Abstract
We report on the cryogenic properties of a low-contraction silicon–aluminum composite, namely Japan Fine Ceramics SA001, to use as a packaging structure for cryogenic silicon devices. SA001 is silicon–aluminum composite material (75% silicon by volume) and has a low thermal expansion coefficient (~1/3 that of aluminum). The superconducting transition temperature of SA001 is measured to be 1.18 K, which is in agreement with that of pure aluminum and is thus available as a superconducting magnetic shield material. The residual resistivity of SA001 is 0.065 µΩm, which is considerably lower than equivalent silicon–aluminum composite material. The measured thermal contraction of SA001 immersed in liquid nitrogen is \( \frac{L_{293 K} - L_{77 K}}{L_{293 K}} = 0.12\% \), which is consistent with the expected rate obtained from the volume-weighted mean of the contractions of silicon and aluminum. The machinability of SA001 is also confirmed with a demonstrated fabrication of a conical feedhorn array, with a wall thickness of 100 µm. These properties are suitable for packaging applications for large-format superconducting detector devices.

Keywords Cryogenics · Superconductor · Thermal contraction · Feedhorn array · Astrophysics

1 Introduction
Large format arrays of superconducting detectors, such as microwave kinetic inductance detectors and transition edge sensors are being developed to enhance the survey speed of astrophysical telescopes. These detectors are often built on silicon wafers, which are packaged with aluminum components like feedhorn antenna arrays and...
wafer support structures [1–4]. However, the large difference in thermal contraction between silicon and these metals can result in serious misalignment of the optical components, and thermal stress damaging the device when cooled to cryogenic temperatures. Although Invar is a solution for differential thermal contraction, it is not widely used because of the performance degradation of superconducting detectors due to ferromagnetism.

Recently, cosmological experiments at millimeter and submillimeter wavelengths (e.g., CLASS [5–7], AdvACT [8]) have introduced the silicon–aluminum composite material, Sandvik-Osprey CE7, produced by the spray-forming method [6], which has a low thermal expansion coefficient (~1/3 that of aluminum). CE7 also has the advantage of being a non-magnetic and superconducting magnetic shield material owing to its superconducting transition temperature of 1.2 K, which is above the operation temperature of the detector stages (≤ 0.3 K).

Herein, we report the measurement results for an alternative silicon–aluminum composite material, Japan Fine Ceramics SA001, in terms of thermal contraction, superconducting transition temperature, and electric resistivity. We also demonstrate the machinability of SA001 with a test cut of a conical feedhorn array.

2 Material

SA001\(^{1}\) is silicon–aluminum composite material with a 75:25 volume ratio produced by the infiltration method, which shows a structure of silicon grains (~10–100 µm in size) filled with aluminum. SA001 is lighter, more rigid, and has a lower thermal expansion coefficient than aluminum and its alloys, and is thus a functional substitute for aluminum or steel alloys in industrial use. The physical properties of SA001 at room temperature are summarized in Table 1. The significant difference between SA001 and CE7 is in the electrical resistivity, which of SA001 is three times smaller than that of CE7. The other properties are almost equivalent to those of CE7.

3 Cryogenic Measurements

3.1 Superconducting Transition Temperature and Resistivity

We measured the resistivity–temperature curve of SA001 to investigate the superconducting transition temperature and material’s electric properties at cryogenic temperature. Two fine (0.42 × 0.15 × 8.5 mm\(^3\)) samples of SA001 were cooled down to 220 mK on the cold stage of the \(^3\)He sorption refrigerator, Simon Chase He-10 (Fig. 1). Resistances of the samples were continuously measured by the 4-terminal method using an AC resistance bridge (AVS-47B) in the course of the cooldown. The temperature of the samples was measured by well-calibrated thermometers Cernox CX-1010 and Ruthenium oxide RX-102A. The result is shown in

Table 1 Physical properties of CE7 and SA001

|                  | CE7\textsuperscript{a} | SA001 |
|------------------|-------------------------|-------|
| **Room**         |                         |       |
| Composition (wt% of silicon) | 70          | 72\textsuperscript{b} |
| Composition (vol% of silicon) | 73\textsuperscript{c} | 75 |
| Thermal expansion coefficient at 200 °C (K\textsuperscript{-1}) | $\sim 9 \times 10^{-6}$ | $9 \times 10^{-6}$ |
| Density (g cm\textsuperscript{-3}) | 2.43 | 2.4 |
| Young’s modules (GPa) | 129.2 | 120 |
| Possion’s ratio | 0.26 | 0.29 |
| Resistivity at 300 K (µΩm) | 1.15 | 0.4 |
| **Cryogenic**    |                         |       |
| Transition temperature $T_c$ (K) | 1.19 | 1.18±0.01 |
| Residual Resistivity at 1.5 K (µΩm) | 0.50 | 0.065±0.001 |
| Thermal conductivity at 1.2 K (Wm\textsuperscript{-1}K\textsuperscript{-1}) | 0.06\textsuperscript{d} | 0.45\textsuperscript{d} |
| Thermal contraction $L_{293K} - L_{77K}$ | 0.1% | 0.120±0.013% |
| Thermal contraction $L_{293K} - L_{4K}$ | 0.1% | 0.12%\textsuperscript{e} |

\textsuperscript{a}Reference [6]
\textsuperscript{b}Calculated from the volume composition
\textsuperscript{c}Calculated from the weight composition
\textsuperscript{d}Estimated using the Wiedemann–Franz law from residual resistivity at 1.5 K
\textsuperscript{e}Volume-weighted mean of thermal contraction at 4 K of silicon and aluminum

![Fig. 1 Cryogenic measurement configuration to determine transition temperature and resistivity (Color figure online)](image)
Fig. 2. The sharp transitions to the superconducting state at the transition temperature $T_c = 1.18 \pm 0.01$ K for both samples assure the reproducibility of the superconducting property of SA001. The measurement error is given by the calibration error of the thermometers. The measured $T_c$ is equivalent to those of pure bulk aluminum ($T_c = 1.18$ K [9]) and CE7 ($T_c = 1.19$ K [6]). Thus, we conclude that SA001 surroundings can efficiently function as a superconducting magnetic shield at the operating temperature of detectors (< 1 K).

We also obtained a residual resistivity (RR, defined at 1.5 K) of 0.065 ± 0.001 µΩm for SA001, which is considerably lower than that of CE7 (0.5 µΩm [6]). Using the Wiedemann–Franz law with the theoretical Lorentz number of $L = 2.44 \times 10^{-8}$ WΩK$^{-2}$, we estimate the thermal conductivity at 1.2 K to be 0.45 and 0.059 Wm$^{-1}$K$^{-1}$ for SA001 and CE7, respectively, suggesting that SA001 has eight times better thermal conductivity than CE7. Below the transition temperature, thermal conductivity of CE7 at 300 mK has been reported to be 0.005 Wm$^{-1}$K$^{-1}$ [6]. The value is expected to be a lower limit for SA001, below the transition temperature. Therefore SA001 can be cooled from room to the operation temperature of detectors very efficiently.

### 3.2 Thermal Contraction

The thermal contraction of SA001 was measured with a simple apparatus made of 6061 aluminum alloy (Fig. 3) [10]. The distance of the two walls on the aluminum alloy plate, with and without steps, was varied by increments of 0.5 mm. This functioned as a ruler for measuring the length of the sample. Both the apparatus and a 200 mm long SA001 sample were immersed in liquid nitrogen. After fitting the $

\footnote{\text{$T_c$ of SA001 is defined at the temperature of half of the normal resistivity, which is consistent with the definition of $T_c$ of CE7 [6].}}
sample to the ruler, a thickness gauge (SUS) was used to accurately determine the sample length. The contractions of the ruler and the thickness gauge were corrected and the length of the sample was derived. As a result of the measurement and the contraction correction, we obtained a thermal contraction of \[ \frac{L_{293\,K} - L_{77\,K}}{L_{293\,K}} = 0.120 \pm 0.013\% \], which is equivalent to that of CE7 (0.1%).

The measured contraction of SA001 at 77 K is can be explained by a volume-weighted mean of contractions (0.116% was estimated from contractions of silicon and pure aluminum, which are 0.023% [11] and 0.393% [9]). We also estimated the contraction at 4 K to be 0.121% in the same method using the contractions of silicon and aluminum (0.022% [11] and 0.415% [9], respectively). This is also consistent within the measured contraction at 77 K.

4 Machining Test

Silicon–aluminum alloys are known to be difficult-to-machine materials; therefore, we performed test cuts of circular waveguides and a 5-pixel conical feedhorn on the SA001 samples. SA001 is a hard and brittle material, and therefore we used diamond-coated tools for machining. Figure 4a shows the cross-section of the circular waveguides with a length of 10 mm and a diameter of 1.5 mm. We confirmed that surface roughness inside the waveguide was achieved to be \( R_z \approx 1 \, \mu \text{m} \).

We also fabricated a 5-pixel feedhorn antenna array with an aperture diameter of 5.4 mm, a full flare angle of 15°, a waveguide diameter of 1.5 mm, and a total length of 16 mm. The thin wall structures between the feedhorns were robustly fabricated with a thickness of 100 µm. The machining method is scalable for more than a 100-pixel array. Thus, we confirmed that SA001 is machinable for conical feedhorn arrays available for large-format superconducting detector instruments.

We also checked the fabrication of more precise structures. Thread holes for M2 and M3 screws can be bored robustly. Although we tried cutting grooves for a corrugated feedhorn inside the conical horn (groove width <0.5 mm), it was still challenging because of the limitation of machining tools and the brittleness of the SiAl composite material.
5 Conclusion

We investigated the cryogenic properties of SA001, which are summarized in Table 1. The measurement results show that SA001 is suitable for detector packaging or feed horn array material. We will use SA001 as the material for the focal plane detector modules in a new multi-color millimeter and submillimeter camera planned for the Greenland telescope [12].
