$, followed by a normalisation that depends only on the same weights since $|i| = n(\ell)$ is a neck.

Hence

$$t_i \geq r_{i[n(\ell - 1)]} \eta^{n(\ell) - n(\ell - 1)} \geq e^{-k} \eta y_k$$

by the definition of $y_k$ and $\Lambda_k$. This gives the second inequality in (c).

For the first inequality take any $\varepsilon > 0$, in which case by (b), a.s. there exists $k_0 = k_0(\omega)$ such that $k \geq k_0$ implies $y_k \leq (c_3 + \varepsilon) \log k$, and so $k \geq k_0$ implies

$$\eta y_k \geq \eta^{(c_3 + \varepsilon) \log k} = k^{-(c_3 + \varepsilon) \log 1/\eta} = k^{-\beta'},$$

where $\beta' = (c_3 + \varepsilon) \log 1/\eta$. Since $\varepsilon > 0$ is arbitrary, this completes the proof. \qed

If $V = 1$ the above can be sharpened to the following.

**Lemma 3.10.** In the case $V = 1$ we have the following.

(a) There exist $c_1, c_2 > 0$ such that if $i \in \Lambda_k$ then

$$c_1 k \leq \ell(i) \leq c_2 k.$$

(b) There exists $c_3 > 0$ such that

$$y_k = 1, \quad z_k \leq c_3 k.$$

(c) There exists $c_4 > 0$ such that if $i \in \Lambda_k$ then

$$c_4 e^{-k} \leq t_i \leq e^{-k}.$$

**Proof.** The first claim follows from (50) and the fact that for $V = 1$ every level is a neck. The second and third follow similarly. \qed
3.5. The Hausdorff dimension in the resistance metric

**Definition 3.11.** The $\alpha$-dimensional Hausdorff measure of $K$ using the resistance metric $R$ is denoted by $\mathcal{H}^\alpha_R(K)$. The Hausdorff dimension of $K$ in the resistance metric is denoted by $d^R_f = d^R_f(K)$.

The following theorem is the analogue of Theorem 2.18. However, the resistance metric $R$ does not scale in the same way as the standard metric in $\mathbb{R}^d$ and so the proof needs to be modified. The proof combines ideas from Section 2 of [26], Section 2 of [27] and Section 4 of [7]. In the case of [7] the corresponding argument is simplified here because of the use of necks. Note that we do not expect the appropriate Hausdorff measure function to be a power function, unlike in [26] and [27].

**Theorem 3.12.** $P_V$ almost surely the Hausdorff dimension in the resistance metric $d^R_f$ of $K$ is the unique power $\alpha_0$ such that

$$E_V \log \sum_{|i|=n(1)} r_i^{\alpha_0} = 0. \quad (59)$$

**Proof.** This will follow from Lemmas 3.14 and 3.17. \qed

**Lemma 3.13.** The function

$$\gamma(\alpha) := E_V \log \sum_{|i|=n(1)} r_i^\alpha, \quad (60)$$

is finite, strictly decreasing and Lipschitz, with derivative in the interval

$$[\log r_{\inf} E_V n(1), \log r_{\sup} E_V n(1)].$$

Since $\gamma(0) > 0$ there is a unique $\alpha_0$ such that $\gamma(\alpha_0) = 0$ and moreover $\alpha_0 > 0$.

**Proof.** If $\alpha < \beta$, then from (33),

$$\gamma(\alpha) + (\beta - \alpha)(\log r_{\inf}) E_V n(1) \leq \gamma(\beta) \leq \gamma(\alpha) + (\beta - \alpha)(\log r_{\sup}) E_V n(1).$$

This gives the Lipschitz estimate.

Since $\gamma(0) = E_V (\log \# \{|i| \in T | |i| = n(1)\})$, it follows that $0 < \gamma(0) < \infty$.

The rest of the lemma now follows. \qed

**Lemma 3.14.** Suppose $\alpha_0$ is as in Lemma 3.13. Then $d^R_f(K) \leq \alpha_0$, $P_V$ a.s.

**Proof.** Suppose $\alpha > \alpha_0$. Using Corollary 3.4,

$$K = \bigcup_{|i|=n(k)} K_i, \quad \sum_{|i|=n(k)} \text{diam}_R^\alpha K_i \leq C^\alpha \sum_{|i|=n(k)} r_i^\alpha. \quad (19)$$

From (19) and Lemma 3.13,

$$\lim_{k \to \infty} \frac{1}{k} \log \sum_{|i|=n(k)} r_i^\alpha = E_V \log \sum_{|i|=n(1)} r_i^\alpha < 0, \quad P_V \text{ a.s.}$$

Hence $P_V$ a.s.,

$$\lim_{k \to \infty} \log \sum_{|i|=n(k)} r_i^\alpha = -\infty, \quad \lim_{k \to \infty} \sum_{|i|=n(1)} r_i^\alpha = 0.$$

Hence $\mathcal{H}^\alpha_R(K) = 0$, and so $d^R_f(K) \leq \alpha_0$. \qed
Definition 3.15. Suppose $0 < \varepsilon < 1$. Then $\Lambda_\varepsilon$ is the set of nodes $j = j_1 \cdots j_n$ such that

$$r_j \leq \varepsilon < r_{j_1 \cdots j_{n-1}}.$$  \hspace{1cm} (61)

Lemma 3.16. There exist non random constants $c$ and $\tilde{M}$, such that for any $0 < \varepsilon < 1$ and $x \in K$,

$$\#\{j \in \Lambda_\varepsilon : \overline{B}_{\varepsilon}(x) \cap K_j \neq \varnothing\} \leq \tilde{M},$$  \hspace{1cm} (62)

where

$$\overline{B}_{\varepsilon}(x) = \{y \in K : R(x,y) \leq c \varepsilon\}.$$

Proof. Suppose $x \in K_i$ where $i \in \Lambda_\varepsilon$.

First note

$$\#\{j \in \Lambda_\varepsilon : K_i \cap K_j \neq \varnothing\} \leq M(d+1),$$  \hspace{1cm} (63)

where $d+1$ is the number of vertices of a regular tetrahedron in $\mathbb{R}^d$ (recall (12)) and $M$ is as in (36).

Let $V_\varepsilon = \bigcup_{j \in \Lambda_\varepsilon} V_j (V_0) = \bigcup_{j \in \Lambda_\varepsilon} \Delta_j$ denote the set of vertices corresponding to the partition $\Lambda_\varepsilon$.

Define $u : V_\varepsilon \to \mathbb{R}$ by $u(y) = 1$ if $y \in \Delta_j$ and $u(y) = 0$ otherwise. Extend $u$ to $u : K \to \mathbb{R}$ by harmonic extension on each $K_j$ for $j \in \Lambda_\varepsilon$. Then $u$ is constant on $K_j$ if $K_i \cap K_j = \varnothing$, and so

$$E(u) = \sum_{\{j : K_i \cap K_j \neq \varnothing\}} \rho_j E_0(u \circ \psi_j) \leq M(d+1) \max_{j \in \Lambda_\varepsilon} \rho_j \leq \frac{M(d+1)}{r_{\inf \varepsilon}},$$

where $M(d+1)$ is from (63) and $d$ is the number of edges in $\Delta_j$ with one vertex in $\Delta_i$.

Setting $c = r_{\inf \varepsilon}/2Md(d+1)$, it follows that $R(x,y) > c \varepsilon$ if $y \in K_j$ where $j \in \Lambda_\varepsilon$ and $K_i \cap K_j = \varnothing$. That is,

$$\overline{B}_{\varepsilon}(x) \cap K_j \neq \varnothing \implies K_i \cap K_j \neq \varnothing.$$  \hspace{1cm} (64)

Combining (64) and (63) gives (62). \hfill \square

Lemma 3.17. Suppose $\alpha < \alpha_0$. Let $\mu$ be the unit mass measure on $K$ constructed as in Definition 3.5 and Lemma 3.8, with weights $\mu_i^F = (r_i^F)^{\alpha}$ for $F \in F$. Then $P_V \ a.s.$, for any $x \in K$ and $0 < \delta < c$, $\mu(B_\delta(x)) < c_1 \delta^\alpha$, where the random constant $c_1$ depends on $\omega$ but not on $x$ or $\delta$.

In particular, by the mass distribution principle, $d'_j(K) \geq \alpha P_V \ a.s.$, and so $d'_j(K) \geq \alpha_0 P_V \ a.s.$

Proof. Fix $x \in K$ and $0 < \delta < c$. If $k$ is a level in the construction of $T$, let $s(k)$ denote the first neck level $\geq k$. All balls are with respect to the resistance metric.

From Lemma 3.16 applied to the cut $\Lambda_{\delta/c}$, and with $\tilde{M}$ as in that lemma, there are at most $\tilde{M}$ sets $K_j$ which meet $\overline{B}_\delta(x)$ and satisfy $j \in \Lambda_{\delta/c}$. That is, satisfy, on setting $j = j_1 \cdots j_k$,

$$r_j \leq \delta/c < r_{j_1 \cdots j_{k-1}}.$$  \hspace{1cm} (65)

It follows that

$$\mu(B_\delta(x)) \leq \sum_{j \in \Lambda_{\delta/c}, B_\delta(x) \cap K_j \neq \varnothing} \mu(K_j),$$  \hspace{1cm} (66)

and there are at most $\tilde{M}$ terms in the sum. For each such $K_j$, using Lemma 3.8,

$$\mu(K_j) = \sum_{j \prec i, |i| = s(k)} \mu(K_i) = \frac{\sum_{j \prec i, |i| = s(k)} r_i^\alpha}{\sum_{|i| = s(k)} r_i^\alpha} \leq \frac{N_{\sup}^{s(k)-k} \rho_j^\alpha}{c^\omega \sum_{|i| = s(k)} r_i^\alpha} \delta^\alpha = : \theta(k) \delta^\alpha.$$  \hspace{1cm} (67)
Here $N_{\text{sup}}$ is an upper bound for the branching number, see (2).

We need to estimate the numerator and denominator of $\theta(k)$ in (67). For this we use estimates (68) and (70).

Until we establish (70) we allow $k$ to be an arbitrary positive integer, not necessarily satisfying (65).

Since $s(k) - k$ is a geometric random variable, by the same argument as in Lemma 3.9(b), there is a constant $c_1$ such that $s(k) - k \approx c_1 \log k \ P_V \ a.s.$, and so there is a constant $c_2(\omega)$ such that

$$s(k) - k \leq c_2 \log k \ P_V \ a.s.$$ (68)

Next let

$$\beta = \mathbb{E} \log \sum_{|i|=n(1)} r_{i}^\alpha.$$ Then $\beta > 0$ since $\alpha < \alpha_0$, see Lemma 3.13. It follows by (19) that as $k \to \infty$

$$\frac{1}{k} \log \sum_{|i|=n(k)} r_{i}^\alpha \to \beta \ P_V \ a.s.$$ Hence for some $\epsilon_0 = \epsilon_0(\omega) > 0$,

$$\sum_{|i|=n(k)} r_{i}^\alpha \geq \epsilon_0 e^{k\beta/2} \text{ for } k > 1, \ P_V \ a.s.$$ (69)

However, we need an estimate similar to (69) involving $s(k)$ rather than $n(k)$. First note, by setting $Y_i = n(i) - n(i-1)$ and $n = 1$ in (16), that for some $c_3 = c_3(\omega)$ we have $n(k) \leq c_3 k \log k \ P_V \ a.s.$ if $k > 1$. Hence

$$\sum_{|i|=n(k)} r_{i}^\alpha \geq \epsilon_0 \exp\left(\frac{n(k)\beta}{2c_3 \log k}\right) \text{ for } k > 1, \ P_V \ a.s.$$ Since $n(k)$ is an arbitrary neck,

$$\sum_{|i|=s(k)} r_{i}^\alpha \geq \epsilon_0 \exp\left(\frac{s(k)\beta}{2c_3 \log k}\right) \text{ for } k > n(1), \ P_V \ a.s.$$ (70)

where $\tilde{k}$ is the number of the neck corresponding to $s(k)$, i.e. $n(\tilde{k}) = s(k)$. Note $s(k) \geq k$. Also note that $\tilde{k} \leq k$. (Otherwise there are at least $k + 1$ necks between levels 1 and $s(k)$ inclusive, and so in particular $s(k) > k$. But then there are at least $k$ necks between levels 1 and $k$ inclusive, and so $k$ is a neck. However that gives $s(k) = k$, a contradiction.) Hence

$$\sum_{|i|=s(k)} r_{i}^\alpha \geq \epsilon_0 \exp\left(\frac{k\beta}{2c_3 \log k}\right) \text{ for } k > n(1), \ P_V \ a.s.$$ (71)

It follows from (68), (70) and the definition of $\theta(k)$ in (67), that $\theta(k) \to 0$ as $k \to \infty$. On the other hand, with $k := |\tilde{j}|$ we have from (65) that

$$k := |\tilde{j}| \geq \log(c/\delta) / \log(1/r_{\text{min}}) \to \infty$$

uniformly for $\tilde{j} \in \Lambda_{\delta/c}$ as $\delta \to 0$. From (67), (66) and the uniform bound $\tilde{M}$ on the number of terms, there exists $\delta_0 = \delta_0(\omega) > 0$ such that

$$\mu(B_{\delta}(x)) \leq \delta^\alpha \text{ for } \delta \leq \delta_0 \ P_V \ a.s.$$ (71)

It now follows by the mass distribution principle that $d_{\tilde{j}}^\alpha(K) \geq \alpha \ P_V \ a.s.$, and so $d_{\tilde{j}}^\alpha(K) \geq \alpha_0 \ P_V \ a.s.$
4. Eigenvalue counting function

4.1. Overview

In this section we consider random $V$-variable gaskets constructed from essentially arbitrary resistances $r^F_i$, from weights $w^F_i$ which determine a measure $\mu$, and from a probability measure $P$ on $F$. See Sections 2.5, 3.2 and 3.3. With every realisation of such a random fractal there is an associated Dirichlet form and a Laplacian. The growth rate of the corresponding eigenvalue counting function is defined to be $d_s/2$, where $d_s$ is called the spectral exponent. We see in Theorem 4.13 that $P_V$ a.s. $d_s$ exists, is constant and is the zero of a pressure function constructed from the crossing times $t_i$. The proof relies on estimates concerning the occurrences of necks and on a Dirichlet–Neumann bracketing argument, see Lemmas 3.9 and 4.8. Lemma 4.8 gives a result which holds for all realizations in $\Omega_{V, \zeta}$.

The natural metric on fractal sets constructed with resistances as here is the resistance metric. We saw in Theorem 3.12 that the Hausdorff dimension $d_f$ in this metric is given by the zero of a certain pressure function. A natural set of weights is $w^F_i = (r^F_i)^{d_f}$. The measure $\nu$ constructed from this set of weights is called the flat measure with respect to the resistance metric. We see in Theorem 4.15 that $\frac{d_s(\nu)}{2} = \frac{d_f}{d_f + 1}$. This establishes the analogue of Conjecture 4.6 in [28] for $V$-variable fractals. In Theorem 4.17 we show that for a fixed set of resistances $r^F_i$, and for arbitrary weights $w^F_i$ and corresponding measure $\mu$, the spectral exponent $d_s(\mu)$ has a unique maximum when $\mu$ is the flat measure $\nu$. The spectral exponent in this case is called the spectral dimension associated with the given resistances.

Finally, in the case of the flat measure $\nu$, we give in Theorem 4.18 an improved $P_V$ almost sure estimate for the counting function itself rather than its log asymptotics.

4.2. Preliminaries

Following the notation of the previous section, we consider a fractal $K = K^\omega$ and write $\partial K = V_0$ for the boundary of $K$. We fix a measure $\mu = \mu^\omega$ on $K$ and, together with the Dirichlet form $\mathcal{E} = \mathcal{E}^\omega$, this allows one to define a Laplace operator $\triangle \mu = \triangle^\omega \mu$. We will be interested in the spectrum of $-\triangle \mu$ as this consists of positive eigenvalues. However, instead of working directly with $-\triangle \mu$, we use a formulation of the Dirichlet and Neumann eigenvalue problems in terms of the Dirichlet form, see [29].

Recall the definition of $\mathcal{F}$ from (29). Let

$$\mathcal{F}^\omega_\mu = \left\{ f \in \mathcal{F}^\omega : f(x) = 0, x \in \partial K \right\}, \quad \mathcal{E}^\omega_\mu(f,f) = \mathcal{E}^\omega(f,f) \quad \text{for } f \in \mathcal{F}^\omega_\mu. \quad (72)$$

and let $(\cdot, \cdot)_{\mu^\omega}$ be the inner product on $L^2(K^\omega, \mu^\omega)$. It follows as in Theorem 3.2 that $(\mathcal{E}_\mu, \mathcal{F}_\mu)$ is a local regular Dirichlet form on $L^2(K \setminus \partial K, \mu)$. Now $\lambda$ is a Dirichlet eigenvalue with eigenfunction $u \in \mathcal{F}^\omega_\mu$, $u \neq 0$, if

$$\mathcal{E}^\omega_\mu(u,v) = \lambda(u,v)_{\mu^\omega} \quad \forall v \in \mathcal{F}^\omega_\mu. \quad (73)$$

Similarly, $\lambda$ is a Neumann eigenvalue with eigenfunction $u \in \mathcal{F}^\omega_\mu$, $u \neq 0$, if

$$\mathcal{E}^\omega(u,v) = \lambda(u,v)_{\mu^\omega} \quad \forall v \in \mathcal{F}^\omega. \quad (74)$$

As usual, we will in future normally omit the dependence on $\omega$.

By standard results [29] the Dirichlet Laplacian has a discrete spectrum

$$0 < \lambda_1 \leq \lambda_2 \leq \cdots \quad \text{where } \lambda_n \to \infty \text{ as } n \to \infty, \quad (75)$$

and similarly for the Neumann Laplacian but with $0 = \lambda_1$.

The Dirichlet and Neumann eigenvalue counting functions are defined by

$$\mathcal{N}_D(s) = \max\{i : \lambda_i \leq s, \lambda_i \text{ is a Dirichlet eigenvalue}\},$$

$$\mathcal{N}_N(s) = \max\{i : \lambda_i \leq s, \lambda_i \text{ is a Neumann eigenvalue}\}. \quad (76)$$
As usual, eigenvalues are counted according to their multiplicity.

The following lemma implies the spectral exponent \( d_s(\mu) \) in Definition 4.10 is at most 2 for any realization of our \( V \)-variable fractals. It is used to prove the second estimate in Lemma 4.6.

**Lemma 4.1.** With the same constant \( C \) as in Corollary 3.4,

\[ \mathcal{N}_D(s) \leq Cs \quad \forall s > 0. \]

**Proof.** The effective resistance between \( x \in K \) and the boundary set \( \partial K = V_0 \) is defined by

\[ R(x, \partial K)^{-1} = \inf \{ \mathcal{E}(f, f) : f \in \mathcal{F}_D, f(x) = 1 \}. \]

From Corollary 3.4 with the same constant \( C \), and for any \( y \in \partial K \),

\[ R(x, \partial K) \leq R(x, y) \leq C. \]

The Green function for the Dirichlet problem in \( K \) is a symmetric function \( g(x, y) \) which has \( g(x, y) \leq g(x, x) = R(x, \partial K) \). See, for example, Proposition 4.2 of [30]. In particular,

\[ g(x, y) \leq C \]

independently of \( \omega \). Moreover, from Theorem 4.5 of [30],

\[ |g(x, y) - g(x, z)| \leq R(y, z). \]

Hence \( g \) is continuous, and in particular uniformly Lipschitz continuous, in the resistance metric.

It follows from Mercer’s theorem (for a proof of the theorem see the argument in [35], pages 344–345) that

\[ g(x, x) = \sum_{i \geq 1} \left( \lambda_i^D \right)^{-1} \phi_i(x)^2 \]

and the series converges uniformly, where \( \phi_i \) are the orthonormal eigenfunctions corresponding to the Dirichlet eigenvalues \( \lambda_i^D \). Integrating with respect to \( x \),

\[ C \geq \sum_{i \geq 1} \left( \lambda_i^D \right)^{-1} \geq \frac{1}{s} \mathcal{N}_D(s), \]

for any \( s > 0. \)

\[ \Box \]

4.3. **Dirichlet–Neumann bracketing**

In this and the following sections, fix a set of weights \( w_i^F \) as in Section 3.3 and let \( \mu \) be the corresponding measure.

In order to deduce properties of the counting function for \( V \)-variable fractals we use the method of Dirichlet–Neumann bracketing.

Let \( \Lambda_k \) be the sequence of cutsets (51). Using the notation of (12) and analogously to (9), define

\[ \tilde{V}_k = \bigcup \{ \psi_i(V_0) : i \in \Lambda_k \}, \]

\[ \tilde{E}_k = \bigcup \{ \psi_i(E_0) : i \in \Lambda_k \}, \]

\[ \tilde{G}_k = (\tilde{V}_k, \tilde{E}_k). \]

Thus \( \tilde{G}_k = (\tilde{V}_k, \tilde{E}_k) \) is the graph associated with the vertices \( \tilde{V}_k \) of the cells determined by \( \Lambda_k \).
Define \((E^k, F^k)\) by

\[
F^k = \{ f : K \setminus \widetilde{V}_k \to \mathbb{R} \mid \forall i \in \Lambda_k \exists f_i \in F^{\sigma_i} : f \circ \psi_i = f_i \text{ on } K^{\sigma_i} \setminus \partial K^{\sigma_i} \},
\]

\[
E^k(f, g) = \sum_{i \in \Lambda_k} \rho_i E^{\sigma_i}(f \circ \psi_i, g \circ \psi_i) \quad \text{for } f, g \in F^k.
\] (78)

The functions in \(F^k\) should be regarded as continuous functions on the disjoint union \(\bigsqcup_{i \in \Lambda_k} K_i\) together with its natural direct sum topology. Note that here we are regarding \(F^k\) as a linear subspace of \(L^2(K, \mu)\).

Define \((E^D_k, F^D_k)\) by

\[
F^D_k = \{ f \in F^k \mid \forall i \in \Lambda_k f_i|_{\widetilde{V}_0} = 0, \text{ where } f_i \text{ is as in (78)} \},
\]

\[
E^D_k(f, g) = E^k(f, g) \quad \text{for } f, g \in F^D_k.
\] (79)

Thus \(F^D_k\) is the restriction of \(F^k\) (and of \(F\)) to those functions which are zero on \(\widetilde{V}_k\), and \(E^D_k\) is the restricted energy functional.

It is straightforward to see that

\[
F^D_k \subset F_D \subset F \subset F^k, \quad E^D_k \subset E_D \subset E \subseteq E^k.
\] (80)

That is, \(E\) is just the restriction to \(F\) of the functional \(E^k\) and similarly for the other cases.

Note that \((E^k, F^k)\) and \((E^D_k, F^D_k)\) are local regular Dirichlet forms on the spaces \(L^2(\bigsqcup_{i \in \Lambda_k} K_i, \mu)\) and \(L^2(K \setminus \widetilde{V}_k, \mu)\) respectively, with discrete spectra and bounded reproducing Dirichlet kernels, see [30].

Analogously to (74) and (73) we define the notion that \(\lambda\) is an \((E^k, F^k)\), respectively \((E^D_k, F^D_k)\), eigenvalue with eigenfunction \(u\). The corresponding counting functions are

\[
\mathcal{N}^k_N(s) = \max \{ i : \lambda_i \leq s, \lambda_i \text{ is an } (E^k, F^k) \text{ eigenvalue} \},
\]

\[
\mathcal{N}^k_D(s) = \max \{ i : \lambda_i \leq s, \lambda_i \text{ is an } (E^D_k, F^D_k) \text{ eigenvalue} \}.
\] (81)

In order to compare the various counting functions, first note that if \(\Lambda = \Lambda_k\) then the decomposition (30) with \(E\) replaced by \(E^k\), and the decomposition (46), both generalise to functions \(f, g \in F^k\). The key observation now is that if \(\lambda\) is a (Neumann) \((E^k, F^k)\) eigenvalue with eigenfunction \(u\), then we have for all \(v \in F^k\) that

\[
\sum_{i \in \Lambda_k} \rho_i E^{\sigma_i}(u \circ \psi_i, v \circ \psi_i) = E^k(u, v) = \lambda(u, v)\mu = \lambda \sum_{i \in \Lambda_k} \mu_i(u \circ \psi_i, v \circ \psi_i)_{\mu^{\sigma_i}}.
\] (82)

If we take \(v\) to be a function supported on a complex with address \(i \in \Lambda_k\), we see that

\[
E^{\sigma_i}(u \circ \psi_i, v \circ \psi_i) = t_i \lambda(u \circ \psi_i, v \circ \psi_i)_{\mu^{\sigma_i}},
\] (83)

since \(t_i = \rho_i^{-1} \mu_i\). Thus \(t_i \lambda\) is an eigenvalue of \((E^{\sigma_i}, F^{\sigma_i})\) with eigenfunction \(u_i = u \circ \psi_i\). Conversely, from \(u_i\) we can construct (Neumann) eigenfunctions and eigenvalues for \((E^k, F^k)\), since

\[
\tilde{u}_i := \begin{cases} u_i \circ \psi_i^{-1}, & \text{on } K_i \subset \bigsqcup_{j \in \Lambda_k} K_j, \\ 0, & \text{on } \bigsqcup_{j \in \Lambda_k \setminus i} K_j \end{cases}
\] (84)

is an eigenfunction with eigenvalue \(\lambda\). Hence

\[
\mathcal{N}^k_N(s) = \sum_{i \in \Lambda_k} \mathcal{N}^{\sigma_i}_N(t_i s), \quad \mathcal{N}^k_D(s) = \sum_{i \in \Lambda_k} \mathcal{N}^{\sigma_i}_D(t_i s),
\] (85)

with the argument in the Dirichlet case being similar to that for the Neumann case.
Lemma 4.2. The following relationships hold for all $s > 0$

$$\sum_{i \in \Lambda_k} N_D^\sigma(t_is) \leq N_D(s) \leq N_N(s) \leq \sum_{i \in \Lambda_k} N_N^\sigma(t_is),$$

$$N_D(s) \leq N_N(s) \leq N_D(s) + d + 1.$$  \hfill (86)

**Proof.** The proofs are a consequence of Dirichlet–Neumann bracketing and are straightforward extensions of those found in [29], Section 4.1 for the p.c.f. fractal case. The upper bound on the difference in the Neumann and Dirichlet counting functions is given by the number of vertices of $V_0$, which is $d + 1$ in our setting. \hfill \Box

4.4. **Eigenvalue estimates**

As in the previous section, fix weights $w^F_i$ and the corresponding measure $\mu$. Let the random variable $\lambda^D_1$ denote the first Dirichlet eigenvalue.

**Lemma 4.3.** If $C$ is the upper bound on the diameter of $K$ in the resistance metric given in Corollary 3.4 then for $n \geq 2$,

$$C^{-1} \leq \lambda^D_1 \leq \frac{d(d + 1)\rho^n_{sup}}{\mu(K \setminus K_{b,n})},$$

$$V = 1 \implies \lambda^D_1 \leq \frac{(d + 1)^2\rho^2_{sup}w^2_{sup}}{w^2_{inf}},$$

where $K_{b,n}$ is the union of the $d + 1$ boundary $n$-complexes attached to the $d + 1$ boundary vertices in $V_0$.

**Proof.** Since the Dirichlet form is a resistance form we have for $f \in F_D$ that

$$\|f(x) - f(y)\|^2 \leq R(x, y)E(f, f).$$

Since $\mu$ is a probability measure and $f \in F_D$, using Corollary 3.4 and the definition of $R(x, y)$ in (31), it follows that

$$\|f\|^2 \leq \sup_{x \in K^{w}} |f(x)|^2 \leq \sup_{x, y \in K} |f(x) - f(y)|^2 \leq \sup_{x, y \in K} R(x, y)E(f, f) \leq C E(f, f).$$

Hence by Rayleigh–Ritz,

$$\lambda^D_1 = \inf_{f \in F_D} \frac{E(f, f)}{\|f\|^2} \geq C^{-1}.$$

Next let $f(x) = 0$ for $x \in V_0$, $f(x) = 1$ for $x \in V_n \setminus V_0$, and harmonically interpolate. Then

$$E(f, f) = E_n(f, f) \leq d(d + 1)\rho^n_{sup},$$

$$\int_{K^n} f(x)^2 \mu(dx) \geq \mu(K \setminus K_{b,n}).$$

Again by Rayleigh–Ritz, this gives the upper bound.

If $V = 1$ note that with $n = 2$ there are at least $d(d + 1)$ interior cells as well as $d + 1$ boundary cells. Since all cells have the same type, from (42) in Lemma 3.6 with $\zeta = w_{inf}/w_{sup}$,

$$\mu(K \setminus K_{b,2}) \geq d \zeta^2 \mu(K_{b,2}) = d \zeta^2(1 - \mu(K \setminus K_{b,2})).$$

\therefore \mu(K \setminus K_{b,2}) \geq \frac{d \zeta^2}{1 + d \zeta^2} \geq \frac{d \zeta^2}{d + 1}.$$
This now gives the result for \( V = 1 \).

In order to obtain \( P_V \)-almost sure results we need to estimate the tail of the bottom eigenvalue random variable. Note that this result is only relevant in the case where \( V > 1 \) as if \( V = 1 \) then \( \lambda_1^D \) is bounded above by (87).

**Lemma 4.4.** There exist constants \( A > 0 \) and \( \gamma > 0 \) such that for any \( x > 0 \),

\[
P_V(\lambda_1^D > x) \leq Ax^{-\gamma}.
\]  \tag{88}

**Proof.** Let \( n = n^w \) be the first neck such that \( n \geq 2 \). It follows from (42) with \( K_{b,n} \) as in Lemma 4.3 that

\[
\text{if } \xi := \frac{w_{\inf}}{w_{\sup}} \text{ then } \mu(K \setminus K_{b,n}) > \frac{\xi^n}{d+1}\mu(K_{b,n}) = \frac{\xi^n}{d+1}(1 - \mu(K \setminus K_{b,n})).
\]

Hence

\[
\mu(K \setminus K_{b,n}) > \frac{1}{1 + (d+1)\xi^{-n}} \geq \frac{\xi^n}{d+2}.
\]

From Lemma 4.3 it follows that

\[
\lambda_1^D < d(d+1)(d+2)\rho_{\sup}^w\xi^{-n} = d(d+1)(d+2)\xi^n \quad \text{where } \xi := \frac{\rho_{\sup} w_{\sup}}{w_{\inf}}.
\]

Hence

\[
P_V(\lambda_1^D > x) \leq P_V\left(d(d+1)(d+2)\xi^n > x\right) = P_V\left(n > \frac{\log x}{\log \xi}\right).
\]

Let \( q \) be the probability that any fixed level is not a neck. Since the event of a neck occurring or not at each level is independent of the corresponding event at all other levels, it follows there exists \( C > 0 \) such that if \( y > 0 \) then

\[
P_V(n > y) \leq Cq^y.
\]

Setting \( \gamma = (1/q)/\log \xi \) and \( A = C/(d(d+1)(d+2))^{\gamma} \) gives the required result. \( \square \)

Define

\[
\widehat{\lambda}_1^k = \max\{\lambda_{1,i^1,D} : i \in \Lambda_k\},
\]

where \( \lambda_{1,i^1,D} \) is the first Dirichlet eigenvalue of the Dirichlet form \((E^{\sigma_i},F) = (E^{\sigma_i\omega},F^\omega)\) with respect to the measure \( \mu^{\sigma_i} = \mu^{\sigma_i\omega} \). Note that \( \widehat{\lambda}_1^0 = \lambda_1^D \).

If \( V = 1 \) by (87) we have \( \widehat{\lambda}_1^k \leq (d+1)^2\rho_{\sup}^2 w_{\sup}^2 / w_{\inf}^2 \) for all \( k \).

**Lemma 4.5.** If \( V > 1 \), then with \( \gamma \) as in Lemma 4.4 and with \( c_4 \) as in Lemma 3.9(b), we have \( P_V \) a.s. that

\[
\widehat{\lambda}_1^k \leq (Vc_4k)^{2/\gamma}.
\]  \tag{90}

**Proof.** In order to apply the growth estimate in the previous lemma and use Lemma 2.16 we use two additional properties:

1. The number of distinct subtrees, and hence eigenvalues, corresponding to each level of \( T \) is uniformly bounded (by \( V \));
2. The maximum level corresponding to nodes in \( \Lambda_k \) is asymptotically bounded by a multiple of \( k \), see Lemma 3.9.
First consider any sequence of random \( V \)-variable IFS trees \( (T_j)_{j \geq 1} \), not necessarily independent but all with the same distribution \( P = P_V \), see Definition 2.11. Let the corresponding random first eigenvalues be \( Y_j \).

Then for all \( x \geq 0 \),

\[
P(Y_j > x) \leq A x^{-\gamma} \quad \text{by Lemma 4.4},
\]

\[
\therefore P(\log Y_j > x) = P(Y_j > e^x) \leq A e^{-\gamma x}, \tag{91}
\]

\[
\therefore \max_{1 \leq j \leq k} \log Y_j \leq \gamma^{-1} \log k, \quad P_V \text{ a.s. by Lemma 2.16,}
\]

\[
\therefore \max_{1 \leq j \leq k} Y_j \leq k^{2/\gamma}, \quad P_V \text{ a.s.}
\]

For any tree \( T = T^\omega \) there are at most \( V \) non-isomorphic subtrees rooted at each level. Let \( (Y_j)_{j \geq 0} \) be the sequence of random variables given by the first eigenvalue of \( T \), followed by the first eigenvalues of non-isomorphic IFS subtrees of \( T \) at level one (there are at most \( V \)), followed by the first eigenvalues of non-isomorphic IFS subtrees of \( T \) at level two (again there are at most \( V \)), etc. If \( Y_j \) corresponds to a subtree rooted at level \( p \) then by construction \( j \leq V p \).

Hence \( P_V \text{ a.s.,} \)

\[
\limsup_{k \to \infty} \frac{\lambda_1^k}{k^{2/\gamma}} \leq \limsup_{k \to \infty} \frac{\max_{1 \leq j \leq V z_k} Y_j}{(V z_k)^{2/\gamma}} \left( \frac{V z_k}{k} \right)^{2/\gamma}
\]

\[
\leq \left( \limsup_{k \to \infty} \frac{V z_k}{k} \right)^{2/\gamma} \quad \text{from (91)}
\]

\[
\leq (V c_k)^{2/\gamma},
\]

since \( z_k \leq c_k k \) from Lemma 3.9(b). This gives the result. \( \square \)

We now wish to determine the limiting behaviour of the counting function. We first give the following result that is true for all \( \omega \in \Omega_{V, \xi} \).

Recall \( \eta(< 1) \) defined in (49), and the quantities defined in (89) and (53)–(55).

**Lemma 4.6.** There exists a constant \( c_1 \) such that if \( \omega \in \Omega_{V, \xi} \) then

\[
N_D(T_k) \leq c_1 M_k, \quad M_k \leq N_D(\lambda_1^k T_k \eta^{-\xi}) \tag{92}
\]

for all \( k \geq 0 \).

**Proof.** For the first estimate we have from (86), (53) and Lemma 4.1,

\[
N_D(T_k) \leq \sum_{i \in \Lambda_k} N_N^{\alpha_i} (t_i T_k) \leq (d + 1) M_k + \sum_{i \in \Lambda_k} N_D^{\alpha_i} (t_i T_k)
\]

\[
\leq (d + 1) M_k + c T_k \sum_{i \in \Lambda_k} t_i \leq c_1 M_k.
\]

Next note from definitions (53), (76) and (89) of \( M_k, N_D \) and \( \lambda_1^k \) respectively, from the fact \( \lambda_1^{\alpha_i},D < \lambda_2^{\alpha_i},D \) for the equality below, and from (86) for the last inequality provided \( t_i^{-1} \leq c(k) \) for all \( i \in \Lambda_k \), that

\[
M_k = \sum_{i \in \Lambda_k} N_D^{\alpha_i} (\lambda_1^{\alpha_i},D) \leq \sum_{i \in \Lambda_k} N_D^{\alpha_i} (\lambda_1^k) \leq N_D(\lambda_1^k c(k)). \tag{93}
\]

But \( t_i^{-1} \leq \eta^{-\xi} e^{\delta} \leq \eta^{-\xi} T_k \) from Lemma 3.9(c) and the definition (53) of \( T_k \). This gives the second estimate. \( \square \)
For $V = 1$ we can improve this to the same estimate as that obtained in [2], Section 7.

**Corollary 4.7.** For $V = 1$, for all $\omega \in \Omega_1$ there exist constants $c_1$ and $c_2$ such that for all $k \geq 0$,

$$M_k \leq N_D(c_1 T_k) \quad \text{and} \quad N_D(T_k) \leq c_2 M_k.$$  

**Proof.** As $V = 1$ the conditions required for the existence of the measure $\mu$ hold for all $\omega \in \Omega_1$. We also know that $\lambda_k^1$ is bounded above and as $y_k = 1$ for all $k \in \mathbb{N}$ the inequality on the right in (92) reduces to $M_k \leq N_D(c_1 T_k)$ as required. $\square$

We next use asymptotic information about the frequency of necks to obtain the following.

**Lemma 4.8.** For $V > 1$ there exist constants $c_1, c_2$ and $\alpha$ such that $P_V$ a.s. there is a $k_0(\omega)$ for which

$$N_D(T_k) \leq c_1 M_k, \quad M_k \leq N_D(c_2 k^\alpha T_k) \quad \text{if} \ k > k_0(\omega).$$  

**Proof.** This follows from Lemma 4.6, since $\lambda_k^1 \lesssim c_2 k^{2/\gamma}$ by (90) and $\eta^{-y_k} \lesssim k^{\beta'}$ by Lemma 3.9(c). $\square$

**4.5. Spectral exponent**

We again fix weights $w^F_i$ and let $\mu$ be the corresponding measure as in Definition 3.5.

**Definition 4.9.** The pressure function $\gamma = \gamma(\beta)$ where $\beta \in \mathbb{R}$, and the constant $\beta_0$, are defined by

$$\gamma(\beta) = E_V \log \sum_{|i| = n(1)} t_i^{\beta/2}. \quad \gamma(\beta_0) = 0. \quad (94)$$

(It follows from Lemma 4.11 that $\beta_0$ is unique.)

The pressure function and its zero can be found computationally. See [7] for similar computations for the fractal dimension.

**Definition 4.10.** The spectral exponent $d_s(\mu)$ for $\mu$ is defined by

$$d_s(\mu) = \frac{1}{2} \lim_{s \to \infty} \frac{\log N_D(s)}{\log s}. \quad (95)$$

We see in Theorem 4.13 that a.s. the spectral exponent exists and equals the constant $\beta_0$. By Lemma 4.2 we could replace $N_D$ by $N_N$.

Recall the definition of $\eta$ in (49) and the estimate for $t_i$ from (50).

**Lemma 4.11.** The function $\gamma(\beta)$ is finite, strictly decreasing and Lipschitz, with derivative in the interval $[\log(\eta^{1/2})E_V n(1), \log(r_{\sup}^{1/2})E_V n(1)]$. Since $\gamma(0) > 0$ there is a unique $\beta_0$ such that $\gamma(\beta_0) = 0$ and moreover $\beta_0 > 0$.

**Proof.** If $\alpha < \beta$ then from (49) and (50),

$$\gamma(\alpha) + \frac{\beta - \alpha}{2} (\log \eta) E_V n(1) \leq \gamma(\beta) \leq \gamma(\alpha) + \frac{\beta - \alpha}{2} (\log r_{\sup}) E_V n(1).$$

This gives the Lipschitz estimate. Since $\gamma(0) = E_V (\log \# \{i \in T||i| = n(1)\})$, it follows that $0 < \gamma(0) < \infty$.

The rest of the lemma follows. $\square$
Proposition 4.12. \( P_V \) a.s. we have
\[
\lim_{k \to \infty} \frac{1}{k} \log \frac{\sum_{|i| = n(k)} t_i^{\beta/2}}{\sum_{|i| = n(k)}} = \gamma(\beta).
\] (96)

**Proof.** The idea is that from the definition of a neck, \( \log \sum_{|i| = n(k)} t_i^{\beta/2} \) is the difference of two random variables, each of which is the sum of \( k \) i.i.d. random variables having the same distribution as \( \sum_{|i| = n(1)} (r_i w_i)^{\beta/2} \) and \( (\beta/2) \log \sum_{|i| = n(1)} w_i \) respectively.

More precisely, suppose \( |i| = n(k) \) and in particular is a neck. Then
\[
t_i = r_i \mu_i = \frac{r_i w_i}{\sum_{|j| = n(k)} w_j}.
\]

and so
\[
\log \frac{\sum_{|i| = n(k)} t_i^{\beta/2}}{\sum_{|i| = n(k)}} = \log \frac{\sum_{|i| = n(k)} (r_i w_i)^{\beta/2}}{\sum_{|i| = n(k)}} - \frac{\beta}{2} \log \sum_{|i| = n(k)} w_i.
\] (97)

If we let \( s_i^F = (r_i w_i^F)^{\beta/2} \) or \( s_i^F = w_i^F \), it follows from (24) and (39) that
\[
0 < s_{\inf} := \inf \{ s_i^F : i \in 1, \ldots, N^F, F \in \mathcal{F} \},
\]
\[
s_{\sup} := \sup \{ s_i^F : i \in 1, \ldots, N^F, F \in \mathcal{F} \} < \infty.
\] (98)

and we can apply Lemma 2.17. Thus (19) applied to each term on the right-hand side of (97) gives the result. \( \square \)

Subsequently we write \( \bar{N} \) for \( N_D \). But note that from the second line in Lemma 4.2 the main estimates in the rest of the paper also apply immediately to \( \bar{N}_N \).

The proof of the following theorem relies on the Dirichlet–Neumann bracketing result in Lemma 4.8 and the estimates in Lemma 3.9(c).

**Theorem 4.13.** The spectral exponent is given by \( \beta_0 \) in that
\[
d_s(\mu) / 2 := \lim_{t \to \infty} \frac{\log \mathcal{N}(s)}{\log s} = \frac{\beta_0}{2}, \quad P_V \text{ a.s.}
\] (99)

**Proof.** Define the unit mass measure \( \nu_\beta \) on \( \partial T \) by setting, for any \( \beta \) and for \( |i| = n(k) \),
\[
\nu_\beta[i] = \frac{t_i^{\beta/2}}{\sum_{|i| = n(k)} t_i^{\beta/2}}.
\]

It is straightforward to check that \( \nu_\beta \) is just the unit mass measure with weights \( (r_i w_i)^{\beta/2} \) as in Definition 3.5.

If \( \gamma(\beta) < 0 \) or equivalently \( \beta > \beta_0 \), then from (96) for \( \varepsilon > 0 \) small enough we have \( P_V \) a.s. that there is a constant \( k_0 \) such that
\[
\nu_\beta[i] \geq t_i^{\beta/2} e^{-k(\gamma(\beta) + \varepsilon)} \geq ct_i^{\beta/2} \quad \text{if} \ k \geq k_0.
\]

As \( \Lambda_k \) is a cut set, by using the lower estimate above we have from Lemma 3.9(c) that \( P_V \) a.s. if \( k \geq k_0 \) then
\[
1 \geq \sum_{i \in \Lambda_k} \nu_\beta[i] \geq \sum_{i \in \Lambda_k} ct_i^{\beta/2} \gtrsim c M_k k^{-\beta'/2} e^{-k^{\beta'/2}} \text{ for some } \beta' > 0.
\]

Thus
\[
M_k \lesssim ck^{\beta'/2} e^{k^{\beta'/2}}, \quad P_V \text{ a.s.}
\] (100)
Suppose $s > 1$ and let $k$ be such that $e^{k-1} < s \leq e^k$. Then $s \leq T_k$ by Lemma 3.9(c) and so

$$\frac{\log N(s)}{\log s} \leq \frac{\log N(T_k)}{\log s} \leq \frac{\log(cM_k)}{k-1} \leq \frac{\beta}{2}, \quad P_V \text{ a.s.,}$$

where the second inequality is from the first estimate in Lemma 4.8 and the third inequality is from (100).

As this holds for all $\beta > \beta_0$ we have

$$\frac{\log N(s)}{\log s} \leq \frac{\beta_0}{2}, \quad P_V \text{ a.s.} \quad (101)$$

Similarly we have an asymptotic lower bound. For this choose $\beta < \beta_0$, or equivalently such that $\gamma(\beta) > 0$. Then for small enough $\varepsilon > 0$ we have $P_V$ a.s. that for some $k_0 = k_0(\omega)$

$$v_{\beta}(i) \leq ct_i^{\beta/2} \quad \text{if} \quad k \geq k_0,$$

and hence from Lemma 3.9(c), that $P_V$ a.s. then

$$1 = \sum_{i \in \Lambda_k} v_{\beta}(i) \leq \sum_{i \in \Lambda_k} ct_i^{\beta/2} \leq cM_ke^{-k\beta/2} \quad \text{if} \quad k \geq k_0.$$

Thus $P_V$ a.s.

$$M_k \geq ce^{k\beta/2} \quad \text{if} \quad k \geq k_0. \quad (102)$$

From the second estimate in Lemma 4.8 and using (102),

$$\frac{\log N(c_2k^\alpha T_k)}{k} \geq \frac{\log M_k}{k} \geq \frac{\beta}{2}, \quad P_V \text{ a.s.} \quad (103)$$

Again choosing $k$ such that $e^{k-1} \leq s < e^k$, we have from Lemma 3.9(c) that for some $\alpha'$,

$$k^\alpha T_k \leq k^{\alpha'}e^{k} \leq e(1 + \log s)^{\alpha'}s, \quad P_V \text{ a.s.}$$

Hence

$$\liminf_{k \to \infty} \frac{\log N(c_2k^\alpha T_k)}{k} \leq \liminf_{s \to \infty} \frac{\log N(2c_2e(1 + \log s)^{\alpha'}s)}{\log s}, \quad P_V \text{ a.s.}$$

Setting $y = y(s) = 2c_2e(1 + \log s)^{\alpha'}$, since $\lim_{s \to \infty} \log y(s)/\log s = 1$ and $y(s) \to \infty$ as $s \to \infty$, it follows

$$\liminf_{k \to \infty} \frac{\log N(c_2k^\alpha T_k)}{k} \leq \liminf_{s \to \infty} \frac{\log N(s)}{\log s}, \quad P_V \text{ a.s.}$$

Combining this with (103), since $\beta < \beta_0$ is arbitrary, implies

$$\frac{\log N(s)}{\log s} \geq \frac{\beta_0}{2}, \quad P_V \text{ a.s.} \quad (104)$$

The required result follows from (101) and (104). \qed

4.6. Spectral dimension

Definition 4.14. The flat measure with respect to the resistance metric is the unit mass measure $\nu$ with weights $w_i^F = (r_i^F)^{d_f^r}$, where $d_f^r$ is the Hausdorff dimension in the resistance metric (see Definition 3.5). The spectral dimension $d_s$ is the spectral exponent for the flat measure.
Further justification for the definition of $d_s$ is given in Theorem 4.17.

Recall from Theorem 3.12 that $d_f'$ is uniquely characterised by

$$\sum_{|i| = n(1)} r_i^{d_f'} = 0.$$ (105)

As a consequence, the following theorem establishes the analogue of Conjecture 4.6 in [28] for $V$-variable fractals.

**Theorem 4.15.** The spectral exponent for the flat measure $\nu$ is given $P_V$ a.s. by

$$\frac{d_s(\nu)}{2} = \frac{d_f'}{d_f' + 1}.$$ (106)

**Proof.** From Definition 4.14, (94), (48) and (41), if $|i| = n(\ell)$ is a neck then

$$t_i := r_i w_i = \frac{r_i w_i}{\sum_{|j| = n(\ell)} w_j} = \frac{1 + d_f'}{\sum_{|j| = n(\ell)} r_j^{d_f'}}.$$ (107)

Hence the spectral exponent $d_s(\nu)$ is uniquely characterised by

$$0 = \gamma(d_s(\nu)) := EM \log \sum_{|i| = n(1)} t_i^{d_s(\nu)/2} = EM \log \sum_{|i| = n(1)} \left( \frac{r_i^{1 + d_f'}}{\sum_{|j| = n(1)} r_j^{d_f'}} \right)^{d_s(\nu)/2}.$$ (108)

Using (105),

$$0 = EM \log \sum_{|i| = n(1)} r_i^{(1 + d_f')d_s(\nu)/2} - \frac{d_s(\nu)}{2} EM \log \sum_{|j| = n(1)} r_j^{d_f'}$$

$$= EM \log \sum_{|i| = n(1)} r_i^{(1 + d_f')d_s(\nu)/2}.$$ (109)

Using (105) again and the uniqueness of $d_f'$, it follows that $d_f' = (1 + d_f')d_s(\nu)/2$, which gives (106). \qed

We next show that the spectral dimension maximises the spectral exponent $d_s(\mu)$ over all measures $\mu$ defined from a set of weights $w_i^F$ as in Section 3.3. A related result for deterministic fractals is established in Theorem A2 of [33] using Lagrange multipliers. Here we need a different argument, but this also establishes uniqueness of the $w_i^F$ and hence of $\mu$.

The proof is partly motivated by [25], in particular Section 4 and the discussion following Corollary 2.7. We first need the following general inequality.

**Proposition 4.16.** Suppose $\{p_1, \ldots, p_N\}$ and $\{q_1, \ldots, q_N\}$ are sets of positive real valued random variables, each with the same random cardinality $N$, on a probability space $(\Omega, \mathbb{P})$. Suppose $EM \log \sum_{k=1}^N p_k = 0$ and that the constant $\gamma$ satisfies $0 < \gamma < 1$. Then

$$EM \log \sum_{k=1}^N p_k q_k^{\gamma} \leq EM \log \left( \sum_{k=1}^N p_k q_k \right)^{\gamma},$$ (109)

with equality iff $q_1 = \cdots = q_N$ a.s.
Proof. For any $N$, a suitable version of Hölder’s inequality for sequences yields

$$\sum_{k=1}^{N} p_k q_k^{\gamma} \leq \left( \sum_{k=1}^{N} p_k \right)^{1-\gamma} \left( \sum_{k=1}^{N} p_k q_k \right)^{\gamma}. \quad (110)$$

Taking logs and expectations, and using the assumption on the random sets $\{p_1, \ldots, p_N\}$ gives

$$E V \log \sum_{k=1}^{N} p_k q_k^{\gamma} \leq (1 - \gamma) \mathbb{E} \log \sum_{k=1}^{N} p_k + \mathbb{E} \log \left( \sum_{k=1}^{N} p_k q_k \right)^{\gamma} = \mathbb{E} \log \left( \sum_{k=1}^{N} p_k q_k \right)^{\gamma}. \quad (111)$$

This gives (109).

If $q_1 = \cdots = q_N = c$ a.s. where $c$ is a random variable, then equality holds in (109) since both sides equal $\mathbb{E} \log c^{\gamma}$.

If it is not the case that $q_1 = \cdots = q_N$ a.s. then strict inequality holds in (110) with positive probability and hence strict inequality holds in (111). \qed

Theorem 4.17. The spectral dimension $d_s$ is the maximum spectral exponent $d_s(\mu)$ over all measures $\mu$ defined on weights $w_i^F$. Equality holds if and only if for some constant $c$, $w_i^F = c (r_i^F)^{d_f^\gamma}$ $P_V$ a.s., in which case the corresponding measure $\mu$ is the flat measure with respect to the resistance metric.

Proof. For $|i| = n(1)$ let $p_i = r_i^{d_f^\gamma}$, so that $E V \log \sum_{|i|=n(1)} p_i = 0$.

Suppose $w = \{w_i^F | f \in F, 1 \leq j \leq N^F\}$ is a set of weights and consider the corresponding $w_i$. Let $q_i = w_i / r_i^{d_f^\gamma}$. Then from (109),

$$E V \log \sum_{|i|=n(1)} (r_i^{d_f^\gamma})^{1-\gamma} w_i^{\gamma} \leq E V \log \left( \sum_{|i|=n(1)} w_i \right)^{\gamma}. \quad (112)$$

Choosing $\gamma$ so that the powers of $r_i$ and $w_i$ are equal, gives $\gamma = d_f^\gamma / (d_f^\gamma + 1)$, i.e. $\gamma = d_s / 2$. Hence

$$E V \log \sum_{|i|=n(1)} r_i^{d_f^\gamma/2} = E V \log \left( \sum_{|i|=n(1)} r_i^{d_f^\gamma/2} w_i \right)^{d_s/2} = 0.$$ 

Moreover, by Proposition 4.16 equality holds if and only if $P_V$ a.s. it is the case that $w_i / r_i^{d_f^\gamma}$ is independent of $i$ for $|i| = n(1)$. Clearly, this is true iff $w_i^F = c (r_i^F)^{d_f^\gamma}$ $P_V$ a.s. for some constant $c$.

From the definition (94) of $d_s(\mu)$, we have $E V \log \sum_{|i|=n(1)} r_i^{d_s(\mu)/2} = 0$. From Lemma 4.11 and the previous inequality, it follows that $d_s(\mu) \leq d_s$, and equality holds iff $w_i^F = c (r_i^F)^{d_f^\gamma}$ $P_V$ a.s. for some constant $c$. \qed

We next give a sharpening of Theorem 4.13 in the case of the flat measure with respect to the resistance metric. This shows that for this measure, for all $V > 1$, we have the same fluctuations as observed in the version of the $V = 1$ case treated in [2]. For this, let

$$\Phi(s) = \sqrt{s \log \log s}, \quad \phi(s) = \exp(\Phi(\log s)) = \exp(\sqrt{s \log s \log \log s}). \quad (112)$$

Theorem 4.18. Suppose $\mu$ is the flat measure in the resistance metric. Then there exist positive (non-random) constants $c_1, c_2, c_3, c_4$, and there exists a positive finite random variable $c_0 = c_0(\omega)$, such that if $s \geq c_0$ then

$$c_1 \phi(s)^{-c_2} \leq N(s) / s^{d_s/2} \leq c_3 \phi(s)^{c_4} \quad P_V \ a.s.$$
Proof. Consider the unit mass measure $\nu_\beta$ constructed in the proof of Theorem 4.13, where now $\beta = d_s$ is the spectral dimension as in (108).

In the following the constant $c$ may change from line to line, and even from one inequality to the next.

If $|i|$ is a neck and $|i| = n(\ell)$ then from (106) and (107),

$$v_{d_s}[i] = \frac{t_i^{d_i/2}}{\sum_{|j| = n(\ell)} t_j^{d_j/2}} = \frac{t_i^{d_i/2}}{\left(\sum_{|j| = n(\ell)} r_j^{d_j/2}\right)^{1/(1+d_i/2)}}. \quad (113)$$

Using the law of the iterated logarithm, as in Theorem 2.19 and from the decomposition (20), $P_V$ a.s. there exists a constant $c$ such that, for $\ell$ sufficiently large,

$$-c \leq \log \frac{\sum_{|i| = n(\ell)} r_i^{d_i/2}}{\Phi(\ell)} \leq c \quad \text{i.e.} \quad e^{-c\Phi(\ell)} \leq \sum_{|i| = n(\ell)} r_i^{d_i/2} \leq e^{c\Phi(\ell)} \quad (114).$$

Since $v_{d_s}$ is a unit mass measure and $\Lambda_k$ is a cut set, it follows from (113) and (114) by summing over $i \in \Lambda_k$ that, for $k$ sufficiently large,

$$\sum_{i \in \Lambda_k} t_i^{d_i/2} e^{-c\Phi(\ell(i))} \leq 1 \leq \sum_{i \in \Lambda_k} t_i^{d_i/2} e^{c\Phi(\ell(i))}, \quad (115)$$

where $\ell(i)$ is defined in (52). But from Lemma 3.9(c) and Lemma 3.9(a) respectively, the following hold $P_V$ a.s. for $i \in \Lambda_k$ and $k$ sufficiently large:

$$c^{-1}k^{-\beta'}e^{-k} \leq t_i \leq e^{-k}, \quad \ell(i) \leq c_2 k.$$ Moreover, $\Phi(ck) \leq e^c\Phi(k)$ for some $e^c = e^c(c)$ and all $k \geq 3$. It follows from (115) that, for $k$ sufficiently large,

$$c^{-1}M_k e^{-k d_s/2} e^{-c \Phi(k)} \leq 1 \leq cM_k e^{-k d_s/2} e^{c \Phi(k)},$$

since $k^{-\beta d_s/2}$ can be absorbed into $e^{-c \Phi(k)}$, with a new $c$. That is

$$c^{-1}e^{k d_s/2} e^{-c \Phi(k)} \leq M_k \leq c e^{k d_s/2} e^{c \Phi(k)}. \quad (116)$$

Given $s > 0$ choose $k$ so $e^{k-1} < s \leq e^k$. Note also from Lemma 3.9(c) that $e^{k} \leq T_k \leq c k^\beta e^k$, for $k$ sufficiently large. Then from Lemma 4.8 and (116),

$$N(s) \leq M_k \leq c e^{k d_s/2} e^{c \Phi(k)} \leq c s^{d_s/2} \phi(s)^c, \quad (117)$$

where for the last inequality we note that $\Phi(k) \leq \Phi(1 + \log s) \leq c \Phi(\log s)$.

Similarly, again from Lemma 4.8 and (116),

$$N(k^\beta T_k) \geq M_k \geq c^{-1} e^{k d_s/2} e^{-c \Phi(k)} \geq c^{-1} s^{d_s/2} \phi(s)^{-c}.$$ But $k^\beta T_k \leq c(\log s)^{\beta'+\beta''} \leq c^s s$ for $s \geq 2$ and $\phi = c^s(c, \beta', \beta'')$. It follows that $N(e^s t) \geq c^{-1} s^{d_s/2} \phi(s)^{-c}$ and so

$$N(s) \geq c^{-1} s^{d_s/2} \phi(t)^{-c} \quad (118)$$

if $\log \log \log s > 0$, hence if $s \geq 16$.

The result follows from (117) and (118).

Remark 4.19. By using the law of the iterated logarithm in the above we can show that the Weyl limit does not exist in that there is a positive constant $c$ such that

$$0 < \limsup_{s \to \infty} \frac{N(s)}{s^{d_s/2} \phi(s)^c}, \quad P_V \text{ a.s.}$$
5. On-diagonal heat kernel estimates

5.1. Overview

The on-diagonal heat kernel is determined for resistance forms by the volume growth of balls. In [8] it is shown how volume estimates can be translated into heat kernel estimates in the case of non-uniform volume growth. We are in the same setting but will express the bounds in a slightly different way. As we have scale irregularity these will give rise to larger scale fluctuations than the fluctuations arising from the spatial irregularity. Note that we will establish bounds for the Neumann heat kernel and are in a setting where the measure is not volume doubling.

In previous work, in the \( V = 1 \) setting of [2], using our notation in (53) and (113), the results obtained were that for all realizations there are non-random constants \( c_1, c_2 \) such that

\[
c_1 M_k \leq p_k^{-1}(x,x) \leq c_2 M_k \quad \forall x \in K, k \geq 0,
\]

while using a sequence chosen according to \( P_1 \), there are non-random constants \( c_1, c_2, c_3, c_4 \) and a random variable \( c_5 \in (0, \infty) \) under \( P_1 \) such that

\[
c_1 t^{-d_i/2} \phi(1/t)^{-c_3} \leq p_t(x,x) \leq c_2 t^{-d_i/2} \phi(1/t)^{c_4} \quad \forall x \in K, 0 < t < c_5, P_1 \text{ a.s.}
\]

In the random recursive case (\( V = \infty \)) with its natural flat measure, as considered in [21], the fluctuations were shown to be smaller in that there are fixed constants \( c_1, c_2, a > 0 \) and a random variable \( c_3 \in (0, \infty) \) under \( P_\infty \) such that

\[
c_1 t^{-d_i/2} |\log t|^{-a} \leq p_t(x,x) \leq c_2 t^{-d_i/2} |\log t|^a \quad \forall 0 < t < c_3, \forall x \in K, P_\infty \text{ a.s.}
\]

We will show here that the on-diagonal heat kernel estimates for \( V \)-variable fractals are determined by the local environment, see Theorems 5.5 and 5.8. In the case of the flat measure in the resistance metric, see Definition 4.14, we show in Theorem 5.13 that the global fluctuations are of the same order as the \( V = 1 \) case for nested Sierpinski gaskets with uniform measure as described in [2]. In the case of a general class of measures we will see in Theorem 5.12 that \( \mu \)-almost every \( x \in K \) does not have the same spectral exponent as the counting function (except when we choose the flat measure) and there will be a multifractal structure to the local heat kernel estimates in the same way as observed in [4,20].

In order to transfer the fluctuations in the measure to the on-diagonal heat kernel we could apply a local Nash inequality, for example [31] or use [8]. However we use more bare hands arguments adapted from those of [2,4] and [20] in order to keep the scale and spatial fluctuations separate.

Note that in [8,32] it is shown that, in the case of resistance forms with non-uniform volume growth and under assumptions which hold in our setting, there exists a heat kernel which is jointly continuous in \((t, x, y) \in (0, \infty) \times K \times K\) for every \( \omega \in \Omega_{V, \xi} \).

5.2. Upper bound

We adapt the scaling argument given in [20] Appendix B to this setting. This is a purely local argument and works for all \( \omega \in \Omega_{V, \xi} \).

Firstly, recall from Theorem 3.2 and the definitions and discussions around (72), (78), (79), that \((\mathcal{E}, \mathcal{F}), (\mathcal{E}_D, \mathcal{F}_D), (\mathcal{E}^k, \mathcal{F}^k)\) and \((\mathcal{E}^k_D, \mathcal{F}^k_D)\) are local regular Dirichlet forms on \( L^2(K, \mu) \), \( L^2(K \setminus V_0, \mu) \), \( L^2(\bigcup_{i \in \Lambda_k} K_i, \mu) \), \( L^2(K \setminus \tilde{V}_k, \mu) \) respectively. For \( \lambda > 0 \) let

\[
\mathcal{E}_\lambda(f, g) = \mathcal{E}(f, g) + \lambda(f, g)_\mu,
\]

with similar expressions for the other Dirichlet forms. The space \( \mathcal{F} \) equipped with norm \( \mathcal{E}_\lambda^{1/2} \) is again a reproducing kernel Hilbert space and we write \( g_\lambda, g_\lambda^D, g_\lambda^k, \delta_\lambda^k, \delta_\lambda^{k,D} \) for the corresponding reproducing kernels.

We state a scaling property of the Dirichlet form.
Lemma 5.1. For all $f, g \in \mathcal{F}$ we have

$$\mathcal{E}_\lambda(f, g) = \sum_{i \in \Lambda_k} \rho_i \mathcal{E}_{\lambda i}^{\sigma_i}(f \circ \psi_i, g \circ \psi_i).$$

Proof. This follows by the scaling in (30) and (46) and the definition of $t_i$ in (48). \qed

Let $g_{\lambda, D, \sigma}^i(x, y)$ be the reproducing kernel associated with the Dirichlet form $\mathcal{E}_{D, \lambda, \sigma}^i$ on $K_{\sigma}^i$ with Dirichlet boundary conditions and let $g_{\lambda, \sigma}^i(x, y)$ be the reproducing kernel for the Dirichlet form $\mathcal{E}_\lambda^{i, \sigma}$ on $K_{\sigma}^i$ with Neumann boundary conditions.

Lemma 5.2. We have for all $i \in \Lambda_k$ and $x \in K_i$, that

$$g_{\lambda, D, \sigma}^i(\psi_i^{-1}(x), \psi_i^{-1}(y)) = \rho_i g_{\lambda t_i}^{D, i}(x, y)$$

and

$$g_{\lambda, \sigma}^i(\psi_i^{-1}(x), \psi_i^{-1}(y)) = \rho_i g_{\lambda t_i}^{i}(x, y).$$

Proof. We consider $g_{\lambda, D, \sigma}^i(\psi_i^{-1}(x), \psi_i^{-1}(y))$, for $x \in K_i$, which is the reproducing kernel for $(\mathcal{E}_{D, \lambda}^{i, \sigma}, \mathcal{F}_{D}^{i})$ on $L^2(K_{\sigma}^i, \mu_{\sigma}^i)$. We note that $g_{\lambda, D, \sigma}^i(\psi_i^{-1}(y), \psi_i^{-1}(x)) = 0$ for all $y \in K \setminus K_i$. Using this, the reproducing kernel property and the scaling, we have for $x \in K_i$,

$$g_{\lambda, D, \sigma}^i(\psi_i^{-1}(x), \psi_i^{-1}(x)) = \mathcal{E}_{D, \lambda}^i(\rho_i, x, g_{\lambda, D, \sigma}^i(\psi_i^{-1}(\cdot), \psi_i^{-1}(x)))$$

$$= \sum_{j \in \Lambda_k} \rho_j \mathcal{E}_{D, \lambda, \sigma}^j(g_{\lambda, D}^j(\psi_j(\cdot), x), g_{\lambda, D, \sigma}^j(\psi_i^{-1}(\psi_j(\cdot)), \psi_i^{-1}(x)))$$

$$= \rho_i \mathcal{E}_{D, \lambda}^i(g_{\lambda}^i(\psi_i(\cdot), x), g_{\lambda, D, \sigma}^i(\cdot, \psi_i^{-1}(x)))$$

$$= \rho_i g_{\lambda t_i}^{D, i}(x, y)$$

as required. The second equation follows by the same argument. \qed

It is straightforward to see that, as

$$\mathcal{F}_D^k \subset \mathcal{F}_D \subset \mathcal{F} \subset \mathcal{F}_D^k,$$

and $g_{\lambda}(x, y) = \inf(\mathcal{E}_\lambda(f, f) : f \in \mathcal{F}, f(x) \geq 1)^{-1}$, (with similar expressions for $g_{\lambda}^k, g_{\lambda}^{k, D}, g_{\lambda}^D$) we have

$$g_{\lambda}^{k, D}(x, x) \leq g_{\lambda}^D(x, x) \leq g_{\lambda}(x, x) \leq g_{\lambda}^k(x, x) \quad \forall x \in K \setminus \tilde{V}_k. \quad (119)$$

Lemma 5.3. There exists a function $C(\lambda)$ such that for all $\lambda < \infty$

$$\sup_{x \in K} g_{\lambda}(x, x) \leq C(\lambda) < \infty.$$

Proof. We follow the proof of [1] Theorem 7.20. Note that for any fixed $x \in K$ we have $g_{\lambda}(x, \cdot) \in \mathcal{F}$ and hence using (31)

$$|g_{\lambda}(x, y) - g_{\lambda}(x, x)|^2 \leq R(x, y)\mathcal{E}_\lambda(g_{\lambda}(x, \cdot), g_{\lambda}(x, \cdot)).$$
By the reproducing kernel property and the global bound on the resistance across $K$ from Corollary 3.4 we have
\[ |g_\lambda(x, y) - g_\lambda(x, x)|^2 \leq C g_\lambda(x, x). \]

Rearranging
\[ g_\lambda(x, y) \geq g_\lambda(x, x) - \left( C g_\lambda(x, x) \right)^{1/2}, \]
and integrating over $y$ against $\mu$ we have
\[ g_\lambda(x, x) \leq \frac{1}{\lambda} + \left( C g_\lambda(x, x) \right)^{1/2}. \]
The result then follows easily.

\[ \square \]

Lemma 5.4. There exists a constant $C$ such that for all $i \in \Lambda_k$ and $x \in K_i$,
\[ g^{-1}_{i-1}(x, x) \leq C \rho_i^{-1}. \]

**Proof.** By Lemma 5.2 and (119) we have for $x \in K_i$
\[ g^D_{i,\sigma}(\psi_{i-1}(x), \psi_{i-1}(x)) = \rho_i g^{k, D}_{i,\lambda}(x, x) \leq \rho_i g_{i-1}(x, x) \]
\[ \leq \rho_i g_i^{k, \lambda}(x, x) = g^\alpha_{i, \lambda}(\psi_{i-1}(x), \psi_{i-1}(x)). \]

Now set $\lambda = 1$ and note that by Lemma 5.3 $g_1$ is uniformly bounded. Thus
\[ g^D_{1,\sigma}(\psi_{i-1}(x), \psi_{i-1}(x)) \leq \rho_i g_{i-1}(x, x) \leq g^\alpha_1(\psi_{i-1}(x), \psi_{i-1}(x)) \leq C. \]
Rearranging we have
\[ g^{-1}_{i-1}(x, x) \leq C \rho_i^{-1}, \]
as required.

\[ \square \]

Theorem 5.5. There exists a constant $c$ such that
\[ p_{i}(x, x) \leq c \mu_i^{-1} \quad \forall x \in K_i, \forall i \in \Lambda_k. \]

**Proof.** As
\[ g_\lambda(x, x) = \int_0^\infty e^{-\lambda t} p_t(x, x) \, dt, \]
we have, by the monotonicity of $p_t(x, x)$ in $t$, that for all $u$
\[ g_\lambda(x, x) \geq p_u(x, x) \int_0^u e^{-\lambda t} \, dt = p_u(x, x) \frac{1 - e^{-\lambda u}}{\lambda}. \]
Thus, setting $\lambda = t_i^{-1} = 1/u$, we have
\[ p_{i}(x, x) \left( 1 - e^{-1} \right) t_i \leq g^{-1}_{i-1}(x, x) \leq C \rho_i^{-1}. \]
Rearranging and the definition of $t_i$ then gives the result.

\[ \square \]
5.3. Lower bound

We follow a standard approach see for instance [2,4]. For this we require an estimate on the exit time distribution for balls. We start with some preliminary results.

Let \{X_t : t \geq 0\} be the diffusion with law \(P\) associated with the Dirichlet form \((E, F)\). We write \(P^x\) for the law of the process with \(X_0 = x\) and \(E^x\) for the corresponding expectation. We write \(T_A = \inf\{t \geq 0 : X_t \in A\}\) for the first hitting time of the set \(A\). For \(i \in \Lambda_k\) we write

\[ D_i = \bigcup_{j \in \Lambda_k} \{K_j : K_j \cap K_i \neq \emptyset\} \]

for the union of the complex \(K_i\) and its neighbours. Let \(\Lambda_k(z) := \{j \in \Lambda_k : z \in K_j\}\). For \(z \in \tilde{V}_k\) we define

\[ D^z_i := \bigcup_{j \in \Lambda_k(z)} K_j, \quad \partial D^z_i := \bigcup_{j \in \Lambda_k(z)} \psi_j(V_0 \setminus \{z\}), \quad \partial D_i := \bigcup_{j \in \Lambda_k \cap K_j \neq \emptyset} \psi_j(V_0 \setminus \psi_i(V_0)). \]

We will also use the notation \(\partial K_i := \psi_i(V_0)\).

Recalling (2), (39) and (54) we let \(\hat{n} = N_{\inf} w_{\inf} / N_{\sup} w_{\sup}\) and write \(\chi(k, n_0) = \eta_{\psi_k} M(k, n_0)\) with \(M(k, n_0) := \max_{1 \leq i \leq c_0 k} (n(\ell + n_0) - n(\ell))\), where \(c_0\) is the constant \(c_2\) given in Lemma 3.9(a).

**Lemma 5.6.** There exist constants \(c_i\) and \(n_0\) such that

\[ c_1 \chi(k, n_0) e^{-k} \leq E^x T_{\partial D_i} \leq \sup_{z \in D_i} E^z T_{\partial D_i} \leq c_2 e^{-k} \quad \forall x \in K_i, \forall i \in \Lambda_k. \]

**Proof.**

We begin by observing that

\[ E^y T_{\partial D_i} = E^x T_{\partial K_i} + \sum_{y \in \partial K_i} P^x(X_{T_{\partial K_i}} = y) E^y T_{\partial D_i}. \]

To treat the first term we note that the Dirichlet form restricted to \(K_i\) with Dirichlet boundary conditions is a reproducing kernel Hilbert space with the associated Green function \(g_{K_i}(x, \cdot)\) as the kernel. Let \(f(y) = g_{K_i}(x, y) / g_{K_i}(x, x)\). By the definition of \(f\) and the reproducing kernel property we have \(E(f, f) = 1 / g_{K_i}(x, x)\). By the definition of the effective resistance we also have that \(g_{K_i}(x, x) = R(x, \partial K_i)\). As \(g_{K_i}\) harmonic away from \(x\) and is 0 on \(\partial K_i\) we have that \(0 \leq f(y) \leq 1\) for all \(y\). Hence, putting these observations together and using Corollary 3.4, we have that, for any \(y \in K_i\),

\[ E^y T_{\partial K_i} = \int_{K_i} g_{K_i}(y, z) \mu(dz) \leq R(y, \partial K_i) \mu(K_i) \leq c_1 e^{-k}, \]

as \(i \in \Lambda_k\).

We next consider the exit time from \(D_i\) started at a point \(y \in \partial K_i\).

Let \(U_0 = 0\) and set \(U_i = \inf\{t > U_{i-1} : X_t \in \tilde{V}_k \setminus \{X_{U_{i-1}}\}\}\). Then \(\tilde{X}_i = X_{U_i}\) is a discrete time Markov chain on \(\tilde{V}_k\). By construction we see that \(\{\tilde{X}_n : n \leq S\}\) can be viewed as a \(d + 1\) state discrete time Markov chain with \(d + 1\) states as the vertices of \(K_i\) and an absorbing state given by amalgamating \(\tilde{X}_i\) as the vertices in \(\partial D_i\). By construction this Markov chain has transition probabilities given by the conductances on \(\tilde{G}_k\). As \(d\) the vertices in \(\partial K_i\) must be internal to a triangle or \(d\)-dimensional tetrahedron in \(K_i[i-1]\) the conductance between the edges across \(\Delta_i\) and at least one edge to \(\partial D_i\) are comparable or otherwise the conductances across \(\Delta_i\) are smaller and hence \(E^y S < \infty\) independent of \(k\).

The time taken for the original process to exit is then \(E^y U_S\). We now compute the time for a step.

The same argument as before for the first term in (120) but using \(g_{D^y_i}\) gives

\[ E^y T_{\partial D^y_i} = \int_{D^y_i} g_{D^y_i}(y, z) \mu(dz) \leq R(y, \partial D^y_i) \mu(D^y_i). \]
Now observe that by the definition of resistance we have
\[ R(y, \partial D_k^y) \leq R(y, z) \quad \forall z \in \partial D_k^y. \]

Thus we have \( R(y, \partial D_k^y) \leq \min_{z \in \partial D_k} R(y, z) \). By our estimate on the resistance in Lemma 3.3 this gives \( R(y, \partial D_k^y) \leq \min_{j \in \Lambda_k(y)} r_j \). Hence, as the number of cells that meet at \( y \) is bounded,
\[ \mathbb{E}^y T_{\partial D_k^y} \leq \min_{j \in \Lambda_k(y)} r_j \sum_{j \in \Lambda_k(y)} \mu_j \leq c \max_{j \in \Lambda_k(y)} r_j \mu_j \leq c e^{-k}. \]

We are now ready to show \( \mathbb{E}^y T_{\partial D_i} \leq C e^{-k} \). To see this we use
\[
\mathbb{E}^y T_{\partial D_i} = \mathbb{E}^y U_S = \mathbb{E}^y \sum_{i=1}^{S} (U_i - U_{i-1}).
\]

Note that \( S \) is a stopping time with respect to \( \{ F_{U_i} \}_{i=0}^{\infty} \), where \( \{ F_t \}_{t \geq 0} \) is the filtration generated by \( X \). As \( \mathbb{E}^y (U_i - U_{i-1} | F_{U_{i-1}}) = \sum_{z \in \tilde{V}_k} I_{\{ X_{U_{i-1}} = z \}} \mathbb{E} T_{\tilde{V}_k \setminus \{ z \}} \), a minor modification of Wald’s identity shows that
\[ \mathbb{E}^y T_{\partial D_i} \leq c e^{-k} \mathbb{E}^y S \quad \forall y \in \partial K_i. \tag{122} \]

Putting this back into (120) gives the upper bound for this \( y \).

Finally we let \( z \in D_i \) and establish our upper bound by showing \( \mathbb{E}^z T_{\partial D_i} \leq c e^{-k} \) for some constant \( c > 0 \). As we have the result for \( z \in K_i \) we assume that \( z \in D_i \setminus K_i \). We can choose \( j \in \Lambda(k) \setminus \{ i \} \) such that \( K_j \cap K_i \neq \emptyset \) and \( z \in K_j \).

Then, decomposing the exit time \( T_{\partial D_i} \) at the first exit time of \( K_j \), we have \( \mathbb{P}_z \) a.s.
\[
T_{\partial D_i} = T_{\partial K_j} + (T_{\partial D_i} \circ \theta_{T_{\partial K_j}}) I_{\partial K_i}(X_{T_{\partial K_j}}),
\]
where \( \theta_{T_{\partial K_j}} \) denotes the shift map for the diffusion process \( \{ X_t \}_{t \geq 0} \). Thus, by the strong Markov property of the diffusion we have
\[
\mathbb{E}^z T_{\partial D_i} = \mathbb{E}^z T_{\partial K_j} + \mathbb{E}^z ( (T_{\partial D_i} \circ \theta_{T_{\partial K_j}}) I_{\partial K_i}(X_{T_{\partial K_j}}) )
\[
= \mathbb{E}^z T_{\partial K_j} + \mathbb{E}^z ( I_{\partial K_i}(X_{T_{\partial K_j}}) ) \mathbb{E}^{X_{T_{\partial K_j}}}(T_{\partial D_i})
\[
\leq c_1 e^{-k} + c_2 e^{-k} = c_3 e^{-k},
\]
where \( \mathbb{E}^z T_{\partial K_j} \leq c_1 e^{-k} \) by (121) and control of the second term comes from (122), completing the proof of the upper bound.

For the mean hitting time lower bound we return to (120) to see that
\[
\mathbb{E}^y T_{\partial D_i} \geq \min_{y \in \partial K_i} \mathbb{E}^y T_{\partial D_i} \geq \min_{y \in \partial K_i} \mathbb{E}^y T_{\partial D_k^y}.
\]

Using the properties of \( g_{D_k^y} \), and setting \( f(z) = g_{D_k^y}(y, z)/g_{D_k^y}(y, y) \), we see that
\[
|f(y) - f(z)|^2 \leq R(y, z) \mathcal{E}(f, f) = \frac{R(y, z)}{g_{D_k^y}(y, y)} = \frac{R(y, z)}{R(y, \partial D_k^y)}.
\]

Let
\[
A_y^* := \{ z : R(y, z) \leq c R(y, \partial D_k^y) \}.
\]

Let \( j^* \in \Lambda_k(y) \) denote the index at which \( \min_{j \in \Lambda_k(y)} r_j \) is attained. Thus, by the boundedness of \( |\Lambda_k(y)| \), we have
\[ R(y, \partial D_k^y) \geq c_1 r_{j^*}. \tag{123} \]
We now show that $A_\gamma^i$ must have measure comparable with $\mu_j^\gamma$.

By decomposing the cell $K_j^{\gamma}$ we have

$$K_j^{\gamma} = \bigcup_{j:|j|=n} \psi_j^{\gamma} j(K(\sigma^j T)),$$

and we write $k$ with $|k| = n$ such that $y \in \psi_j^{\gamma} k(K(\sigma^j k T)) = K_j^{\gamma} k$. Then, by Corollary 3.4, for any $z \in K_j^{\gamma} k$ we have a constant $c$ such that

$$R(y, z) \leq c \gamma_j^{\gamma} k \leq c \gamma_j^{\gamma} r_{\sup}^n,$$

and hence by (123)

$$R(y, z) \leq c r_{\sup}^n = c r_{\sup}^n (y, \partial D_k^\gamma).$$

Thus, if we take $n_0 = \inf \{n : r_{\sup}^n < c_1/c\}$ and set $c_2 = c r_{\sup}^n_{c_1}$, we have $K_j^{\gamma} k \subset A_\gamma^c$ where $c_2 < 1$.

Hence for $z \in K_j^{\gamma} k$ we have $|f(y) - f(z)|^2 \leq c_2$. As $f(y) = 1$ we see that we must have $f(z) \geq c' = 1 - \sqrt{c_2}$. Thus for any $y \in \partial K_i$ we have, writing $k_0 + |j^*|$ for the first neck after $n_0 + |j^*|$, 

$$\mathbb{E}^\gamma T_{\partial D_k^\gamma} \geq \int_{D_k^\gamma} g_{D_k^\gamma}(y, z) \mu(dz) = c' g_{D_k^\gamma}(y, y) \mu(K_j^{\gamma} k) \geq c' R(y, \partial D_k^\gamma) \mu_j^\gamma, \sum\{|k_i| = k_0, i \in T^{\sigma_j} \}.$$ 

We now give an upper bound on $k_0$. Let $\ell := \ell(|j^*|)$. Then $n(\ell) = |j^*|$ and, since there are at most $n_0$ necks in the levels from $|j^*| + 1$ to $|j| + k_0$, we have $|j^*| + k_0 \leq n(\ell + n_0) = n(\ell(|j^*|) + n_0)$. Hence by Lemma 3.9(a),

$$k_0 \leq \max_{1 \leq \ell \leq c_0} (n(\ell + n_0) - n(\ell)) = M(k, n_0).$$

Now applying (123) and the fact that $r_j^{\gamma} \mu_j^\gamma \geq \eta^y e^{-k}$ by Lemma 3.9(c), we have

$$\mathbb{E}^\gamma T_{\partial D_k^\gamma} \geq c_3 c_j^{\gamma} \mu_j^\gamma, N_{\inf}^{-k_0} \left( \frac{w_{\inf}}{w_{\sup}} \right)^{k_0} \geq c_3 \eta^y e^{-k} N_{\inf}^{-k_0} \eta^{k_0} \geq c_3 \eta^y e^{-k} M(k, n_0) = c_4 \chi(k, n_0) e^{-k}$$

as required. \hfill \Box

**Lemma 5.7.** There exist constants $c_3, c_4$ such that for $x \in K_i, i \in \Lambda_k$

$$P^x(T_{\partial D_i} \leq t) \leq 1 - c_3 \chi(k, n_0) \quad \text{for } t \leq \frac{1}{2} \chi(k, n_0) e^{-k}.$$ 

**Proof.** We note that

$$T_{\partial D_i} \leq t + 1_{[T_{\partial D_i} > t]}(T_{\partial D_i} - t).$$

Taking expectations
\[ \mathbb{E}^x T_{\partial D_i} \leq t + \mathbb{E}^x \left( I_{\{T_{\partial D_i} > t\}} \mathbb{E}^{X,t} T_{\partial D_i} \right) \]
\[ \leq t + \mathbb{E}^x (T_{\partial D_i} > t) \sup_{y \in D_i} \mathbb{E}^{y} T_{\partial D_i}. \]

Rearranging and then applying our exit time estimates from Lemma 5.6
\[ \mathbb{P}^x (T_{\partial D_i} \leq t) \leq t + \frac{\mathbb{E}^x T_{\partial D_i}}{\sup_{y \in D_i} \mathbb{E}^{y} T_{\partial D_i}} \]
\[ \leq c_1 e^{k \chi(k, n_0)^{-1}} + 1 - c_2 \chi(k, n_0). \]

Thus, if \( t \leq \frac{1}{2} c_2 c_1^{-1} \chi(k, n_0)^2 e^{-k} \), we have
\[ \mathbb{P}^x (T_{\partial D_i} \leq t) \leq 1 - \frac{1}{2} c_2 \chi(k, n_0), \]
as required. □

**Theorem 5.8.** There are constants \( c, \alpha' \) such that for \( t \leq c_4 e^{-k} \chi(k, n_0)^2 \)
\[ p_t(x, x) \geq c \chi(k, n_0)^2 \mu(D_i)^{-1} \forall x \in K_i, i \in \Lambda_k. \]

**Proof.** A standard argument gives the following. If \( t \leq \frac{1}{2} c_4 \chi(k, n_0)^2 e^{-k} \), then by Lemma 5.7
\[ (c_2 \chi(k, n_0))^2 \leq P^x (X_t \in D_i)^2 = \left( \int_{D_i} p_t(x, y) \mu(dy) \right)^2 \leq \mu(D_i) p_{2t}(x, x), \]
as required. □

Finally we can estimate \( \chi(k, n_0) \) to provide a \( P_V \) a.s. estimate in terms of the scale factors.

**Theorem 5.9.** There are constants \( c, \beta \) such that \( P_V \) a.s. for sufficiently large \( k \), for \( t \leq c e^{-k} k^{-\beta} \)
\[ p_t(x, x) \geq c \mu(D_i)^{-1} k^{-\beta} \forall x \in K_i, i \in \Lambda_k. \]

**Proof.** We first need to estimate \( M(k, n_0) = \max_{1 \leq \ell \leq c_0 k} (n(\ell + n_0) - n(\ell)) \). As \( n(\ell + n_0) - n(\ell) = \sum_{i=1}^{n_0} n(\ell + i) - n(\ell + i - 1) \) is a sum of \( n_0 \) geometric random variables it has the negative binomial distribution. If we set \( Y_\ell = n(\ell + n_0) - n(\ell) \), then there is an \( A \) and a \( p \) such that \( Y_\ell \) satisfies the tail estimate required to apply Lemma 2.16 (15) giving \( \limsup_{k \to \infty} M(k, n_0)/\log k \leq 1/\log(1/p) \), \( P_V \) a.s. Thus, \( P_V \) a.s. for sufficiently large \( k \) there is a constant \( c \) such that
\[ \hat{\eta} M(k, n_0) \leq \hat{\eta} c \log k. \]

Using this and the estimates on \( y_k \) from Lemma 3.9(b) we have \( P_V \) a.s. for sufficiently large \( k \) there is a \( \beta \) such that
\[ \chi(k, n_0) \geq c' k^{-\beta/2} \]
and using Theorem 5.8 gives the result. □

**Remark 5.10.** In a different setting [4] obtained a finer estimate on the exit time from a complex which enables the derivation of a finer form of this on-diagonal estimate. We do not derive such a result here though we expect that the same techniques could be applied to do so. Our result is enough to enable us to compute the \( \mu \)-almost everywhere local spectral exponent.
5.4. Local spectral exponent

As in [4] we will see that the local spectral dimension obtained by considering the limit as \( k \to \infty \) of \( p_t(x, x) \) for \( x \in K_i, i \in \Lambda_k \) will in general not coincide with the global spectral dimension.

We have the following preliminary result. Let \( i^x \in \partial T \) be such that \( K_{i^x|k} \to \{x\} \) as \( k \to \infty \).

**Lemma 5.11.** There exists a constant \( c \) such that \( D_{i^x|n(k+[c \log k])} \subseteq K_{i^x|n(k)} \) for all sufficiently large \( k \) for \( \mu \) a.e. \( x \in K, P_V \) a.s.

**Proof.** Let \( T_{n(m),b} \) denote the addresses of the \( d + 1 \) boundary cells at the \( m \)th neck. By Lemma 3.6 we must have

\[
a := E_V \max_{j \in T_{n(1),b}} \mu_j < 1.
\]

Now for \( i \in \{ j \in T : |j| = n(k+m) \} \) we have \( D_i \subset K_i|n(k) \) if \( K_i \cap \partial K_i|n(k) = \emptyset \). Then, setting \( A = \{ K_i : i \in \{ j \in T : |j| = n(k+m) \}, K_i \cap \partial K_i|n(k) \neq \emptyset \} \), we have

\[
\begin{align*}
E_V \mu(A) &= E_V \sum_{i \in \{ j \in T : |j| = n(k+m) \}} \mu_i I_{(K_i \cap \partial K_i|n(k)) \neq \emptyset} \\
&= E_V \sum_{i \in \{ j \in T : |j| = n(k) \}} \mu_i \sum_{j \in T_{n(k+m),b}} \frac{\mu_j}{\mu_i}
\end{align*}
\]

By construction the terms \( \mu_i^{(j)} = \frac{\mu_{i|n(j)}}{\mu_{i|n(j-1)}} \) are independent and equal in distribution to \( \mu_{i|n(1)} \), allowing us to write

\[
\begin{align*}
E_V \mu(A) &= E_V \sum_{i \in \{ j \in T : |j| = n(k) \}} \mu_i E_V \sum_{j \in T_{n(k+m),b}} \prod_{j=1}^m \mu_i^{(j)} \\
&\leq (d + 1)a^m.
\end{align*}
\]

Thus we have

\[
E_V \sum_{k=1}^{\infty} \mu(x \in K : D_i|n(k+[c \log k]) \not\subseteq K_i|n(k)) \leq c_1 \sum_{k=1}^{\infty} a^{c \log k} < \infty,
\]

for large enough \( c \). Hence \( P_V \) a.s. we have

\[
\mu(x \in K : D_i|n(k+[c \log k]) \not\subseteq K_i|n(k) \text{ i.o.}) = 0,
\]

as required. \( \square \)

For the rest of this section we write \( T_{n(1)} = \{ j \in T : |j| = n(1) \} \) for the tree up to the first neck. Take another set of weights \( \{ \hat{w}^F_{i} \}_{i=1}^{F} \) \( F \in F \) satisfying the conditions of Section 3.3 and define the associated measure \( \hat{\mu} \).

Observe that by (43) and the definition of \( \eta \) we have

\[
\mu_i \geq \left( \frac{\eta}{r_{\inf}} \right)^{n(1)}, \quad t_i \geq \eta^{n(1)}, \quad i \in T_{n(1)}.
\]

Thus \( \log \mu_i \geq n(1) \log (\frac{\eta}{r_{\inf}}) \) and as

\[
0 > \sum_{i \in T_{n(1)}} \hat{\mu}_i \log \mu_i \geq n(1) \log \frac{\eta}{r_{\inf}},
\]
we have
\[ EV \left| \sum_{i \in T_n} \hat{\mu}_i \log \mu_i \right| \leq c EV n(1) < \infty. \]

We can control \( EV \left| \sum_{i \in T_n} \hat{\mu}_i \log t_i \right| \) in the same way.

As in [4] we can now determine the local spectral exponent for the heat kernel \( p_t(x, x) \) defined with respect to the reference measure \( \mu \) for \( \hat{\mu} \) almost every \( x \).

**Theorem 5.12.** \( P_V \) almost surely, for \( \hat{\mu} \)-almost every \( x \in K \) we have
\[
\lim_{t \to 0} \frac{\log p_t(x, x) - \log t}{-\log t} = \frac{\hat{d}_V(\hat{\mu})}{2} = \frac{EV \sum_{i \in T_n} \hat{\mu}_i \log \mu_i}{EV \sum_{i \in T_n} \hat{\mu}_i \log t_i}.
\]

**Proof.** For \( x \in K \) we have a sequence \( i \in n(k) \) for which \( D_i \in n(k) \) \( \to x \) as \( k \to \infty \). By monotonicity of the diagonal heat kernel in time for \( t \in (t_i \in n(k), t_i \in n(k-1)] \) we have \( p_t(x, x) \leq p_{t_i \in n(k)}(x, x) \) and thus
\[
\limsup_{t \to 0} \frac{\log p_t(x, x)}{-\log t} \leq \limsup_{k \to \infty} \frac{\log p_{t_i \in n(k)}(x, x)}{-\log t_i \in n(k-1)}, \quad P_V \text{ a.s.}
\]

Now using Theorem 5.5 we have
\[
\log p_{t_i \in n(k)}(x, x) \leq C - \log \mu_{t_i \in n(k)}(x, x) = C - \sum_{j=1}^k \log \frac{\mu_{t_i \in n(j)}}{\mu_{t_i \in n(j-1)}}.
\]

We now consider the probability measure \( d\hat{\mu}dP_V \) on \( \{1, \ldots, N_{sup}\}^\mathbb{N} \times \Omega V \) (with the product \( \sigma \)-algebra). If the point \( x \) is chosen according to \( \hat{\mu} \), then the terms \( \mu_{t_i \in n(j)}(x, x) \) are independent and equal in distribution to \( \mu_{t_i \in n(1)} \) under \( d\hat{\mu}dP_V \). We can also express \( -\log p_{t_i \in n(k)} \) in terms of independent random variables \( i \in n(k) \) defined in the same way. It is easy to see that \( \log t_{i \in n(k)}/\log t_{i \in n(k-1)} \to 1 \) for any \( x \in K \), \( P_V \)-almost surely and hence
\[
\limsup_{t \to 0} \frac{\log p_t(x, x)}{-\log t} \leq \limsup_{k \to \infty} \frac{\log p_{t_i \in n(k)}(x, x)}{-\log t_i \in n(k)} \leq \limsup_{k \to \infty} \frac{1}{k} \sum_{j=1}^k \log \mu_{i \in n(j)}^{(j)}.
\]

As the mean of \( \log \mu_{i \in n(j)}^{(j)} \) is finite we can apply the strong law of large numbers under \( d\hat{\mu}dP_V \) to see that
\[
\lim_{k \to \infty} \frac{1}{k} \sum_{j=1}^k \log \mu_{i \in n(j)}^{(j)} = EV \sum_{i \in T_n} \hat{\mu}_i \log \mu_i, \quad \hat{\mu} \text{ a.e. } x \in K, P_V \text{ a.s.}
\]

Similarly we can find the limit for the denominator in (124). Thus we have
\[
\limsup_{k \to \infty} \frac{\log t_{i \in n(k)}}{-\log t_{i \in n(k)}} \leq \frac{EV \sum_{i \in T_n} \hat{\mu}_i \log \mu_i}{EV \sum_{i \in T_n} \hat{\mu}_i \log t_i}.
\]

For the lower bound we define \( \ell(i, k) = \ell \) if \( i \in n(\ell) \in \Lambda_k \). Thus
\[
-\log t_{i \in n(\ell(i, k)-1)} < k \leq -\log t_{i \in n(\ell(i, k))}.
\]

Hence, it is clear that, by the independence
\[
\lim_{k \to \infty} \frac{\ell(i, k)}{k} = \lim_{\ell \to \infty} \frac{-\ell}{\log t_{i \in n(\ell)}} = -\frac{1}{EV \sum_{i \in T_n} \hat{\mu}_i \log t_i}, \quad \hat{\mu} \text{ a.e. } x \in K, P_V \text{ a.s.} \quad (125)
\]
Now, from Theorem 5.9, \( P_V \) a.s. for sufficiently large \( k \), for \( ce^{-(k+1)(k+1)^{-\beta}} < t \leq ce^{-k} \) we have for \( x \in K_i, i \in \Lambda_k \),

\[
\frac{\log p_t(x, x)}{-\log t} \geq \frac{\log (c\mu(D_1)^{-1}k^{-\beta})}{\log (ce^{-(k+1)(k+1)^{-\beta}})} = \frac{\log c - \beta \log k - \log \mu(D_1)}{\log c - k - 1 - \beta \log (k+1)}.
\]

Thus for \( x \in K, i \in \partial T \) with \( D_{i|n(k)} \to \{x\} \),

\[
\liminf_{t \to 0} \frac{\log p_t(x, x)}{-\log t} \geq \liminf_{k \to \infty} -\frac{\log \mu(D_{i|n(\ell(i,k))})}{k}.
\]

We now observe that by Lemma 5.11 we have a constant \( c' \) such that \( P_V \) a.s. for \( \tilde{\mu} \) a.e. \( x \in K \), for sufficiently large \( k \),

\[
-\log \mu(D_{i|n(\ell(i,k))}) \geq -\log \mu_{i|n(\ell(i,k))}[c' \log \ell(i,k)].
\]

Using this, (125) and writing \( \ell(i, k) = \ell(i, k) - [c' \log \ell(i, k)] \), we have

\[
-\lim_{k \to \infty} \frac{\log \mu_{i|n(\ell(i,k))}}{k} = -\lim_{k \to \infty} \frac{\tilde{\ell}(i, k)}{k} \lim_{k \to \infty} \frac{1}{\tilde{\ell}(i, k)} \sum_{j=1}^{\ell(i,k)} \log \mu_i^{(j)} = \frac{E_V \sum_{i \in T_{n(i)}} \hat{\mu}_i \log \mu_i}{E_V \sum_{i \in T_{n(i)}} \hat{\mu}_i \log t_i},
\]

for \( \hat{\mu} \) a.e. \( x \in K \), \( P_V \) almost surely, as required.

In the case where the reference measure \( \mu \) is the flat measure \( \nu \) in the resistance metric, the weights are proportional to \( r_i^{d_f} \) and \( E_V \log \sum_{i \in T_{n(i)}} r_i^{d_f} = 0 \), a simple calculation shows that

\[
\frac{\hat{d}_s(\hat{\mu})}{2} = \frac{E_V \sum_{i \in T_{n(i)}} \hat{\mu}_i \log \mu_i}{E_V \sum_{i \in T_{n(i)}} \hat{\mu}_i \log t_i}
= \frac{E_V \sum_{i \in T_{n(i)}} \hat{\mu}_i \log \sum_{j \in T_{n(i)}} r_j^{d_f}}{\sum_{j \in T_{n(i)}} r_j^{d_f}}
= \frac{E_V \sum_{i \in T_{n(i)}} \hat{\mu}_i \log \sum_{j \in T_{n(i)}} r_j^{d_f}}{1 + \sum_{j \in T_{n(i)}} d_f}
= \frac{d_f' E_V \sum_{i \in T_{n(i)}} \hat{\mu}_i \log r_i}{1 + d_f'}
= \frac{d_f' E_V \sum_{i \in T_{n(i)}} \hat{\mu}_i \log r_i}{\sum_{i \in T_{n(i)}} r_i^{d_f}}
\]

Indeed in this case we can go further and give a bound on the size of the scale fluctuations.

**Theorem 5.13.** If \( \nu \) is the flat measure in the resistance metric we have constants \( c_1, c_2, c_3, c_4 \in (0, \infty) \) and a random variable \( 0 < c_5 \) such that \( P_V \) a.s. for any \( x \in K \)

\[
c_1\phi(1/t)^{-c_2}t^{-d_s/2} \leq p_t(x, x) \leq c_3\phi(1/t)^{c_4}t^{-d_s/2}, \quad 0 < t < c_5.
\]
Proof. We begin by observing that for \( i \in \Lambda_k \) we have \( t_i \leq e^{-k} \) and thus substituting in the upper bound estimate from Theorem 5.5, for \( x \in K_i \)

\[
p_{e^{-k}}(x, x) \leq p_i(x, x) \leq cv_i^{-1}.
\]

By (114) we have that \( P_V \) almost surely for sufficiently large \( k \), \( v_i \geq r_i^{d_f} \exp(-c\Phi(\ell(i))) \) and hence \( r_i^{1+d_f} \exp(-c\Phi(\ell(i))) \leq t_i \leq e^{-k} \). Thus, using Lemma 3.9,

\[
r_i \leq e^{-k/(1+d_f)} \exp(c\Phi(\ell(i)))
\]

and

\[
p_{e^{-k}}(x, x) \leq e^{k \frac{d_f}{1+d_f}} \exp(c''\Phi(\ell(i))).
\]

Thus, for \( e^{-k} \leq t < e^{-k+1} \), and as \( \max_{i \in \Lambda_k} \ell(i) \leq ck \leq -c \log t \), we have for any \( x \in K \),

\[
p_t(x, x) \leq Ct^{-d_i/2} \exp(c'\Phi(\log(1/t))) = Ct^{-d_i/2} \phi(1/t)'', \quad P_V \text{ a.s.}
\]

For the lower bound we observe from Theorem 5.9 that \( P_V \) almost surely for sufficiently large \( k \), for \( t \leq ce^{-k}k^{-\beta} \)

\[
p_t(x, x) \geq cv(D_i)^{-1}k^{-\beta} \quad \forall x \in K_i, i \in \Lambda_k.
\]

For \( j \in \Lambda_k \), as \( e^{-k} \geq t_j = r_jv_j \geq r_j^{1+d_f} \exp(-c\Phi(\ell(j))) \) \( P_V \) almost surely, we have

\[
r_j \leq e^{-k/(1+d_f)} \exp(c'\Phi(\ell(j))).
\]

Then as the number of cells in \( D_i \) is bounded and \( \ell(j) \leq ck \) by Lemma 3.9(a), we have, using (114),

\[
v(D_i) = \sum_{j \in \Lambda_k} \sum_{j' \mid j' = n(\ell(j))} r_j^{d_f} I_{(K_i \cap K_j) \neq \emptyset} I_{K_i \cap K_j} \leq \sum_{j \in \Lambda_k} r_j^{d_f} I_{(K_i \cap K_j) \neq \emptyset} \exp(c\Phi(\ell(j))) \leq ce^{-kd_f/(1+d_f)} \exp(c''\Phi(k)).
\]

Thus, \( P_V \) a.s. for sufficiently large \( k \) for \( t \leq ce^{-k}k^{-\beta} \),

\[
p_t(x, x) \geq ck^{-\beta} e^{kd_f/(1+d_f)} \exp(-c''\Phi(k)) \quad \forall x \in K.
\]

For \( ce^{-(k+1)}k^{-\beta} < t \leq ce^{-k}k^{-\beta} \) we have \( c_1e^{-k}k^{-\beta} < t \) so that \( e^k k^\beta > c_2 t^{-1} \) and

\[
p_t(x, x) \geq ck^{-(2d_f+1)\beta/(d_f+1)}t^{-d_f/(1+d_f)} \exp(-c''\Phi(k)) \quad \forall x \in K.
\]

Now as \( k \leq \log c + \log(1/t) \) we have for sufficiently small \( 0 < t \), for any \( x \in K \)

\[
p_t(x, x) \geq b' \log t^{-\beta} t^{-d_i/2} \exp(-c''\Phi(|\log t|)).
\]

By adjusting \( c'' \) we can absorb the logarithm into the exponential term and we have the result. 
\( \square \)
Acknowledgement

We particularly wish to thank an anonymous referee for unusually careful and detailed sets of comments. Addressing these has led to a number of improvements in the results of the paper.
