Abstract
Background: Animal data have suggested that the transient receptor potential ankyrin-1 (TRPA1) ion channel plays a key role in promoting airway inflammation in asthma and may mediate effects of paracetamol on asthma, yet confirmatory human data are lacking. To study associations of TRPA1 gene variants with childhood asthma and total IgE concentration, and interactions between TRPA1 and prenatal paracetamol exposure on these outcomes.

Methods: We analysed associations between 31 TRPA1 single nucleotide polymorphisms (SNPs) and current doctor-diagnosed asthma and total IgE concentration at 7.5 years in the Avon Longitudinal Study of Parents and Children (ALSPAC) birth cohort. We sought to confirm the most significant associations with comparable outcomes in the Prevention and Incidence of Asthma and Mite Allergy (PIAMA) and Generation R birth cohorts. In ALSPAC, we explored interactions with prenatal paracetamol exposure.

Results: In ALSPAC, there was strong evidence for association between six SNPs and asthma: rs959974 and rs1384001 (per-allele odds ratio for both: 1.30 (95% CI: 1.15–1.46), p = 0.00001), rs7010969 (OR 1.28 (1.13–1.46), p = 0.00004), rs3735945 (OR 1.30 (1.09–1.55), p = 0.003), rs920829 (OR 1.30 (1.09–1.54), p = 0.004) and rs4738202 (OR 1.22 (1.07–1.39), p = 0.004). In a meta-analysis across the three cohorts, the pooled effect estimates confirmed that all six SNPs were significantly associated with asthma. In ALSPAC, TRPA1 associations with asthma were not modified by prenatal paracetamol, although associations with IgE concentration were.

Conclusion: This study suggests that TRPA1 may play a role in the development of childhood asthma. (249 words)

Introduction
The transient receptor potential ankyrin-1 (TRPA1) ion channel is expressed on peripheral endings of primary afferent neurons and is a highly conserved sensor of noxious reactive electrophiles; these form covalent adducts with the receptor to activate the neurons (1). In particular, TRPA1 is a major oxidant sensor in the airways (2), sensing exogenous airborne...
irritants as well as endogenous by-products of oxidative stress (3). In keeping with this function, the TRPA1 receptor is thought to play a key role in the cough reflex (4) and in promoting airway inflammation in asthma (3, 5). Experiments using knockout mice and TRPA1 antagonists have shown that TRPA1 plays a critical role in allergic and non-allergic neurogenic airway inflammation and hyper-reactivity (6, 7). However, evidence implicating TRPA1 in asthma in humans is lacking.

Following our initial discovery of an association between frequent paracetamol (acetaminophen) use and asthma in adults (8), we and others have reported that maternal use of paracetamol in pregnancy was associated with an increased risk of childhood asthma, wheezing and elevated total IgE concentration (9). Nassini et al. (10) subsequently showed in a rodent model that systemic administration of therapeutic doses of paracetamol led to generation of its electrophilic and reactive metabolite in the lung which, in turn, caused neurogenic airway inflammation through activation of TRPA1; they proposed that this mechanism might explain the epidemiological link between paracetamol exposure and asthma in humans.

In a population-based birth cohort, we investigated whether TRPA1 (8q13) gene variants are associated with childhood asthma and IgE concentration, and whether these associations were modified by prenatal exposure to paracetamol. We also sought to obtain confirmatory evidence for the most significant SNP associations in the Prevention and Incidence of Asthma and Mite allergy (PIAMA) and Generation R birth cohorts.

Methods

Avon Longitudinal Study of Parents and Children

Subjects

The Avon Longitudinal Study of Parents and Children (ALSPAC) is a population-based birth cohort that recruited 14,541 predominantly white pregnant women resident in Avon, UK, with expected dates of delivery 1st April 1991–31st December 1992. Of these pregnancies, there were 14,062 live births and 13,988 children alive at 1 year of age. The cohort has been followed since birth with annual questionnaires and, since age 7 years, with objective measures in research clinics. The study protocol has been described previously (11, 12) (further information: http://www.alspac.bris.ac.uk). Ethics approval was obtained from the ALSPAC Ethics and Law Committee (IRB 00003312) and the Local Research Ethics Committees.

Outcomes

When the children were 7.5 years old, mothers were asked: ‘Has your child had any of the following in the past 12 months: wheezing; asthma?’ Children were defined as having current doctor-diagnosed asthma (primary outcome) if mothers responded positively to the question ‘Has a doctor ever actually said that your study child has asthma?’ and positively to one or both of the questions on wheezing and asthma in the past 12 months.

Serum total IgE concentration (kU/l) was measured by fluoroimmunoassay using the Pharmacia UNICAP system (Pharmacia & Upjohn Diagnostics AB, Uppsala, Sweden) at 7 years.

Prenatal paracetamol exposure

Mothers were asked at 18–20 weeks how often they had taken paracetamol (‘not at all, sometimes, most days, every day’) during their pregnancy. At 32 weeks, they were asked the same question about use in the previous 3 months. Hence, we defined use of paracetamol (Yes/No) in early (<18–20 weeks) and late (20–32 weeks) pregnancy.

Genotyping and selection of TRPA1 SNPs

DNA samples were extracted from lymphoblastoid cell lines, cord blood or venous blood collected at 7 years of age, with a small number extracted from venous blood collected at 43–61 months. A total of 9912 subjects were genotyped at 500,527 SNPs using the Illumina HumanHap550 quad genomewide SNP genotyping platform. After applying rigorous exclusion criteria, genotype data were available for 8365 unrelated individuals (see Online Supplement for further details).

We identified 29 SNPs in TRPA1 (8q13) which had been included in a genetic association study of cough (13). The participating cohorts in that study were part of a large European GWAS of asthma (the GABRIEL consortium) (14). All SNPs within the gene region had been selected, allowing capture of the majority of common haplotype variations of the gene (13, 14). In addition, we identified 11 SNPs (four of which had already been selected) associated with various pain phenotypes (15–17) and with menthol preference in smokers (18). Of the 36 potential SNPs, five had not been typed or could not be imputed, leaving 31 SNPs to be analysed. Of these SNPs, 21 were genotyped and 10 were imputed. Where genotyped data were missing, these were replaced by imputed data if possible (see Online Table S1 and Supplement for further details).

Statistical analysis of ALSPAC data

Although the GWAS data set only included individuals of European ancestry, we excluded mother–child pairs from all analyses if the mother’s reported ethnicity was non-white or unknown (14.1% of the cohort) to further reduce potential confounding by population substructure. We used logistic regression to analyse relations of child TRPA1 genotype with asthma, and linear regression to analyse associations with log-transformed total IgE concentration. All analyses were carried out using Stata (version 10.1). Univariate gene main effects were evaluated as continuous per-allele effects and using between genotype comparisons. We used Haploview (19) to compute linkage disequilibrium (LD) statistics for the 31 TRPA1 SNPs of interest. The population attributable fraction (PAF) was calculated using the formula: PAF = 1–PUF, where PUF is the population unattributable fraction (20). We used the Nyholt approach (21) updated by Li and Ji (22) to estimate the effective number of independent marker loci in our data (12.8 of 31) and the threshold required to keep type I error rate at 5% after adjusting for multiple testing (p value=0.05/12.8 = 0.004).
PIAMA and Generation R (Netherlands)

The Prevention and Incidence of Asthma and Mite Allergy (PIAMA) birth cohort is a multicentre study that selected 4146 pregnant women in the Netherlands in 1996/1997 (23, 24). The Generation R Study is a population-based prospective cohort study of pregnant women and their children in Rotterdam (25, 26). All children were born between April 2002 and January 2006, and currently followed until young adulthood. Current doctor-diagnosed asthma at 8 years and at 6 years was defined in PIAMA and Generation R, respectively (see Online Supplementary for further details).

We analysed the associations between TRPA1 (for SNPs most significantly associated with asthma in ALSPAC) and asthma separately in PIAMA and Generation R, and then undertook a meta-analysis across the three cohorts, using a fixed-effects model.

Other European asthma studies

In other European studies included in the GABRIEL study (14), we explored associations between doctor-diagnosed asthma ‘ever’ (of childhood-onset) and the TRPA1 SNPs most significantly associated with asthma in ALSPAC. We carried out these subsidiary analyses using publicly available data from GABRIEL and meta-analysed the data using a fixed-effects model.

Results

In ALSPAC, information on current doctor-diagnosed asthma at age 7.5 years was obtained for 7221 children. After excluding non-white mother–child pairs, and applying quality criteria to imputed genotype data, TRPA1 genotype data were available for 6901 children, generating a final sample of 5141 white children with complete data on asthma and genotype, of whom 614 (11.9%) children had current doctor-diagnosed asthma at age 7.5 years. A total of 53.9% and 42.3% of white children with complete data on asthma and genotype, of whom 614 (11.9%) children had current doctor-diagnosed asthma at age 7.5 years. A total of 53.9% and 42.3% of white children were exposed to paracetamol in utero during early and late pregnancy, respectively. Data on total IgE concentration and genotype were available for 3834 children.

TRPA1 genotype data are summarized in Table S1. TRPA1 genotype frequencies did not deviate from Hardy–Weinberg equilibrium for the 31 SNPs of interest (p > 0.05). In PIAMA, information on current doctor-diagnosed asthma at age 8 years was obtained for 3253 children, and TRPA1 genotype data were available for 1968 children, generating a final sample of 1877 white children with data on asthma and genotype, of whom 89 (4.7%) had current doctor-diagnosed asthma at age 8 years. In Generation R, data on TRPA1 genotype and current doctor-diagnosed asthma at age 6 years were available for 2073 children, after excluding twins and restricting to Caucasians only, based on genetic ancestry. Of these, 64 children (3.1%) had current doctor-diagnosed asthma.

Gene main effects in ALSPAC

Table 1 shows the per-allele associations between TRPA1 genotypes and asthma in ALSPAC. Of the 31 SNPs tested, 13 were associated with asthma (p < 0.05). The six SNPs (five genotyped, one imputed) that were most significantly associated with asthma (p < 0.005) were as follows: rs959974 and rs1384001 (per-allele odds ratio for both SNPs: 1.30 (95% CI: 1.15–1.47), p = 0.00001), rs7010969 (OR 1.28 (1.13–1.46), p = 0.064), rs4738202 (OR 1.47 (1.07–1.96), p = 0.00001). Adjustment for multiple testing suggested that associations with these six SNPs (and especially the first four) were unlikely to have arisen by chance (adjusted p value threshold 0.004). With a more rigorous p value threshold of 0.001, evidence against the null hypothesis was still very strong for 3 SNPs.

Additional effect estimates using between genotype comparisons for these six SNPs in relation to asthma are shown in Table 2. This shows that, for four of these SNPs, children who were homozygous for the risk allele were approximately 70% more likely to have asthma than children who were homozygous for the non-risk allele. Of the 31 SNPs tested, only three (rs959974, rs1384001, rs4738202) were nominally associated with total IgE concentration (p < 0.05) (Table S2).

weighted per-allele associations of the six SNPs with asthma.

In Generation R, none of the six SNPs were significantly associated with asthma. Fig. 1 shows the Forest plots for the associations between the six most significantly associated SNPs in ALSPAC and current doctor-diagnosed asthma at 7–8 years in ALSPAC and PIAMA, and current doctor-diagnosed asthma at 6 years in Generation R.

Table 2 also shows the associations between the six SNPs most significantly associated with asthma in ALSPAC and asthma in the PIAMA and Generation R cohorts. In PIAMA, there was some evidence for association (p < 0.05) with asthma for the three SNPs most significantly associated with asthma in ALSPAC, with effect estimates that were larger than those in ALSPAC. In Generation R, none of the six SNPs were associated with asthma. Fig. 1 shows the Forest plots for the weighted per-allele associations of the six SNPs with asthma.

For all six SNPs, the pooled effect estimates confirmed significant associations with asthma.

**Gene main effects in other European asthma studies**

Fig. S2–S6 online show Forest plots for the meta-analysis of the associations between TRPA1 and childhood-onset asthma across GABRIEL studies, for five of the six SNPs most significantly associated with asthma in ALSPAC (rs920829 was not genotyped in GABRIEL; it was imputed in ALSPAC, but it is in strong LD with rs3735945). The plots compare associations with current doctor-diagnosed asthma in ALSPAC and PIAMA versus associations with doctor-diagnosed asthma ‘ever’ (of childhood-onset) across other GABRIEL studies, with three studies which were exclusively of children separated from remaining studies. The pooled effect estimates do not confirm associations with asthma ‘ever’. Furthermore, there was evidence of substantial heterogeneity in the effect estimates for the three childhood GABRIEL studies.

**Paracetamol analyses in ALSPAC**

For the 13 SNPs associated with asthma (p < 0.05), we stratified the per-allele associations by early and late childhood-onset asthma, two (rs959974 and rs1384001) were in one block, 31 SNPs; 29 of those SNPs are located in four LD blocks. Of the six SNPs most significantly associated with asthma, two (rs959974, rs7010969 and rs4738202) to separately estimate significantly associated SNPs from different LD blocks. Of the six SNPs most significantly associated with asthma in ALSPAC and asthma in Generation R, none of the six SNPs were significantly associated with asthma. Fig. 1 shows the Forest plots for the weighted per-allele associations of the six SNPs with asthma.

For the 13 SNPs associated with asthma (p < 0.05), we stratified the per-allele associations by early and late childhood-onset asthma, two (rs959974 and rs1384001) were in one block, 31 SNPs; 29 of those SNPs are located in four LD blocks. Of the six SNPs most significantly associated with asthma, two (rs959974, rs7010969 and rs4738202) to separately estimate significantly associated SNPs from different LD blocks. Of the six SNPs most significantly associations with asthma in ALSPAC and current doctor-diagnosed asthma at 7–8 years in ALSPAC and PIAMA, and current doctor-diagnosed asthma at 6 years in Generation R.

Table 2 shows the associations between the six SNPs most significantly associated with asthma in ALSPAC and asthma in the PIAMA and Generation R cohorts. In PIAMA, there was some evidence for association (p < 0.05) with asthma for the three SNPs most significantly associated with asthma in ALSPAC, with effect estimates that were larger than those in ALSPAC. In Generation R, none of the six SNPs were associated with asthma. Fig. 1 shows the Forest plots for the weighted per-allele associations of the six SNPs with asthma.

For all six SNPs, the pooled effect estimates confirmed significant associations with asthma.

**Gene main effects in other European asthma studies**

Figs S2–S6 online show Forest plots for the meta-analysis of the associations between TRPA1 and childhood-onset asthma across GABRIEL studies, for five of the six SNPs most significantly associated with asthma in ALSPAC (rs920829 was not genotyped in GABRIEL; it was imputed in ALSPAC, but it is in strong LD with rs3735945). The plots compare associations with current doctor-diagnosed asthma in ALSPAC and PIAMA versus associations with doctor-diagnosed asthma ‘ever’ (of childhood-onset) across other GABRIEL studies, with three studies which were exclusively of children separated from remaining studies. The pooled effect estimates do not confirm associations with asthma ‘ever’. Furthermore, there was evidence of substantial heterogeneity in the effect estimates for the three childhood GABRIEL studies.

**Paracetamol analyses in ALSPAC**

For the 13 SNPs associated with asthma (p < 0.05), we stratified the per-allele associations by early and late childhood-onset asthma, two (rs959974 and rs1384001) were in one block, 31 SNPs; 29 of those SNPs are located in four LD blocks. Of the six SNPs most significantly associated with asthma, two (rs959974, rs7010969 and rs4738202) to separately estimate significantly associated SNPs from different LD blocks. Of the six SNPs most significantly associations with asthma in ALSPAC and current doctor-diagnosed asthma at 7–8 years in ALSPAC and PIAMA, and current doctor-diagnosed asthma at 6 years in Generation R.

Table 2 shows the associations between the six SNPs most significantly associated with asthma in ALSPAC and asthma in the PIAMA and Generation R cohorts. In PIAMA, there was some evidence for association (p < 0.05) with asthma for the three SNPs most significantly associated with asthma in ALSPAC, with effect estimates that were larger than those in ALSPAC. In Generation R, none of the six SNPs were associated with asthma. Fig. 1 shows the Forest plots for the weighted per-allele associations of the six SNPs with asthma.
gestation paracetamol exposure. Associations were similar in exposed and unexposed children for the six SNPs most significantly associated with asthma overall (Table 3) and for the remaining 7 SNPs (data not shown). For the three SNPs associated with IgE concentration (p < 0.05), we similarly stratified the per-allele associations by prenatal paracetamol exposure (Table 4). TRPA1 was associated with IgE concentration amongst children who were exposed, especially in later gestation, but not amongst non-exposed children (p-interaction 0.02 for rs959974 and rs1384001, and 0.06 for rs4738202).

**Discussion**

We found strong evidence for an association between TRPA1 polymorphisms and asthma in children at 7–8 years of age in the population-based ALSPAC birth cohort. Of the six SNPs most significantly associated with asthma in ALSPAC, three showed some evidence of association (and larger effect estimates) with a similar asthma phenotype in the PIAMA birth cohort, whilst none of the six SNPs were associated with asthma at 6 years in Generation R. However, both PIAMA and Generation R were considerably smaller and had a lower prevalence of current asthma, than ALSPAC, and hence lacked statistical power to replicate findings individually. When we meta-analysed across all three birth cohorts, the pooled effect estimates confirmed associations with asthma overall. Given the *a priori* selection of SNPs, the level of statistical significance for the ‘top hits’ in the ALSPAC discovery data set, and supportive evidence in PIAMA and following meta-analysis across all three cohorts, we believe these results may represent a causal influence of the TRPA1 gene on the risk of active childhood asthma. Other genes in the vicinity of TRPA1 are unlikely to explain our findings as there is little apparent LD extending between TRPA1 and other nearby genes (1000 Genomes Phase 1 CEU (www.1000genomes.org)). To our knowledge, these findings are novel and suggest that TRPA1 may play a role in the development of childhood asthma. Whilst a recent study reported correlations between two TRPA1 polymorphisms and asthma control in children with asthma (27), it was underpowered and statistical evidence was weak.
Importance of asthma phenotype

There is likely to be genetic heterogeneity of asthma phenotypes in childhood (28), as demonstrated for adult asthma phenotypes (29). This may partly explain why \textit{TRPA1} was not associated with asthma in the other European studies. A limitation of the GABRIEL asthma GWAS was that the asthma ‘ever’ phenotype was not directly comparable to the ‘current’ asthma phenotype used in ALSPAC, PIAMA and Generation R; a doctor diagnosis of asthma ‘ever’ is likely to comprise many different phenotypes or endotypes which, when analysed together, may lead to dilution of effects of genetic variants (30). For example, in children, ‘asthma ever’ may capture early transient childhood wheezing. We confirmed that the effect estimates for the association between \textit{TRPA1} and asthma were smaller in ALSPAC, and especially in PIAMA, when we analysed ‘ever’ asthma rather than ‘current’ asthma in these cohorts. Other possible reasons for the lack of association

---

**Table 3** Per-allele associations between the six most significantly associated \textit{TRPA1} SNPs and current doctor-diagnosed asthma, stratified by prenatal paracetamol exposure during early and late gestation in ALSPAC

| SNP     | N  | Paracetamol early in pregnancy OR (95% C.I.) | p-value | N  | Paracetamol later in pregnancy OR (95% C.I.) | p-value |

across the other European studies include differences in how cases were selected, which may have contributed to heterogeneity of the asthma phenotype; unreliability of recall of childhood-onset asthma amongst the adult studies in GABRIEL; and variation in the prevalence of environmental exposures that interact with the gene across different European populations (31).

Mechanisms

Given that reactive oxygen species are thought to play an important role in the pathogenesis of airways disease (32), and the TRPA1 receptor is an important oxidant sensor expressed on sensory neurons innervating the airways (2), it seems plausible that TRPA1 may play a critical role in asthma pathogenesis. Activation of TRPA1 can, through release of neuropeptides, promote neurogenic airway inflammation (3, 5). Conversely, in murine models of airway inflammation induced by allergen, cigarette smoke and paracetamol, deletion or antagonism of TRPA1 has been shown to reduce airway inflammation and hyper-reactivity (6, 10, 33). However, as neurogenic inflammation has not been demonstrated in human asthma, there are two other mechanisms to consider. First, TRPA1 may also influence airway inflammation non-neuronally, as confirmed in animals (34), and recent in vitro studies have shown that TRPA1 is functionally expressed in human lung, including pulmonary epithelial cells (34, 35), smooth muscle cells (34) and lung fibroblasts (35). Second, a neuronal reflex mechanism may be involved, as suggested by experiments in rodents (36).

The lack of modification of the association between TRPA1 and asthma by prenatal paracetamol exposure suggests that, even if foetal TRPA1 is activated by exposure to the metabolite of paracetamol (10) in utero, this mechanism is unlikely to explain the association between prenatal paracetamol and asthma. The apparent interaction we observed between prenatal paracetamol exposure and TRPA1 genotype on IgE concentration is intriguing, but may be a chance finding and we cannot offer a mechanistic explanation. We speculate that other prenatal and post-natal oxidant exposures may be more important than paracetamol as activators of TRPA1, thus contributing to the association we have found between TRPA1 genotype and childhood asthma.

Conclusions and future work

Our findings suggest, for the first time, that TRPA1 may play a role in the development of childhood asthma. In terms of therapeutic implications, these data lend further support to the proposition that TRPA1 antagonists may have promising potential in asthma (4). It is important that our findings are further replicated in adequately powered studies with comparable asthma phenotypes, and we plan to explore interactions between TRPA1 and other oxidant exposures such as tobacco smoke and air pollution on childhood respiratory outcomes.

Acknowledgments

We are extremely grateful to all the families who took part in the ALSPAC study, the midwives for their help in recruiting them, and the whole ALSPAC team, which includes interviewers, computer and laboratory technicians, clerical workers, research scientists, volunteers, managers, receptionists and nurses. We would like to thank all participants of the PIAMA birth cohort, and Roger Newson for advice on calculation of population attributable fraction. ALSPAC GWAS data were generated by Sample Logistics and Genotyping Facilities at the Wellcome Trust Sanger Institute, Cambridge, UK, and LabCorp (Laboratory Corporation of America), Burlington, NC, USA, using support from 23 and Me. The Generation R Study gratefully acknowledges the contributions of the children and their parents, the general practitioners, the hospitals and the midwives and pharmacies in Rotterdam. They thank M. Jhamai, M. Ganesh, P. Arp, M. Verkerk, L. Herrera and M. Peters for their help in creating, managing and performing quality control for the genetic database. Also, they thank K. Estrada and C. Medina-Gomez for their support in the creation and analysis of imputed data. The Generation R Study is conducted by the Erasmus Medical Center in close collaboration with the School of Law and the Faculty of Social Sciences of Erasmus University Rotterdam, the Municipal Health Service, Rotterdam area, the Rotterdam Homecare Foundation and the Stichting Trombosedienst & Arsenelaboratorium Rijnmond (STAR-MDC; Rotterdam). The generation and management of genotype data for the Generation R Study were performed at the Genetic Laboratory of the Department of Internal Medicine at Erasmus Medical Center.

Funding

The UK Medical Research Council, the Wellcome Trust (Grant ref: 102215/2/13/2) and the University of Bristol provide core support for ALSPAC. The PIAMA study is supported by grants from the Dutch Lung Foundation (grant numbers 3.4.01.26, 3.2.06.022, and 3.2.09.0811U), ZonMW (the Netherlands Organization for Health Research and Development), the Netherlands Ministry of Spatial Planning, Housing and the Environment, the Netherlands Ministry of Health, Welfare and Sport. Genomewide genotyping in PIAMA was supported by BBMRI-NL (CP29) and the European Commission (Gabriel study, contract number 018996). FND is supported by a grant from the UBbo Emmius Foundation. The Generation R Study is made possible by financial support from the Erasmus Medical Center (Rotterdam), the Erasmus University Rotterdam and the Netherlands Organization for Health Research and Development (ZonMw; 21000074). Dr Vincent Jaddoe received an additional grant from the Netherlands Organization for Health Research and Development (ZonMw-VIDI) and a European Research Council Consolidator Grant (ERC-2014-CoG-648916). Dr Liesbeth Duijts received funding from the Lung Foundation Netherlands (no 3.2.12.089; 2012).
