Abstract

We consider the non-relativistic limit of gravity in four dimensions in the first order formalism. First, we revisit the case of the Einstein-Hilbert action and formally discuss some geometrical configurations in vacuum and in the presence of matter at leading order. Second, we consider the more general Mardones-Zanelli action and its non-relativistic limit. The field equations and some interesting geometries, in vacuum and in the presence of matter, are formally obtained. Remarkably, in contrast to the Einstein-Hilbert limit, the set of field equations is fully determined because the boost connection appears in the action and field equations. The fate of the cosmological constant in the non-relativistic limit is analyzed. It is found that the cosmological constant must disappear in the non-relativistic Mardones-Zanelli action at leading order. The conditions for Newtonian absolute time be acceptable are also discussed. It turns out that Newtonian absolute time can be safely implemented with reasonable conditions.

1 Introduction

One of the most important features of a new larger theory is that it must be reduced to the known, well established, smaller theory at some particular limit. General Relativity (GR) is a celebrated example [1–3]. In fact, Newtonian gravity can be obtained from GR by a suitable weak field limit. In the context of GR described as a gauge theory for the Poincaré group\(^1\) [4–6], the so-called first order formalism, GR can be reduced to Newtonian gravity by an appropriate Inönü-Wigner (IW) contraction [9], see for instance [10] and references therein. On the one hand, one can take the ultra-relativistic limit of the Poincaré group and end up in the so-called Carroll gravity. On the other hand, the non-relativistic limit of the Poincaré group leads to the Galilei group and Galilei gravity. Galilei gravity is then a gauge theory based on the Galilei group and describes a geometrodynamical theory which, under appropriate assumptions [11–14], is equivalent to Newton theory of gravity. An important condition is known as twistless torsion constraint which is necessary to define the Newtonian absolute time. Nevertheless, Galilei gravity is far more general than Newtonian gravity, carrying, for instance, torsion degrees of freedom [15]. For the earlier works in NC geometrodynamics we refer to the seminal papers of E. Cartan [16,17] and also [1,18–22]. In contrast to the non-relativistic limit of GR as the gauge theory for the Galilei group, one can start directly from the Galilei algebra and its extensions in order to construct more general Newton-Cartan (NC) gravity theories [23–25]. Two renowned examples are the Bargmann and Shrödinger groups. A particularly appealing feature of these extensions [11,13,26] is that it can be used as a base for constructing Hořava-Lifshitz gravity models [27]. Moreover, NC geometries have renowned importance in string and brane scenarios, see for instance [28–31] and references therein.

The gauge approach to describe GR allows torsion degrees of freedom to enter in the context in a natural way [4–8]. Moreover, the differential form language shows itself to be a useful and natural framework in this scenario because it allows to work in a coordinate independent manner. This approach enables one to write down more general actions, going beyond the Einstein-Hilbert (EH). In fact, in [7] Mardones and Zanelli were able to generalize Lovelock gravity theory [32] in order to account for torsion terms in any spacetime dimension. These theories, known as Lovelock-Cartan (LC) gravities, are described by first order, and polynomially local actions with explicit Lorentz gauge symmetry, called Mardones-Zanelli (MZ) actions\(^2\). Moreover, in differential form language, MZ actions do not depend explicitly on the metric tensor. The aim of the present work is to develop the non-relativistic limit of such theories and go beyond EH action in the study of non-relativistic gravity systems. In this first endeavor, we stick to four dimensions. In four-dimensional MZ action, besides the EH term, gravity gains topological terms (which do not affect the classical dynamics of gravity), a cosmological constant term and two extra terms associated with torsion. Thus, the present study opens the door in the understanding of the possible effects of the cosmological constant and torsion (or if the lack of them can be accommodated in the non-relativistic MZ theory) in non-relativistic gravitational systems.

In LC gravities, the EH action is a particular case. Hence, before considering the four-dimensional LC theory we review the EH case. Galilei gravity is obtained from the EH action by employing the appropriate IW contraction of the Poincaré group. The field equations are derived and solutions are formally discussed. We analyze torsionless and torsional solutions in vacuum and in the presence of matter in a quite general way. Particularly, we discuss twistless torsion conditions in the presence of other torsion components. Furthermore, an explicit example beyond Newtonian absolute time is worked out. In this example, we find a Weintzenböck-like geometry [33–36] with conformally flat metrics.

\(^1\)More precisely, only the Lorentz sector is gauged, since the Poincaré group is not a semi-simple Lie group. Nevertheless, the translational sector is used to expand the vierbein degrees of freedom, which is fundamental to encode the equivalence principle [4–8].

\(^2\)In this work we equally refer to such theories as MZ or LC theories.
As mentioned before, the main target of the present work is the four-dimensional full MZ action. Its non-relativistic limit is performed and the field equations derived. Obviously, the residual gauge symmetry is again described by the Galilei group. To distinguish from the Galilei gravity obtained from the EH action, we call the non-relativistic theory obtained from the MZ action by Galilei-Cartan (GC) gravity. The first interesting result is that, differently from the EH case, the boost connection is explicitly present at the action and field equations. Thence, the system of field equations are fully determined. Second, it is shown that for the non-relativistic limit of the maximally symmetric vacuum solution of the MZ action to be a solution of the GC gravity in vacuum, the cosmological constant must vanish in the non-relativistic limit. This result reduces the final form of the GC action to one which has no cosmological constant. The third result is the establishment of the properties that the GC theory must fulfill in order to accept Newtonian absolute time. Hence, a formal discussion about torsionless and torsional solutions in the presence of matter is provided.

This work is organized as follows: In Section 2 we review the construction of the LC theory of gravity in four dimensions and the maximally symmetric vacuum solution is derived. In Section 3 a discussion about the IW contraction from the Poincaré group towards Galilei group is provided. As an intermediate illustrative step, the four-dimensional non-relativistic limit of the EH action is obtained in Section 4. Also in this section, some novel solutions are discussed. The non-relativistic limit of the four-dimensional LC theory of gravity is considered in Section 5. Formal solutions in vacuum and in the presence of matter distributions are obtained. The fate of the cosmological constant and the acceptance of Newtonian absolute time are also analyzed in this section. Finally, our conclusions are displayed in Section 6.

2 Lovelock-Cartan gravity

In this section we review the construction of the LC theory of gravity in four dimensions [7, 8] which generalizes Lovelock gravity theories [32] within Einstein-Cartan first order formalism by including torsional terms in the gravity action. The scenario is a four-dimensional manifold $M$ with local Minkowski metric, $\eta = \text{diag}(-, +, +, +)$. The construction is fundamentally based on the 10 parameter Poincaré group $\text{ISO}(1, 3) = \text{SO}(1, 3) \times \mathbb{R}^{1, 3}$, whose algebra is given by

$$
[\Sigma_{AB}, \Sigma_{CD}] = \frac{1}{2} \left( \eta_{AD} \Sigma_{BC} - \eta_{AC} \Sigma_{BD} + \eta_{BC} \Sigma_{AD} - \eta_{BD} \Sigma_{AC} \right),
$$

$$
[\Sigma_{AB}, P_C] = \frac{1}{2} \left( \eta_{BC} P_A - \eta_{AC} P_B \right),
$$

$$
[P_A, P_B] = 0,
$$

(2.1)

with $\Sigma_{AB} = -\Sigma_{BA}$ being the 6 generators of the Lorentz group $\text{SO}(1, 3)$ and $P_A$ the 4 generators of the translational group $\mathbb{R}^{1, 3}$. Capital Latin indices run through $\{0, 1, 2, 3\}$. The Poincaré group is not a semi-simple Lie group, a property that makes the task of constructing a gauge invariant action quite difficult\(^3\). A solution for this problem is to consider only the Lorentz sector for gauging while keeping the translational sector of the group to expand a vector representation of the Lorentz gauge group. Aiming the construction of a general gravity action, we consider the fundamental independent 1-form fields: the vierbein $E$ and the Lorentz connection $Y$, defined respectively through

$$
E = E^A P_A,
$$

$$
Y = Y^{AB} \Sigma_{AB},
$$

(2.2)

\(^3\)Some exceptions do exist. For instance, in odd dimensions it is possible to work with Chern-Simons theories, see [7].
The vierbein $E^A$ ensures the equivalence principle by defining a local isomorphism between generic spacetime coordinates $x^\mu$ (Lowercase Greek indices refer to spacetime indices and run through $\mu, \nu, \alpha \ldots \in \{0, 1, 2, 3\}$) with inertial coordinates $x^A$. The latter can be identified with coordinates in the tangent space $T(M)$ at the point $x \in M$. The Lorentz connection $Y^{AB}$ carries information about the parallel transport on $M$ because it is directly related to the affine connection on $M$. Since $E$ and $Y$ are independent fields, the geometric properties of metricity and parallelism are also independent concepts in the first order formalism. The corresponding 2-form field strengths constructed out from $E$ and $Y$ are the curvature and torsion, respectively defined by

$$\Omega^{AB} = dY^{AB} + Y^C_A Y^{CB},$$
$$W^A = \nabla E^A = dE^A + Y_B^A E^B,$$

(2.3)

with $\nabla \cdot \equiv d \cdot + [Y, \cdot]$ standing for the Lorentz covariant derivative. The Bianchi hierarchy relations are easily found,

$$W^A = \nabla E^A,$$
$$\nabla W^A = \Omega^{AB} E^B,$$
$$\nabla \Omega^{AB} = 0.$$

(2.4)

The gauge (local Lorentz) transformations are defined through

$$Y' = u^{-1}(d + Y)u \approx Y + \nabla \alpha,$$
$$E' = u^{-1}Eu \approx E + [E, \alpha],$$

(2.5)

where $u = \exp \alpha \approx 1 + \alpha$ is a Lorentz group element and $\alpha = \alpha^{AB} \Sigma_{AB}$ is assumed to be an infinitesimal algebra-valued parameter.

The inverse of the vierbein $E_A$ is assumed to exist in such a way that

$$E^A_E^B \approx \delta^A_B,$$
$$E^A_E^\nu \approx \delta^\nu_\mu.$$

(2.6)

Moreover, spacetime and locally invariant metrics, $g_{\mu\nu}$ and $\eta^{AB}$, respectively, obey

$$\eta^{AB} = E_A^E_B \eta^E_{\mu\nu},$$
$$\eta_{AB} = E_A^E_B \eta^E_{\mu\nu},$$
$$g_{\mu\nu} = E_A^E_B g_{\mu\nu},$$
$$g^{\mu\nu} = E_A^E_B \eta^{AB},$$

(2.7)

with $g_{\mu\alpha} g^{\alpha\nu} = \delta^\nu_\mu$ and $\eta_{AC} \eta^{CB} = \delta^B_A$. Moreover, besides $\delta^B_A$, we have the gauge invariant skew-symmetric object $\epsilon_{ABCD}$, the Levi-Civita symbol at our disposal.

The MZ theorem [7,8] states that the most general four-dimensional action which is gauge invariant, polynomially local, explicitly metric independent, and that depends only on first order derivatives is given by

$$S_{MZ} = \kappa \int \epsilon_{ABCD} \left( \Omega^{AB} E^C E^D + \frac{\Lambda}{2} E^A E^B E^C E^D \right) + \int \left( z_1 \Omega^{AB} E_A E_B + z_2 W^A W_A \right) + \int \left( z_3 \epsilon_{ABCD} \Omega^{CD} \Omega^{AB} + z_4 \Omega^{AB} \Omega_{AB} \right) + S_m.$$

(2.8)

The gauge parameter does not need to be infinitesimal, MZ actions are generally invariant under finite gauge transformations.
The first term is the usual EH action while the second is the cosmological constant term. Hence, $\kappa$ is related to the inverse of Newton’s constant and $\Lambda$ is the cosmological constant. Third and fourth terms are essentially the same, up to surface terms. The parameters $z_1$ and $z_2$ carry mass squared dimension and when $z_2 = -z_1$ these terms are reduced to the Nieh-Yan topological term [7, 8, 37–39]. The fifth and six terms are, respectively, Gauss-Bonnet and Pontryagin topological terms [7, 8, 40, 41]. Being topological, these terms do not contribute to the field equations. Clearly, $z_3$ and $z_4$ are dimensionless topological parameters. Finally, $S_m$ stands for the matter content of fields and particles which, up to some considerations, we will keep as general as possible in this paper.

The field equations are quite easily obtained by varying the MZ action (2.8) with respect to $E^A$ and $Y^{AB}$, respectively,

$$\kappa \epsilon_{ABCD} \left( \Omega^{BC} E^D + \Lambda E^B E^C E^D \right) + (z_1 + z_2) \Omega_{AB} E^B = -\frac{1}{2} \frac{\delta S_m}{\delta E^A},$$

$$\kappa \epsilon_{ABCD} W^C E^D + \frac{(z_1 + z_2)}{2} (W_A E_B - E_A W_B) = -\frac{1}{2} \frac{\delta S_m}{\delta Y^{AB}}. \quad (2.9)$$

For further use, we can derive a torsionless vacuum solution of the field equations (2.9),

$$\Omega_0^{AB} = a_0 \Lambda E^A E^B - \frac{\kappa}{(z_1 + z_2)} (1 + a_0) \Lambda \epsilon^{AB CD} E^C E^D,$$

$$W_0^A = 0,$$  \quad (2.10)

with $a_0 \in \mathbb{R}$. It can be easily checked that the substitution of solutions (2.11) in Bianchi identities (2.4) leads to $a_0 = -1$. Hence, the torsionless vacuum solution (2.10) of the MZ action is a maximally symmetric spacetime

$$\Omega_0^{AB} = -\Lambda E^A E^B,$$

$$W_0^A = 0. \quad (2.11)$$

For a solution with general $a_0$, one should, perhaps, consider non-trivial torsion.

The specific case of GR can be obtained as a particular case of the MZ action (2.8) by setting $\Lambda = z_i = 0$, namely

$$S_{EH} = \kappa \int \epsilon_{ABCD} \Omega^{AB} E^C E^D. \quad (2.12)$$

Before we discuss the non-relativistic limit of MZ action in Section 5, we will revisit the non-relativistic limit of the Einstein-Hilbert (2.12) in Section 4. But first, let us take a look at the In"on"u-Wigner contraction [9] from the Poincaré group to the Galilei group in the next Section.

3 In"on"u-Wigner contraction of the Poincaré group

The first step towards the non-relativistic limit of actions (2.8) and (2.12) is to split the Poincaré group as $ISO(1,3) = SO(3) \times L(3) \times \mathbb{R}^3 \times \mathbb{R}^3$ where $SO(3)$ describes spatial rotations, $L(3)$ refers to Lorentz boosts, $\mathbb{R}^3$ to space translations, and $\mathbb{R}^3$ to time translations. The corresponding algebra is easily obtained by projecting the algebra (2.1) in spatial and temporal components. We define

$$\Sigma_{AB} \equiv (\Sigma_{ab}, \Sigma_{a0}) = (\Sigma_{ab}, J_a),$$

$$P_{A} \equiv (P_a, P_0) = (P_a, T), \quad (3.1)$$
with lowercase Latin indices running as $a, b, c, \ldots, h \in \{1, 2, 3\}$. The algebra (2.1) decomposes as

\[
\begin{align*}
[\Sigma_{ab}, \Sigma_{cd}] &= \frac{1}{2} (\delta_{ad}\Sigma_{bc} - \delta_{ac}\Sigma_{bd} + \delta_{bc}\Sigma_{ad} - \delta_{bd}\Sigma_{ac}) , \\
[\Sigma_{ab}, J_c] &= \frac{1}{2} (\delta_{bc}J_a - \delta_{ac}J_b) , \\
[J_a, J_b] &= -\frac{1}{2} \Sigma_{ab} , \\
[\Sigma_{ab}, P_c] &= \frac{1}{2} (\delta_{bc}P_a - \delta_{ac}P_b) , \\
[J_a, P_b] &= -\frac{1}{2} \delta_{ab}T , \\
[J_a, T] &= \frac{1}{2} P_a ,
\end{align*}
\]

and zero otherwise. The consequences for the fields are

\[
\begin{align*}
E &= e^a P_a + q T , \\
Y &= \omega^{ab}\Sigma_{ab} + \theta^a J_a ,
\end{align*}
\]

where $e^a$, called here simply by *space vierbein*, relates coordinates in spacetime $M$ with coordinates in the tangent space of 3-manifolds $T_3(M)$. The time-projected vierbein, here called *time vierbein* $q$, connects coordinates in spacetime with $T(M)/T_3(M)$. In the same spirit, $\omega^{ab}$ is called *spin connection* while $\theta^a$ is the *boost connection*.

For the field strengths we have

\[
\begin{align*}
W &= T^a P_a + QT , \\
\Omega &= \Omega^{ab}\Sigma_{ab} + S^a J_a ,
\end{align*}
\]

with

\[
\begin{align*}
T^a &= D e^a - \frac{1}{2} q \theta^a = K^a - \frac{1}{2} q \theta^a , \\
Q &= dq - \frac{1}{2} \theta_a e^a = Q - \frac{1}{2} \theta_a e^a ,
\end{align*}
\]

and

\[
\begin{align*}
\Omega^a_b &= d\omega^a_b + \omega^a_c \omega^c_b - \frac{1}{4} \theta^a \theta_b = R^a_b - \frac{1}{4} \theta^a \theta_b , \\
S^a &= D\theta^a .
\end{align*}
\]

In the above expressions, the covariant derivative $D \equiv d \cdot + [\omega, \cdot]$ is taken with respect to the $SO(3)$ sector. The field $R^{ab}$ will be called *space curvature* while $S^a$ is the *boost curvature*. The fields $T^a$, $K^a$, and $Q$ are named, respectively, *space torsion*, *reduced torsion*, and *time torsion*.

The non-relativistic limit of the Poincaré group is obtained following reference [10]. First, the boost and temporal translational generators are redefined by

\[
\begin{align*}
J_a &= \zeta G_a , \\
T &= \zeta^{-1} H ,
\end{align*}
\]

together with the rescalings

\[
\begin{align*}
\theta^a &\mapsto \zeta^{-1} \theta^a , \\
q &\mapsto \zeta q .
\end{align*}
\]
in such a way that definitions (3.3) remain unchanged. At this point, the limit \( \zeta \to \infty \), which is equivalent to consider \( 1/c \to 0 \), can be performed. The consequence for the Poincaré algebra (3.2), at leading order, is that it is contracted down to the Galilei algebra, namely,

\[
[\Sigma_{ab}, \Sigma_{cd}] = \frac{1}{2} (\delta_{ad} \Sigma_{bc} - \delta_{ac} \Sigma_{bd} + \delta_{bc} \Sigma_{ad} - \delta_{bd} \Sigma_{ac}) ,
\]

\[
[\Sigma_{ab}, P_c] = \frac{1}{2} (\delta_{bc} P_a - \delta_{ac} P_b) ,
\]

\[
[\Sigma_{ab}, G_c] = \frac{1}{2} (\delta_{bc} G_a - \delta_{ac} G_b) ,
\]

\[
[G_a, H] = \frac{1}{2} P_a ,
\]

and zero otherwise. Thence, the limit implies on an İnönü-Wigner contraction [9] of the form \( ISO(1, 3) \to G(1, 3) = SO(3) \times B(3) \times \mathbb{R}^3 \times \mathbb{R}_t \) with \( B(3) \) being the Galilean boosts, see for instance [10, 25]. From the algebra (3.9), one easily observes that the Galilei group is not a semi-simple Lie group since the annexes \( B(3) \times \mathbb{R}^3_\text{s} \) and \( \mathbb{R}_t \) are normal Abelian subgroups of the Galilei group. Hence, there is no invariant Killing form. In fact, the isometries of the Galilei group imply on degenerate metric tensors:

\[
\begin{align*}
\eta_t &\equiv \text{diag}(1, 0, 0, 0) , \\
\eta_s &\equiv \text{diag}(0, 1, 1, 1) .
\end{align*}
\] (3.10)

Clearly, \( \eta_s \equiv \delta_{ab} \) is the 3-dimensional Euclidean flat metric while \( \eta_t \) is its equivalent at time axis. These metrics are orthogonal to each other. The local invariant metrics (3.10) induces two sets of metrics on \( \mathcal{M} \),

\[
\tau_{\mu\nu} = q_{\mu} q_{\nu} ,
\]

\[
g_{\mu\nu} = e_{\mu}^a e_{\nu}^b \delta_{ab} .
\] (3.11)

and

\[
\tau^{\mu\nu} = q_{\mu} q_{\nu} ,
\]

\[
g^{\mu\nu} = e_{\mu}^a e_{\nu}^b \delta_{ab} .
\] (3.12)

Moreover, due to the relations (2.6) and (2.7), the following inverse relations hold

\[
e_{\mu}^a e_{\mu}^b = \delta_{ab} ,
\]

\[
q^{\mu} q_{\mu} = 1 ,
\]

\[
q^{\mu} e_{\mu}^a = q_{\mu} e_{\mu}^\nu = 0 ,
\]

\[
e_{\mu}^a e_{\nu}^b = \delta_{\nu}^\nu - q_{\mu} q_{\nu} .
\] (3.13)

Metrics (3.11) and (3.12) relate through

\[
\tau^{\mu\alpha} \tau^{\nu\nu} = q_{\mu} q_{\nu} ,
\]

\[
g_{\mu\alpha} g^{\nu\nu} = \delta_{\nu}^\nu - q_{\mu} q_{\nu} .
\] (3.14)

The fields (3.3) remains unchanged but the fields (3.5) and (3.6) reduce to

\[
T^a = K^a - \frac{1}{2} q \theta^a ,
\]

\[
Q = dq ,
\]

\[
\Omega^a_b = R^a_b ,
\]

\[
S^a = D \theta^a .
\] (3.15)
The infinitesimal gauge transformations (2.5) of the fields are contracted down to Galilei gauge transformations,

\[
\begin{align*}
\delta \omega^a_b &= D \alpha^a_b, \\
\delta \theta^a &= D \alpha^a - \alpha^a_b \theta^b, \\
\delta e^a &= -\alpha^a_b e^b - \frac{1}{2} \alpha^a q, \\
\delta q &= 0,
\end{align*}
\]

where \( \alpha = \alpha_{ab} \Sigma_{ab} + \alpha^a G_a \). For completeness, we write down the gauge transformations of curvatures and torsions,

\[
\begin{align*}
\delta R^a_{bc} &= R^a_{cd} \alpha^d_b - R^c_d \alpha^a_b, \\
\delta S^a &= S^b_\alpha a^a + R^a_b \alpha^b, \\
\delta T^a &= T^b_\alpha a^b - \frac{1}{2} Q \alpha^a, \\
\delta Q &= 0.
\end{align*}
\]

Up to tautological relations, the hierarchy relations (2.4) lead to the following set of self-consistent equations

\[
\begin{align*}
dQ &= 0, \\
DK^a &= R^a_b e^b, \\
DS^a &= R^a_b \theta^b, \\
DR^a_{bc} &= 0.
\end{align*}
\]

The consequences of the In"on"u-Wigner contraction setup here discussed are the basis to study the non-relativistic limit of gravity theories. We begin with the EH action as a first example in the following section.

## 4 Galilei gravity

What we call in this work Galilei gravity can be obtained from the non-relativistic limit of the Einstein-Hilbert action (4) at leading order in the \( 1/c \) expansion. This task is achieved by considering the In"on"u-Wigner contraction of the Poincaré group to the Galilei group, as described in Sect. 3. See for instance \([10]\). Thence, employing decompositions (3.3) and (3.4), the Einstein-Hilbert action (2.12) reads

\[
S_{EH} = \kappa \int \epsilon_{abc} \left( 2q R^{a}_{bc} e^c - \frac{1}{2} q \theta^a b^b e^c - S^a e^b e^c \right) + S_m.
\]

Performing the rescalings (3.8) we get

\[
S_{EH} = \kappa \int \epsilon_{abc} \left( 2\zeta q R^{a}_{bc} e^c - \frac{1}{2} \zeta^{-1} q \theta^a b^b e^c - \zeta^{-1} S^a e^b e^c \right) + S_m.
\]

The non-relativistic limit is then obtained by taking \( \zeta \longrightarrow \infty \) together with the coupling rescaling \( \kappa \longrightarrow \zeta^{-1} \kappa \). The result is the Galilei gravity action \([10,25]\),

\[
S_G = 2\kappa \int \epsilon_{abc} q R^{a}_{bc} e^c + S_m.
\]

\[\footnote{The rescaling \( \alpha^a_0 \longrightarrow \zeta^{-1} \alpha^a_0 \) must be taken.}\]
In this procedure, we assume that the corresponding limit of the matter action $S_m$ is consistent.

It is worth mentioning that the pure gravitational sector of action (4.3), $S_{pG} = S_G - S_m$, is invariant under local scale invariance [10, 25]

\[ q \mapsto \exp(-\phi)q, \quad e^a \mapsto \exp(\phi)e^a, \]  

(4.4)

with $\phi = \phi(x)$ being a local gauge parameter. In functional form, symmetry (4.4) implies on

\[ e^a \frac{\delta S_{pG}}{\delta e^a} - q \frac{\delta S_{pG}}{\delta q} = 0. \]  

(4.5)

Identity (4.5) assigns a global charge $\pm 1$ for $e$ and $q$, respectively.

The field equations can be easily computed from the action (4.3) for the fields $q$, $e$, $\omega$, and $\theta$, respectively given by

\[ \epsilon_{abc} R^{ab} e^c = -\frac{1}{2\kappa} \delta S_m \frac{\delta S_m}{\delta q}, \]

\[ \epsilon_{abc} q R^{bc} = \frac{1}{2\kappa} \delta S_m \frac{\delta S_m}{\delta e^a}, \]

\[ \epsilon_{abc} (Q e^c - q K^c) = -\frac{1}{2\kappa} \delta S_m \frac{\delta S_m}{\delta \omega^{ab}}, \]

\[ 0 = \delta S_m \frac{\delta S_m}{\delta \theta^a}. \]  

(4.6)

The last equation implies on two important features of Galilei gravity: First, it establishes a constraint saying that the non-relativistic limit of the matter content must not couple with the boost connection; And second, that the field $\theta^a$ remains free, since it does not appear in the field equations (nor in the action (4.3)). Typically, this problem is solved by considering higher order corrections in $\zeta^{-1}$ at the non-relativistic limit of the Einstein-Hilbert action (4.1). Otherwise, a constraint for $\theta^a$ must be implemented by hand. The second equation in (4.6) implies on another constraint on the matter content, namely,

\[ q \frac{\delta S_m}{\delta e^a} = 0. \]  

(4.7)

Moreover, combining the first and second equations in (4.6) we get

\[ e^a \frac{\delta S_m}{\delta e^a} - q \frac{\delta S_m}{\delta q} = 0, \]

(4.8)

saying that symmetry (4.4) must be obeyed by the non-relativistic limit of the matter content as well. Constraint (4.7) states that whenever $e^a$ appears at the matter action, a $q$ must be there as well, i.e., $e^a$ and $q$ always come in pairs $qe^a$. Constraint (4.8) reinforces constraint (4.7) by saying that the matter action must be linear in $e^a$.

### 4.1 Vacuum solutions

The field equations (4.6) in vacuum are of particular interest. The first two equations imply on

\[ R^{ab}_{\mu\nu} e^\mu e^\nu = R^{ab}_{cd} = 0. \]  

(4.9)
The third equation, assumes the form

\[ Qe^a - qK^a = 0. \]  

(4.10)

We focus in this equation to complement the curvature solution (4.9) with possible torsional solutions in vacuum (other than the trivial inconsistent solution \( q = 0 \)). It is important to keep in mind that boost connection and boost curvatures remain free.

### 4.1.1 A no-go constrained solution

As a no-go result, let \( e^a \) and \( q \) be related by

\[ e^a = qn^a, \]  

(4.11)

with \( n^a \) being an arbitrary algebra-valued 0-form. This tentative ansatz is a solution of equation (4.10), as one can easily check. Nevertheless, such attempt is inconsistent with the degenerate nature of the metric. For instance, this is evident by contracting the ansatz (4.11) with \( q_\mu q^\mu \), resulting in \( q_\mu q^\mu = 0 \), which contradicts relations (3.13). In other words, \( q \) and \( e^a \) are orthogonal by definition while the proposal (4.11) enforces these fields to be parallel.

### 4.1.2 Weak twistless torsion solution

In tensor notation, equation (4.10) can be manipulated to provide the following geometric relations

\[ e^\mu_b e^\nu_c Q_{\mu\nu} = Q_{bc} = 0, \]

\[ 2q^\mu Q_{\mu\nu} e^\nu_b + K^a_{\alpha\nu} e^\nu_b e^\alpha_a = 2Q_{\nu\sigma} + K^a_{\nu\sigma} = 0, \]

\[ \frac{1}{2} \left( K^d_{\nu\mu} \delta^a_c - K^d_{\nu\mu} \delta^a_b \right) + K^a_{bc} = 0, \]  

(4.12)

with \( \Phi \) standing for the time direction in tangent space. The first equation in (4.12) is the well known twistless torsion condition. It fixes a specific spacetime foliation for which time torsion \( Q \) has no projection on the locally inertial leaves. This condition allows the implementation of Newtonian absolute time and spatial causality. Equations (4.9) and (4.12) synthesize the well-known results of Galilei gravity in vacuum [10, 11]. We call this solution weak twistless torsion solution since it still gives room for non-vanishing time torsion solutions. Notice that, imposition of \( K^a_{bc} = 0 \) leads to \( Q_{bc} = 0 \) in tangent projections. Moreover, \( Q_{ab} = Q_{0a} = 0 \) does not imply on \( Q = 0 \). The latter constitutes what we call here strong twistless condition, which we discuss in the next section.

### 4.1.3 Strong twistless torsion solution

As just mentioned, strong twistless torsion solution is given by

\[ Q = 0, \]  

(4.13)

which is clearly a stronger condition than the first equation in (4.12). The consequence of the strong twistless torsion condition (4.13) is that the time vierbein can be chosen as an exact field, \( q = dT \). Thus, time vierbein is defined by an arbitrary scalar function \( T(x) \) which, among an infinity number of possibilities, can be fixed as the time coordinate \( t \). Since \( q \) is gauge invariant, this solution is absolute.
up to time translations \( t \mapsto t + \text{constant} \). Hence, \( t \) is identified with the absolute Newtonian time. If no other assumption is made over \( q \), equation (4.10) is satisfied for

\[
K^a = 0 .
\]  

(4.14)

If \( S^a \) remains free, equations (4.13) and (4.14) compose a torsional solution case, \( T^a \propto q \theta^a \). For a torsionless solution, one might choose \( \theta^a = 0 \). Nevertheless, (4.14) is not a requirement. Equation (4.10) together with (4.13) imply on the softer condition for the reduced torsion

\[
e^\mu_\nu e^\nu_\delta K^\alpha_\mu\nu = K^\alpha_\beta\gamma = 0 ,
\]  

(4.15)

with \( \theta^a \) and \( S^a \) still free to be fixed.

### 4.1.4 A Weitzenböck-like solution

An ansatz for \( Q \) can be made,

\[
Q = q n \Rightarrow (d + n) q = 0 ,
\]  

(4.16)

with \( n \) being an arbitrary gauge invariant 1-form field. Combining (4.10) with (4.16) provides \( q(n e^a - K^a) = 0 \), which is satisfied, for instance, by

\[
K^a = n e^a \Rightarrow (D - n) e^a = 0 .
\]  

(4.17)

The first Bianchi identity in (3.18) states that \( q n \) must be closed,

\[
d(q n) = 0 .
\]  

(4.18)

Using now the second Bianchi identity of (3.18), we find the curvature associated to the proposed solution (4.16) and (4.17),

\[
R^a_b = d n \delta^a_b ,
\]  

(4.19)

which is inconsistent due to the symmetry properties of the indices \( a \) and \( b \). Hence, inevitably, space curvature must vanish and \( n \) must be closed

\[
R^a_b = 0 \Rightarrow d n = 0 .
\]  

(4.20)

Combination of equations (4.18) and (4.20) implies on the strong twistless torsion solution (4.13). Hence, \( q \) must be parallel to \( n \). Condition \( Q = 0 \) together with equations (4.17) and (4.20) define a twistless torsion solution with vanishing space curvature and non-vanishing reduced torsion. Hence, spacetime will be a Weitzenböck-like space\(^6\) [33] if we also demand \( S^a = 0 \).

In the particular case where \( n \) is a constant field, equation (4.16) is easily solved for

\[
q = a \exp(-n_\mu x^\mu) + b n ,
\]  

(4.21)

where \( a \) is another constant 1-form field and \( b \) a constant scalar field. It can be easily checked that, with the help of equation (4.20), expression (4.21) satisfies equation (4.18). To be even more specific in this example, we consider ADM formalism in the temporal gauge \([1]\). In the first order formalism this means that \( E^0_0 = 0 \) and \( E^0_0 = N \), with \( N \) being the lapse function. Then, \( q = E^0_0 dt + E^0_0 dx^i = N dt \), with \( t \)

\(^6\)In GR, Weitzenböck spacetimes serve as scenario for the so called Teleparallel Gravity theories. See, for instance [34–36] and references therein.
being the Newtonian absolute time. Also, choosing\(^7\) \(n = ndt\) and \(a = adt\), with \(n\) and \(a\) being positive constants, we get
\[
N = a \exp(-nt) + bn .
\] (4.22)
Since \(N = N(t) \neq 1\), the lapse function characterizes a non-trivial time different from the absolute time \(t\). On the other hand, (4.22) also says that \(q \rightarrow bn\) as time evolves. Hence, \(bn\) is the asymptotic lapse function. We can set then \(b = n^{-1}\) in order to identify the asymptotic time with the Newtonian absolute time where \(N_{abs} = 1\). Hence,
\[
N = a \exp(-nt) + 1 .
\] (4.23)
Notice that for this specific case, \(Q = 0\) because \(q\) is parallel to \(n\), even though \(q \neq dt\), except asymptotically. Nevertheless, it is possible to write \(q = dT\) where
\[
T = -\frac{a}{n} \exp(-nt) + t + c ,
\] (4.24)
with \(c\) a constant to be fixed. In fact, if we interpret \(T\) as a non-Newtonian time, we can fix \(c\) by demanding \(T\) to be positive definite in the domain \(t \in [0, \infty]\). Since \(T \in [-a/n + c, \infty]\), for \(T \geq 0\) we get that \(c \geq a/n\). Thence, we can set
\[
T = \frac{a}{n} \left[1 - \exp(-nt)\right] + t ,
\] (4.25)
to have the range \(T \in [0, \infty)\). Note that \(T(t) \big|_{t \to \infty} \sim t + a/n\). Moreover, \(N = dT/dt\) characterizes the time flow rate with respect to the Newtonian time. Thus, non-Newtonian and Newtonian time intervals, respectively \(\Delta T = T_2 - T_1\) and \(\Delta t = t_2 - t_1\), are related by
\[
\Delta T = \int_{t_1}^{t_2} N(t)dt = T \bigg|_{t_1}^{t_2} = -\frac{a}{n} \exp(-nt_2) + \frac{a}{n} \exp(-nt_1) + \Delta t \approx (1 + a) \Delta t + O(n) .
\] (4.26)
This is an explicit example of time dilation in NC gravity. A nice discussion about time dilation in NC gravity can be found in [42].

Finally, still in this example, space torsion reads (see (4.17))
\[
K^a = n c^a dt dx^i ,
\] (4.27)
with lowercase Latin indices \(i, j, \ldots, s\) running through \(\{1, 2, 3\}\). Thence, while \(R_{\mu\nu} = S_{\mu\nu} = Q_{\mu\nu} = K^a_{\mu\nu} = 0\), we have \(K^a_{0i} \neq 0\). The non-triviality of spacetime geometry is encoded in (4.27). We remark that we can easily set the Newtonian absolute time by choosing \(a = 0\). Nevertheless, expression (4.27) remains valid since it does not depend on the 1-form \(a\). To find the components of \(\epsilon_i^a\), we can set \(\omega_{ab} = 0\), which solves (4.9) \(\text{a la Weitzenböck}\) while giving room for torsional degrees of freedom. Thence, equation (4.27) can be directly integrated to provide
\[
\epsilon_i^a = c_i^a \exp(nt) dx^i ,
\] (4.28)
with \(c^i = c^a_i dx^i\) being a constant 1-form field. Relations (3.13) allow to construct the full vierbein solution whose non-vanishing components are
\[
\begin{align*}
q_0 &= N , \\
q_0 &= N^{-1} , \\
\epsilon_i^a &= \frac{a}{(N - 1)} c_i^a , \\
\epsilon_i^a &= \frac{a}{(N - 1)} c^a_i ,
\end{align*}
\] (4.29)
\(^7\)In that case, \(n\) itself can be used to define a consistent foliation with \(n\) being dual to the normal vector of the spatial leaves.
with
\[ e^i_a e^j_b = \delta^i_b, \]
\[ e^i_a e^0_b = \delta^i_j. \] (4.30)

It can be checked using (3.11) and (3.12) that this solution induces conformally flat metrics of the form
\[ \tau^{00} = N^{-2}, \]
\[ \tau^{ij} = 0, \]
\[ g^{ij} = \frac{(N - 1)^2}{a^2} \delta^{ij}, \]
\[ g^{00} = 0, \] (4.31)

and
\[ \tau_{00} = N^2, \]
\[ \tau_{ij} = 0, \]
\[ g_{ij} = \frac{a^2}{(N - 1)^2} \delta_{ij}, \]
\[ g_{00} = 0. \] (4.32)

One can reach an Euclidean three-dimensional metric by performing a conformal transformation while respecting the symmetry (4.4). To see this property, we perform the following transformations, which keep the action (4.3) invariant,
\[ e^a_i \rightarrow \exp(-nt)e^a_i, \]
\[ q \rightarrow \exp(nt)q. \] (4.33)

Henceforth, the space metric trivializes while the new temporal metric reads
\[ \tau^{00} = \frac{(1 - N^{-1})^2}{a^2}, \]
\[ \tau_{00} = \frac{a^2}{(1 - N^{-1})^2}. \] (4.34)

One can also trivialize temporal metric while keeping space metric conformally flat by performing an appropriate conformal transformation. To trivialize all metrics simultaneously, Newtonian time must be evoked by setting \( a = 0 \).

4.2 Solutions in the presence of matter

Going back to equations (4.6) in the presence of matter, we rewrite them as
\[ \epsilon_{abc} R^{ab} e^c = -\frac{1}{2\kappa} \tau, \]
\[ q R^{ab} = \frac{1}{4\kappa} \epsilon^{abc} \tau_c, \]
\[ Q e^a - q K^a = -\frac{1}{4\kappa} \epsilon^{abc} \sigma_{bc}, \]
\[ 0 = \sigma_a, \] (4.35)
with the following definitions

\[ \tau = \frac{\delta S_m}{\delta q}, \quad \tau_a = \frac{\delta S_m}{\delta e^a}, \quad \sigma_{ab} = \frac{\delta S_m}{\delta \omega^{ab}}, \quad \sigma_a = \frac{\delta S_m}{\delta \theta^a}, \]  \tag{4.36}

with \( \tau \) and \( \tau_a \) being 3-forms associated with the energy-momentum tensor of the matter content while \( \sigma_a \) and \( \sigma_{ab} \) are 3-forms describing the spin-density of the matter content. In terms of \( \tau \) and \( \tau_a \), constraints (4.7) and (4.8) are rewritten as

\[ q\tau_a = 0, \]
\[ e^a \tau_a - q\tau = 0. \]  \tag{4.37}

These equations suggest that \( \tau \) and \( \tau_a \) can be chosen as

\[ \tau = -4e^a m_a, \]
\[ \tau_a = 4qm_a, \]  \tag{4.38}

with \( m_a \) being a 2-form describing the matter content. The factor 4 is just a convenient normalization factor. We notice that \( m_a \) does not depend on \( q \) nor \( e^a \) (See the argument below (4.8)). Moreover, there is no need in defining \( m \), the \( m_a \) time counterpart, since the second of (4.37) (which is just (4.8)) defines a constraint between \( \tau \) and \( \tau_a \). The matter content is then written as

\[ S_m = -4 \int qe^a m_a. \]  \tag{4.39}

Thus,

\[ \sigma_{ab} = -4qe^c \frac{\delta m_c}{\delta \omega^{ab}}, \quad \frac{\delta m_b}{\delta \theta^a} = 0. \]  \tag{4.40}

Imposing strong twistless torsion condition (4.13), applying \( D \) on the second of (4.35), and using Bianchi identities (3.18), one also finds

\[ D\tau = 0. \]  \tag{4.41}

The field equations (4.35) read now

\[ \epsilon_{abc} \mathbf{R}^{ab} e^c = \frac{2}{\kappa} e^a m_a, \]
\[ q\mathbf{R}^{ab} = \frac{1}{\kappa} qe^{abc} m_c, \]
\[ qK^a = \frac{1}{\kappa} e^{abc} qe^d \frac{\delta m_d}{\delta \omega^{bc}}. \]  \tag{4.42}

Clearly, reduced torsionless geometry requires that the matter content does not depend on the spin connection or, at least, that \( K^a \) has a part independent of \( q \). For fully torsionless geometry, one also has to set \( \theta^a = 0 \), see (3.5). The first two equations in expressions (4.42) are satisfied for

\[ \mathbf{R}^{ab} = \frac{1}{\kappa} e^{abc} m_c. \]  \tag{4.43}

The third equation admits the solution

\[ K^a = -\frac{1}{\kappa} e^{abc} qe^d s_{bcd}, \]  \tag{4.44}

\footnote{We remark that this form of the matter action is not general. It works fine for external sources. In the case of dynamical fields, the Hodge star usually enters in the game. Moreover, even if the matter action \( S_m \) does not respect the symmetry (4.4) explicitly, the symmetry will then enforce a constraint between the matter fields.}
with \( s_{abc} = \frac{\delta m_c}{\delta \omega^{ab}} \) being a 1-form related to the spin-density matter distribution. It is more convenient to define the 2-form \( s_{ab} = -e^c s_{abc} \). Thence,

\[
K^a = \frac{1}{\kappa} e^{abc} s_{bc} .
\] (4.45)

Equation (4.45) and the Bianchi identity (3.18) imply on the extra constraint for the matter action \( S_m \)

\[
Ds_{ab} = \frac{1}{2} (e_a m_b - e_b m_a) .
\] (4.46)

It remains to fix \( S^a \). Field equations say nothing about it. But the Bianchi identities (3.18) imply on

\[
DS^a = \frac{1}{\kappa} e^{abc} m_c \theta_b .
\] (4.47)

We can fix \( \theta^a \) or \( S^a \) at will as long as (4.47) is respected. For instance, the trivial solution \( \theta^a = 0 \Rightarrow S^a = 0 \) is allowed. Non-trivially, we may set, for example,

\[
S^a = a e^{abc} s_{bc} ,
\] (4.48)

where \( a \in \mathbb{R} \). Thus, from (4.45), we get the constraint

\[
\theta^a = \kappa a \left( e^a + \bar{\theta}^a \right) \Rightarrow S^a = \kappa a K^a .
\] (4.49)

The field \( \bar{\theta}^a \) is introduced because \( \theta^a \) and \( e^a \) transform differently under Galilei gauge transformations. Thus, \( \bar{\theta}^a \) must obey the following properties,

\[
D \bar{\theta}^a = 0 ,
\]

\[
\delta \bar{\theta}^a = -\delta e^a + \frac{1}{\kappa a} \delta \theta^a = -\alpha^a_b \bar{\theta}^b + \frac{1}{2} \alpha^a q + \frac{1}{\kappa a} D \alpha^a .
\] (4.50)

Thence, up to an arbitrary dimensionless non-vanishing real constant \( a \), \( \theta^a \) is totally fixed. Obviously, \( a = 0 \) sets \( \theta^a = 0 \) and \( S^a = 0 \).

The main conclusion of this section is that Galilei gravity accepts consistent solutions in the presence of matter within Newtonian absolute time. Moreover, we found spaces for strong twistless torsion condition while having non-trivial curvatures and reduced torsion.

5 Galilei-Cartan gravity

We now consider the non-relativistic limit of the Mardones-Zanelli action (2.8). Decompositions (3.3) and (3.4), imply on

\[
S_{MZ} = \kappa \int \left[ \epsilon^{abc} \left( 2 q R^{ab} e^c - \frac{1}{2} q \theta^a \theta^b e^c - S^a e^b e^c \right) + 2 \Lambda \epsilon_{abc} q e^a e^b e^c \right] + \\
+ \int \left[ z_1 \left( R^{ab} e_a e_b - q e_a S^a + \frac{1}{4} e_a \theta^a e_b \theta^b \right) + z_2 \left( Q^2 + K^a K_a - q \theta^a K_a + e_a \theta^a Q + \frac{1}{4} e_a \theta^a e_b \theta^b \right) \right] + \\
- \int \left[ 2 z_3 \epsilon_{abc} S^a \left( R^{bc} - \frac{1}{4} \theta^b \theta^c \right) - z_4 \left( R^{ab} R_{ab} + \frac{1}{2} S^a S_a - \frac{1}{2} R^{ab} \theta_a \theta_b \right) \right] + S_m .
\] (5.1)
From the rescaling of the fields (3.8), we get

\[
S_{MZ} = \kappa \int \left[ \varepsilon_{abc} \left( 2\zeta q R^{ab} e^c - \frac{1}{2} \zeta^{-1} q \theta^a \theta^b e^c - \zeta^{-1} S^a e^b e^c \right) + 2\Lambda \varepsilon_{abc} q e^a e^b e^c \right] + ,
\]

\[
+ \int \left[ z_1 \left( R^{ab} e_a e_b - q e_a S^a + \frac{1}{4} \zeta^{-2} e_a \theta^a e_b \theta^b \right) \right] +
\]

\[
+ z_2 \left( \zeta^2 Q^2 + K^a K_a - q \theta^a K_a + e_a \theta^a Q + \frac{1}{4} \zeta^{-2} e_a \theta^a e_b \theta^b \right) \right] +
\]

\[
- \int \left[ 2z_3 \varepsilon_{abc} \left( \zeta^{-1} S^a R^{bc} - \frac{1}{4} \zeta^{-3} S^a \theta^b \theta^c \right) - z_4 \left( R^{ab} R_{ab} + \frac{1}{2} \zeta^{-2} S^a S_a - \frac{1}{4} \zeta^{-2} R^{ab} \theta_a \theta_b \right) \right] +
\]

\[+ S_m . \]  

(5.2)

The corresponding non-relativistic limit is obtained by taking \(\zeta \rightarrow \infty\) together with the coupling rescalings\(^9\)

\[
\kappa \mapsto \zeta^{-1} \kappa ,
\]

\[
\Lambda \mapsto \Lambda ,
\]

\[
z_1 \mapsto z_1 ,
\]

\[
z_2 \mapsto \zeta^{-2} z_2 ,
\]

\[
z_3 \mapsto z_3 ,
\]

\[
z_4 \mapsto z_4 . \]  

(5.3)

Thus, the MZ action (5.2) reduces to its non-relativistic limit at leading order,

\[
S_{GMZ} = 2\kappa \int \varepsilon_{abc} g \left( R^{ab} e^c + \Lambda e^a e^b e^c \right) + \int \left[ z_1 \left( R^{ab} e_a e_b - q e_a S^a \right) + z_2 Q^2 + z_4 R^{ab} R_{ab} \right] + S_m . \]  

(5.4)

It is a straightforward exercise to check that this action is invariant under the Galilei gauge transformations (3.16) and (3.17). For now, we will refer to this theory as Galilei-Cartan gravity. The first term in the action (5.4) is the same that appears in the non-relativistic limit of the Einstein-Hilbert action (4.3). The second term is a non-relativistic cosmological relic. The terms accompanied by \(z_1\) are new and will affect the dynamics. Terms with factors \(z_2\) and \(z_4\) are of topological nature (Abelian and non-Abelian Pontryagin actions, respectively) and do not contribute to the field equations. Moreover, it is assumed that the non-relativistic limit of \(S_m\) is consistent. One can readily note that transformations (4.4) do not constitute a symmetry of action (5.4).

The field equations generated by the action (5.4) are\(^10\)

\[
2\kappa \varepsilon_{abc} \left( R^{ab} e^c + \Lambda e^a e^b e^c \right) - z_1 e_a S^a = -\tau ,
\]

\[
2\kappa \varepsilon_{abc} g \left( R^{bc} + 3\Lambda e^b e^c \right) - z_1 \left( 2R_{ab} e^b + q S_a \right) = \tau_a ,
\]

\[
2\kappa D(\varepsilon_{abc} q e^c) + z_1 D(e_a e_b) - \frac{z_1}{2} q (e_a \theta_b - e_b \theta_a) = -\sigma_{ab} ,
\]

\[
z_1 \left( Q e^a - q K^a \right) = \sigma_a . \]  

(5.5)

We may have lost the scale symmetry (4.4), but now we have an extra equation (the last of equations (5.5)) associated with \(\theta^a\). Moreover, the boost connection appears explicitly in the field equations. This

\(^9\)In (5.3), the parameters were modified, if needed, in order to eliminate potential divergences at the limit \(\zeta \rightarrow \infty\). As will be demonstrated in the sequence, a rescale of the cosmological constant will be necessary.

\(^10\)See definitions (4.36).
is a welcome feature of the non-relativistic limit of the MZ action: The system of equations is now fully determined already at leading order. Combining the first and second equations in (5.5) we get

\[ 4\kappa\Lambda\varepsilon_{abc} e^a e^b e^c + 2z_1 R^{ab} e_a e_b = q\tau - e^a \tau_a. \] (5.6)

In the same spirit, we can combine the third and fourth equations in (5.5) to get

\[ e_b \left( K_a - \frac{1}{2} q\theta_a \right) - e_a \left( K_b - \frac{1}{2} q\theta_b \right) = -\frac{1}{z_1} \sigma_{ab} - 2 \frac{\kappa}{z_1} \varepsilon_{abc} \sigma^c. \] (5.7)

In the next section we show that, for consistency, the cosmological constant term in (5.4) must disappear already at leading order in the non-relativistic limit.

### 5.1 Vacuum solution and the fate of the cosmological constant

We consider first the field equations (5.5) in vacuum,

\[ \begin{align*}
2\kappa \varepsilon_{abc} \left( R^{ab} e^c + \Lambda e^a e^b e^c \right) - z_1 e_a S^a &= 0, \\
2\kappa \varepsilon_{abc} q \left( R^{bc} + 3\Lambda e^b e^c \right) - z_1 \left( 2R^{ab} e_b + qS_a \right) &= 0, \\
2\kappa D(\varepsilon_{abc} e^c) + z_1 D(e_a e_b) - \frac{z_1}{2} q(e_a \theta_b - e_b \theta_a) &= 0, \\
Q e^a - qK^a &= 0.
\end{align*} \] (5.8)

It can be straightforwardly checked that the first two equations in (5.8) accepts a general solution with curvatures of the form

\[ \begin{align*}
R^{ab} &= -2\frac{\kappa \Lambda}{z_1} e^a e^b e^c + (b\Lambda + cz_1) e^a e^b, \\
S^a &= 2\kappa \left[ \frac{\Lambda}{z_1} (1 + b) \right] e^a e^b e^c + a q e^a,
\end{align*} \] (5.9)

with \( b \) and \( c \) being dimensionless parameters and \( a \) a mass squared parameter. Note that, due to the presence of the cosmological constant, vanishing curvatures do not satisfy the first two field equations (5.8). Substitution of (5.9) in the third Bianchi identity in (3.18) implies on the relation

\[ 4\kappa \left[ \frac{\Lambda}{z_1} (1 + b) + c \right] e^a e^b K^c e^c = 2\frac{\kappa \Lambda}{z_1} e^a e^b q \theta^b e^c + (b\Lambda + cz_1) e^a e^b \theta^b, \] (5.10)

where the fourth equation in (5.8) was employed. On the other hand, curvatures (5.9) relate to each other through

\[ \frac{\Lambda}{z_1} q S^a = \left[ \frac{\Lambda}{z_1} (1 + b) \right] R^a e^b. \] (5.11)

Applying the covariant derivative in relation (5.11) one finds

\[ \frac{\Lambda}{z_1} Q S^a - \frac{\Lambda}{z_1} q R^a e^b \theta^b = \left[ \frac{\Lambda}{z_1} (1 + b) + c \right] R^a e^b K^b. \] (5.12)

Now, for the theory to be physically consistent, a torsionless vacuum solution should be acceptable,

\[ \begin{align*}
Q &= 0, \\
K^a &= \frac{1}{2} q \theta^a.
\end{align*} \] (5.13)
This solution satisfies the third and fourth field equations in (5.5). For this solution be consistent with the relation (5.10), one can quickly verify that we need to set
\[ c = -\frac{\Lambda}{z_1} b. \] (5.14)

However, (5.13) together with (5.14) do not satisfy (5.12). In fact, (5.12) will only be satisfied if the cosmological constant is set to zero. This is important if one wishes torsionless vacuum solutions together with non-trivial curvatures which might be associated with the mass parameters of the theory. The present analysis suggests that is safer to consider that the cosmological constant scale as
\[ \Lambda \rightarrow \zeta^{-\xi} \Lambda, \] (5.15)
in the non-relativistic limit of the MZ action. The parameter $\xi$ is some dimensionless positive real number to be determined (see below). In this case, the cosmological constant term vanishes in the non-relativistic limit. It is worth mentioning that there may exist solutions different of (5.9) which are consistent with vanishing torsion. Nevertheless, as we will show in the sequence, the vanishing of the cosmological constant is in fact needed if one requires that the non-relativistic limit of the maximally symmetric solution (2.11) is also a solution of the non-relativistic MZ field equations.

The action (5.4) with vanishing cosmological constant simplifies to
\[ S_{GMZ0} = \int \left[ 2\kappa \epsilon_{abc} R^{ab} e^c + z_1 \left( R^{ab} e_a e_b - q e_a S^a \right) + z_2 Q^2 + z_4 R^{ab} R_{ab} \right] + S_m. \] (5.16)

and the corresponding field equations are now
\[ 2\kappa \epsilon_{abc} R^{ab} e^c - z_1 e_a S^a = -\tau, \]
\[ 2\kappa \epsilon_{abc} q R^{bc} - z_1 \left( 2 R^{ab} e^b + q S_a \right) = \tau_a, \]
\[ 2\kappa D(\epsilon_{abc} q e^c) + z_1 D(e_a e_b) - \frac{z_1}{2} q(e_a \theta_b - e_b \theta_a) = -\sigma_{ab}, \]
\[ z_1 (Q e^a - q K^a) = \sigma_a. \] (5.17)

From now on, we will refer to the theory described by the action (5.16) and field equations (5.17) as *Galilei-Cartan gravity* and we consider it for the rest of the paper. Torsionless configurations (5.13) and the curvatures
\[ R^{ab} = 0, \quad S^a = a q e^a, \] (5.18)
with $a$ being a squared mass parameter, are then solutions of the field equations (5.17) in vacuum. Moreover, it can be easily checked that this solution (expressions (5.13) and (5.18)) satisfies the Bianchi identities (3.18).

We still need to fix $\xi$ and $a$. This task can be achieved by looking at the non-relativistic limit of the maximally symmetric relativistic solution (2.11). Its decomposed version reads
\[ \left( R^{ab} - \frac{1}{4} \theta^a \theta^b \right) \Sigma_{ab} = -\Lambda e^a e^b \Sigma_{ab}, \]
\[ S^a_o J_a = 2\Lambda q e^a J_a. \] (5.19)
To obtain the non-relativistic limit of these relations we first perform the rescalings (3.7), (3.8), and (5.15) in (5.19),

\[
\left( R^{ab}_a - \frac{1}{4} \zeta^{-2} g^a g^b \right) \Sigma_{ab} = -\zeta^{-\xi} \Lambda e^a e^b \Sigma_{ab} ,
\]

\[
S_o^a G_a = 2 \zeta^{-\xi+2} \Lambda q e^a G_a .
\]  

(5.20)

If we demand that, at the limit \( \zeta \to \infty \), the solution (5.18) coincides with (5.20), we must set

\[
\xi = 2 , \quad a = 2 \Lambda .
\]  

(5.21)

This procedure fixes \( a \) by connecting the solutions (5.13) and (5.18) with the original relativistic vacuum solution (2.11) of the MZ action.

In summary, for the non-relativistic limit of the maximally symmetric solution (2.11) be a solution of the non-relativistic limit of the MZ action, the cosmological constant must scale according to \( \Lambda \to \zeta^{-2} \Lambda \) in the non-relativistic limit process; Thence, the non-relativistic limit of the MZ action is actually independent of \( \Lambda \); Nevertheless, \( \Lambda \) could still be probed in non-relativistic limits of gravitational systems through the solution (5.18); We remark that the configurations (5.18) are not solutions of the field equations (5.5) in vacuum. See also [43, 44] for discussions about the non-relativistic limit of de Sitter and anti-de Sitter spacetimes.

### 5.2 Newtonian absolute time

An important feature that a Newton-Cartan gravity theory must have is to accept twistless torsion condition. This means that Newtonian absolute time can be safely employed. To show that this property is well accepted by the full set of field equations (5.17), let us impose \( Q = 0 \) to them. This imposition has no direct effect on the first two equations of the field equations (5.17). On the fourth equation, however, implies on

\[
qK^a = -\frac{1}{z_1} \sigma^a .
\]  

(5.22)

For this equation to be true, \( K^a \) must have a part which is independent of \( q \). If not, then \( S_m \) must not depend on the boost connection. Applying \( Q = 0 \) and expression (5.22) on the third equation of the field equations (5.17), we get

\[
e_b \left( K_a - \frac{1}{2} q \theta_a \right) - e_a \left( K_b - \frac{1}{2} q \theta_b \right) = -\frac{1}{z_1} \sigma_{ab} - \frac{1}{z_1^2} 2 \kappa \epsilon_{abc} \sigma^c .
\]  

(5.23)

The first two equations of equations (5.17) together with equations (5.22) and (5.23) are the field equations for strong twistless torsion condition. In other words, the set of equations to be solved if one wishes to work within Newtonian absolute time.

### 5.3 Solutions in the presence of matter

To find solutions of equations (5.17) in the presence of matter we first constrain \( S_m \) to be of the form (4.39). Notice that, differently from the Galilean case, \( m_a \) can depend on \( e, \omega, \) and \( \theta \), but not on \( q \). This
form of $S_m$ is a bit restrictive, but sufficient for our initial purposes in probing the existence of consistent solutions in the presence of matter, at least at formal level. The field equations (5.17) reduce to

\begin{align}
2\kappa\epsilon_{abc}R^{ab}e^c - z_1e_aS^a &= 4\epsilon^am_a, \\
2\kappa\epsilon_{abc}qR^{bc} - z_1\left(2R_{ab}e^b + qS_a\right) &= 4qm_a - 4qe_b\frac{\delta m_b}{\delta e^a}, \\
2\kappa D(e_{abc}q^c) + z_1D(e_aeb) - \frac{z_1}{2}q(e_a\theta_b - e_b\theta_a) &= 4qe^c\frac{\delta m_c}{\delta \omega^{ab}}, \\
z_1(Qe_a - qK_a) &= -4qe^c\frac{\delta m_c}{\delta \theta^a}. 
\end{align}

Combination of the first and second equations of the system (5.25) gives

\begin{align}
R_{ab} &= -\frac{1}{z_1}q\left(\frac{\delta m_b}{\delta e^a} - \frac{\delta m_a}{\delta e^b}\right), \\
S_a &= aqe_a - \frac{4}{z_1}m_a - \frac{2}{z_1}\kappa\epsilon_a^e\frac{\delta m_e}{\delta e^c}, 
\end{align}

with $a$ being identified with the same $a = 2\Lambda$ of (5.18). Thus, the solution (5.26) reduces to the vacuum solution (5.18) as $m^a \to 0$ outside the matter distribution.

Third and fourth equations in the system (5.25) can be solved, for instance, by

\begin{align}
K_a &= \frac{1}{2}q\theta_a - \frac{2}{z_1}q\left(\frac{\delta m_b}{\delta \omega^{ab}} + 2\frac{\kappa}{z_1}\epsilon_{ab}e^e\frac{\delta m_e}{\delta \theta^c}\right), \\
Q &= \frac{4}{3z_1}q\frac{\delta m^a}{\delta \theta^a}. 
\end{align}

The immediate conclusion is that, for the proposed solution, Newtonian absolute time can only be defined in the presence of a matter distribution if the 1-form $\delta m^a/\delta \theta^b$ is traceless. Obviously, a matter content that does not depend on the boost connection also ensures the existence of Newtonian absolute time in the presence of matter. A third, yet improbable, possibility is that $\delta m^a/\delta \theta^a$ is parallel to $q$. We remark that this does not contradict the previous result that Newtonian absolute time can always be chosen. In fact, the result says that we can always set $Q = 0$ if $K$ carries a $q$-independent sector or if the matter distribution does not depend on the boost connection. In solution (5.27), the reduced torsion does not have a $q$-independent part. Moreover, torsions (5.27) reduce to (5.13) as $m^a \to 0$ outside the matter distribution.

It would be nice, however, to obtain a consistent geometry in the presence of matter within Newtonian absolute time. Nevertheless, the form of the matter action (4.39) prohibits such solution unless it does not depend on the boost connection. To show this impossibility, we maintain curvatures (5.26) and set $Q = 0$ to the field equations. Thence, equations (5.22) and (5.23) read now

\begin{align}
qK_a &= \frac{4}{z_1}qe_a\frac{\delta m_e}{\delta \omega^{ab}}, \\
e_b\left(K_a - \frac{1}{2}q\theta_a\right) - e_a\left(K_b - \frac{1}{2}q\theta_b\right) &= \frac{4}{z_1}q\left[\epsilon^e\frac{\delta m_e}{\delta \omega^{ab}} + 2\frac{\kappa}{z_1}\epsilon_{abe}e^e\frac{\delta m_b}{\delta \theta^a}\right]. 
\end{align}

\begin{align}
11\text{Clearly,} \\
\sigma_{ab} &= -4qe^e\frac{\delta m_e}{\delta \omega^{ab}}, \\
\sigma_a &= -4qe^e\frac{\delta m_e}{\delta \theta^a}. 
\end{align}
We found earlier that for a strong twistless torsion solution be acceptable either $S_m$ must not depend on the boost connection or $K^a$ must have a piece which is independent of $q$. The first of (5.28) suggests that this independent part could be

$$X_a = \frac{4}{z_1} e^c \delta_{m_c} \delta_{\theta^a}.$$

Hence, the solution for $K^a$ can be obtained by combining the first of (5.27) with (5.29),

$$K_a = \frac{1}{2} q \theta_a - \frac{2}{z_1} q \left( \frac{\delta m^b}{\delta \omega^{ab}} + \frac{2}{z_1} \kappa_{ab} \frac{\delta m^b}{\delta \theta^c} \right) + \frac{4}{z_1} e^c \delta_{m_c} \delta_{\theta^a}.$$

Substitution of this reduced torsion in the second of (5.28) results in the condition

$$q \left( e_b \frac{\delta m_c}{\delta \theta^a} - e_a \frac{\delta m_c}{\delta \theta^b} \right) = 0,$$

which suggests again that the only way to accommodate Newtonian absolute time in the presence of matter for a matter content in the form (4.39) is indeed to impose that $m_c$ does not depend on the boost connection. It is also possible to show that expression (5.31) is satisfied for $\delta m^a / \delta \theta^a = 0$.

6 Conclusions

In this work we have studied the non-relativistic limit of gravity theories in the first order formalism. Particularly, the Einstein-Hilbert and Mardones-Zanelli actions were considered [7, 8]. The differential form language was extensively employed. This formalism allowed us to formally obtain some interesting new results. We remark that our main strategy to solve the field equations was to look for solutions for the curvatures and torsions 2-forms. This strategy is very useful because the field equations are algebraic with respect to curvatures and torsions.

In the case of the EH action, the non-relativistic limit is widely known, see for instance [10, 15, 25]. Nevertheless, we were able to obtain some novel results which are listed below:

- Starting from the field equations (4.6) in vacuum, we have firstly obtained a solution constraining the space and time vierbeins, see (4.11). Even though this proposal solves the field equations (4.10), it is inconsistent with the degenerate Galilean metric nature;

- Next, in the strong twistless torsion context, characterized by equation (4.13), non-trivial space curvature $R$ and reduced torsion $K$ were found, see equations (4.9) and (4.15). In agreement with the known literature [15]. Of course, in all cases boost curvature $S^a$ is free, since the boost connection $\theta$ does not appear in the action;

- We have considered the possibility of non-trivial torsional solutions in vacuum by defining a 1-form field $n$ and the solutions (4.16) and (4.17). By setting $R = S = 0$, the field equations are satisfied and a kind of Newtonian Weitzenböck spacetime is obtained. In this context, by setting $n$ to be constant, an explicit solution was found for the time vierbein $q$ as displayed in expression (4.21). A non-Newtonian time was then derived as a function of the Newtonian absolute time, see (4.24). Asymptotically, the non-Newtonian and Newtonian time coincide. Nevertheless, the obtained solution still describes a strong twistless torsion situation since the time vierbein is parallel to $n$. In this example, by setting the spin connection to vanish, we were able to find a complete solution in terms of the explicit expressions of the vierbeins, see (4.29). Interestingly, the
corresponding spacetime metric tensors, displayed in expressions (4.31) and (4.32), are conformally flat. To trivialize these metrics while respecting the conformal symmetry (4.4), one needs to set Newtonian time by imposing $a = 0$. Otherwise one can only trivialize space or time metrics, but not both simultaneously;

- Finally, a solution in the presence of matter was developed under strong twistless torsion scenario. The accidental scale symmetry (4.4) allowed us to write down the matter action in the quite general form (4.39). Space curvature and reduced torsion were found to be directly given by the matter distribution, see (4.43) and (4.45). For vanishing reduced torsion one needs a matter content not depending on the spin connection. Moreover, a consistent choice constraining the space vierbein and boost connection was developed. The resulting boost curvature is given in (4.48) and (4.49) with $S \propto K$. In this solution for the boost curvature, the vanishing case is also contemplated.

The main novelty of the present work is the non-relativistic limit of the MZ action (2.8). At a first glance, the result is the action (5.4) containing a cosmological constant term. It was then argued that, for consistency, the cosmological constant must disappear at the non-relativistic limit at leading order. The actual non-relativistic limit of the MZ action is then the action (5.16). The resulting field equations are displayed in (5.17). The main results are listed below.

- We have found that the cosmological constant must scale as $\Lambda \rightarrow \zeta^{-2} \Lambda$ in the non-relativistic limit. Thence, the non-relativistic limit of the maximally symmetric solution (2.11) is solution of the non-relativistic equations (5.17) in vacuum. Although the cosmological constant does not appear in the action (5.16) nor in field equations (5.17), it is still present as a relic in the solution (5.18) where the mass parameter $a$ was fixed by linking the solution (5.18) with the non-relativistic of the maximally symmetric vacuum solution (2.11);

- It was shown that Newtonian absolute time is well accepted by the non-relativistic limit of MZ theory, i.e., by the Galilei-Cartan action (5.16) and its field equations (5.17). By imposing strong twistless torsion condition to the field equations we found that Newtonian absolute time can be implemented in vacuum if $qK = 0$ (see equation (5.22)). In the presence of matter, $K$ must have a part independent of $q$ (in this case space torsion will be non-trivial, $T \neq 0$) or the matter content must not depend on the boost connection (in this case, torsionless solution is allowed). The typical matter field actions are [45, 46]: Klein-Gordon scalar theory; Dirac spinorial theory; Maxwell theory; Yang-Mills theories; and all their super-symmetric extensions. At least in most of them, the boost connection decouples at leading order [10, 44] and $\sigma^a = 0$ would be a safe choice;

- Finally, we have considered a generic external matter distribution of the form (4.39) in the context of GC gravity. In such situation $m_a$ may depend on all fields, except $q$. We have found the curvatures (5.26) and torsions (5.27). These configurations reduce to the vacuum solutions (5.18) and (5.13) in the limit $m_a \rightarrow 0$. Particularly, the second of (5.27) says that, for the matter content of the form (4.39), Newtonian absolute time can be employed in the presence of matter only if at least one of the following conditions is satisfied: $m_c$ do not depend on the boost connection; the 1-form $\delta m^a / \delta \theta^b$ is parallel to $q$; the 1-form $\delta m^a / \delta \theta^b = 0$ is traceless.

Although many physical insights were obtained from our formal analysis, it remains to apply the results to actual physical systems. These tests could provide some interesting bounds for some parameters of the MZ action, specifically $z_1$. Moreover, new effects could emerge from these generalized gravity theory which could be tested in the non-relativistic context. Another point to be explored is the fact that MZ theorem holds for any spacetime dimension. So, generalization of the present results in other dimensions
could be developed in the future. Furthermore, one could consider the usual extensions of the Galilei group, such as Bargmann and Schrödinger groups, in order to construct more general theories [25]. As mentioned in the Introduction, these theories could be relevant in Hořava-Lifshitz [13] and string [30,31] contexts.
