Multiterminal ballistic Josephson junctions coupled to normal leads

Régis Mélin

Univ. Grenoble-Alpes, CNRS, Grenoble INP, Institut NEEL, 38000 Grenoble, France

Multiterminal Josephson junctions have aroused considerable theoretical interest recently and numerous works aim at putting the predictions of correlations among Cooper (i.e. the so-called quartets) and simulation of topological matter to the test of experiments. The present paper is motivated by recent experimental investigation from the Harvard group reporting \(h/4e\)-periodic quartet signal in a four-terminal configuration containing a loop pierced by magnetic flux, together with inversion controlled by the bias voltage, i.e. the quartet signal can be larger at half-flux quantum than in zero magnetic field. Here, we theoretically focus on devices consisting of finite-size quantum dots connected to four superconducting and to a normal lead. In addition to presenting numerical calculations of the quartet signal within a simplified modeling, we reduce the device to a non-Hermitian Hamiltonian in the infinite-gap limit. Then, relaxation has the surprising effect of producing sharp peaks and log-normal variations in the voltage-sensitivity of the quartet signal in spite of the expected moderate fluctuations in the two-terminal DC-Josephson current. The phenomenon is reminiscent of a resonantly driven harmonic oscillator having amplitude inverse proportional to the damping rate, and of the thermal noise of a superconducting weak link, inverse proportional to the Dynes parameter. Perspectives involve quantum bath engineering multiterminal Josephson junctions in the circuits of cavity quantum electrodynamics.

I. INTRODUCTION

BCS superconductors \([1]\) are characterized by macroscopic phase variable \(\varphi\) and energy gap \(\Delta\) between the ground state and the first quasiparticles. Anderson demonstrated \([2, 3]\) that Coulomb interaction produces collective modes in bulk superconductors, yielding the Higgs mechanism as an explanation to the Meissner effect. Josephson \([4]\) demonstrated that gauge invariance implies DC-supercurrent between two phase-biased superconductors, and AC-current oscillations with voltage-biasing. The so-called Andreev bound states (ABS) \([5, 6]\) contribute to the DC-Josephson supercurrent flowing through any type of weak link, see for instance Refs. \([9, 13]\). Recently, the ABS were probed with microwave spectroscopy \([14, 17]\), but the life-time of this “Andreev qubit” \([18]\) turns out not to be infinite. In general, understanding the mechanisms of quasiparticle poisoning \([19, 20]\) is a central issue in the studies of circuits of quantum engineering \([27–31]\). In bulk superconductors, the electron-phonon coupling or the electron-electron repulsive Coulomb interaction produce finite quasiparticle life-time \([32, 35]\) captured by adding small imaginary part \(\eta\) to their energy. This small Dynes parameter \(\eta\) \([32, 35]\) produces exponential time-decay of the quasiparticle wave-functions. In the following paper, we investigate multiterminal Josephson junctions coupled to normal leads, and demonstrate that small relaxation produced by the coupling to those normal conductors has drastic effect on the current. Based on previous works related to infinite-gap Hamiltonians \([18, 36, 37]\), we also here-consider the infinite-gap limit, where non-Hermitian Hamiltonians emerge for quantum dots coupled to superconducting and normal leads. Those non-Hermitian Hamiltonians receive interpretation of describing the coherent oscillations and damping in the ABS dynamics, and they capture the degrees of freedom of the ABS having spatial extent set by the BCS coherence length, which is vanishingly small in the infinite-gap limit. The present paper also suggests the interest of future quantum bath engineering for multiterminal Josephson junctions connected to cavity-quantum electrodynamics resonators.

Now, we specifically introduce the considered four-terminal Josephson junctions, starting with the three-terminal Cooper pair beam splitters that have been the subject of intense investigations since more than twenty years. Entangled Andreev pairs can split if two independent voltages are applied in three-terminal \(F_SF_b\) ferromagnet-superconductor-ferromagnet or \(N_{o}S_{b}\) normal metal-superconductor-normal metal Cooper pair beam splitters \([33, 65]\). “Nonlocal” or “crossed” Andreev reflection (CAR) appears if the separation between the \(N_o\)S and \(S_N\) interfaces is comparable to the zero-energy superconducting coherence length. Spin-up electron from lead \(N_b\) can be Andreev reflected as spin-down hole into \(N_a\), leaving a Cooper pair in the “central” S. This yields nonlocal current response reflecting production of nonlocally split Cooper pairs. In addition, the positive current-current cross-correlations of Cooper pair splitting \([40, 66–72]\) were experimentally revealed \([59, 60]\).

The double quantum dot experiments \([57, 58, 60]\) provide evidence for nonlocal two-particle Andreev resonance in \(N_{o}S_{a}\)-dot-\(S_{b}\)-dot-\(N_{b}\) devices, on the condition of the opposite energy levels \(\varepsilon_a = -\varepsilon_b\) on both quantum dots. In the following, we demonstrate how “nonlocal two-particle Andreev resonance” in \(N_{o}S_{a}\)-dot-\(S_{b}\)-dot-\(N_{b}\) Cooper pair beam splitters can be generalized to “nonlocal two-Cooper pair resonance” in all-superconducting three-terminal Josephson junctions.

Those two-Cooper pair resonances build on nonlocal two-Cooper pair states, the so-called quartets \([78–92]\) that appear in \((S_a, S_c, S_b)\) three-terminal Josephson junctions, where \(S_a\) and \(S_b\) are voltage-biased at \(V_a\) and \(V_b\), the superconducting lead \(S_c\) being grounded at \(V_c = 0\). Andreev scattering yields quartet phase-sensitive DC-current response if the condition \(V_a = -V_b = V\) is fulfilled. On this quartet line \(V_a = -V_b\), the elementary transport process transfers two Cooper pairs from \(S_a\) and \(S_b\) into the grounded \(S_c\), while exchanging partners \([78–92]\). By the time-energy uncertainty relation, this phase-sensitive quartet current is DC, since, on the quartet line, the energy \(E_f = 2e(V_a + V_b)\) of two Cooper pairs from \(S_a\) and \(S_b\) in the initial state is equal to the final state energy \(E_f = 4eV_c\) of the two Cooper pairs transmitted into \(S_c\).
Several experiments were recently performed on multiterminal Josephson junctions [93,104]. Some of those explored the possibility of nontrivial topology [97,92,94,105,120]. On the other hand, three groups reported compatibility with the quartets [78–92]: the Grenoble group experiment with metallic structures [93], the Weizmann Institute group experiment with semiconducting nanowires [95] and the more recent Harvard group experiment on ballistic graphene-based four-terminal Josephson junctions [97]. This third experiment [97] is summarized in figures 1a and 1b. The latter shows typical experimental variations for the quartet critical current as a function of the bias voltage $V$ and the magnetic flux $\Phi$ through the loop. The experiment features the counterintuitive voltage-$V$-tunable inversion, i.e. the possibility of stronger quartet critical current at half-flux quantum $\Phi = \pi$ than in zero field $\Phi = 0$, see figure 1b. The present paper is motivated by exploring interpretation of this experiment, in the continuation of our previous papers I and II [87,88]. We also underline two recent experimental preprints reporting the quartet line in ballistic devices [111,104].

Zero-dimensional (0D) quantum dots were used in Ref. 121 to model two-terminal graphene-superconductor hybrids, in connection with experimental evidence for the Floquet replica of the Andreev spectrum under microwave radiation. The goal of the present paper is to similarly describe four-terminal graphene-based Josephson junctions with effective models based on quantum dots, in the absence of Coulomb interaction. We argue that multilevel quantum dots coupled to four superconducting and to a normal lead are “minimal models” of four-terminal Josephson junctions that are intermediate between the short- and long-junction limits. In addition, we further simplify the description in terms of double 0D quantum dots. Four or more ABS are within the gap in the equilibrium limit, instead of two ABS for a single 0D quantum dot.

Importantly, nonproximitized regions can appear in the two-dimensional (2D) metal, typically in the “cross-like region” formed in between the contacts with the superconductors, see figure 1a. Then, the quantum transport process can have initial or final states in those normal regions of the circuit. Current lines can be converted by Andreev reflection as supercurrent flowing in the grounded superconducting loop. Namely, current conservation for symmetric coupling to the superconducting leads implies that the 2D metal chemical potential is at the same zero energy as in the superconducting loop. Thus, the normal carriers transmitted through the 2D metal can be transferred into the grounded superconducting loop without taking or giving energy.

Now, we explain the connection between the present work and our previous papers. Compared to our previous Ref. 83, we implement a double 0D quantum dot, instead of the single quantum dot Dynes parameter [32,35] model of Ref. 83. We also include four superconducting leads, instead of three in our previous Ref. 83. Our previous paper I [87] presented an expansion of the quartet critical current in perturbation in the tunneling amplitudes between a 2D metal and four superconducting leads. The present paper addresses resonances that appear beyond the weak coupling limit. Our previous paper II [88] treated single quantum dot with relaxation solely originating from the continua of BCS quasiparticles. Relaxation then produces nonvanishingly small line-width broadening $\delta_0$ for the Floquet resonances, which behaves like log $\delta_0 \sim -\Delta/eV$ at low bias voltage energy $eV$ compared to the superconducting gap $\Delta$ [33,84,88,116]. In the four-terminal device of paper II [88], Landau-Zener quantum tunneling reduces the quartet current by coherent superpositions in the dynamics of the two opposite current-carrying ABS, at voltage values that are close to avoided crossings in the Floquet spectra. This mechanism is analogous to the reduction of the DC-Josephson current in microwave-irradiated weak links [122]. Conversely, in the present work, the interplay between the time-periodic dynamics and finite line-width broadening due to the attached normal lead restores the expected sharp resonance peaks in the voltage-dependence of the quartet current. For instance, a resonantly driven harmonic oscillator has amplitude inverse proportional to the damping rate. In addition, we note that the zero-frequency noise of a single superconducting weak link at finite temperature is inverse proportional to the rate set by the Dynes parameter [32,35] in some parameter window, see Ref. [123]. The same scaling holds in this reference for the noise at frequency $2\omega_0$, where $\omega_0$ is the ABS energy. The quartets in four-terminal devices [87,88,97] offer several parameters to probe this physics, such as the quartet phase variable and the “knobs” of the bias voltage and magnetic flux.
The paper is organized as follows. The Hamiltonians are presented in section II. The mechanism for the two-Cooper pair resonance is discussed in section III. The mechanism for the inversion is presented in section IV. Section V shows numerical results. The low-voltage limit is discussed in section VI. Concluding remarks are presented in the final section VII.

II. HAMILTONIANS

In this section, we provide the Hamiltonians on which the paper is based. Subsection II A presents the full Hamiltonians of the superconductors, quantum dots and normal leads. It goes beyond the goal of the present paper to produce numerical results for the voltage-biased four-terminal Josephson junctions described by the general Hamiltonians of subsection II A in a realistic geometry. This is why we present in subsection II B simplified model Hamiltonians which will subsequently be used for numerical calculations.

A. General Hamiltonians

Now, we introduce in subsection II A 1 the BCS Hamiltonian of the superconducting leads. Subsections II A 2 and II A 3 introduce the Hamiltonians of the quantum dots and normal leads respectively. As it is mentioned above, the numerical calculations presented below are based on simplifications of those Hamiltonians.

1. Superconductors

The Hamiltonian of a BCS superconductor is the following:

$$\mathcal{H}_{BCS} = -W \sum_{(i,j)} \sum_{\alpha = \uparrow, \downarrow} \left( c_{i,\alpha}^+ c_{j,\alpha} \sigma_i^+ \sigma_j + c_{j,\alpha}^+ c_{i,\alpha} \sigma_j^+ \sigma_i \right)$$

$$- \Delta \sum_i \left( \exp(i\phi_i) c_{i,\uparrow}^+ c_{i,\downarrow}^+ + \exp(-i\phi_i) c_{i,\downarrow} c_{i,\uparrow} \right),$$

where $\sum_{(i,j)}$ denotes summation over pairs of neighboring tight-binding sites labeled by $i$ and $j$, and $\sigma_i$ is the component of the spin along quantization axis. The bulk hopping amplitude is denoted by $W$ and the superconducting gap $\Delta$ is taken identical in all superconducting leads $S_a$, $S_b$, $S_{c1}$ and $S_{c2}$. The variable $\phi_i$ denotes the superconducting phase variable at the tight-binding site labeled by $i$. In the following, the current is weak and $\phi_i$ is approximated as being uniform in space, with the values $\phi_a$, $\phi_b$, $\phi_{c1}$, and $\phi_{c2}$ in $S_a$, $S_b$, $S_{c1}$ and $S_{c2}$ respectively.

We assume short distance between the contact points $c_1$ and $c_2$ (at the interfaces between $S_{c1}$ or $S_{c2}$ and the quantum dot), and we use the approximation of the gauge

$$\phi_{c1} = \phi_c,$$

$$\phi_{c2} = \phi_c + \Phi,$$

where $\Phi$ is the flux enclosed in the loop terminated by $S_{c1}$ and $S_{c2}$.

2. Double quantum dots

A legitimate approximation is to discard the Coulomb electron-electron repulsion at high transparency. Then the finite-size quantum dot is described by the Hamiltonian

$$\mathcal{H}_{dot} = -W \sum_{(i,j)} \sum_{\alpha = \uparrow, \downarrow} \left( c_{i,\alpha}^+ c_{j,\alpha} \sigma_i^+ \sigma_j + c_{j,\alpha}^+ c_{i,\alpha} \sigma_j^+ \sigma_i \right),$$

$$- \varepsilon_g \sum_{i} c_{i,\alpha}^+ c_{i,\alpha},$$

where the hopping amplitude $W$ is identical to Eq. (1), and $\varepsilon_g$ is proportional to the gate voltage. The summation over pairs of neighboring tight-binding sites is restricted to the region of finite dimension defining the quantum dot.

Conversely, the Hamiltonian of a single 0D quantum dot $D_x$ at location $x$ is the following:

$$\mathcal{H}_{D_x,0D} = \varepsilon_x \sum_{\alpha} c_{D_x,\alpha}^+ c_{D_x,\alpha},$$

where $\varepsilon_x$ is the on-site energy. Similarly, the double quantum dot $(D_x, D_y)$ is characterized by the on-site energies $\varepsilon_x$ and $\varepsilon_y$ with tunneling amplitude $\Sigma(0)$ between them:

$$\mathcal{H}_{D_x,0D} = \varepsilon_x \sum_{\alpha} c_{D_x,\alpha}^+ c_{D_x,\alpha},$$

$$\mathcal{H}_{D_y,0D} = -\Sigma(0) \sum_{\alpha} c_{D_y,\alpha}^+ c_{D_y,\alpha} + h.c.$$ (8)

At the exception of one of the numerical calculations presented in section V, we use $\varepsilon_x = \varepsilon_y = 0$ in the paper, thus with

$$\mathcal{H}_{D_x,0D} = 0,$$

$$\mathcal{H}_{D_y,0D} = 0.$$

3. Normal leads

The Hamiltonian of a normal lead is given by

$$\mathcal{H}_N = -W \sum_{(i,j)} \sum_{\alpha = \uparrow, \downarrow} \left( c_{i,\alpha}^+ c_{j,\alpha} \sigma_i^+ \sigma_j + c_{j,\alpha}^+ c_{i,\alpha} \sigma_j^+ \sigma_i \right)$$

where the normal lead chemical potential is vanishingly small, and the hopping amplitude $W$ is identical to Eq. (1). Eq. (11) is similar to the quantum dot Hamiltonian given by Eq. (4) but now, the summation over the pairs of neighboring tight-binding sites runs over an infinite lattice.

B. Simplified model Hamiltonians

Our previous paper I [87] was based on perturbation theory in the tunneling amplitudes between a 2D metal and four superconducting leads, in the $V = 0^+$ adiabatic limit. In this paper I, the poles of the Green’s functions are at the gap edge singularities and those perturbative calculations do not yield small voltage scales in the quartet critical current-voltage characteristics. In our previous paper II, we addressed the connection
The “direct” coupling \( \Sigma \) responding Hamiltonian is provided in section II B 2. The coupling leads to the four grounded normal leads \( N_1, N_2, N_3 \) and \( N_4 \). The tunneling between the multilevel quantum dot and the superconducting leads is provided in Eqs. (12)–(15). The tunneling to the normal leads is provided in Eq. (20). This model will be used in the following sections III A III B 1 III B 2 III C and III D.

FIG. 2. The four-terminal superconducting multilevel quantum dot: The figure shows a multilevel quantum dot connected to the four superconducting leads \( S_a, S_b, S_{c,1} \) and \( S_{c,2} \) biased at \( V_{a,b} = \pm V \) and \( V_{c,1} = V_{c,2} = 0 \), and to the four grounded normal leads \( N_1, N_2, N_3 \) and \( N_4 \). The corresponding Hamiltonian is provided in section II B 2. The coupling \( \Sigma^{(1)} \) directly couples the two quantum dots \( D_1 \) and \( D_2 \), see Eq. (8). The “direct” coupling \( \Sigma^{(2)} \) connects \( D_1 \) to \( S_a, D_1 \) to \( S_{c,1}, D_2 \) to \( S_b \), see Eqs. (21)–(25). The “crossed” coupling \( \Sigma^{(2)} \) connects \( D_3 \) to \( S_b \), \( D_4 \) to \( S_{c,2}, D_4 \) to \( S_a \) and \( D_3 \) to \( S_{c,1} \), see Eqs. (26)–(30). The coupling \( \Sigma^{(3)} \) connects the 0D quantum dot \( D_1 \) to \( N_1 \) and \( D_2 \) to \( N_1 \), where \( N_1 \) and \( N_2 \) are the two tight-binding sites on the normal lead \( N \)-side of the contacts, see Eqs. (31)–(33). This model will be used in the following sections III A III B 1 III B 2 III B 3 III C and III D.

1. Multilevel quantum dot

Now, we consider the Hamiltonian of a multilevel quantum dot connected to superconducting and normal leads. We also provide a physical discussion. This defines a first stage in reducing the four-terminal device to simpler Hamiltonians.

We assume that the multilevel quantum dot on figure 2 is intermediate between the short- and long-junction limits, i.e. it has dimension \( \gtrsim 2 \xi_0 \), where \( \xi_0 = h v_F / \Delta \) is the BCS coherence length, with \( v_F \) the Fermi velocity. Thus, more than two ABS are formed at equilibrium.

The Hamiltonian: We consider finite-size discrete levels on the multilevel quantum dot of figure 2 at the energies \( \Omega_\psi \). The corresponding Hamiltonian takes the form

\[
H_{n\text{ult}} = \sum_\psi \Omega_\psi \sum_\sigma c_{\psi, \sigma}^+ c_{\psi, \sigma},
\]

where \( c_{\psi, \sigma}^+ \) creates a fermion with spin-\( \sigma \) in the state \( |\psi\rangle \). The superconducting leads \( S_a, S_b, S_{c,1} \) and \( S_{c,2} \) are described by the BCS Hamiltonian given by Eq. (1). The normal
lead is described by Eq. (11). Tunneling between the leads $(S_a, S_b, S_{c,1}, S_{c,2})$ biased at $(V, -V, 0, 0)$ and the multilevel quantum dot is described by multi-channel contacts at the time $\tau$:

$$\mathcal{H}_{T,\mu}(\tau) = -\Sigma_{\nu}^{(1)} \exp(-iV \tau / \hbar) \sum_{s} \sum_{\sigma_i} c_{\sigma_i}^{+} c_{\sigma_i} + h.c.$$  

(12)

$$\mathcal{H}_{T,\nu}(\tau) = -\Sigma_{\nu}^{(1)} \exp(iV \tau / \hbar) \sum_{t} \sum_{\sigma_t} c_{\sigma_t}^{+} c_{\sigma_t} + h.c.$$  

(13)

$$\mathcal{H}_{T,\sigma}(\tau) = -\Sigma_{\sigma}^{(1)} \sum_{\gamma} c_{\gamma}^{+} c_{\gamma} \pm h.c.$$  

(14)

$$\mathcal{H}_{T,\pi}(\tau) = -\Sigma_{\pi}^{(1)} \sum_{\nu} c_{\nu}^{+} c_{\nu} + h.c.$$  

(15)

where the integers $s, t, u$ and $v$ label the collection of hopping amplitudes in real space, thus realizing a multichannel interface. As an approximation, the hopping amplitudes in Eqs. (12)-(15) were chosen identical within each contact: $\Sigma_{\nu}^{(1)} = \Sigma_{\nu}^{(1)} = \Sigma_{\nu}^{(1)} = \Sigma_{\nu}^{(1)}$ and $\Sigma_{\nu}^{(1)} = \Sigma_{\nu}^{(1)}$. The contact transparencies are parameterized by

$$\Gamma_a = \left(\Sigma_a^{(1)}\right)^2 / W,$$

(16)

$$\Gamma_b = \left(\Sigma_b^{(1)}\right)^2 / W,$$

(17)

$$\Gamma_c = \left(\Sigma_c^{(1)}\right)^2 / W,$$

(18)

$$\Gamma_d = \left(\Sigma_d^{(1)}\right)^2 / W.$$  

(19)

The notations $c_{\alpha_i,\alpha_i}^{+}$, $c_{\beta_i,\beta_i}^{+}$, $c_{\gamma_i,\gamma_i}^{+}$ and $c_{\delta_i,\delta_i}^{+}$ refer to creating a spin-$\sigma_i$ fermion at the tight-binding sites labeled by $\alpha_i$, $\beta_i$, $\gamma_i$ and $\delta_i$, respectively. We assume that $q_0$ normal leads labeled by $n_q = 1, ..., q_0$ are connected to the multilevel quantum dot by the following tunneling Hamiltonian:

$$\mathcal{H}_{T,N_q} = -\Sigma_{n_q}^{(1)} \sum_{w} \sum_{\sigma_i} c_{n_q,w,\sigma_i}^{+} c_{n_q,w,\sigma_i} + h.c.$$  

(20)

where $n_q,w$ is the tight-binding site labeled by $w$ in the lead $N_q$, and $v_{n_q,w}$ is its counterpart on the multilevel quantum dot. We took in Eq. (20) the same tunneling amplitudes $\Sigma_{n_q}^{(1)} = \Sigma_{n_q,w}$ at each contact. For instance, for $q_0 = 4$, the tight-binding sites $(n_1, n_1, n_2, n_2)$, $(n_3, n_3, n_4, n_4)$ belonging to the normal leads $N_1$, $N_2$, $N_3$ and $N_4$, respectively are shown in figure 2, together with their counterparts $(v_1, v_1, v_2, v_2)$, $(v_3, v_3, v_4, v_4)$ in the multilevel quantum dot.

This model will be used in the following sections III B 1, III B 2, III C and III D.

Physical remarks: Two antagonist effects appear:

(i) In absence of coupling to the superconductors, increasing the coupling to the normal leads has the tendency to smoothen the energy-dependence of the local density of states.

(ii) In the presence of coupling to the superconducting leads, the Floquet resonances have the tendency to produce sharp peaks in the local density of states as a function of energy.

Physically, the above item (i) captures the metallic limit of “weak sample-to-sample fluctuations in the quartet critical current". The item (ii) corresponds to “strong sample-to-sample fluctuations in the quartet current", where samples differ by the number of channels at the contacts, or by fluctuations in the shape of the multilevel quantum dot. The metallic limit (i) is ruled out for compatibility with the experiment in Ref. [27] because it does not produce small voltage scales. This is why we focus here on the regime (ii) of weak coupling to the normal leads.

In most of the work, we make an additional assumption about the spectrum $\{\Omega_{\nu}\}$ of the multilevel quantum dot, see Eq. (11). Namely, we assume pairs of levels at opposite energies, i.e. there are values $\psi_1, \psi_2$ of the label $\psi$ such that $\Omega_{\psi_1} = -\Omega_{\psi_2}$. Then, two-Cooper pair resonance emerges at specific values of the bias voltage, such as $2 e V = \Omega_{\psi_1} - \Omega_{\psi_2} = 2 \Omega_{\psi_1}$ in the limit of weak coupling. However, within the considered models, we will find in section IV robustness of the sharp resonances with respect to detuning from the condition of opposite energy levels.

Next, we simplify the multilevel quantum dot into phenomenological models of double 0D quantum dots that seem to be the “minimal models” for the two-Cooper pair resonance.

2. Phenomenological model of double 0D quantum dot with normal lead in parallel

Now, we present the Hamiltonian of a double 0D quantum dot with normal lead in parallel, and additionally connected to superconducting leads. We also provide a physical discussion. This defines a second stage in proposing models that can practically be numerically implemented.

The Hamiltonian: Specifically, we consider a second model, i.e. a “phenomenological model of double 0D quantum dot with normal lead in parallel”, see figure 3. The quantum dots $D_1$ and $D_2$ have the vanishingly small Hamiltonians of Eqs. (9) and (10). The coupling between $D_1$ and $D_2$ is given by Eq. (8) with the hopping amplitude $\Sigma^{(0)}$ shown as a light blue line in figure 3. Again, the superconducting leads $S_n$, $S_{b}, S_{c,1}$ and $S_{c,2}$ are described by the BCS Hamiltonian, see Eq. (4). Tunneling between the leads $S_{a}, S_{b}, S_{c,1}$ and $S_{c,2}$ and the double 0D quantum dot $(D_1, D_2)$ is described by single-
The Hamiltonian of the normal lead is given by Eq. (11). We parameterize the crossed contact transparency with \( \Sigma \) and we assume

\[
\mathcal{H}_{T,D_a,\alpha}(\tau) = -\Sigma_{D_a,\alpha}^{(2)} \exp(-ieV\tau/h) \sum_{\sigma} c_{D_a,\alpha}^+ c_{D_a,\sigma} + h.c.
\]

(21)

and we assume

\[
\Sigma_{D_a,\alpha}^{(2)} = \Sigma_{D_b,\alpha}^{(2)} = \Sigma_{D_x,\alpha}^{(2)} = \Sigma_{D_y,\alpha}^{(2)} = \Sigma^{(2)}.
\]

(25)

We parameterize the contact transparency with \( \Gamma = \left( \Sigma^{(2)} \right)^2/W \).

In addition, we include the following “crossed tunneling terms” between \( D_x \) and \( S_b, S_{c,2} \) and between \( D_y \) and \( S_a, S_{c,1} \):

\[
\mathcal{H}_{T,D_x,b}(\tau) = -\Sigma_{D_x,b}^{(2)} \exp(ieV\tau/h) \sum_{\sigma} c_{D_x,b}^+ c_{D_x,\sigma} + h.c.
\]

(26)

\[
\mathcal{H}_{T,D_y,a}(\tau) = -\Sigma_{D_y,a}^{(2)} \exp(-ieV\tau/h) \sum_{\sigma} c_{D_y,a}^+ c_{D_y,\sigma} + h.c.
\]

(27)

\[
\mathcal{H}_{T,D_x,c_1} = -\Sigma_{D_x,c_1}^{(2)} \sum_{\sigma} c_{D_x,c_1}^+ c_{D_x,\sigma} + h.c.
\]

(28)

\[
\mathcal{H}_{T,D_y,c_2} = -\Sigma_{D_y,c_2}^{(2)} \sum_{\sigma} c_{D_y,c_2}^+ c_{D_y,\sigma} + h.c.
\]

(29)

and we assume

\[
\Sigma_{D_x,b}^{(2)} = \Sigma_{D_y,a}^{(2)} = \Sigma_{D_x,c_1}^{(2)} = \Sigma_{D_y,c_2}^{(2)} = \Sigma^{(2)}.
\]

(30)

We parameterize the crossed contact transparency with \( \Gamma' = \left( \Sigma^{(2)} \right)^2/W \).

The Hamiltonian of the normal lead is given by Eq. (11). Tunneling between the quantum dots \( D_x, D_y \) and the normal lead \( N \) is realized with the single-channel contacts \( (D_x,N_c) \) and \( (D_y,N_c) \):

\[
\mathcal{H}_{T,D_x,N_c} = -\Sigma_{D_x,N_c}^{(3)} \sum_{\sigma} c_{N_c,\sigma}^+ c_{D_x,\sigma} + h.c.
\]

(31)

\[
\mathcal{H}_{T,D_y,N_c} = -\Sigma_{D_y,N_c}^{(3)} \sum_{\sigma} c_{N_c,\sigma}^+ c_{D_y,\sigma} + h.c.
\]

(32)

\( N_x \) and \( N_y \) being tight-binding sites belonging to the normal lead, and connected to \( D_x \) and \( D_y \) respectively by Eqs. (31)-(32). We additionally assume that \( \Sigma_{D_x,N_x}^{(3)} \) and \( \Sigma_{D_y,N_y}^{(3)} \) are identical:

\[
\Sigma_{D_x,N_x}^{(3)} = \Sigma_{N_x,D_x}^{(3)} = \Sigma_{D_y,N_y}^{(3)} = \Sigma_{N_y,D_y}^{(3)} \equiv \Sigma^{(3)}.
\]

(33)

This model will be used in the following sections III A, III B, III C and III D.

Physical remarks: Once disconnected from the superconducting or normal leads, this phenomenological model of double 0D quantum dot with normal lead in parallel naturally yields the pair of opposite-energy levels that is relevant to the two-Cooper pair resonance.

Now, we consider in section III B 3 another phenomenological model that also includes the possibility of quartet current oscillating at the scale of the Fermi wave-length as a function of the dimension of the device.

![Fig. 4. The four-terminal phenomenological model of superconducting double 0D quantum dot with normal lead in series.](image)

3. Phenomenological model of double 0D quantum dot with normal lead in series

Now, we consider the Hamiltonian of a double 0D quantum dot with normal lead in series, and connected to superconducting leads. We also provide a physical discussion. The numerical calculations presented in the forthcoming section V are based on this third stage of the simplifications.

The Hamiltonian: Namely, we consider a third model, i.e. a “phenomenological model of double 0D quantum dot with
normal lead in series connected by single-channel contacts through a 2D metal, see figure 4. The difference with the previous section II B 2 is in the coupling to the normal lead.

As in the above section II B 2, the quantum dots $D_x$ and $D_y$ have the vanishingly small Hamiltonians of Eqs. (9) and (10), the superconducting leads $S_a$, $S_b$, $S_c$, and $S_d$ are described by the BCS Hamiltonian given by Eq. (1) and the normal lead is described by Eq. (11). Tunneling between the leads $S_a$, $S_b$, $S_c$, and $S_d$ and the double quantum dot $(D_x, D_y)$ is described by the same single-channel contacts as in the above Eqs. (21) - (24). In addition, the crossed tunneling amplitudes given by Eqs. (26) - (29) are also included for completeness.

The coupling to the normal lead is phenomenologically accounted for by replacing the tunneling amplitude $\Sigma^{(0)}$ between the quantum dots by propagation through the normal conductor $N'$ connected to the dots $D_x$ and $D_y$ by the single-channel tunneling amplitudes $\Sigma^{(0)}_{D_xN'_x}$ and $\Sigma^{(0)}_{D_yN'_y}$ respectively:

$$\mathcal{H}_{T, D_xN'_x} = -\Sigma^{(4)} \sum_{\sigma, \sigma'} c^\dagger_{N'_x, \sigma} c_{D_x, \sigma'} + h.c. \quad (34)$$

$$\mathcal{H}_{T, D_yN'_y} = -\Sigma^{(4)} \sum_{\sigma, \sigma'} c^\dagger_{N'_y, \sigma} c_{D_y, \sigma'} + h.c. \quad (35)$$

where we assume

$$\Sigma^{(4)}_{D_xN'_x} = \Sigma^{(4)}_{N'_xD_x} = \Sigma^{(4)}_{D_yN'_y} = \Sigma^{(4)}_{N'_yD_y} = \Sigma^{(4)}. \quad (36)$$

The normal conductor $N'$ is characterized by the local Green's functions at $N'_x$ or $N'_y$, in addition to nonlocal ones from $N'_x$ to $N'_y$ or from $N'_y$ to $N'_x$ across $N'$. The nonlocal Green’s function between $N'_x$ and $N'_y$ generally has to be a complex number.

This model will be used in the following sections III B 1, III B 2, III B 3, III C and VI.

**Physical remarks:** Within this phenomenological model of double 0D quantum dot with normal lead in series, the quartet critical current at resonance is sensitive to the Green’s function connecting the two quantum dots $D_x$ and $D_y$. This Green’s function is itself sensitive to the microscopic details of the model, i.e. the value of the separation $R_0$ between the tight-binding sites $N'_x$ and $N'_y$ within the interval $[R'_0 - \lambda_F/2, R'_0 + \lambda_F/2]$, where $\lambda_F$ is the Fermi wave-length. Thus, this phenomenological model of double 0D quantum dot with normal lead in series produces strong sample-to-sample fluctuations of the quartet current, where different samples correspond to different values of $R_0$.

Once disconnected from the superconducting or normal leads, this phenomenological model of double 0D quantum dot with normal lead in series also yields the pair of energy levels that is central to the two-Cooper pair resonance.

In section VI we present numerical results for this model in the regime of strong sample-to-sample fluctuations.

4. Further physical remarks on the choice of a model

Now, we explain why we focus on the double quantum dot Hamiltonians presented in the above subsections II B 2, III B 2 and III B 3 instead of a single, three or four-quantum dot Hamiltonians.

First, we comparatively examine single and double 0D quantum dots.

At equilibrium, the ABS of a single 0D quantum dot have energy scale $\Gamma$ typically set by $\Gamma = \Sigma^2 / W$, where $\Sigma$ is the tunneling amplitude between the dot and the superconducting leads. It turns out that, at small $\Gamma$, the quasiadiabatic regime $V \lesssim V_\gamma$ with $eV_\gamma \sim \Gamma$, does not produce enhanced quartet critical current according to the forthcoming subsection III C where the two-Cooper pair resonance is put in correspondence with nonadiabatic effects.

At equilibrium, double 0D quantum dots are characterized by levels at the opposite energies $\pm \Omega$, where $\Omega$ is set by the tunneling amplitude $\Sigma^{(0)}$ between the dots, see Eq. (12). Then,
the voltage energy \( eV_a = \Omega \) of the first resonance remains finite in the weak-coupling limit, which implies nonadiabatic behavior and enhancement of the quartet critical current at low \( V \) if \( \Omega \) is small compared to the superconducting gap \( \Delta \).

Double 0D quantum dots are thus better candidates than single 0D quantum dots to produce large quartet critical current at small bias voltage because the two-Cooper pair resonance is also there in the weak-coupling regime of small-\( \Gamma \), see also the forthcoming section \( \text{VII} \).

The interest of double 0D quantum dots is also related to the observation that the corresponding four energy levels can accommodate the four fermions of a quartet as a “real state”. In this sense, the double 0D quantum dots have the “minimal complexity” in comparison with three- or four-quantum dot devices.

III. MECHANISM FOR THE TWO-COOPER PAIR RESONANCE

In this section, we present a general mechanism for emergence of the two-Cooper pair resonance. We start in subsection \( \text{III A} \) with introducing the three-terminal junctions and introducing the three-terminal Cooper pair beam splitters, and the above subsection \( \text{III B} \) three-terminal Josephson junctions. We start in subsection \( \text{III C} \) in connection with emergence of resonances. Current conservation is discussed in subsection \( \text{III D} \).

A. Three-terminal two-Cooper pair resonance

In this subsection, we introduce the two-Cooper pair resonance in three-terminal Josephson junctions, i.e. in \( S_a \)-dot-\( S_c \)-dot-\( S_b \) devices, starting with nonlocal resonances in the three-terminal \( N_a \)-dot-\( S_c \)-dot-\( N_b \) devices.

Figures 5a, 5b and 5c show the condition for nonlocal resonance of elastic cotunneling (EC) \( E a \) in \( N_a \)-dot-\( S_c \)-dot-\( N_b \) Cooper pair beam splitters. EC transfers single-particle states from \( N_a \) to \( N_b \) across \( S_c \), and contributes to negative nonlocal conductance \( \mathcal{G}_{a,b} = \partial I_a / \partial V_b \) on the voltage biasing condition \( V_a = -V_b \), where \( I_a \) is the current transmitted into the normal lead \( N_a \). EC is resonant if both quantum dots \( D_a \) and \( D_b \) have levels at the same energy \( \epsilon_a = \epsilon_b \), where \( \omega = \epsilon_a = \epsilon_b \) is the energy of the incoming electron in figure 5a.

Figures 5d, 5e, 5f show CAR \( E a \) in \( N_a \)-dot-\( S_c \)-dot-\( N_b \) Cooper pair beam splitters, which reflects by nonlocal Andreev reflection spin-up electron impinging from \( N_a \) as spin-down hole transmitted into \( N_b \), leaving a Cooper pair in the central \( S_c \). CAR contributes for positive value to the nonlocal conductance \( \mathcal{G}_{a,b} \) at the bias voltages \( V_a = V_b = 0 \). The nonlocal CAR resonance is obtained if the quantum dots \( D_a \) and \( D_b \) have levels at the opposite energies \( \epsilon_a = -\epsilon_c = \omega \).

Concerning \( S_a \)-dot-\( S_c \)-dot-\( S_b \) three-terminal Josephson junctions, figures 5g, 5h, 5i feature double elastic cotunneling (dEC) \( E a \), which transfers Cooper pairs from \( S_a \) to \( S_b \) across \( S_c \) at the bias voltages \( V_a = V_b \). This process is resonant if \( \omega = E_0 \) (for the spin-up electron crossing \( D_a \) or \( D_b \)) and \( -\omega + 2eV = -E_1 \) (for the spin-down hole crossing \( D_a \) or \( D_b \)). Thus, dEC is resonant if \( eV = (E_0 - E_1)/2 \) and \( \omega = E_0 \).

Concerning double crossed Andreev reflection (dCAR) in \( S_a \)-dot-\( S_c \)-dot-\( S_b \) three-terminal Josephson junctions in figures 5j, 5k and 5l, two Cooper pairs from \( S_a \) and \( S_b \) biased at the voltages \( \pm V \) cooperatively enter the grounded \( S_c \), producing transient correlations among four fermions, i.e. the so-called quartets. Then,

\[
\omega = E_0
\]

\[
-\omega + 2eV = -E_1
\]  

\[
(37)
\]

\[
(38)
\]

are obtained at resonance. Conversely, the same Eqs. \( (37)-(38) \) are obtained for resonance of the spin-up electron and spin-down holes crossing \( D_y \).

Now, we assume that \( D_a \) and \( D_b \) are gathered into a single multilevel quantum dot. Assuming the opposite energies \( E_0 = -E_1 \equiv \Omega \) implies \( \omega = \Omega \) and \( -\omega + 2eV = \Omega \), which yields

\[
eV = \omega = \Omega \]

\[
(39)
\]

for the nonlocal quartet resonance.

Overall, the argument leading to Eq. \( (39) \) confirms that nonlocal quartet resonance is produced at voltage energy \( eV \) that can be much smaller than the superconducting gap \( \Delta \), if the energy scales \( \pm \Omega \) are also within \( \pm \Delta \), see also the preceding subsection \( \text{III B 4} \).

B. Effective non-Hermitian self-energy and Hamiltonian

In this subsection, we present how effective non-Hermitian self-energies or Hamiltonians can be obtained in the infinite-gap limit from the models presented in the above section \( \text{III} \).

We start in section \( \text{III B} \) with the Dyson equations for the three models presented in the above subsections \( \text{II B 1} \) and \( \text{II B 2} \) and \( \text{II B 3} \) Emergence of non-Hermitian self-energy in the infinite-gap limit is discussed in subsection \( \text{III B 2} \). Non-Hermitian Hamiltonians are next presented for double quantum dots in the infinite-gap limit, see subsection \( \text{III B 3} \).

1. Closing the Dyson equations

In this subsection, we provide the starting-point Dyson equations. We adopt a general viewpoint on the three models of subsections \( \text{II B 1} \) and \( \text{II B 2} \) and \( \text{II B 3} \) i.e. multilevel quantum dots, double 0D quantum dots connected in parallel and in series respectively, see also figures 2, 3 and 4.

The “quantum dot \( D \)” is coupled to \( p_0 \) superconducting leads labeled by \( n_p = 1, \ldots, p_0 \) and to \( q_0 \) normal leads labeled by \( n_q = 1, \ldots, q_0 \), where \( p_0 = q_0 = 4 \) are used in figure 2. The
Dyson equations take the form
\[ \hat{G}_{D,D} = \hat{g}_{D,D} + \sum_{n_q=1}^{q_0} \sum_{n_p=1}^{q_0} \hat{g}_{D,D}^{N_{n_q}N_{n_q}} \hat{g}_{N_{n_q}N_{n_q}}^{(5)} \hat{g}_{N_{n_q}N_{n_q}}^{(5)} \hat{g}_{D,D} \]
+ \sum_{n_p=1}^{q_0} \hat{g}_{D,D}^{N_{n_q}N_{n_q}} \hat{g}_{S_{n_p}S_{n_p}}^{(1)} \hat{g}_{S_{n_p}S_{n_p}}^{(1)} \hat{g}_{D,D}.

(40)

The notation “D” in Eq. (40) refers to the collection of the tight-binding sites in absence of coupling to the superconducting or normal leads, and to the direct coupling between them. For instance, D represents finite-size tight-binding multilevel quantum dot, see subsection II B 1 or D_c-D_s, double quantum dot, see subsections II B 2 and II B 3. The notation $\Sigma^{(5)}$ denotes generic hopping amplitude, with the normal lead $N_{n_q}$ (corresponding to $\hat{g}_{D,D}^{N_{n_q}N_{n_q}} = \Sigma^{(5)}_{N_{n_q}N_{n_q}}$), or with the superconducting lead $S_{n_p}$ (corresponding to $\hat{g}_{D,D}^{N_{n_q}N_{n_q}} = \Sigma^{(5)}_{S_{n_p}S_{n_p}}$).

The notations $\hat{g}_{N_{n_q}N_{n_q}}$ and $\hat{g}_{S_{n_p}S_{n_p}}$ stand for the bare Green’s functions of the normal or superconducting leads $N_{n_q}$, $N_{n_q}$, or $S_{n_p}$, respectively, and $\hat{g}_{D,D}$, $\hat{G}_{D,D}$ are the bare and fully dressed quantum dot Green’s functions. The bare Green’s functions are given by
\[ \hat{g}_{D,D}^{1.1} = \frac{1}{\omega - \varepsilon - i\eta} \langle \psi | \psi \rangle \]
\[ \hat{g}_{D,D}^{2.2} = \frac{1}{\omega + \varepsilon - i\eta} \langle \psi | \psi \rangle, \]

(41)
(42)

where $\omega$ is the real-part of the energy and “1.1”, “2.2” refer to the electron-electron and hole-hole channels respectively. In addition, $\hat{g}_{D,D}^{A.1.1} = \hat{g}_{D,D}^{A.2.2} = 0$ because of the absence of superconducting pairing on the quantum dot. The Dynes parameter $\eta$ in Eqs. (41) - (42) makes the distinction between the advanced and retarded Green’s functions, and it can be used to capture relaxation on the quantum dot [83, 122]. As in the previous Eq. (11), the notation $| \psi \rangle$ in Eqs. (41) - (42) stands for the single-particle states, and $\langle x | \psi \rangle$, $\langle y | \psi \rangle$ are the corresponding wave-functions at the tight-binding sites $x$ and $y$.

The bare and fully dressed Green’s functions $\hat{g}_{D,D}$ and $\hat{G}_{D,D}$ have entries in the Nambu labels, and in the tight-binding sites making the contacts between the dot and the normal or superconducting leads $N_{n_q}$ or $S_{n_p}$. In addition, those matrices have entries in the set of the harmonics of the Josephson frequency.

2. Effective non-Hermitian self-energy

In this subsection, we explain how effective non-Hermitian self-energy is obtained in the infinite-gap limit. It was already mentioned in the introductory section that the infinite-gap limit was introduced and considered over the last few years, see for instance Refs. [18, 56] and [77] to cite but a few.

Specifically, Eq. (40) is rewritten as
\[ \left[ \hat{g}_{D,D}^{-1}(\omega) - \sum_{n_q=1}^{q_0} \sum_{n_p=1}^{q_0} \hat{g}_{D,D}^{N_{n_q}N_{n_q}} \hat{g}_{N_{n_q}N_{n_q}}^{(5)} \hat{g}_{N_{n_q}N_{n_q}}^{(5)} \hat{g}_{D,D} \right.
- \sum_{n_p=1}^{q_0} \hat{g}_{D,D}^{N_{n_q}N_{n_q}} \hat{g}_{S_{n_p}S_{n_p}}^{(1)} \hat{g}_{S_{n_p}S_{n_p}}^{(1)} \hat{g}_{D,D} \times
\[ \hat{G}_{D,D}(\omega) = \hat{I}. \]

In addition, $\hat{g}_{S,S}$ is independent on $\omega$ in the considered infinite-gap limit, and the local Green’s function $\hat{g}_{N_{n_q}N_{n_q}}$ in the normal leads is also taken as being independent on energy. Then, Eq. (43) can be rewritten as
\[ [\omega - \hat{\Sigma}_{\text{NonHer}}(\omega)]^{-1} \hat{G}_{D,D}(\omega) = \hat{I}, \]

where the self-energy
\[ \hat{\Sigma}_{\text{NonHer}}(\omega) = \omega - \hat{g}_{D,D}^{-1}(\omega) \]
\[ + \sum_{n_q=1}^{q_0} \sum_{n_p=1}^{q_0} \hat{g}_{D,D}^{N_{n_q}N_{n_q}} \hat{g}_{N_{n_q}N_{n_q}}^{(5)} \hat{g}_{N_{n_q}N_{n_q}}^{(5)} \hat{g}_{D,D} \]
\[ + \sum_{n_p=1}^{q_0} \hat{g}_{D,D}^{N_{n_q}N_{n_q}} \hat{g}_{S_{n_p}S_{n_p}}^{(1)} \hat{g}_{S_{n_p}S_{n_p}}^{(1)} \hat{g}_{D,D} \]

in non-Hermitian, due to $\hat{g}_{n_q,n_q}^{N_{n_q}N_{n_q}}$.

3. Specializing to double quantum dots

In this subsection, we discuss emergence of non-Hermitian Hamiltonian for the phenomenological model of double 0D quantum dots. The normal leads in parallel, see subsections II B 2 are treated in the same framework as normal leads in series, see subsection II B 3.

The retarded and advanced Green’s functions $\sim 1/(\omega - \varepsilon^{R})$ and $\sim 1/(\omega - \varepsilon^{A})$ are obtained from the effective non-Hermitian Hamiltonians $\mathcal{H}^{R}_{eff} = \mathcal{H}_{eff}$ and $\mathcal{H}^{A}_{eff} = (\mathcal{H}_{eff})^{\dagger}$ respectively. Their complex eigenvalues receive interpretation of the real and imaginary parts of the ABS energies, yielding coherent oscillations and damping in the ABS dynamics, respectively.

We make use of the same compact notations as in the previous subsections II B 1 and II B 3. Then we show that the effective non-Hermitian self-energy $\hat{\Sigma}_{\text{NonHer}}(\omega)$ in Eq. (45) becomes energy-independent for those double 0D quantum dots, thus defining the effective non-Hermitian Hamiltonian $\mathcal{H}^{\text{eff}}(\omega) \equiv \hat{\Sigma}_{\text{NonHer}}$ in the infinite-gap limit.

The matrices in Eq. (43) have entries in the tight-binding sites at the boundary of the quantum dot, where the tunneling self-energy between the dot and the superconducting or normal leads is acting. The boundary is identical to the bulk for the double 0D quantum dots $D_{x}-D_{y}$ isolated from the leads. Thus, $g_{D,D}$ takes the value
\[ g_{D,D}^{g} = (\omega + i\eta - \mathcal{H}_{dot})^{-1}, \]

(46)
where $\mathcal{H}_{\text{dot}}$ is the double 0D quantum dot Hamiltonian. The retarded Green’s functions of the double 0D quantum dots with normal leads in parallel, see figure [3] can then be expressed as
\[
\mathcal{G}_{D,D}^{R} = \left( \omega + i\eta - \mathcal{H}_{\text{eff}}^{(\omega)} \right)^{-1},
\]
where the infinite-gap-limit effective Hamiltonian
\[
\mathcal{H}_{\text{eff}}^{(\omega)} = \mathcal{H}_{\text{dot}} + \sum_{n_{q}=1}^{0} \sum_{n_{p}=1}^{0} \xi_{N_{q}N_{p}} \Sigma_{N_{q}D}^{(5)} \Sigma_{N_{p}D}^{(5)} (48)
\]
is non-Hermitian, due to $\hat{g}_{N_{q}N_{p}}$.

We note that infinite-gap Hamiltonians can more generally be deduced from the self-energy $\Sigma_{\text{NonHerm}} \left( \omega \right)$ in Eq. (45) by extending the domain of definition of the tunneling amplitude to all tight-binding sites of the quantum dots, and associating vanishingly small tunneling amplitudes to those fictitious superconducting leads.

C. Emergence of resonances in the transport formula

In this subsection, we demonstrate that the current at resonance is inverse-proportional to the damping rate.

Using the same notations as in the previous subsections [ II B 1 ] and [ II B 2 ] and [ II B 3 ] the current flowing from the multilevel quantum dot into the superconducting lead $S_{np}$ is given by the following energy-integral [11] [11] [123] [124]:
\[
I_{D,S_{np}} = \frac{e}{\hbar} \int d\omega \times \left( \sum_{k',\mu} \mathcal{R}_{D,k',\mu}^{R} \right) \left[ \mathcal{A}_{D,k',\mu} \right] \left( 52 \right)
\]
where $\hat{g}_{S_{np}S_{np}}^{\pm -} = 0$ are vanishingly small if the infinite-gap limit is taken, and $\hat{g}_{N_{q}N_{p}}^{\pm -} \neq 0$ is nonvanishingly small in the normal leads, due to the corresponding finite value of the normal density of states.

The two terms $\Sigma_{D,S_{np}}^{(5)} \hat{G}_{S_{np}D}^{\pm -}$ and $\Sigma_{D,S_{np}}^{(5)} \hat{G}_{S_{np}D}^{\pm -}$ in Eq. (49) can be expanded as follows:
\[
\Sigma_{D,S_{np}}^{(5)} \hat{G}_{S_{np}D}^{\pm -} = \left( 50 \right)
\]
\[
\Sigma_{S_{np},D}^{(5)} \hat{G}_{S_{np}D}^{\pm -} = \left( 51 \right)
\]
where $N_{q}$ and $N_{p}$ run over the interfaces between the quantum dot and the normal lead.

Then, Eqs. (49)–(51) become
\[
I_{D,S_{np}} = \frac{e}{\hbar} \int d\omega \times \left( \sum_{k',\mu} \mathcal{R}_{D,k',\mu}^{R} \right) \left[ \mathcal{A}_{D,k',\mu} \right] \left( 52 \right)
\]
where
\[
\mathcal{R}_{D,k',\mu}^{R} = \frac{\Gamma_{D,k',\mu}^{R}}{\hbar} \left( 54 \right)
\]
\[
\mathcal{A}_{D,k',\mu} = \frac{\Gamma_{D,k',\mu}^{A}}{\hbar} \left( 55 \right)
\]
where $k'$, $l'$, $k''$ and $l''$ are four integers, $E_{\mu}$, $E_{\nu}$ and $\delta_{l'}$, $\delta_{l''}$ are the Floquet energies and line-width broadening, and $\mathcal{R}_{D,k',\mu}^{R}$, $\mathcal{A}_{D,k',\mu}^{A}$ are the matrix residues. Then, inserting Eqs. (54)–(55) into Eq. (52) and integrating over the energy $\omega$ yields
\[
I_{D,S_{np}} = \frac{\pi e}{2\hbar} \sum_{(k,l)} \delta_{l} \left( \sum_{k',\mu} \mathcal{R}_{D,k',\mu}^{R} \right) \left[ \mathcal{A}_{D,k',\mu} \right] \left( 56 \right)
\]
where $[\ldots,\ldots]$ denotes summation over the pairs of labels $k$ and $l$ such that $k' eV + E_{\mu} = k'' eV + E_{\nu} = keV + E_{l}$.

Thus, we find that the current is inverse proportional to the damping rate set by the parameter $\delta_{l}$.

D. Current conservation

Now, we consider that the effective non-Hermitian Hamiltonian with complex eigenvalues originates from the Hermitian Hamiltonians presented in the above section [II] see also Appendix [A]. It turns out that the total current is conserved once the fraction of the current transmitted into the normal lead has been taken into account. Current conservation can be demonstrated by assuming that the average number of fermions $\langle N_{\text{dot}} \rangle$ on the quantum dot is stationary. The Hamiltonian $\mathcal{H}$ can be written as a sum of the Hamiltonians of the quantum dot, of the lead, and tunneling between them. Then, $d\langle N_{\text{dot}} \rangle/dt = 0$ is equivalent to current conservation. Thus, non-Hermitian effective Hamiltonian does not contradict current conservation. We note that self-consistent algorithms were used in Ref.[33] to impose current conservation in three-terminal Josephson junctions in the presence of a phenomenological Dynes parameter $\eta$. 

IV. MECHANISM FOR THE INVERSION

We discussed in the previous section III how sharp resonance peaks can appear in the voltage-dependence of the quartet critical current. Now, we provide simple arguments for the magnetic flux-$\Phi$ sensitivity of the quartet critical current in the $V = 0^+$ adiabatic limit, focusing on how the quartet critical current $I_{q,c}(\Phi = 0)$ in zero field $\Phi = 0$ compares to $I_{q,c}(\Phi = \pi)$ at half-flux quantum $\Phi = \pi$. Inversion corresponds to larger quartet critical current at $\Phi = \pi$ than at $\Phi = 0$, i.e. $I_{q,c}(\Phi = \pi) > I_{q,c}(\Phi = 0)$. Absence of inversion corresponds to $I_{q,c}(\Phi = \pi) < I_{q,c}(\Phi = 0)$.

Figure 6 shows a sequence of microscopic processes for the quartets in the presence of the two energy levels $E = \pm \Omega$ on the quantum dot. Figure 6(b) shows spin-up electron at energy $E = \Omega$ on the left-part of the two-level quantum dot, and how it moves to the right-part. Figure 6(c) shows spin-up electron at energy $E = \Omega$ on the right-part of the junction, and how it is converted by Andreev reflection into spin-down hole at energy $E = -\Omega$ by Andreev reflection at the interface with $S_{c,1}$. Figure 6(g) shows the resulting spin-down hole on the right-part of the junction at the energy $E = \Omega$, together with absorption of a Cooper pair taken from $S_a$, thus coming back to the initial state in figure 6(b).

Overall the transition between figures 6(b) and 6(c) implies negative sign for the “split quartets” transmitting a Cooper pair into $S_{c,1}$ and another one into $S_{c,2}$, and a positive sign for the “unsplit quartets”, corresponding to two Cooper pairs transmitted into $S_{c,1}$ or into $S_{c,2}$. The resulting opposite signs in the “split” and “unsplit” channels imply the inversion, see our previous paper I [87]. This physical picture for “emergence of inversion in the $V = 0^+$ limit” is confirmed by the calculations presented in Appendix B 2.

Thus, we demonstrated that “inversion between $\Phi = 0$ and $\Phi = \pi$” or “absence of inversion” is linked to the quantum dot single-particle wave-functions, i.e. to the number of nodes in their wave-functions.

V. NUMERICAL RESULTS

In this section, we present a selection of the numerical results for the phenomenological model of double 0D quantum dot with normal lead in series, see figure 4 and the Hamiltonian in subsection II.B.3. The quantum dots $D_x$ and $D_y$ are coupled to each other by the tunneling amplitude $\Sigma^{(0)}$ defined
The voltage-dependence of the quartet critical current is expected to produce log-normal distribution of strong sample-to-sample fluctuations, where different samples are characterized by different values of $R_0$. In this section, we specifically investigate the regime of strong log-normal distribution coming back on the interface, a process that is not possible at high transparency in the absence of disorder. In addition to being physically motivated, the condition $B_R = B_I = 0$ allows restricting the parameter space to be explored in the numerical calculations.

The assumption of 0D quantum dots implies that the quartet critical current depends on the value of the Green’s function crossing the conductor $N'$ between $N'_x$ and $N'_y$, see $N', N'_x$ and $N'_y$ in figure 4. The nonlocal Green’s function of $N'$ oscillates with the combinations $\cos(k_F R_0)$ and $\sin(k_F R_0)$, where $R_0$ is the separation between $N'_x$ and $N'_y$, and $k_F$ is the Fermi wave-vector. Sharp resonance peaks emerge at fixed $k_F R_0$ in the voltage-$V$ dependence of the quartet current, see the previous section [3] and the numerical results in the present section. The interplay between those $k_F R_0$-oscillations in space and the sharp Floquet resonances in the voltage-dependence of the quartet critical current is expected to produce log-normal distribution of strong sample-to-sample fluctuations, where different samples are characterized by different values of $R_0$. In this section, we specifically investigate the regime of strong log-normal distribution

The eV/Δ-dependence of the quartet critical current. Each panel of this figure shows $I_{q,c}(eV/Δ, Φ = 0)$ and $I_{q,c}(Φ = π, eV/Δ)$ as a function of the normalized bias voltage eV/Δ, for $A_I = 0$ and $A_R = 0.3/W$ (a), $A_R = 0.2/W$ (b) and $A_R = 0.1/W$ (c). Panels d, e and f correspond to $A_I = 0.05/W$ and $A_R = 0.3/W$ (d), $A_R = 0.2/W$ (e) and $A_R = 0.1/W$ (f) and panels g, h, i show $I_{q,c}(Φ = 0, eV/Δ)$ and $I_{q,c}(Φ = π, eV/Δ)$ for $A_I = 0.1/W$ and $A_R = 0.3/W$ (g), $A_R = 0.2/W$ (h) and $A_R = 0.1/W$ (i). We use $Γ/Δ = 1$, $Γ′/Δ = 0$, $B_R = B_I = 0$, and $ε_s = ε_0$. The notation $W$ is used for the band-width.

in Eq. [48]. The coupling $Γ = \left(Σ^{(2)}\right)^2/W$ is defined for hopping between $D_1$ and $S_1$, $D_2$ and $S_2$, $D_3$ and $S_3$, and $D_4$ and $S_4$, see $Σ^{(2)}$ in Eq. [25]. We add the coupling $Γ′ = \left(Σ^{(2)}\right)^2/W$ between $D_1$ and $S_1$, $D_2$ and $S_2$, $D_3$ and $S_3$, and $D_4$ and $S_4$, see $Σ^{(2)}$ in Eq. [30]. The Green’s functions of $N'$ are given by

\begin{align}
\delta_{N'_1,N'_2}' &= \delta_{N'_1,N'_2} = A_R + iA_I \\
\delta_{N'_2,N'_3}' &= \delta_{N'_2,N'_3} = -A_R + iA_I \\
\delta_{N'_1,N'_4}' &= \delta_{N'_1,N'_4} = B_R + iB_I \\
\delta_{N'_2,N'_4}' &= \delta_{N'_2,N'_3} = -B_R + iB_I,
\end{align}

where $(A_R, A_I)$, and $(B_R, B_I)$ are four real-valued parameters for the nonlocal and local Green’s functions $\delta_{N'_1,N'_2} = \delta_{N'_1,N'_2}'$ and $\delta_{N'_2,N'_3}, \delta_{N'_1,N'_4}, \delta_{N'_2,N'_4}'$, respectively, within the assumption $\delta_{N'_1,N'_2} = \delta_{N'_1,N'_2}'$. All of the numerical calculations presented below are within the assumption $B_R = B_I = 0$, which is justified as mimicking perfect transmission for highly transparent extended interfaces between the superconductors and the ballistic 2D metal. This assumption yields vanishingly small value for the local Green’s function involving “U-turn” of the quasiparticle coming back on the interface, a process that is not possible at high transparency in the absence of disorder. In addition to being physically motivated, the condition $B_R = B_I = 0$ allows restricting the parameter space to be explored in the numerical calculations.

FIG. 7. The eV/Δ-dependence of the quartet critical current. Each panel of this figure shows $I_{q,c}(eV/Δ, Φ = 0)$ and $I_{q,c}(Φ = π, eV/Δ)$ as a function of the normalized bias voltage eV/Δ, for $A_I = 0$ and $A_R = 0.3/W$ (a), $A_R = 0.2/W$ (b) and $A_R = 0.1/W$ (c). Panels d, e and f correspond to $A_I = 0.05/W$ and $A_R = 0.3/W$ (d), $A_R = 0.2/W$ (e) and $A_R = 0.1/W$ (f) and panels g, h, i show $I_{q,c}(Φ = 0, eV/Δ)$ and $I_{q,c}(Φ = π, eV/Δ)$ for $A_I = 0.1/W$ and $A_R = 0.3/W$ (g), $A_R = 0.2/W$ (h) and $A_R = 0.1/W$ (i). We use $Γ/Δ = 1$, $Γ′/Δ = 0$, $B_R = B_I = 0$, and $ε_s = ε_0$. The notation $W$ is used for the band-width.
of sample-to-sample fluctuations and make the physically-motivated assumption that fixing $A_R, A_I$ yields quartet critical current-voltage dependence that is qualitatively representative of the signal in this regime of strong sample-to-sample fluctuations.

The codes have been developed over the last few years [82–84, 88, 91, 95, 97, 116]. They are based on recursive calculations as a function of the harmonics of the Josephson frequency [10, 11] (see also the Appendix of Ref. [82]) and on sparse matrix algorithms for matrix products. We specifically adapted the code of our recent Ref. [91] to include the local and nonlocal Green’s functions given by Eqs. [58]–[61].

In the forthcoming figures [7] and [8] we present numerical results for the voltage-dependence of the quartet critical current $I_{q,c}$ defined as

$$I_{q,c}(\Phi = 0, eV/\Delta) =$$

$$\max_{\phi_q} [I_q(\Phi = 0, \phi_q, eV/\Delta) - I_q(\Phi = 0, -\phi_q, eV/\Delta)]$$

$$- \min_{\phi_q} [I_q(\Phi = 0, \phi_q, eV/\Delta) - I_q(\Phi = 0, -\phi_q, eV/\Delta)]$$

$$I_{q,c}(\Phi = \pi, eV/\Delta) =$$

$$\max_{\phi_q} [I_q(\Phi = \pi, \phi_q, eV/\Delta) - I_q(\Phi = \pi, -\phi_q, eV/\Delta)]$$

$$- \min_{\phi_q} [I_q(\Phi = \pi, \phi_q, eV/\Delta) - I_q(\Phi = \pi, -\phi_q, eV/\Delta)].$$

In addition, we present colormaps for the sign of $I_{q,c}$ as a function of the model parameters (see the forthcoming figures [9] and [10]).

Figure [7] shows the normalized bias voltage-$eV/\Delta$-dependence of the quartet critical currents $I_{q,c}(\Phi = 0, eV/\Delta)$ and $I_{q,c}(\Phi = \pi, eV/\Delta)$ at the flux values $\Phi = 0$ and $\Phi = \pi$. The coupling parameters $\Gamma/\Delta = 1$ and $\Gamma'/\Delta = 0$ are used in figure [7].

Figures [7], [7] and [8] correspond to absence of relaxation with $A_I = 0$, producing small quartet critical current. Fig-
The parameter $\lambda$ for $D$ and $I$ of the quartet critical current $I_{q,c}$ is the “direct” coupling between $D_z$ and $S_\alpha$. The numerical results in figure 7 produce detuning from perfectly opposite levels. Namely, the parameter $\lambda = \Gamma'/\Gamma$ is set to $\lambda = 1/2$ in figure 10. Moving away from $\varepsilon_0/\Delta = 0$ in figure 10 produces typical voltage-dependence of $I_{q,c}(\lambda, \Phi = 0, eV/\Delta)$ with “noninverted” behavior at low $V < V_c$ and “inversion” at higher $V > V_c$, see for instance the moderately small values $-0.5 < \varepsilon_0/\Delta < 0.5$ in figure 10. With the considered parameters, the ratio $eV_c/\Delta$ is in the range $eV_c/\Delta \approx 0.1$. Thus, our model is compatible with the experimental data [97] shown in figure 10.

VI. LOW-VOLTAGE LIMIT

In this section, we focus on the low-voltage limit and insert in Eq. (52) the equilibrium fully dressed advanced and retarded Green's functions. We present an explanation for why the numerical calculations of the preceding section [11] suggest that the line-width broadening $\delta_0$ in Eq. (56) appears to be much smaller than $\sim A_I$ in Eqs. (58)-(61).

As in the previous numerical calculations presented in section [11] we consider normal leads in series, see figure 4 and the Hamiltonian in subsection 1B.3. The Dyson Eqs. (40) take the form

$$
\left( \omega - im \right) \hat{G}^{(a,a)}_{x,x} - \hat{G}^{(x,1,c)}_{x,x} - \hat{G}^{(N',N')}_{x,x} \right) \hat{G}^{\ast}_{x,x}
$$

$$
- \hat{G}^{(x,y)}_{y,y} \hat{G}^{\ast}_{y,y} = \hat{G}^{(x,y)}_{x,y} + \hat{G}^{(y,x)}_{y,x}
$$

$$
\left( \omega - im \right) \hat{G}^{(b,b)}_{y,y} - \hat{G}^{(1,c,1)}_{y,y} - \hat{G}^{(N',N')}_{y,y} \right) \hat{G}^{\ast}_{y,y}
$$

$$
- \hat{G}^{(x,y)}_{x,y} \hat{G}^{\ast}_{x,y} = 0;
$$

with

$$
\hat{G}^{(a,a)}_{x,x} = -\Gamma_{a} \left( \begin{array}{cc}
0 & \exp(-i\varphi_a) \\
\exp(i\varphi_a) & 0
\end{array} \right)
$$

$$
\hat{G}^{(x,1,c)}_{x,x} = -\Gamma_{c1} \left( \begin{array}{cc}
0 & \exp(-i\varphi_{c1}) \\
\exp(i\varphi_{c1}) & 0
\end{array} \right)
$$

$$
\hat{G}^{(b,b)}_{y,y} = -\Gamma_{b} \left( \begin{array}{cc}
0 & \exp(-i\varphi_b) \\
\exp(i\varphi_b) & 0
\end{array} \right)
$$

$$
\hat{G}^{(x,y)}_{x,y} = -\Gamma_{ce} \left( \begin{array}{cc}
0 & \exp(-i\varphi_{c2}) \\
\exp(i\varphi_{c2}) & 0
\end{array} \right),
$$

a discussion of the inversion in the $eV/\Delta = 0^+$ limit. In figure 9 increasing the coupling $\Gamma'$ between $D_z$ and $(S_\alpha, S_{\alpha'})$ or between $D_t$ and $(S_{\alpha'}, S_{\alpha'})$ in addition to $\Gamma$ between $D_z$ and $(S_{\alpha'}, S_{\alpha'})$ or between $D_t$ and $(S_{\alpha'}, S_{\alpha'})$, makes the double 0D quantum dot behave closer to a pair of single quantum dots. This favors the “noninverted behavior” typical of single quantum dots, as opposed to the “inverted behavior” appearing at $\lambda = \Gamma'/\Gamma = 0$ in a double 0D quantum dot, see Appendix B.
where the couplings \( \Gamma_a, \Gamma_b, \Gamma_{e,1} \) and \( \Gamma_{e,2} \) are between the double quantum dot and the superconducting leads \( S_a, S_b, S_{e,1} \) and \( S_{e,2} \), see figure 4 and the analogous Eqs. (16)-(19). In addition, \( \Gamma_x^{N_x,N'_x}, \Gamma_y^{N_y,N'_y}, \) and \( \Gamma_{xy}^{N_x,N'_y} \) are given by

\[
\Gamma_x^{N_x,N'_x} = \Gamma_{N_x,N'_x} \begin{pmatrix} W g_{N_x,N'_x}^{1,1} & 0 \\ 0 & W g_{N_x,N'_x}^{2,2} \end{pmatrix} \\
\Gamma_y^{N_y,N'_y} = \Gamma_{N_y,N'_y} \begin{pmatrix} W g_{N_y,N'_y}^{1,1} & 0 \\ 0 & W g_{N_y,N'_y}^{2,2} \end{pmatrix} \\
\Gamma_{xy}^{N_x,N'_y} = \Gamma_{N_x,N'_y} \begin{pmatrix} W g_{N_x,N'_y}^{1,1} & 0 \\ 0 & W g_{N_x,N'_y}^{2,2} \end{pmatrix},
\]

which is now considered in absence of the local couplings \( \Gamma_x^{N_x,N'_x} = \Gamma_{N_x,N'_x} \equiv 0 \), corresponding to the use of \( B_R = B_l = 0 \) in the above numerical calculations, see the discussion following Eqs. (58)-(61) in section V. Then, the square of the \( 4 \times 4 \) infinite-gap Hamiltonian decouples into a pair of \( 2 \times 2 \) blocks, see also Appendix B:

\[
\mathcal{H}^{(\text{in})} = \begin{pmatrix} \Gamma_x^{(a,a)} & \Gamma_x^{(a,c)} \\ \Gamma_y^{(c,a)} & \Gamma_y^{(c,c)} \end{pmatrix} \Gamma_{xy},
\]

with \( \Gamma_{N_x,N'_x} = (\Sigma_{N_x,N'_x})^2/W, \Gamma_{N_y,N'_y} = (\Sigma_{N_y,N'_y})^2/W, \Gamma_{N_x,N'_y} = (\Sigma_{N_x,N'_y})^2/W, \Gamma_{N_y,N'_x} = (\Sigma_{N_y,N'_x})^2/W \), where \( N_x \) and \( N'_y \) are the normal-metal tight-binding sites making the contacts with the 0D quantum dots \( D_x \) and \( D_y \) respectively.

The Dyson Eqs. (64)-(65) define the infinite-gap Hamiltonian

\[
\mathcal{H}^{(\text{in})} = \begin{pmatrix} \Gamma_x^{(a,a)} & \Gamma_x^{(a,c)} \\ \Gamma_y^{(c,a)} & \Gamma_y^{(c,c)} \end{pmatrix} \Gamma_{xy}.
\]

with

\[
\epsilon_{a,c}^{1,1} = |\gamma_{D_x,D_x}|^2 + \left( \Gamma_{N_x,N'_x} \right)^2 W^2 g_{N_x,N'_x}^{1,1},
\]

\[
\epsilon_{a,c}^{2,2} = |\gamma_{D_x,D_y}|^2 + \left( \Gamma_{N_x,N'_y} \right)^2 W^2 g_{N_x,N'_y}^{2,2},
\]

\[
\epsilon_{b,c}^{1,1} = |\gamma_{D_y,D_x}|^2 + \left( \Gamma_{N_y,N'_x} \right)^2 W^2 g_{N_y,N'_x}^{1,1},
\]

\[
\epsilon_{b,c}^{2,2} = |\gamma_{D_y,D_y}|^2 + \left( \Gamma_{N_y,N'_y} \right)^2 W^2 g_{N_y,N'_y}^{2,2}.
\]
where

$$
\gamma_{\alpha,\beta} = \Gamma_{\alpha} \exp(i\varphi_{\alpha}) + \Gamma_{\epsilon} \exp(i\varphi_{\epsilon}),
$$

$$
\gamma_{\alpha,\beta} = \Gamma_{\beta} \exp(i\varphi_{\beta}) + \Gamma_{\epsilon} \exp(i\varphi_{\epsilon}).
$$

Within each $2 \times 2$ block, the eigenvalues take the form

$$
\lambda_{\pm} = \frac{1}{2} \left[ \varepsilon_{a,\epsilon}^{1,1} + \varepsilon_{b,\epsilon}^{2,2} \pm \sqrt{\left( \varepsilon_{a,\epsilon}^{1,1} - \varepsilon_{b,\epsilon}^{2,2} \right)^2 + 4\kappa_{1,2}^2 \kappa_{2,1}^2} \right],
$$

where the following quantities

$$
\varepsilon_{a,\epsilon}^{1,1} + \varepsilon_{b,\epsilon}^{2,2} =
$$

$$
|\gamma_{D,\alpha}|^2 + |\gamma_{D,\beta}|^2 + 2 \left( \Gamma_{N, N'} \right)^2 W^2 (A_R - A_I^2)
$$

$$
\left( \varepsilon_{a,\epsilon}^{1,1} - \varepsilon_{b,\epsilon}^{2,2} \right)^2 = 4\kappa_{1,2}^2 \kappa_{2,1}^2 =
$$

$$
(\gamma_{D,\alpha}|^2 - |\gamma_{D,\beta}|^2)^2 - 16 \left( \Gamma_{N, N'} \right)^2 W^2 A_R A_I^2
$$

$$
+ 4 \left( \Gamma_{N, N'} \right)^2 W^2 A_R^2 |\gamma_{D,\alpha} + \gamma_{D,\beta}|^2
$$

$$
- 4 \left( \Gamma_{N, N'} \right)^2 W^2 A_I^2 |\gamma_{D,\alpha} - \gamma_{D,\beta}|^2
$$

are both real-valued.

It can also be shown that $\lambda_{\pm}$ is real-valued and positive at small $A_I$ because

$$
|\gamma_{D,\alpha} - \gamma_{D,\beta}|^2 \left( \Gamma_{N, N'} \right)^2 W^2 s_{N, N'}^{1,1} s_{N, N'}^{2,2}
$$

is positive, which implies

$$
\left| \gamma_{D,\alpha} - \gamma_{D,\beta} \right|^2 \left( \Gamma_{N, N'} \right)^2 W^2 s_{N, N'}^{1,1} s_{N, N'}^{2,2}
$$

$$
> \left( \Gamma_{N, N'} \right)^2 W^2 s_{N, N'}^{1,1} s_{N, N'}^{2,2}
$$

$$
\left| \gamma_{D,\alpha} - \gamma_{D,\beta} \right|^2 \left( \Gamma_{N, N'} \right)^2 W^2 s_{N, N'}^{1,1} s_{N, N'}^{2,2}
$$

where we used the approximation $s_{N, N'}^{1,1} \simeq s_{N, N'}^{2,2}$ at small $A_I$. Thus, we obtain

$$
\left( \gamma_{D,\alpha} \gamma_{D,\beta} \right)^2 \left( \Gamma_{N, N'} \right)^2 W^2 s_{N, N'}^{1,1} s_{N, N'}^{2,2}
$$

$$
\times \left( \gamma_{D,\alpha} \gamma_{D,\beta} \right)^2 \left( \Gamma_{N, N'} \right)^2 W^2 s_{N, N'}^{1,1} s_{N, N'}^{2,2}
$$

$$
\times \left( \gamma_{D,\alpha} \gamma_{D,\beta} \right)^2 \left( \Gamma_{N, N'} \right)^2 W^2 s_{N, N'}^{1,1} s_{N, N'}^{2,2}
$$

from which we deduce

$$
\left( \gamma_{D,\alpha} \gamma_{D,\beta} \right)^2 \left( \Gamma_{N, N'} \right)^2 W^2 s_{N, N'}^{1,1} s_{N, N'}^{2,2}
$$

at small $A_I$. Then, the eigenvalues $\lambda_{\pm}$ of the squared infinite-gap Hamiltonian are both real-valued at arbitrary $A_I$ [see Eqs. (87) and (88)] and positive at small $A_I$ [see Eq. (92)].

In addition, we carried out complementary numerical calculation for the eigenvalues of the equilibrium $4 \times 4$ infinite-gap Hamiltonian defined by Eqs. (66) and (74), see figure 9. We find the possibility of imaginary part of the ABS energies smaller (but not orders of magnitude smaller) than $A_I$ and $B_I$ with
VII. CONCLUSIONS

Now, we provide final remarks. The paper is summarized in subsection VII A and perspectives are presented in subsection VII B.

A. Summary of the paper

We proposed models of ballistic multiterminal Josephson junctions made with superconducting leads evaporated on a 2D metal. The models consist of multilevel quantum dots connected to superconducting and normal leads. We argued that the qualitative physics of the two-Cooper pair resonance can be captured with phenomenological double quantum dots connected to superconducting and normal leads. The coupling to the nonproximitized regions of the ballistic conductor produces relaxation, and a fraction of the quartet-phase sensitive current is transmitted into the normal parts of the circuit.

We found resonances in calculations that account for both the time-periodic dynamics and small relaxation, if the multilevel or double quantum dot support levels at opposite energies. A related effect was previously found in the thermal noise of a superconducting weak link [123]. In addition, we addressed detuning from perfectly opposite energy levels.

Noninverted-to-inverted cross-over numerically emerges as the bias voltage increases, where “inversion” means “larger quartet critical current” at half flux-quantum $\Phi = \pi$ than in zero field at $\Phi = 0$. The corresponding cross-over voltage $V_\text{c}$ is small compared to the superconducting gap, typically $eV_\text{c} \approx \Delta/10$ with the parameters of our calculations, which is compatible with the recent Harvard group experiment [97].

B. Perspectives

A challenge for the theory is to model devices that are quite complex, with e.g. extended interfaces, four or more superconducting leads, nonequilibrium voltage biasing conditions, loops connecting superconducting terminals, possibly with radio-frequency radiation. Direct diagonalizations of the Bogoliubov-de Gennes Hamiltonian would apparently lead to prohibitive computational expenses. In the field of mesoscopic superconductivity, Nazarov and co-workers (see Ref. [129] and references therein) proposed and developed finite element theory for the superconducting-normal metal circuits that describe the proximity effect, i.e. the interplay between Andreev reflection and multiple scattering on disorder. This dirty-limit circuit theory was proposed for multiterminal Josephson junctions [106, 126]. The dirty limit implies short elastic mean free path, a condition that is not directly met in the ballistic metals that are currently used in some experiments on superconducting hybrid structures, such as carbon nanotubes [127], semiconducting nanowires [102] or graphene [121, 128]. Specifically, tunneling spectroscopy of carbon nanotube Josephson junctions [127] revealed discrete ABS. Andreev molecules were realized with semiconducting nanowires [102]. Evidence for superconducting phase difference-sensitive continuum of ABS was obtained in superconductor-graphene-superconductor Josephson junctions [14, 15]. As it is mentioned above, microwave experiments on short superconductor-graphene-superconductor Josephson junctions were recently carried out, and modeled with single-level quantum dots [121].

Several issues related to averaging could be investigated in the future:

First, it would be interesting to numerically average over a distribution of the nonlocal Green’s function for double 0D quantum dots. A related issue is to implement quantum dots having dimension that is large compared to the Fermi wavelength $\lambda_F$ instead of the 0D quantum dots of the present paper. On the other hand, the “metallic” regime of weak sample-to-sample fluctuations of the quartet critical current can be addressed with quasiclассис. For instance, discretized Usadel equations were used to evaluate multiple Andreev reflections in two-terminal devices in the dirty limit [129] and three-terminal devices were addressed within assumptions about the interface transparencies, also with Usadel equations [78].

Second, the use of Nazarov’s circuit theory implies that the Green’s function is uniform within a node, which is also satisfied by ballistic chaotic cavities [130]. Thus Nazarov’s circuit theory is also appropriate to describe a ballistic device if the coupling to the terminals is made through interfaces with small cross-sections, to ensure that the metal behaves like a chaotic cavity.

Third, an interesting perspective is to solve Eilenberger equations for the four-terminal device shown in figure [1].

Fourth, it would also be interesting to average over voltage fluctuations, the strength of which being controlled by the electromagnetic environment.

To summarize this discussion, perspectives are about the interplay between: (i) The “Floquet effects” that produce “non-selfaveraging-like” sharp resonance peaks in the voltage-dependence of the quartet signal for single-channel contacts, and (ii) The effect of averaging in space over extended contacts or in energy over the voltage fluctuations induced by the electromagnetic environment.

Finally, probability current is conserved in the one-dimensional normal metal-superconductor junction treated by Blonder, Tinkham and Klapwijk [131] [see Eqs. (A7)-(A8) in this paper]. We leave as open the question of rigorously discussing probability conservation in the considered four-terminal device connected to normal leads, in connection with introducing the phenomenological Dynes parameter $\eta \neq 0$ and vanishingly small imaginary part of the local Green’s function $B_I = 0$ (as it was done here), or with $\eta = 0$ and $B_I \neq 0$ (as it could be done in the future).

To conclude, the present paper suggests interest of “quantum bath engineering” multiterminal Josephson junctions in...
the circuits of cavity-quantum electrodynamics.

ACKNOWLEDGEMENTS

The author wishes to thank K. Huang, Y. Ronen and P. Kim for stimulating discussions about their experiment. The author wishes to thank R. Danneau for useful discussions and comments on the manuscript, and F. Levy-Bertrand and her colleagues H. Cercellier, K. Hasselbach, M.A. Measson for useful remarks during an informal seminar on this topic. The author thanks the Infrastructure de Calcul Intensif et de Données (GRICAD) for use of the resources of the Mésocentre de Calcul Intensif de l’Université Grenoble-Alpes (CIMENT). The author acknowledges support from the French National Research Agency (ANR) in the framework of the Graphmon project (ANR-19-CE47-0007).

Appendix A: Spectrum in absence of coupling to the superconductors

In this Appendix, we consider the “phenomenological model of double 0D quantum dots with normal lead in series”, see subsection II.B.3, and show that pairs of opposite energies emerge in the spectrum.

We start with the simple limit where the four superconducting leads are disconnected, i.e. \( \Gamma = \Gamma' = 0 \), and consider that the two quantum dots \( D_x \) and \( D_y \) are connected to the tight-binding sites \( N'_x \) and \( N'_y \) by the tunneling amplitudes \( \Sigma^{(A)} = \Sigma^{(A)}_{N'_x,D_x} \) and \( \Sigma^{(A)} = \Sigma^{(A)}_{N'_y,D_y} \). The tight-binding sites are self-connected by the Green’s functions \( g_{N'_x,N'_x} \) and \( g_{N'_y,N'_y} \), and connected to each other by the nonlocal Green’s functions \( g_{N'_x,N'_y} \) and \( g_{N'_y,N'_x} \). We denote by \( g^{A}_{D_x,D_y} = g^{A}_{D_x,D_y} = 1/(\omega - i\eta) \) the Green’s functions of the “isolated” quantum dots \( D_x \) and \( D_y \), see Eqs. (9)–(10) in Eq. (9). In addition \( g^{A}_{D_x,D_y} \) are the counterparts for the connected double 0D quantum dot, and by \( g^{A}_{D_x,D_y} \) are the corresponding nonlocal Green’s functions. The Dyson equations relate the \( g^{A} \) to the \( g^{A} \) according to

\[
\begin{align*}
\tilde{g}^{A}_{D_x,D_y} &= g^{A}_{D_x,D_y} + g^{A}_{D_x,D_y} \Sigma^{(4)}_{N'_x,N'_x} g^{(4)}_{N'_y,N'_y} \Sigma^{(4)}_{N'_y,N'_y} \tilde{g}^{A}_{D_y,D_x}, \quad (A1) \\
\tilde{g}^{A}_{D_y,D_x} &= g^{A}_{D_y,D_x} + g^{A}_{D_y,D_x} \Sigma^{(4)}_{N'_y,N'_y} g^{(4)}_{N'_x,N'_x} \Sigma^{(4)}_{N'_x,N'_x} \tilde{g}^{A}_{D_x,D_y}, \quad (A2)
\end{align*}
\]

which leads to the secular equation

\[
\begin{vmatrix}
\omega - \Gamma^{(A)}_{N'_x,N'_x,D_x} & -\Gamma^{(A)}_{N'_y,N'_y,D_x} \\
-\Gamma^{(A)}_{N'_y,N'_y,D_x} & \omega - \Gamma^{(A)}_{N'_x,N'_x,D_y}
\end{vmatrix} = 0, \quad (A3)
\]

where

\[
\begin{align*}
\Gamma^{(A)}_{N'_x,N'_x,D_x} &= \Sigma^{(4)}_{N'_x,N'_x} g^{(4)}_{N'_x,N'_y} \Sigma^{(4)}_{N'_y,D_x}, \\
\Gamma^{(A)}_{N'_y,N'_y,D_x} &= \Sigma^{(4)}_{N'_y,N'_y} g^{(4)}_{N'_x,N'_y} \Sigma^{(4)}_{N'_x,D_x}, \\
\Gamma^{(A)}_{N'_y,N'_y,D_y} &= \Sigma^{(4)}_{N'_y,N'_y} g^{(4)}_{N'_x,N'_y} \Sigma^{(4)}_{N'_x,D_y}, \\
\Gamma^{(A)}_{N'_x,N'_x,D_y} &= \Sigma^{(4)}_{N'_x,N'_x} g^{(4)}_{N'_x,N'_y} \Sigma^{(4)}_{N'_y,D_y},
\end{align*}
\]

Assuming symmetric contacts yields \( \Gamma^{(A)}_{N'_x,N'_x,D_x} = \Gamma^{(A)}_{N'_x,N'_x,D_y} = \Gamma_{loc} \) and \( \Gamma^{(A)}_{N'_y,N'_y,D_x} = \Gamma_{nloc} \). The energy levels are given by

\[
\omega_{\pm} = \Gamma_{loc} \pm \Gamma_{nloc}
\]

Appendix B: \( V = 0^+ \) adiabatic limit

In this Appendix, we examine the \( V = 0^+ \) adiabatic limit of four-terminal Josephson junctions containing a single or two quantum dots (see subsections B.1 and B.2 below).

1. Single quantum dot

We start with single 0D quantum dots in the \( V = 0^+ \) adiabatic limit, summarizing a fraction of the Supplemental Material of our previous paper II [88].

The Dyson equations take the following form for the considered 0D quantum dot connected to \( p_0 \) superconducting leads by the tunnel amplitudes \( \Sigma^{(5)}_{N,D_p} = \Sigma^{(5)}_{N,D_p} \), with \( n_p = 1, \ldots, p_0 \)

\[
\hat{G}_{D_p,D_q} = \hat{g}_{D_p,D_q} + \hat{g}_{D_p,D_q} \sum_{n_p=1}^{p_0} \Sigma^{(5)}_{N,D_p} \hat{g}_{N,S_{n_p}} \Sigma^{(5)}_{N,D_p} \hat{G}_{D_p,D_q}, \quad (B1)
\]

In the infinite-gap limit, Eq. (B1) can be expressed with the infinite-gap Hamiltonian \( \hat{H}_{eff,single dot}^{(\infty)} \)

\[
\hat{G}_{D_p,D_q} = \left( \omega - i\eta - \hat{H}_{eff,single dot}^{(\infty)} \right)^{-1}, \quad (B2)
\]

where

\[
\hat{H}_{eff,single dot}^{(\infty)} = \sum_{n_p=1}^{p_0} \Sigma^{(5)}_{N,D_p} \hat{g}_{N,S_{n_p}} \Sigma^{(5)}_{N,D_p} \hat{G}_{D_p,D_q}, \quad (B3)
\]

Specifically, we obtain the following with \( p_0 = 4 \) superconducting leads:

\[
\hat{H}_{eff,single dot}^{(\infty)} = \begin{pmatrix}
0 & \hat{g}_{D_q,D_q} \\
(\hat{g}_{0,D_q})^* & 0
\end{pmatrix}, \quad (B4)
\]

where

\[
\hat{g}_{0,D_q} = \Gamma_a \exp(i\varphi_a) + \Gamma_b \exp(i\varphi_b) + \Gamma_{c1} \exp(i\varphi_{c1}) + \Gamma_{c2} \exp(i\varphi_{c2}), \quad (B5)
\]
and $\Gamma_{np} = \left( \frac{\gamma^{(5)}_{D_1}\gamma^{(6)}_{S_{np}}}{W} \right)^2$ parameterizes the line-width broadening of the quantum dot level in the normal state.

The $(S_{c,1}, S_{c,2})$ superconducting leads can be gathered into the single $S_{c,\text{eff}}$ coupled by

$$\Gamma_{c,\text{eff}} = \Gamma_{c,1} \exp(i\varphi_{c,1}) + \Gamma_{c,2} \exp(i\varphi_{c,2}). \quad (B6)$$

Using the identical $\Gamma_{c,1} = \Gamma_{c,2} = \Gamma_c$ and the gauge given by

$$\exp\left[ i \varphi_{c,1} \right] = \exp\left[ i \varphi_{c,2} \right] \implies \exp\left[ i \varphi_{c,1} \right] = 1$$

and $\exp\left[ i \varphi_{c,2} \right] = 1$.

Eqs. (2)-(3) yields

$$\Gamma_{c,\text{eff}} = \Gamma_c \left[ 1 + \exp(\pi \Phi) \right] \exp\left( i \varphi_{c,1} \right). \quad (B7)$$

It was shown in the Supplemental Material of our previous paper II that nonsymmetric coupling to the superconducting leads can produce inversion between $\Phi = 0$ and $\Phi = \pi$ in the infinite-gap limit. But Eq. (B7) implies $|\Gamma_{c,\text{eff}}| = 2\Gamma_c$ if $\Phi = 0$ and $\Gamma_{c,\text{eff}} = 0$ if $\Phi = \pi$ for symmetric couplings to the superconducting leads, i.e. the quartet current at $\Phi = \pi$ is vanishingly small, thus it is automatically smaller than at $\Phi = 0$.

2. Double 0D quantum dot

In this subsection, we provide simple argument for emergence of inversion in the double 0D quantum dot with normal lead in parallel in figure in the limits $eV/\Delta = 0^+$ and $\Gamma' = 0$.

In the infinite-gap limit, the $4 \times 4$ Hamiltonian of a double 0D quantum dot with normal leads in parallel is given by

$$\mathcal{H}^{(\infty)}_{\text{eff, double dot}} = \begin{pmatrix}
0 & \gamma_{D_1,D_1} & \Sigma^{(0)} & 0 \\
(\gamma_{D_1,D_1})^* & 0 & 0 & -\Sigma^{(0)} \\
\Sigma^{(0)} & 0 & 0 & \gamma_{D_1,D_2} \\
0 & -\Sigma^{(0)} & (\gamma_{D_1,D_2})^* & 0
\end{pmatrix}, \quad (B8)$$

where we assumed $\Gamma' = 0$, and $\gamma_{D_1,D_1}$, $\gamma_{D_1,D_2}$ are given by the above Eqs. (84)-(85). Squaring the infinite-gap Hamiltonian given by Eq. (B8) leads to

$$\left( \mathcal{H}^{(\infty)}_{\text{eff, double dot}} \right)^2 = \begin{pmatrix}
0 & |\gamma_{D_1,D_1}|^2 + (\Sigma^{(0)})^2 & \Sigma^{(0)} & |\Sigma^{(0)}| \left[ (\gamma_{D_1,D_1})^* - (\gamma_{D_1,D_1}) \right] \\
0 & (\gamma_{D_1,D_1})^2 + (\Sigma^{(0)})^2 & 0 & 0 \\
0 & 0 & |\gamma_{D_1,D_2}|^2 + (\Sigma^{(0)})^2 & 0 \\
-\Sigma^{(0)} & \left[ (\gamma_{D_1,D_1})^* - (\gamma_{D_1,D_1}) \right] & 0 & |\gamma_{D_1,D_2}|^2 + (\Sigma^{(0)})^2
\end{pmatrix}, \quad (B9)$$

which decouples into the following $2 \times 2$ blocks:

$$\left[ \mathcal{H}^2 \right]^{(0)}_{2 \times 2} = \begin{pmatrix}
|\gamma_{D_1,D_1}|^2 + (\Sigma^{(0)})^2 & \Sigma^{(0)} & |\gamma_{D_1,D_1}|^2 + (\Sigma^{(0)})^2 \\
-\Sigma^{(0)} & \left[ (\gamma_{D_1,D_1})^* - (\gamma_{D_1,D_1}) \right] & 0
\end{pmatrix}, \quad (B10)$$

and

$$\left[ \mathcal{H}^2 \right]^{(2)}_{2 \times 2} = \begin{pmatrix}
|\gamma_{D_1,D_2}|^2 + (\Sigma^{(0)})^2 & \Sigma^{(0)} & |\gamma_{D_1,D_1}|^2 + (\Sigma^{(0)})^2 \\
\Sigma^{(0)} & \left[ (\gamma_{D_1,D_1})^* - (\gamma_{D_1,D_1}) \right] & 0
\end{pmatrix}. \quad (B11)$$

Thus,

$$\gamma_{D_1,D_1} - \gamma_{D_1,D_2} = \Gamma_a \exp(i\varphi_a) + \Gamma_{c,1} \exp(i\varphi_{c,1}) \quad (B12)$$

and the coupling to the effective $S_{c,\text{eff}}$ is now given by the difference

$$\Gamma_{c,\text{eff}} = \Gamma_{c,1} \exp(i\varphi_{c,1}) - \Gamma_{c,2} \exp(i\varphi_{c,2}) \quad (B13)$$

instead of the previous Eq. (B6) for a single 0D quantum dot.
Eq. (B13) goes to

\[ \Gamma_{c,\text{eff}}(\Phi) = \Gamma[1 - \exp(i\Phi)]\exp(i\Phi_{c,\text{eff}}) \]  

(B14)

in the considered limit \( \Gamma_{c,1} = \Gamma_{c,2} \equiv \Gamma \) of symmetric couplings. Thus, the interference \( |\Gamma_{c,\text{eff}}(\Phi = 0) = 0 \) and \( |\Gamma_{c,\text{eff}}(\Phi = \pi) = 2\Gamma \) yields inversion between \( \Phi = 0 \) and \( \Phi = \pi \) with symmetrical coupling to the superconducting leads. This contrasts with absence of inversion for single 0D quantum dots, see section [B11] in this Appendix.
