Proliferating Cell Nuclear Antigen as a Molecular Biomarker for Spermatogenesis in PTU-Induced Hypothyroidism of Rats

Ehab Tousson, PhD¹, Ehab M. M. Ali, PhD², Wafaa Ibrahim, MD³, and Mohammed A. Mansour, BSc²

Abstract
The thyroid hormone has few serious effects on the testes except during the neonatal stage. There is little knowledge concerning the prolonged effect of thyroid hormone deficiency throughout the rat’s life span and its effect on spermatogenesis. Proliferating cell nuclear antigen (PCNA) is a nuclear matrix protein, which is essential for multiple cell cycle pathways. Here we used PCNA immunohistochemistry as a marker to differentiate between the testes of control and hypothyroid rats. About 20 rats were equally divided into 2 groups; the first group was the control group, while the second group was the experimental group in which rats were fed 0.05% 6-n-propyl thiouracil (PTU) in drinking water for 6 weeks. Immunohistochemistry, using an antibody against PCNA, showed at least 3 differences in the pattern of PCNA immunoreactivity (PCNA-ir). First, PCNA-ir was not detected in Sertoli and Leydig cells in the testes of control rats and detected in some of the hypothyroid rats. Second, in the control group more than 96% of spermatogonia were PCNA-positive cells; however, hypothyroidism caused the reduction to approximately 25% PCNA staining in spermatogonia. The third difference was in the abnormal distribution of spermatogonia seen in the hypothyroid rat testis, not in the control one. These results suggest that prepubertal hypothyroidism affects the proliferation of spermatogenic cells leading to impaired spermatogenesis and that PCNA index is a useful marker for assessing germ cell kinetics and spermatogenesis in prepubertal hypothyroidism.

Testes, hypothyroidism, PTU, spermatogenesis, PCNA, rats

Introduction
Appropriate level of thyroid hormone is essential for normal development and metabolism in most vertebrate tissues, and altered thyroid status adversely affects them.¹,² For many years, the testis was regarded a thyroid hormone unresponsive organ, but consistent evidence accumulated in the past 2 decades has definitively changed this classical view.

The testes are mainly regulated by the gonadotrophin follicle-stimulating hormone (FSH) and luteinizing hormone (LH), the latter acting through the intermediate testosterone secreted by the Leydig cells.³,⁴ It is well accepted that these systemic hormones and local testicular paracrine–autocrine factors work together to initiate and maintain testicular function and sperm production.⁵ Apart from gonadotrophins, thyroid hormone has also been shown to play an important role in testicular physiology.²,⁶,⁷ It is now established that triiodothyronine (T₃) regulates the maturation and growth of testis, in rats and other mammal species, by inhibiting immature Sertoli cell proliferation and stimulating their functional differentiation.⁸⁻¹⁰ Similarly, thyroid hormone has also been shown to play a critical role in the onset of Leydig cell differentiation and stimulation of steroidogenesis in postnatal rat testis.¹¹,¹²

Although the basic mechanisms involved in the regulatory actions of thyroid hormone in testicular cells are still undefined, the presence of thyroid hormone receptors (TRs) in human and rat testes throughout development and in adulthood implies that T₃ may act directly via the classical genomic pathway in this organ.²,⁸,¹³

Altered thyroid status, experimentally induced or occurring in adult life, is frequently associated with some kind of sexual dysfunction and/or morphological testicular degeneration.¹⁴⁻¹⁷ Because most experimental studies to date have focused on thyroid hormone effects on the developing testes, only limited data are available on its role in spermatogenesis.

Proliferating cell nuclear antigen (PCNA) is a well-known 36-kDa nuclear matrix protein, which is essential for multiple cell cycle pathways, including DNA replication, DNA elongation (leading strand synthesis), and DNA excision repair.\textsuperscript{18,19} It is also utilized in cell cycle control through direct interaction with cyclin/cdk complexes, allowing progression through the G1/S boundary of the cell cycle.\textsuperscript{20} Proliferating cell nuclear antigen is an essential component of the DNA replication machinery, acting as the processing factor for polymerases.\textsuperscript{21} In addition to its role in replication, PCNA is also required for nucleotide excision repair and plays a role in 1 pathway of base excision repair.\textsuperscript{22} Analysis of proteins that interact with PCNA has shown that it not only interacts with enzymes involved in the mechanics of DNA repair and replication but also binds to cell cycle regulatory proteins such as p21 and Gadd45.\textsuperscript{23,24} Proliferating cell nuclear antigen is useful for the diagnosis of germinal arrest because there are significantly reduced PCNA levels in germinal arrest, which is an indication of DNA synthesis deterioration.\textsuperscript{25} In this study, a detailed histopathological examination was performed, including PCNA immunohistochemistry of rat testicular tissue to analyze the proliferation rate of the germ cells and to examine the effects of 6-n-propyl thiouracil (PTU)-induced hypothyroidism on the proliferative aspects of spermatogenesis.

Materials and Methods

The experiments were performed on 20 male albino rats (\textit{Rattus norvigicus}) weighing 120 g (± 10 g) and of 6 to 7 weeks' age. They were obtained from Helwan laboratory farms of the Egyptian Organization for Vaccine and Biologic Preparations. The rats were kept in the laboratory for 1 week before the experimental work and maintained on a standard diet and water available ad libitum. The temperature in the animal room was maintained at 23 ± 2°C with a relative humidity of 55% ± 5%. Light was on a 12:12-hour light–dark cycle. The experimental protocol was approved by local ethics committee and animals research. The rats were equally divided into 2 groups: the first group was the control group in which rats never received any treatment; while the second group was the experimental group in which rats received 0.05% PTU in drinking water for 6 weeks.\textsuperscript{26}

At the end of the experimental period, 5 rats from each group were euthanized with intravenous injection with sodium pentobarbital and subjected to a complete necropsy. Blood samples were individually collected from each rat in nonheparinized glass tubes. Serum was separated by centrifugation at 3000 rpm for 15 minutes. The collected serum was stored at −18°C until analysis. Serum was analyzed to determine the T3 and thyroid-stimulating hormone (TSH) levels.

\textbf{Determination of Serum T3 and TSH Concentrations}

Serum T3 was assayed using commercial kit supplied by Coat-A-Count TSH IRMA, Los Angeles, California.

\textbf{Proliferating Cell Nuclear Antigen Immunohistochemistry}

The other 5 rats from each group were anesthetized with thiopental. Through surgical incision on the sternum, the thorax was opened and the perfusion was done from left ventricle and right atrium. A rinsing solution was perfused before the fixation solution (Bouin fluid). Due to the narrow testicular artery branches from the abdominal aorta near the renal artery, it is probably constricted and occluded during the perfusion process. Perfusion with rinsing solution helped overcome this problem. To make rinsing solution, 9.0 g NaCl, 25 g polyvinylpyrrolidone, 0.25 g heparin, and 5.0g procaine-HCL were dissolved in 1 L of water by thorough stirring. The pH was adjusted to 7.35 with 1 N NaOH and twice filtered through Millipore filters of 3.0 µm or less pore size. The perfusion of both solutions was performed using a scalp vein attached to a 50 cc syringe. Testes were immediately removed, taking care to handle specimens gently to minimize trauma to the delicate seminiferous tubules prior to the placement of each testis into fixative solution. The tunica albuginea was shallowly pierced at each pole 5 times with a 21-gauge needle to aid in the penetration of the fixative solution. Fixation time was limited to 24 hours and tissues were transferred to 70% ethyl alcohol. Alcohol was changed 3 times daily for 2 days before transferring the specimens to a saturated solution of 70% ethyl alcohol and lithium carbonate to neutralize the picric acid in Bouin fluid. The ethyl alcohol-lithium carbonate solution was changed 3 or more times until the yellow color of Bouin fluid was almost completely depleted from the tissue. Testes were stored in 70% ethyl alcohol until they were processed.\textsuperscript{27} The fixed testes were dehydrated through a graded series of ethanol and embedded in paraffin, according to standard procedures. Paraffin sections (5 µm thick) were mounted on gelatin chromalum-coated glass slides and stored at room temperature until further processing. The 5 µm thick paraffin sections were used for PCNA immunohistochemical staining method.\textsuperscript{28}

Testicular distribution of PCNA receptor subunits were examined in deparaffinized sections (5 µm) of Bouin fixed testes of rats using an avidin–biotin–peroxidase (ABC) immunohistochemical method (Elite-ABC, Vector Laboratories, California) against PCNA (dilution 1:100, DAKO Japan Co, Ltd, Tokyo, Japan). Briefly, sections were deparaffinized, rehydrated, washed in phosphate buffered saline (PBS) 3 × 5 minutes) and peroxidase activity was quenched using 0.3% \( \text{H}_2\text{O}_2 \) in methanol for 30 minutes. Subsequently, samples were washed in PBS and incubated with blocking solution at room temperature for 10 minutes. After rinsing with PBS, sections were incubated with biotinylated mouse PCNA primary antibody in moist chamber for 30 to 60 minutes and then rinsed with PBS. Samples were incubated with streptavidin peroxidase at room temperature for 10 minutes and washed with PBS. The antibody–peroxidase complex was developed using the
diaminobenzidine (DAB) chromogen at 18-24°C for 2-5 min. Finally, the sections were washed with PBS, counterstained with hematoxylin for 1 min, washed with tap water then PBS for 30 seconds, dehydrated through ascending grades of alcohol, delipidated in xylene, and coverslipped with Mount-Quick (Daido Sangyo, Tokyo). All stained slides were viewed using Olympus microscope and images were captured by a digital camera (Canon PowerShot A620). Brightness, contrast, and analysis of the images were adjusted using Adobe Photoshop software (version 4.0.1; Adobe Systems, Mountain View, California).

**PCNA-Labeling Index**

We determined the PCNA labeling index (PCNA-LI) in the PCNA immunoreactive slides by slide examination under the light microscope with a magnification of ×200 and with the help of PAX-it image analysis software. Selected sections were evaluated for PCNA immunostaining. Microscopic fields were chosen at random and 5 fields per slide were evaluated. Only the basal germ cells of the seminiferous tubules were counted, as they are the cells where active DNA synthesis took place. The PCNA-LI for each seminiferous tubule was estimated as a percentage of immunolabeled cells (cells with brown nuclear staining PCNA+) to all basal cells. The average PCNA index in each case was obtained by dividing the sum of all PCNA indices by the number of seminiferous tubules in which the calculation was carried out. For each specimen the mean ± SD was calculated.

**Statistical Analysis.** Data were expressed as mean values ± SD and statistical analysis was performed using 1-way analysis of variance (ANOVA) to assess significant differences among treatment groups. The criterion for statistical significance was set at $P < .05$. All statistical analyses were performed using SPSS statistical version 16 software package (SPSS Inc., IBM Company; Somers, NY 10589 USA).

**Results**

Serum T3 levels were significantly lower in hypothyroid rats compared with the control. On the other hand, serum TSH levels in rats were significantly higher than those found in the control rats (Table 1).

The light microscopy examination of the testes of the control rats showed a normal structure completely enveloped by a thick capsule, tunica albuginea, which is composed mainly of dense collagenous fibrous connective tissue. The structural components of the testis are the seminiferous tubules and interstitial tissues (Figure 1A). The interstitial cells (Leydig cells) of control rats are found in the connective tissue between the seminiferous tubules and showed a negative reaction for PCNA-ir (Figure 1B). The seminiferous tubules are of 2 types of cells, the Sertoli cells, resting on the thin basal lamina (basement membrane) and the spermatogenic cells. Figure 1F shows a negative reaction for PCNA-ir in Sertoli cells of control rats, which can be identified by their oval- or pear-shaped vesicular nuclei lying perpendicular on the basement membrane of seminiferous tubules (data not shown). The spermatogenic cells are arranged in many layers, namely, the spermatogonia; primary and secondary spermatocytes; spermatids; and finally mature spermatozoa. Only the spermatogonia in control animals showed a positive strong reaction for PCNA-ir (Figure 1), while the other spermatogenic cell types showed negative reaction (Figure 1C and D). The lumen of the seminiferous tubules in the control group was fully packed with sperms that showed a negative reaction for PCNA-ir (Figure 1A-C).

Table 1. Serum T3 and TSH Levels and PCNA Index in Testes Tissues of Control and Hypothyroid Rats

| Groups | Parameters | Total T3 (ng/dL) | TSH (mIU/mL) | PCNA-LI |
|--------|------------|-----------------|--------------|---------|
| C1 (control) | mean ± SD | 155.8 ± 30.335 | 0.014 ± 0.006 | 96.33 ± 5.59 |
| C2 (PTU-induced hypothyroidism) | mean ± SD | 56 ± 11.023* | 4.1 ± 0.7 × 10^-3* | 19.45 ± 3.55 |

Abbreviations: T3, tri-iodothyronine; TSH, thyroid-stimulating hormone; PCNA, proliferating cell nuclear antigen; LI, labeling index; PTU, 6-n-propyl thiouracil; SD, standard deviation.

* $P < .001$ vs control rats.

The testes of hypothyroid rats showed many immunohistochemical changes in testicular tissues (Figure 2). Table 1 presents the index PCNA value and the number of PCNA-ir positive germ cells per tubule cross-section significantly decreased following PTU treatment (19.45 ± 3.55) in comparison to the control group (96.33 ± 5.59). The number of spermatozoa is less in hypothyroid rats, where the lumen of some seminiferous tubules was clear and the spermatozoa were not seen (Figure 2A and B). Some of the Sertoli cells in the seminiferous tubules of hypothyroid rats showed positive reaction for PCNA in contrast to the control group (Figure 2C). Figure 2D shows positive reaction for PCNA in some Leydig interstitial cells lying between seminiferous tubules of hypothyroid rats in contrast to the control group. The distribution of spermatogonia in seminiferous tubules of hypothyroid rats is not homogenous as in control animals (Figure 2E and F). Some of the spermatogonia in the testes of hypothyroid rats were observed in the lumen of the seminiferous tubules and between the spermatocytes (Figure 2E and F).

**Discussion**

The thyroid hormone is essential for the development and maintenance of the testes. In previous studies, the thyroid hormone has few serious effects on the testes except during the neonatal stage when the thyroid hormone receptor is mainly present. However, there is little knowledge concerning the prolonged effect of thyroid hormone deficiency throughout the rat’s life span. We designed our study to investigate the role

PCNA indicates proliferating cell nuclear antigen.
of thyroid hormone on the testicular function at the prepubertal stage of rats. In order to achieve this target, we made a deficient state of thyroid hormones by a reversible goitrogen. 6-n-propyl thiouracil is known to decrease the conversion of peripheral T4 to T3 and thereby reduces serum T3 concentration. 6-n-propyl thiouracil has been linked with several side effects, such as transient leucopenia, jaundice, hepatomegaly, and vasculitis. It was administered to the rats in the drinking water within a period of 6 weeks to investigate the changes through a complete spermatogenic cycle.

In order to ensure the hypothyroid state, we regularly determined the serum T3 and TSH through the dose period, where serum T3 concentration is depressed and serum TSH concentration is significantly elevated. During normal spermatogenesis, controlled cell proliferation is of fundamental importance, assuming highly coordinated mechanisms between the mitotically inactive Sertoli cells and the germ cells undergoing mitosis and meiosis. Efficiency of spermatogenesis depends on the proliferative activity of spermatogonia and the loss of germ cells during meiosis and spermiogenesis. Mitosis counts, tritiated thymidine ([3H]Thy) or 5-bromodeoxyuridine (BrdU) labeling have traditionally been used for the assessment of cell proliferation. However, these methods are less suitable for use under certain experimental conditions. For instance, [3H]Thy labeling requires use of radioisotopes, visualization by autoradiography, and in vivo administration, thus not enabling the use of this method in postmortem tissue. With the development of monoclonal antibodies to DNA-incorporated BrdU, the use of radioisotopes and autoradiographic visualization was eliminated. However, variability in BrdU concentration during the incubation period can affect the quality of labeling and thus influence the labeling index value. Moreover, these methods require long fixation and development periods. Recently, the use of immunocytochemical assays, based on antibodies to cell proliferation-related antigens, has been shown to be effective in the assessment of cell proliferation. One such cell proliferation-related protein is PCNA that has been identified as an auxiliary protein of DNA polymerase δ, found in the nuclei of proliferating cells. This antigen, which is differentially expressed during the cell cycle, reaches its maximum level of expression during late G1/S phase and begins to decrease during late G2/M to G1 phase. Comparisons of PCNA- and BrdU-labeling indices have shown that not only does PCNA-labeling produce similar results to that of BrdU labeling, but it is a faster and easier method to use for the detection of cell proliferation. In addition, because the PCNA method is based on an antigen–antibody reaction, it can be performed in situ, on routinely processed tissue sections. Quantitation of PCNA expression is becoming routinely used as a diagnostic tool in clinical pathology, for the assessment of tumor cell proliferation. However, we believe that because PCNA expression and synthesis is linked to cell proliferation, and its presence subsequent to immunohistochemical processing can be observed microscopically, this technique may be used for the purpose of providing direct visual evidence of cell proliferation under various experimental conditions.

The seminiferous epithelium contains 2 distinct cell populations, namely somatic Sertoli cells and spermatogenic cells. Spermatogonia undergo successive rounds of mitotic divisions and later the resulting daughter cells enter meiotic division to provide sperm. In the current study, we used immunohistochemistry to map the distribution of PCNA immunoreactivity in the testes of the control and hypothyroid rats. Proliferating cell nuclear antigen has been used extensively in the identification of proliferating spermatogonia and spermatocytes, which we observed as brownish black stained cells in our samples.

Our results indicate that hypothyroidism adversely affects spermatogenesis, suggesting that thyroid hormone might play an important role not only in controlling normal testicular development, but also in maintaining normal testicular function and spermatogenesis. These results indicate at least 4 differences in the pattern of PCNA immunoreactivity in the testes of hypothyroid rats in comparison to control ones. First, PCNA-ir were not detected in Sertoli cells in the testes of control rats and detected in hypothyroid rats. This finding confirmed the findings of Van Haaster et al., Tarulli et al., and Jansen et al. regarding the role of thyroid hormone in regulating the maturation and growth of testis, in rats and other mammal species, by inhibiting immature Sertoli cell proliferation and stimulating their functional differentiation. Second, PCNA-ir were not detected in Leydig cells in the testes of control rats and were detected in hypothyroid rats confirming what mentioned by Mendis-Handagama and Ariyaratne and Lin et al. regarding the critical role of thyroid hormones in the onset of Leydig cell differentiation and stimulation of steroidogenesis in postnatal rat testis. The third difference was in the number of spermatogonia that have a positive reaction for PCNA-ir in control and hypothyroid rats, all spermatogonia on routinely processed tissue sections, namely somatic Sertoli cells and spermatogenic populations, namely somatic Sertoli cells and spermatogenic cells. The fourth difference was in the abnormal distribution of spermatogonia seen in the hypothyroid rats in contrast to the control one, indicating a role of thyroid hormone in maintaining the normal distribution of the spermatogenic cells in the seminiferous tubules.
