ABSTRACT

BACKGROUND AND PURPOSE: The aspiration technique has gained a prominent role in mechanical thrombectomy. The thrombectomy goal is successful revascularization (modified TICI $\geq 2b$) and first-pass effect. The purpose of this study was to evaluate the impact of the vessel-catheter ratio on the modified TICI $\geq 2b$ and first-pass effect.

MATERIALS AND METHODS: This was a retrospective, single-center, cohort study. From January 2018 to April 2020, $111/206$ ($53.9\%$) were eligible after applying the exclusion criteria. Culprit vessel diameters were measured by 2 neuroradiologists, and the intraclass correlation coefficient was calculated. The receiver operating characteristic curve was used for assessing the vessel-catheter ratio cutoff for modified TICI $\geq 2b$ and the first-pass effect. Time to groin puncture and fibrinolysis were weighted using logistic regression. All possible intervals (interval size, 0.1; sliding interval, 0.01) of the vessel-catheter ratio were plotted, and the best and worst intervals were compared using the $\chi^2$ test.

RESULTS: Modified TICI $\geq 2b$ outcome was achieved in $75/111$ ($67.5\%$), and first-pass effect was achieved in $53/75$ ($70.6\%$). The MCA diameter was $2.1\text{mm}$ with an intraclass correlation coefficient of $0.92$. The optimal vessel-catheter ratio cutoffs for modified TICI $\geq 2b$ were $\leq 1.51$ (accuracy = $0.67$, $95\%$ CI, $0.58–0.76$; $P = 0.001$), and for first-pass effect, they were significant ($\leq 1.33$; $P = 0.31$). The modified TICI $\geq 2b$ odds ratio and relative risk were $9.2$ ($95\%$ CI, $2.4–36.2$; $P = 0.002$) and $3.2$ ($95\%$ CI, $1.2–8.7$; $P = 0.024$). The odds ratio remained significant after logistic regression ($7.4$; $95\%$ CI, $1.7–32.5$; $P = 0.008$). First-pass effect odds ratio and relative risk were not significant ($2.1$ and $1.5$; $P > 0.05$, respectively). The modified TICI $\geq 2b$ best and worst vessel-catheter ratio intervals were not significantly different ($55.6\%$ versus $85.7\%$, $P = 0.12$). The first-pass effect best vessel-catheter ratio interval was significantly higher compared with the worst one ($78.6\%$ versus $40.0\%$, $P = 0.03$).

CONCLUSIONS: The aspiration catheter should be selected according to culprit vessel diameter. The optimal vessel-catheter ratio cutoffs were $\leq 1.51$ for modified TICI $\geq 2b$ with an odds ratio of $9.2$ and a relative risk of $3.2$.

ABBREVIATIONS: ADAPT = a direct aspiration first-pass technique; mTICI = modified TICI

S

stroke represents the second leading cause of death in the world; however, the case fatality rate has decreased in recent decades due to primary prevention and treatment improvements. After the introduction in various guidelines, patients treated with mechanical thrombectomy showed a significant decrease of disability at 90 days compared with controls ($OR = 2.49$; $95\%$ CI, $1.76–3.53$; $P < .0001$) and a reduction of decompressive hemicraniectomy for malignant cerebral edema (range, $11.4\%–4.8\%$; $P < .001$). Recently, a direct aspiration first-pass technique (ADAPT) has gained a level of I-B-R for mechanical thrombectomy in the 2019 guidelines for stroke management. An modified TICI (mTICI) of grade 2b/3 is the mechanical thrombectomy goal for increasing good functional outcome; in addition, first-pass effects have earned a prominent role in stroke prognosis.

Nikoubashman et al demonstrated, in an experimental animal study, that large-bore catheters should have an inner diameter of $>1.016$ mm for the MCA and $>1.524$ mm for the ICA. Moreover, Alawieh et al showed a higher rate of recanalization and first-pass effect using larger diameter catheters versus smaller ones (ACE64/ACE68 [Penumbra] versus 5MAX ACE [Penumbra], $85\%$/81% versus 61%, $P < .05$, respectively). However, no differences were found...
in terms of first-pass effect, reperfusion, and clinical outcome among different large-bore catheters selected (Catalyst 6, Stryker; Sofia, MicroVention; Navien, Covidien; ACE68, Penumbra; $P > .05$).11 The aim of this study was to evaluate the impact of the vessel-catheter ratio on successful revascularization and first-pass effect in a tertiary center (Azienda Ospedaliera San Camillo/Forlanini) for cerebrovascular disease treatment.

**MATERIALS AND METHODS**

This study was approved by the ethics institutional review board. Informed consent was waived due to the retrospective nature of this study.

The manuscript was drafted according to the Strengthening the Reporting of Observational Studies in Epidemiology (STROBE) guidelines.12

This was a retrospective, single-arm, single-center, cohort study. From January 2018 to April 2020, we evaluated all patients admitted to the stroke unit of a tertiary hub center who underwent endovascular thrombectomy according to current guidelines.3 The exclusion criteria for the study were the following: non-MCA and mechanical thrombectomy technique different from ADAPT. Because there is no definitive indication regarding which endovascular technique should be used for thrombectomy,4 the choice was left to the interventional neuroradiologist at the time of the procedure. The clinical details of the cohort are given in Table 1.

Technical success was defined with a mTICI 2b or 3.3,4 The first-pass effect would be mTICI $\geq 2b$. Furthermore, the impact on successful revascularization of the adequate vessel-catheter ratio was weighted with fibrinolysis and time to groin puncture. Subanalysis was performed for first-pass effect versus a control group (non-first-pass effect revascularization + mTICI $\leq 2a$). The secondary outcome was to evaluate the impact of different cutoff values on the likelihood of obtaining a successful revascularization and a first-pass effect.

### Vessel-Diameter Measurement

The diameter of the occluded vessel was measured by 2 neuroradiologists (S.F. and L.B. with 20 and 8 years of experience, respectively) in the straight tract of the closest vessel before the thrombus on DSA.14 The simple mean between these measurements was taken for further analysis, and the intraclass correlation agreement was calculated.

### Endovascular Technique

All patients were treated using ADAPT by 5 experienced neurointerventional radiologists ($\geq 7$ years’ experience) in a dedicated angiostu (biplane Artis zee; Siemens).

All procedures were performed via arterial access with the patient under sedation or general anesthesia according to the present clinical status and stroke severity. ADAPT was performed through femoral access using a 6F long vascular sheath (Neuro MAX 088, Penumbra; or AXS Infinity LS, Stryker Neurovascular) positioned in the ICA of the culprit side. The size of the intermediate aspiration catheters was chosen by the neurointerventional radiologist at the time of the procedure; in 1/111 (0.9%), a distal aspiration catheter was used. The intermediate catheters used were both Stryker and Penumbra systems and were divided according to their inner diameter into the following: 1.37 mm (5MAX ACE), 1.47 mm (AXS Catalyst 5; Stryker), 1.52 mm (AXS Catalyst 6), 1.62 mm (AXS Catalyst 7), 1.63 mm (ACE64), and 1.73 mm (ACE68). The distal aspiration catheter used has an inner distal lumen of 1.09 mm (Penumbra); the ADAPT was always performed without a microguidewire inside the lumen and with an aspiration pump (Pump MAX; Penumbra).3,5 See Table 2 for frequency.

### Study Outcome

The primary outcome was to evaluate the cutoff value of the vessel-catheter ratio, maximizing the likelihood of obtaining mTICI $\geq 2b$. Furthermore, the impact on successful revascularization of the adequate vessel-catheter ratio was weighted with fibrinolysis and time to groin puncture. Subanalysis was performed for first-pass effect versus a control group (non-first-pass effect revascularization + mTICI $\leq 2a$). The secondary outcome was to evaluate the impact of different cutoff values on the likelihood of obtaining a successful revascularization and a first-pass effect.

### Data Base Preparation

Clinical data were retrospectively derived from a prospective data base drafted by the stroke unit. The radiologic parameters were evaluated through Radiology and Imaging Specialists/PACS systems by 1 neuroradiologist (5 years of experience) not involved in the procedure. The angiographic measurements of culprit vessel

Two-hundred six consecutive patients underwent brain angiography for mechanical thrombectomy; after applying the exclusion criteria, 95/206 (46.1%) were further excluded from the analysis. Thirty-six of 95 (37.9%) of the strokes involved the ICAs, 25/96 (26.3%) had posterior circulation stroke, and in 34/95 (35.8%) ADAPT was not used as the first-line technique. The final population encompassed 111/206 (53.9%) patients with MCA stroke treated with ADAPT; the clinical details are provided in Table 1. Twenty-three of 111 (20.7%) were wake-up strokes. The flow-chart of the study is shown in Fig 1. The rate of mTICI ≥ 2b was 75/111 (67.5%), and the first-pass effect was 53/75 (70.6%). All patients with mTICI ≥ 2a (36/111 [32.5%]) underwent a rescue technique. The median vessel diameter was 2.1 mm (95% CI, 2.0–2.1; range, 1.3–3.9; mean, 2.1 [SD, 0.4]); the intraclass correlation coefficient was 0.92 (95% CI, 0.84–0.97). Technical parameters are shown in Table 2.

The optimal vessel-catheter ratio cutoff for maximizing the likelihood of obtaining mTICI ≥ 2b was ≤1.51 (accuracy = 0.67; 95% CI, 0.58–0.76; P = 0.001). With a vessel-catheter ratio of ≤1.51 as a cutoff, the chances of obtaining mTICI ≥ 2b were significantly higher compared with the vessel-catheter ratio of >1.51 (OR, 9.2; 95% CI, 2.4–36.2; P = 0.002; relative risk, 3.2; 95% CI, 1.2–8.7; P = 0.02). The number of patients to be treated to observe a benefit with a vessel-catheter ratio of ≤1.51 was 2.0 (95% CI, 1.3–4.0). The likelihood of achieving successful revascularization also remained significant after logistic regression both for all patients and for those with non-wake-up stroke (OR = 9.6; 95% CI, 2.4–38.7; P = 0.0014; OR = 7.3; 95% CI, 1.7–32.1; P = .008, respectively) (see Tables 3 and 4 for details). No significant cutoff was found for first-pass effect likelihood as outcome, though the highest Youden index was for vessel-catheter ratio of ≤1.33 (accuracy = 0.56; 95% CI, 0.46–0.65; P = .31). With the vessel-catheter ratio of ≤1.33, there was a trend toward first-pass effect likelihood, although not statistically significant (OR = 2.1; 95% CI, 0.93–5.0; P = .07 with a relative risk of 1.5; 95% CI, 0.93–2.5; P = .10, respectively). The ORs of logistic regression analysis were not statistically significant either (Tables 3 and 4).

The percentage of successful revascularizations of the 0.1 interval ranged from 0.0% to 85.7% (median, 66.7%; 95% CI, 64.6%–70.0%). Considering exclusively the interval below 1.51, the percentage ranged from 55.6% to 85.7% (median 68.8%; 95% CI, 64.6%–70.0%). The optimal vessel-catheter ratio cutoff for maximizing the likelihood of obtaining mTICI ≥ 2b was ≤1.51 (accuracy = 0.67; 95% CI, 0.58–0.76; P = 0.001). With a vessel-catheter ratio of ≤1.51 as a cutoff, the chances of obtaining mTICI ≥ 2b were significantly higher compared with the vessel-catheter ratio of >1.51 (OR, 9.2; 95% CI, 2.4–36.2; P = 0.002; relative risk, 3.2; 95% CI, 1.2–8.7; P = 0.02). The number of patients to be treated to observe a benefit with a vessel-catheter ratio of ≤1.51 was 2.0 (95% CI, 1.3–4.0). The likelihood of achieving successful revascularization also remained significant after logistic regression both for all patients and for those with non-wake-up stroke (OR = 9.6; 95% CI, 2.4–38.7; P = 0.0014; OR = 7.3; 95% CI, 1.7–32.1; P = .008, respectively) (see Tables 3 and 4 for details). No significant cutoff was found for first-pass effect likelihood as outcome, though the highest Youden index was for vessel-catheter ratio of ≤1.33 (accuracy = 0.56; 95% CI, 0.46–0.65; P = .31). With the vessel-catheter ratio of ≤1.33, there was a trend toward first-pass effect likelihood, although not statistically significant (OR = 2.1; 95% CI, 0.93–5.0; P = .07 with a relative risk of 1.5; 95% CI, 0.93–2.5; P = .10, respectively). The ORs of logistic regression analysis were not statistically significant either (Tables 3 and 4).

The percentage of successful revascularizations of the 0.1 interval ranged from 0.0% to 85.7% (median, 66.7%; 95% CI, 64.6%–70.0%). Considering exclusively the interval below 1.51, the percentage ranged from 55.6% to 85.7% (median 68.8%; 95%
CI, 65.0%–71.4%). No statistically significantly differences were found between the percentage of the worst interval (1.34–1.44) and the best one (1.28–1.38; 55.6% versus 85.7%; P = .12, respectively) (Fig 2). The percentage for obtaining a successful revascularization in 1 passage ranged from 0.0% to 80.0%; considering the interval below 1.33, the percentage ranged from 40.0% to 78.6% (median, 47.4%; 95% CI, 44.7%–52.9%). The percentage for obtaining first-pass revascularization of the best interval (range, 1.26–1.36) was significantly higher compared with the worst one (range, 1.05–1.15; 78.6% versus 40.0%; P = .03, respectively) (Fig 2).

**DISCUSSION**

The best cutoff of the vessel-catheter ratio to maximize the likelihood for achieving mTICI ≥ 2b was ≤1.51 (accuracy = 0.67, P = .0012, OR = 9.2), with a percentage of successful revascularization spanning 55.6% to 85.7% (vessel-catheter ratio interval, 1.0–1.51). For the first pass, the optimal cutoff, though not statistically significant, was 1.33 (accuracy = 0.56, P = .31, OR = 2.1), with a range of first-pass effect from 40.0% to 78.6% (vessel-catheter ratio interval, 1.0–1.33).

Different companies tried to increase the diameter of large-bore catheters (from 1.37 to 1.82 mm) for ADAPT, based on the assumption that “the bigger the catheter is, the better the result will be,” with the lessening of maneuverability for larger catheters.9 This paradigm is supported by the concept that a larger inner diameter increases the aspiration flow rate and therefore the likelihood of thrombus aspiration.15 These results are supported by the present study, which showed a cutoff of the vessel-catheter ratio for reaching mTICI ≥ 2b of ≤1.51 with an OR = 9.2 (95% CI, 2.4–36.2) and a number of patients treated of 33%, P = .04), and the ACE68 was an independent predictor of successful reperfusion and good clinical outcome (OR = 1.67 and 6.2, respectively).18 Although not significant, a statistical trend for first-pass effect was found with a vessel-catheter ratio of ≤1.33 (accuracy = 0.56; 95% CI, 0.46–0.65; P = .31) and an OR = 2.1 (95% CI, 0.93–5.0; P = .07). Considering the interval between 1.0 and 1.33, the percentage of first-pass effect ranged from 40.0% to 78.6%, superior to all of cases in the Contact Aspiration vs Stent Retriever for Successful Revascularization (ASTER) trial subanalysis (26.3%),18 and in line with the results of Delgado Almandoz et al (53%).19 This discrepancy may be explained by the unknown vessel-catheter ratio in these studies. In fact, a significantly better first-pass effect prevalence was found in the best interval (1.26–1.36) compared with the worst one (1.05–1.15; 78.6% versus 40.0%; P = .03) (Fig 2).

The reported mean diameter of the MCA is 2.3 mm, which is similar to our finding of 2.1 (SD, 0.4) mm.14 Setting a vessel-catheter ratio of ≤1.51 (cutoff for mTICI ≥ 2b) and considering the reported diameter of 2.3 mm, the minimum catheter inner diameter was 1.5 mm.

Our study had several limitations. First, this was a single-center, nonrandomized study with a control group. Second, the large-bore catheters used were mostly Catalyst 6 (26.1%) and ACE68 (64.0%). Third, the sample size was low, especially for a first-pass effect, as shown by the large 95% CI of our findings, though the number of patients (n = 111) was in line with those in monocentric stroke studies.

**CONCLUSIONS**

The catheter selection for ADAPT should be performed keeping in mind the goal of a vessel-catheter ratio of ≤1.51 for increasing

---

**FIG 2.** The plot shows the trend of successful revascularization (line with dot) and a first-pass effect (dotted line with triangle) together with the tendency line among different intervals of vessel-to-catheter ratios. As observed, after the respective cutoff (=1.51 and ≤1.33) for mTICI ≥ 2b and first-pass effect, the trend remains stable.
to mTICI ≥ 2b. For achieving mTICI ≥ 2b, considering the average diameter of middle cerebral artery, the inner diameter of the intermediate catheter should be ≥1.5 mm.
