Abstract

The Sac10b protein family is regarded as a group of nucleic acid-binding proteins that are highly conserved and widely distributed within archaea. All reported members of this family are basic proteins that exist as homodimers in solution and bind to DNA and/or RNA without apparent sequence specificity in vitro. Here, we reported a unique member of the family, Mth10b from Methanobacterium thermoautotrophicum ΔH, whose amino acid sequence shares high homology with other Sac10b family proteins. However, unlike those proteins, Mth10b is an acidic protein; its potential isoelectric point is only 4.56, which is inconsistent with the characteristics of a nucleic acid-binding protein. In this study, Mth10b was expressed in Escherichia coli and purified using a three-column chromatography purification procedure. Biochemical characterization indicated that Mth10b should be similar to typical Sac10b family proteins with respect to its secondary and tertiary structure and in its preferred oligomeric forms. However, an electrophoretic mobility shift analysis (EMSA) showed that neither DNA nor RNA bound to Mth10b in vitro, indicating that either Mth10b likely has a physiological function that is distinct from those of other Sac10b family members or nucleic acid-binding ability may not be a fundamental factor to the actual function of the Sac10b family.

Introduction

Sac10b, generally regarded as a chromosomal DNA-binding protein, was first isolated from the hyperthermophile Sulfolobus acidocaldarius by Grote et al. in the 1986 [1]. After an initial routine biochemical characterization [1–3], study of the protein lagged until 1999, when Forterre et al. found that the gene sac10b, which encodes Sac10b, has one or two homologs in each of the archaean organisms whose genomes had been sequenced [4]. The proteins encoded by these genes were classified as members of the Sac10b family proteins. However, chromatin immunoprecipitation results imply that Sso10b is associated with both types of nucleic acids in vivo [17]. In 2002, the crystal structure of Sso10b was determined by Wardleworth et al. [16]. Sso10b is a small, basic protein that forms a homodimer in solution. The crystal structure of Sso10b revealed that the monomer has a mixed α/β fold comprising two α-helices and four β-sheets and resembles that of the C-terminal domain of the bacterial translation initiation factor IF3 [16]. The shape of the Sso10b dimer resembles a body with two long, outstretched β-hairpin arms that can be docked onto a DNA duplex, where they contact equivalent minor groove regions and allow the highly basic central body to contact the major groove [16]. Then in the following several years, the structures of various other Sac10b proteins, including Sso10b2 from Sulfolobus solfataricus [18,19], Ssh10b from Sulfolobus shibatae [7], Mja10b from Methanothermobacter jannaschii [22], Afi10b from Archaeoglobus fulgidus [23], Ape10b2 from Aeropyrum pernix K1 [24], and Pho10b from Pyrococcus horikoshii OT3 [25], have been solved in succession. They are all small, basic homodimeric proteins with a highly superimposable β₁αβ₂αβ₃β₄ topology. Although the lengths of the flexible β-hairpin arms vary, the central presumed DNA-binding surfaces are all distributed with positively charged residues predominantly.
The most extensively studied methanogen, *Methanobacterium thermoautotrophicum ADH*, is a lithoautotrophic, thermophilic archaeon that grows at temperatures in the range of 40–70 °C, with an optimal temperature of 65 °C [26]. Like most Archaea, its genome also includes a member of the Sac10b protein family, Mth10b, whose amino acid sequence shares high homology with typical Sac10b protein family members (Figure 1). However, unlike other Sac10b proteins, Mth10b is an acidic protein with an isoelectric point of 4.56 (Table 1), which is inconsistent with the characteristics of a nucleic acid-binding protein. An interesting question therefore arises: is Mth10b a nucleic acid-binding protein?

To answer this question, we cloned and expressed Mth10b in *Escherichia coli* cells and developed an efficient protocol for Mth10b purification. Biochemical characterization suggested that Mth10b has a structure similar to the structures of other typical Sac10b proteins. However, an electrophoretic mobility shift analysis (EMSA) showed that neither DNA nor RNA bound to Mth10b in vitro, suggesting that either Mth10b likely has a physiological function that is distinct from those of other Sac10b family members or nucleic acid-binding ability may not be a fundamental factor to the actual function of the Sac10b family.

## Results

### Identification of the *mth10b* gene

The amino acid sequence of Sso10b, a typical member of the Sac10b protein family, was used to perform a BLAST search [27] in genebank. After analyzing the amino acid compositions of the Sac10b family proteins returned by the search, we found a unique putative protein from *Methanobacterium thermoautotrophicum ADH*, encoded by the gene MTH1483, which we termed Mth10b. The amino acid sequence of Mth10b shares identities with Sso10b, Sso10b2, Ssh10b, Mja10b, Afu10b, Ape10b2, and Pho10b of 50.5, 30.9, 50.5, 56.0, 45.1, and 61.3%, respectively (Figure 1), indicating the protein may have a structure similar to those of typical Sac10b family proteins. However, unlike all reported members of the Sac10b family, Mth10b is an acidic protein. Table 1 lists the acidic residue numbers, the basic residue numbers and potential isoelectric points of Mth10b and other seven reported members of the Sac10b protein family. As shown in the table, all those typical Sac10b family members are basic proteins with potential isoelectric point higher than 8 and have more basic amino acid residues than acidic ones. While Mth10b has many more acidic amino acid residues (13) than basic ones (8), and its potential isoelectric point is only 4.56, which is inconsistent with the characteristics of a nucleic acid-binding protein.

### Protein expression and purification

The *mth10b* gene was cloned into the expression vector pET11a and expressed in *Escherichia coli* BL21 (DE3) cells as described in methods. Analysis by 15% SDS-PAGE (Figure 2) showed that it

Figure 2. SDS-PAGE analysis of Mth10b expression and purification in \textit{Escherichia coli}. lane 1, low molecular weight marker; lane 2, total cell lysate after induction; lane 3, samples purified after Q Sepharose Fast Flow column; lanes 4, samples purified after Phenyl Sepharose High Performance column; lanes 5, purified Mth10b after Resource-S column.

doi:10.1371/journal.pone.0019977.g002

has an apparent molecular weight of approximately 14 kDa. This size is slightly larger than expected, an effect that could be explained by the abnormal distribution of negatively charged residues in Mth10b. When the SDS-PAGE gel was scanned and analyzed by Scion Image, Mth10b constituted approximately 30% of the total protein.

For purification of recombinant thermophilic or hyperthermophilic proteins in \textit{Escherichia coli}, maintaining cells lysate at high temperature for several minutes is usually an efficient method to precipitate those unwanted proteins. However, though \textit{Methanobacterium thermoautotrophicum} \textit{DH} grows optimally at 65°C, the recombinant protein Mth10b was precipitated absolutely after the cells lysate was maintained at 60°C for 20 minutes. This phenomenon suggested that some external factors contribute to the thermostability of Mth10b in \textit{Methanobacterium thermoautotrophicum} cells.

Cells containing the target protein were lysed by ultrasonication, and the supernatant was subjected to the three-column chromatography purification procedure described in Methods to yield a homogeneous product (Figure 2). Protein purity was greater than 95%, as confirmed by 15% SDS-PAGE. MALDI-TOF mass spectrometry revealed a mass of 9846.48 Da (Figure 3), in agreement with the calculated molecular mass of Mth10b lacking the N-terminal methionine residue. N-terminal sequencing of the purified protein confirmed its identity (data not shown).

Secondary structure of Mth10b

Far-UV circular dichroism (CD) is a common method to study protein secondary structure because different types of regular secondary structure found in proteins give rise to characteristic CD spectra in the far UV region. Using Ssh10b, a typical member of the Sac10b family, as a control, we investigated the secondary structure of Mth10b with far-UV CD spectroscopy. The far-UV CD spectrum of Mth10b, recorded at pH 7.5 and 25°C and presented in Figure 4, reveals a typical spectrum of a mixed α/β structure. As shown in the Figure, the overall shape of the spectrum is very similar with that of Ssh10b, which is consistent with that of previous reported [5,8,14]. The spectrum of Mth10b is also similar to those of other typical members of the Sac10b family, including Pho10b [25], and Mvo10b [28]. These results suggested that the secondary structure of Mth10b is similar to those of typical members of the Sac10b family.

Tertiary structure of Mth10b

A preliminary study on the tertiary structure of Mth10b was carried out by using NMR. Due to the wild type Mth10b tending to aggregate at concentrations beyond 0.4 mM which results in seriously less signals than needed in three-dimensional spectra, such as $^{15}$N-$^{13}$C CBCA(CO)NH, HNCACB, we tried to introduce some mutations in Mth10b to improve its quality for NMR study. Fortunately, a triple mutant Mth10b[M15QL19TV22Q], in which Met$^{15}$, Leu$^{19}$ and Val$^{22}$ are replaced by Gln$^{15}$, Thr$^{19}$ and Gln$^{22}$ respectively, was found no longer aggregate in higher concentrations and can give qualified three-dimensional spectra. Using the three-dimensional spectra of this triple mutant, we finished the backbone assignment. The 2D $^1$H-$^1$N HSQC spectrum of the Mth10b variant Mth10b [M15QL19TV22Q], presented in Figure 5, shows a set of well-dispersed cross-peaks for almost all residues in the protein (each cross-peak represents a signal from a single N-H pair), indicating that the recombinant Mth10b has a well-folded tertiary structure. As shown in Figure 5, the chemical shifts of $^{15}$N resonances are distributed from approximately 107 ppm to 130 ppm, and the chemical shifts of $^1$H resonances are distributed from 6.5 ppm to 9.5 ppm. Due to the amino acid sequence of Mth10b sharing highly identity with its archaeal homologs, not surprisingly, those conserved residues in Mth10b and other typical Sac10b family members, such as Ssh10b [7], share highly similar distribution. Combining the facts that Mth10b shares high similarity with other typical Sac10b family members with respect to the primary structure and secondary structure, similar 2D $^1$H-$^1$N HSQC spectrum suggest that the three-dimensional structure of Mth10b is similar to the three-dimensional structures of typical Sac10b family proteins.

Mth10b exists as a dimer in solution

The association state of Mth10b in solution was analyzed by analytical ultracentrifugation. According to the experimental results, as shown in figure 6, the apparent molecular mass of Mth10b is 21.5 kDa and 20.3 kDa in buffer F at protein concentrations of 1.0 and 0.6 mg/mL, respectively. These values are close to the expected value of Mth10b dimer (19.7 kDa), indicating that Mth10b exists primarily as a stable dimer in solution. Moreover, gel filtration analysis indicated that Mth10b is present predominantly as a dimer in solution (data not shown). These results indicate that Mth10b exists in solution in an oligomeric form that is similar to those typical members of the Sac10b protein family.
Nucleic acid-binding affinity

The nucleic acid-binding affinity of Mth10b was investigated by agarose gel electrophoresis using Ssh10b as a positive control. Increasing quantities of recombinant proteins were incubated with supercoiled plasmid pAS22 or total RNA from *Escherichia coli* DH5α in binding buffer, followed by separation of bound and free species using an agarose gel and visualization by ethidium bromide staining. Figure 7a shows the results of DNA-binding experiments: for Ssh10b, 370 ng of supercoiled plasmid DNA were visibly shifted at protein quantities greater than 0.7 μg. At higher quantities of Ssh10b, the plasmid DNA was progressively retarded until it was apparently saturated at recombinant protein levels greater than 2 μg and could not enter the gel. The plasmid DNA showed no significant band shift in samples incubated with Mth10b, even at protein quantities of 50 μg. Figure 7b shows the results of RNA-binding experiments: for Ssh10b, 1.1 μg of total RNA from *Escherichia coli* DH5α were visibly shifted at protein quantities greater than 1 μg. At higher quantities of Ssh10b, the RNA became progressively retarded until it apparently saturated the RNA at recombinant protein levels greater than 5 μg, preventing the RNA from entering the gel. The total RNA samples incubated with Mth10b showed no significant band shift, even at protein quantities of 50 μg. These results indicated that DNA and RNA can bind to Ssh10b with similar affinities in vitro [5,6], Guo et al. found that it binds exclusively to RNA in vivo using ultraviolet irradiation [6]. Using chromatin immunoprecipitation, Marsh et al. found that Sso10b is associated with all investigated chromosomal regions but was released from the insoluble chromatin-containing pellet by treatment with either DNase I or RNase A. This result indicated that Sso10b is associated with both DNA and RNA in vivo [17].

Discussion

Although originally identified as DNA-binding proteins, there is evidence that Sac10b protein family members can also bind RNA. Using immunogold electron microscopy, Bohrmann et al. found that Sac10b is located exclusively in the cytoplasm rather than in the nucleus [3]. Although Ssh10b binds to DNA and RNA with similar affinities in vitro [5,6], Guo et al. found that it binds exclusively to RNA in vivo using ultraviolet irradiation [6]. Using chromatin immunoprecipitation, Marsh et al. found that Sso10b is associated with all investigated chromosomal regions but was released from the insoluble chromatin-containing pellet by treatment with either DNase I or RNase A. This result indicated that Sso10b is associated with both DNA and RNA in vivo [17]. The overall structures of typical Sac10b protein family members are reminiscent of the C-terminal domain of bacterial translation initiation factor IF3 and the N-terminal domain of DNase I. Aravind et al. used a bioinformatics analysis to show that the Sac10b protein family is related to two eukaryotic protein families involved in RNA metabolism [29]. They suggested that highly conserved Sac10b homologs may have an additional or exclusive role in RNA metabolism, especially in organisms for which there is no evidence of a major chromosomal role [29]. In general, the exact physiological functions of Sac10b protein family members remain unclear, though considerable efforts have been invested in recent years. However, all previous studies presumed that the nucleic acid-binding ability of Sac10b family proteins was associated with their actual functions.

In this study, we identified Mth10b from *Methanobacterium thermoautotrophicum* AH, a unique member of the Sac10b protein family whose amino acid sequence shares high homology with other members of the Sac10b protein family. Interestingly, Mth10b has many more acidic amino acid residues than basic residues, and its isoelectric point is only 4.56 (Table 1), which is inconsistent with the characteristics of a nucleic acid-binding protein. We expressed Mth10b in *Escherichia coli* and purified the protein using a three-column chromatography purification procedure. Biochemical characterization indicated that Mth10b shares secondary, tertiary and even quaternary structure with typical members of the Sac10b protein family. However, EMSA
showed that neither DNA nor RNA bound to Mth10b in vitro, a finding that distinguishes Mth10b from other members of the Sac10b protein family. Therefore, we hypothesize that either Mth10b likely has a physiological function that is distinct from the functions of most Sac10b family members or nucleic acid-binding ability may not be a fundamental factor to the actual function of the Sac10b family. The nature of this novel physiological function, however, is not known. Experiments to clarify the structure and actual function of Mth10b, combining crystallography, NMR and cell biology, are in progress.

**Materials and Methods**

**Materials**

The *Methanobacterium thermoautotrophicum* ΔH strain was obtained from the American Type Culture Collection (ATCC). The plasmid pET11a from Novagen was used to make the vector-DNA construct. *Escherichia coli* DH5α and BL21 (DE3) cells were used for plasmid cloning and protein expression, respectively. The expression plasmid pET11a-ssh10b containing the ssh10b gene was obtained from our laboratory stocks. Enzymes and reagents for
DNA manipulations were purchased from TAKARA. Plasmid miniprep kits were obtained from OMEGA. Yeast extract and tryptone were purchased from OXOID. Isopropyl β-D-thiogalactoside (IPTG) was obtained from MERCK. 15N-labeled ammonium chloride and 13C-labeled glucose were purchased from Cambridge Isotope Laboratories, Inc. All chemicals were of analytical grade for biochemical use. All apparatus and chromatography materials were purchased from GE.

Plasmid construction

The mth10b gene (ID code: MTH1483) was amplified from Methanobacterium thermoautotrophicum ΔH using polymerase chain reaction (PCR) with the forward primer 5'-TACATATGGAGGAGAAATGTAG-3' and reverse primer 5'-CCGGATCC-TATTATTTCCGGGAGCTGA-3'. PCR introduced NdeI and BamHI restriction sites (underlined and in boldface) at the 5’ and 3’ ends, respectively, of the amplified fragment. The PCR product was digested with NdeI and BamHI and ligated into the expression plasmid pET11a, which was linearized with the same two enzymes. The constructed plasmid pET11a-mth10b was confirmed by DNA sequencing. Using the parental plasmid pET11a-ssh10b, the expression plasmid of the Mth10b variants were constructed. All mutations were introduced by site-directed mutagenesis through overlap extension PCR and verified by DNA sequencing.

Protein expression and purification

Recombinant Ssh10b protein was expressed in the Escherichia coli BL21 (DE3) expression strain and purified as described previously [9]. For expression of Mth10b and its variants, the constructed plasmid pET11a-mth10b was also transformed into the Escherichia coli BL21 (DE3) expression strains. A single colony was picked and grown in 100 ml of LB media containing 100 μg/ml ampicillin with shaking (approximately 200 rpm) at 37°C overnight. The cultures were diluted 1:50 in fresh antibiotic-containing LB media, and the cells were grown at 37°C until reaching an OD600 of 0.8. Protein expression was induced by the addition of IPTG at a final concentration of 0.3 mM and incubating at 25°C overnight. The cells were harvested by centrifugation at 4,000 rpm for 30 min.

For purification, the harvested cell pellets from 3-L cultures were resuspended in 75 ml of buffer A (20 mM Tris-HCl/pH 7.5) and disrupted by ultrasonication in ice bath. After centrifugation at 16,000 rpm for 30 min, the supernatant was loaded onto a 15-ml Q Sepharose Fast Flow column equilibrated with buffer A. After centrifugation at 16,000 rpm for 30 min, the supernatant was loaded onto a 20-ml Phenyl Sepharose High Performance column equilibrated with buffer D (1 M (NH₄)₂SO₄, 20 mM Tris-HCl/pH 7.5), and proteins were eluted with a 0–100% gradient (120 ml) of buffer A. Fractions containing the target protein, identified by SDS-PAGE, were dialyzed against buffer E (50 mM NH₄HCO₃) and lyophilized. All chromatography experiments were performed on an AKTA Purifier-10 system.

Far-UV CD measurements

The far-UV CD measurements were performed on a PStar-180 spectrometer (Applied Photophysics Ltd, UK) at 25°C. The protein samples were prepared in buffer F (50 mM Na₂HPO₄-NaH₂PO₄/pH 7.5) at a concentration of 0.25 mg/ml. Measurements were carried out by using a rectangular quartz cuvette with a path-length of 1 mm over the 190- to 250-nm wavelength range.

Figure 6. The apparent molecular mass of Mth10b in buffer F determined by analytical ultracentrifugation: a. at protein concentration of 1.0 mg/mL; b. at protein concentration of 0.6 mg/mL.

doi:10.1371/journal.pone.0019977.g006
with a 2-nm bandwidth. Each spectrum was the average of five scans and was corrected for spurious signals generated by the solvent.

NMR spectroscopy

The uniformly $^{15}$N/$^{13}$C-labeled proteins were expressed in Escherichia coli BL21 (DE3) in M9 minimal medium containing $^{15}$NH$_4$Cl and $^{13}$C-glucose as the sole nitrogen and carbon sources, respectively. The labeled proteins were purified as described above. The purity of the protein was demonstrated by its visualization on SDS-PAGE and an ultraviolet absorbance ratio of $A_{280}/A_{260}$ ≥ 1.7. Samples for NMR measurements contained 1.0–2.0 mM labeled proteins, 90% H$_2$O/10% D$_2$O, 200 mM NaCl, 5 mM DTT, 0.02% NaN$_3$, 1 mM EDTA and 0.01% sodium-2,2-dimethyl-2-silapentane-5-sulfonate (DSS) in 20 mM Tris-HCl buffer (pH 7.5).

All NMR experiments were carried out at 37°C on a Bruker Advance DMX 600 MHz spectrometer equipped with a triple resonance cryo-probe. Resonance assignments for backbone $^1$H, $^{15}$N, $^{13}$C$^\alpha$ and $^{13}$C$^\beta$ nuclei were identified using 2D $^1$H-$^{15}$N HSQC, 3D CBCA(CO)NH and HNCACB experiments. All NMR spectra were processed and analyzed using FELIX98 software (Accelrys Inc.). Proton chemical shifts and $^{15}$N and $^{13}$C chemical shifts were referenced to internal DSS and indirectly to DSS, respectively [30].

Analytical ultracentrifugation

Sedimentation velocity experiments were performed on a Beckman-Coulter XL-A analytical ultracentrifuge using two-channel centerpieces with an An60Ti rotor at 60000 rpm and 20°C. Sedimentation was monitored using absorption at UV 238 nm with protein concentrations of 0.6 and 1.0 mg/mL in...
buffer F. UV absorption was scanned every 30 s for 6 h. Data were analyzed with software provided by Beckman Instruments (Palo Alto, CA).

Nucleic acid binding

The nucleic acid-binding affinity of Mth10b was analyzed by EMSA using Shh10b, a typical member of the Sac10b protein family, as a positive control. Approximately 370 ng of supercoiled plasmid pAS22 (3709 bp) or 1.1 µg total RNA from *Escherichia coli* DH5α cells were incubated with varying quantities of purified recombinant protein in buffer G (10 mM HEPES, 100 mM NaCl/pH 7.0) to a total volume of 15 µl at room temperature for 15 min. The samples were resolved by electrophoresis in 1.2% agarose gels in 1×TAE buffer at constant voltage. After electrophoresis, the gels were stained with ethidium bromide and visualized under UV light.

Acknowledgments

We thank professor Ji-Feng Wang and Mrs. Xiao-Xia Yu (Institute of Biophysics, Chinese Academy of Sciences) for NMR and analytical ultracentrifugation technical help.
