I. General Information

Unless noted otherwise, all solvents were dried by filtration through a Pure-Solv MD-5 Solvent Purification System (Innovative Technology). 1,4-dioxane and toluene were distilled freshly over sodium. Reaction temperatures were reported as the temperatures of the bather surrounding the flasks or vials. Sensitive reagents and solvents were transferred under nitrogen into a nitrogen-filled glovebox with standard techniques. Cesium carbonate was purchased from Strem and stored in the glovebox. Analytical thin-layer chromatography (TLC) was carried out using 0.2 mm commercial silica gel plates (silica gel 60, F254, EMD chemical). Vials (15 x 45 mm 1 dram (4 mL) / 17 x 60 mm 3 dram (7.5 mL) with PTFE lined cap attached) were purchased from Qorpak and flame-dried prior to use. Mass spectra were recorded on an Agilent 6530 LC Q-TOF mass spectrometer using electrospray ionization with fragmentation voltage set at 115 V and processed with an Agilent MassHunter Operating System. X-ray diffraction data were collected at 100(2) K on a Bruker-Nonius Kappa CCD or Agilent SuperNova AtlasS2 CCD. Infrared spectra were recorded on a Nicolet 380 FTIR using neat thin film technique. Nuclear magnetic resonance spectra (1H NMR and 13C NMR) were recorded with a Bruker Model DMX 500 or 400. Chemical shifts are reported in parts per million (ppm, δ), downfield from tetramethylsilane (TMS, δ=0.00ppm) and are referenced to residual solvent (CDCl₃, δ=7.26 ppm (1H) and 77.00 ppm (13C)). Coupling constants were reported in Hertz (Hz). Data for 1H NMR spectra were reported as follows: chemical shift (ppm, referenced to protium, s = singlet, d = doublet, t = triplet, q = quartet, quin = quintet, dd = doublet of doublets, td = triplet of doublets, ddd = doublet of doublet of doublets, m = multiplet, coupling constant (Hz), and integration). All other materials were obtained from Aldrich Chemical Company or Combi-blocks and were used as received.
II. Experimental Procedure and Characterization Data

Preparation of modified norbornenes:

N2,\(^1\) N3,\(^2\) N4,\(^3\) N5,\(^4\) N6,\(^4\) N7,\(^5\) N8\(^4\) and N9\(^4\) were known compounds and were synthesized according to reported procedures.

N10 – N17 were synthesized according to the following procedures.

**N18** was synthesized according to the following procedure:

An oven-dried 4.0 mL vial was charged with **N18-1**$^2$ (28.6 mg, 0.1 mmol, 1.0 equiv.), Mo(CO)$_6$ (13.2 mg, 0.05 mmol, 0.5 equiv.), methylamine hydrochloride (13.5 mg, 0.2 mmol, 2.0 equiv.), Pd(OAc)$_2$ (0.6 mg, 0.0025 mmol, 2.5 mol%), Xantphos (2.9 mg, 0.005 mg, 5.0 mol%) and Cs$_2$CO$_3$ (97.8 mg, 0.3 mmol, 3.0 equiv.). The vial was partially capped and transferred in a nitrogen-filled glovebox. In the glovebox, tetrahydrofuran (1 mL) was addition and the vial was tightly sealed, transferred out of glovebox and stirred on a pie-block preheated to 80 °C for 5 h. Upon completion of the reaction, the mixture was filtered through a thin pad of silica gel. The filter cake was washed with ethyl acetate, and the combined filtrate was concentrated. The residue was purified by flash column chromatography on silica gel to yield the desired product.

Preparation of vinyl halides or triflates:

\(5a,^5\) 5q,^6 5r,^7 5s,^8 5t,^9 5x,\(^{10}\) 5y,\(^{11}\) 5z,\(^{12}\) 5aa,\(^{13}\) 5ab,\(^{14}\) 5ac,\(^{15}\) 5ad,\(^{16}\) 5ae,\(^{17}\) and 5af\(^{12}\) are known compounds and were synthesized according to reported procedures. 5ag was purchased from Sigma-Aldrich.

\(5u\) was synthesized by the following procedure:

To the solution of KHMDS (1.60 g, 8.05 mmol, 1.15 equiv.) in anhydrous THF (10 mL) was slowly added a solution of \(5u-1\)\(^{18}\) (1.52 g, 7.0 mmol, 1.0 equiv.) in anhydrous THF (15 mL) at –78 °C. After 1 h at –78 °C under a nitrogen atmosphere, a solution of Comin’s reagent (3.03 g, 7.7 mmol, 1.1 equiv.) in anhydrous THF (15 mL) was slowly added to the reaction mixture at –78 °C. The solution mixture was allowed to warm to room temperature over 1 h and stirred for additional 3 h. The resulting solution was treated with saturated aqueous NaHCO\(_3\) (20 mL) and extracted with Et\(_2\)O (3 × 20 mL). The combined organic extracts were washed with brine (20 mL), dried over anhydrous MgSO\(_4\), filtered, and the solvent was removed in vacuo. The resulting crude product was purified by column chromatography.
5u: Colorless oil. (7.0 mmol scale, 1.37 g, 56% yield). R_f = 0.25 (hexane/ethyl acetate = 10:1).

5v and 5w were synthesized by the following procedure:

To a solution of corresponding carboxylic acid (2.2 mmol, 1.1 equiv.) and 1 drop of DMF in dichloromethane (1.0 mL) was added oxalyl chloride (203 μL, 2.4 mmol, 1.2 equiv.) dropwise at 0 °C. The reaction mixture was stirred at room temperature for another 1 h until the bubbling stopped. A mixture of 5v-1 (354 mg, 2.0 mmol, 1.0 equiv.) and pyridine (161 μL, 2.0 mmol, 1.0 equiv.) were then added and the reaction was stirred for another 3 h. The organic layer was washed with diluted hydrochloric acid and then concentrated under vacuum. The resulting crude product was purified by column chromatography.

5ai, 5aj, and 5ak were synthesized by the following procedure:

Following a known procedure\textsuperscript{19}: A mixture of 5ai-1 (12.1 g, 49 mmol, 1.0 equiv.) and pyridinium bromide perbromide (17.1 g, 53.5 mmol, 1.1 equiv.) in 1,2-dichloroethane (0.1 M) was stirred at room temperature for 12–14 h. 1,8-Diazabicyclo[5.4.0]undec-7-ene (22.6 mL, 150 mmol, 3.1 equiv.) was added to the reaction mixture at 0 ºC and the reaction mixture was then heated to 60 ºC. The reaction was quenched with 1 M aqueous HCl, and the reaction mixture was extracted with dichloromethane, concentrated in vacuo, and purified by silica gel column chromatography to afford 5ai-2 (14.3 g, 89%).

To a solution of 5ai-2 (10 g, 30.5 mmol, 1.0 equiv.) in tetrahydrofuran (60 mL) was added 2M aqueous NaOH solution (30.5 mL, 61 mmol, 2.0 equiv.) dropwise at room temperature. The reaction mixture was stirred at room temperature overnight. The reaction mixture was treated with 1 M HCl (aq) and extracted with Et\textsubscript{2}O (3 × 60 mL). The combined organic extracts were washed with brine (40 mL), dried over anhydrous MgSO\textsubscript{4}, filtered, and the solvent was removed in vacuo. The resulting crude product was purified by column chromatography to afford 5ai-3 (4.83 g, 88%).

To a solution of 5ai-3 (1.79 g, 10.0 mmol, 1.0 equiv.) and N,N-diisopropylethylamine (2.17 mL, 12.5 mmol, 1.25 equiv.) in dichloromethane (30 mL) was added chloromethyl methyl ether (1.14 mL, 15.0 mmol, 1.5 equiv.) dropwise at 0 ºC. The reaction mixture was stirred at room temperature overnight. The reaction mixture was treated with 1 M HCl (aq) and extracted with Et\textsubscript{2}O (3 × 30 mL). The combined organic extracts were washed with brine (20 mL), dried over anhydrous MgSO\textsubscript{4}, filtered, and the solvent was removed in vacuo. The resulting crude product was purified by column chromatography to afford 5ai (2.00 g, 90%).

General procedure for Pd/NBE-catalyzed alkenyl Catellani reaction

Unless otherwise noted, an oven-dried 8.0 mL vial was charged with Pd(cod)Cl₂ (8.6 mg, 0.03 mmol, 0.10 equiv) and Ph-DavePhos (11.4 mg, 0.03 mmol, 0.10 equiv). The vial was partially capped and transferred in a nitrogen-filled glovebox. In the glovebox, 1,4-dioxane (1 mL) was addition and the mixture was stirred for 1 min. Vinyl triflate 5 (0.30 mmol, 1.0 equiv), alkyl iodide 2 (0.9 mmol, 3.0 equiv), olefin 3 (0.45 mmol, 1.5 equiv), N11 (22.7 mg, 0.15 mmol, 0.50 equiv), 5-(trifluoromethyl)-2-pyridinol (9.8 mg, 0.06 mmol, 0.20 equiv), Cs₂CO₃ (293 mg, 0.9 mmol, 3.0 equiv), and additional 1,4-dioxane (5 mL) were added to the vial. The vial was tightly sealed, transferred out of glovebox and stirred on a pie-block preheated to 100 °C for 16 h. Upon completion of the reaction, the mixture was filtered through a thin pad of silica gel. The filter cake was washed with ethyl acetate, and the combined filtrate was concentrated. The residue was directly purified by flash column chromatography on silica gel to yield the desired product. (Note: an accurate palladium/ligand ratio and good solvent quality are important for the reproducibility.)

General procedure for acyclic vinyl bromide substrates

An oven-dried 8.0 mL vial was charged with Pd(cod)Cl₂ (8.6 mg, 0.03 mmol, 0.10 equiv) and Ph-DavePhos (11.4 mg, 0.03 mmol, 0.10 equiv). The vial was partially capped and transferred in a nitrogen-filled glovebox. In the glovebox, 1,4-dioxane (1 mL) was addition and the mixture was stirred for 1 min. Vinyl bromide 5 (0.30 mmol, 1.0 equiv), alkyl iodide 2 (0.9 mmol, 3.0 equiv), olefin 3 (0.45 mmol, 1.5 equiv), N11 (22.7 mg, 0.15 mmol, 0.50 equiv), 5-(trifluoromethyl)2-pyridinol (9.8 mg, 0.06 mmol, 0.20 equiv), K3PO4 (191 mg, 0.9 mmol, 3.0 equiv), and additional 1,4-dioxane (2 mL) and toluene (3 mL) were added to the vial. The vial was tightly sealed, transferred out of glovebox and stirred on a pie-block preheated to 100 °C for 16 h. Upon completion of the reaction, the mixture was filtered through a thin pad of silica gel. The filter cake was washed with ethyl acetate, and the combined filtrate was concentrated. The residue was directly purified by flash column chromatography on silica gel to yield the desired product. (Note: an accurate Pd/ligand ratio and good solvent quality are important for the reproducibility.)

Following a reported procedure: To a solution of 13 (11.3 mg, 0.05 mmol) in 4 mL dry pyridine was added a solution of OsO₄ in toluene (0.05 M, 1.1 mL, 0.055 mmol). The dark reaction mixture was stirred overnight. Aqueous NaHSO₃ solution was added. After further reaction for 90 min, the mixture was diluted with water and extracted with CHCl₃ (3 × 10 mL) and then with ethyl acetate (3 × 10 mL). Drying over MgSO₄ and evaporation of the solvent from the organic phase gave residue that can be used directly in the next step. To a solution of the above crude diol in 3 mL THF/H₂O (1:1) was added NaIO₄ (11.8 mg, 0.055 mmol) at 0 °C. The solution was warmed to room temperature and stirred for additional 3 hours, and then diluted with ethyl acetate before it was quenched with aqueous Na₂S₂O₅ solution. The organic layer was separated, washed with water and brine, dried over anhydrous MgSO₄, filtered and concentrated. The residue was purified by flash column chromatography to afford 14 in 52% yield over two steps.

The assignment of the major and minor structures was based on the following analysis:

1. The proton chemical shift for H₁ in the major product is 5.86 ppm while that of the minor product (H₁') is 5.16 ppm. (vide infra)

![Chemical structures with proton shifts and NOE signals](image)

2. Based on NOESY, the H₁ in the major component has nOe signals with the three protons highlighted below. The assignment of these three peaks were confirmed by COSY. In contrast, the H₁' in the minor component only has one nOe signal.

![Chemical structures with NOE signals](image)

To further prove our structure, chemical shifts for the two structures were predicted at mPW1PW91/6-311+G(2d,p) (giao, smd)/ B3LYP/6-31+G(d,p) (gas phase) level of theory, following a method described by Tantillo.²⁰ Calculated chemical shifts matched well with experimental data.

III. Kinetic Studies

General method

The reaction between vinyl triflate 5a, butyl iodide 2a, and methyl acrylate 3a was selected as the model reaction for the kinetic studies (see the scheme below). The kinetics of the alkenyl Catellani reaction was monitored by $^1$H NMR. The reaction procedure was similar to that described in the general procedure section. Stock solutions of 5a, 2a, 3a, N11, and 5-trifluoromethyl-2-pyridinol in 1,4-dioxane were prepared prior to use. Six identical reactions were set up in six different vials. For each reaction, Pd(cod)Cl$_2$, L1, and Cs$_2$CO$_3$ were weighted into a 4 mL vial, and indicated volume of the above stock solutions were added to the vial by syringe in the glovebox. The vials were transferred out of the glovebox and put into an aluminum block preheated to 100 °C. Timing was started and a vial was taken out of the pie-block every 20 min. The sampled reaction mixture was quickly filtered through a thin pad of silica gel. The filter cake was washed with ethyl acetate, and the combined filtrate was concentrated. The yields were determined by $^1$H NMR using dichloroethane as the internal standard.

Supplementary Table 7. Yield Dependence for 4a and 4a'' on [N11]

| [N11] | Yield (4a) | Yield (4a'') |
|-------|------------|--------------|
| 100 mol% | 77 | n.d.          |
| 50 mol% | 76 | 4             |
| 25 mol% | 53 | 14            |
| 20 mol% | 40 | 20            |
| 15 mol% | 28 | 36            |
Derivation of the rate law:

\[
\begin{align*}
\frac{d[4a]}{dt} &= k_1 \frac{K[N11]}{1 + K[N11]} [Pd] \\
\frac{d[4a'']}{dt} &= k_2 \frac{1}{1 + K[N11]} [Pd]
\end{align*}
\]

If \( K \) is very large, then:

\[
\begin{align*}
\frac{d[4a]}{dt} &= k_1 [Pd] \\
\frac{d[4a'']}{dt} &= k_2 \frac{1}{K[N11]} [Pd]
\end{align*}
\]

Therefore, these kinetic data suggest that the equilibrium for norbornene N11 insertion favors B over A. Although in theory only a catalytic amount (10 mol\%) of N11 was required, 50 mol\% of N11 is needed in this reaction in order to suppress Heck side product 4a” by shifting the pre-equilibrium towards B.
Measurement of the kinetic isotopic effect (KIE):

**Parallel kinetic isotope effect:** following the general method, parallel kinetic isotope effect (KIE) in the C−H metallation process was measured by two sets of parallel experiments employing 5a and 5a-d₃, respectively. The KIE was obtained by the ratio of reaction rates ($k_H/k_D$):

$$KIE = \frac{k_H}{k_D} = \frac{0.1648}{0.1129} = 1.5$$

**Supplementary Figure 14.** Kinetic time courses for measuring the parallel KIE.

**Competition kinetic isotope effect:** following the general procedure, the reaction was run with a mixture of 5a (50 mol%) and 5a-d₃ (50 mol%) as the reactants. The reaction was stopped at 1h and 2h, respectively. After isolation of the products by column chromatography, the competition KIE was obtained by the ratio of yields of products 4a and 4a-d₂ ($P_H/P_D$):

**Supplementary Table 8.** Competition KIE values obtained from different reaction times

| Reaction time | Ratio of 4a : 4a-d₂ | KIE |
|---------------|---------------------|-----|
| 1 h           | 61.5% : 38.5%       | 1.6 |
| 2 h           | 60.5% : 39.5%       | 1.5 |
Discussion:

**Supplementary Figure 15.** Hypothetical reaction profile.

According to the literature, a parallel KIE of 1.5 and competition KIE of 1.6 are most consistent with the reaction profile in Supplementary Figure 15.

Consider the rate law for the reaction profile above:

\[
\frac{d[P]}{dt} = k_2[B] = \frac{k_1 k_2 [A]}{k_{-1} + k_2} \quad (eq \ 1)
\]

(1) If \(k_{-1} \ll k_2\), then (eq 1) could be reduced to:

\[
\frac{d[P]}{dt} = k_1 [A]
\]

a **large primary** KIE (>3) would be expected.

(2) If \(k_{-1} \gg k_2\), then (eq 1) could be reduced to:

\[
\frac{d[P]}{dt} = \frac{k_1 k_2}{k_{-1}} [A]
\]

an equilibrium isotope effect (in this case, close to 1 or less than 1) would be expected.

(3) If \(k_{-1} \approx k_2\), C–H cleavage is only partially turnover-limiting and that another elementary step either before or after C–H cleavage (e.g. ligand dissociation/exchange) also contributes to the catalytic turnover rate. We are expecting to get a **small primary** KIE in this case. This scenario is most consistent with our experimental results.
Preparation of 5a-\textit{d}_4:

A suspension containing 4-phenylcyclohexan-1-one (3.48 g, 20 mmol, 1.0 equiv.) and potassium carbonate (5.52 g, 40 mmol, 2.0 equiv.) in 35 mL of deuterium oxide and 5 mL of acetone-\textit{d}_6 was heated at reflux for 16 h. After cooling, the reaction mixture was extracted with ether, and the combined organic phase was concentrated under reduced pressure. H/D exchange was repeated to afford 5a-\textit{d}_4, which was directly used in the next step without further purification.

To the solution of KHMDS (955 mg, 4.8 mmol, 1.2 equiv.) in anhydrous THF (5 mL) was slowly added a solution of 5a-\textit{d}_4 (712 mg, 4.0 mmol, 1.0 equiv.) in anhydrous THF (10 mL) at −78 °C. After 1 h at −78 °C under a nitrogen atmosphere, a solution of Comin’s reagent (1.89 g, 4.8 mmol, 1.2 equiv.) in anhydrous THF (10 mL) was slowly added to the reaction mixture at −78 °C. The solution mixture was allowed to warm to room temperature over 1 h and stirred for additional 3 h. The resulting solution was treated with saturated aqueous NaHCO$_3$ (20 mL) and extracted with Et$_2$O (3 × 20 mL). The combined organic extracts were washed with brine (20 mL), dried over anhydrous MgSO$_4$, and filtered. The solvent was removed in vacuo. The resulting crude product was purified by column chromatography.

Identification of the actual ligand:

The isolation of cyclic phosphine oxide 10 and by-product 11 led us to propose a reaction mechanism of how the active catalyst was generated. The reaction is initiated by the \( \text{C}-\text{H} \) palladation of \( \text{L2} \) with \( \text{PdX} \text{2} \) to form the cyclopalladated complex \( \text{A} \). Subsequent reductive elimination from \( \text{A} \) leads to the formation of phosphonium \( \text{B} \) along with \( \text{Pd(0)} \). The phosphonium \( \text{B} \) can then undergo oxidative addition with \( \text{Pd(0)} \), which provides complex \( \text{C} \) through cleavage of the \( \text{C}--\text{P} \) bond. The resulting phenyl \( \text{Pd(II)} \) species could undergo migratory insertion into \( \text{N11} \), and further a normal Catellani reaction takes place to give the actual catalyst \( \text{E} \) along with 11 as the by-product.

**Supplementary Figure 16.** Proposed mechanism for the formation of the active catalyst.

To confirm that \( \text{L7} \) was the actual active ligand, the parallel kinetic study of reactions using \( \text{L2} \) or \( \text{L7} \) as the ligand was conducted, following the general method. A sacrificial additional 10 mol% of \( \text{L7} \) was used to reduce \( \text{Pd(II)} \) into \( \text{Pd(0)} \), which was not required in the case of \( \text{L2} \).

One B-Alert: PLAT410_Alert_2_B Type_2 Test for short non-bonding intra H...H contacts. Author response: The atom H13D is included in the disordered \(n\)-butyl group. Because of low occupancy [22%] and thermal motion of the \(n\)-butyl group, the short contact of H17...H13D is unavoidable in the crystal.
