ON THE $S_n/n$ PROBLEM

SÖREN CHRISTENSEN,* ∗ ∗ AND
SIMON FISCHER,* ∗ ∗ ∗ Christian-Albrechts-Universität zu Kiel

Abstract

The Chow–Robbins game is a classical, still partly unsolved, stopping problem introduced by Chow and Robbins in 1965. You repeatedly toss a fair coin. After each toss, you decide whether you take the fraction of heads up to now as a payoff, otherwise you continue. As a more general stopping problem this reads $V(n, x) = \sup_{\tau} E\left[\frac{x + S_\tau n}{n + \tau}\right]$, where $S$ is a random walk. We give a tight upper bound for $V$ when $S$ has sub-Gaussian increments by using the analogous time-continuous problem with a standard Brownian motion as the driving process. For the Chow–Robbins game we also give a tight lower bound and use these to calculate, on the integers, the complete continuation and the stopping set of the problem for $n \leq 489 \, 241$.

Keywords: Brownian motion; Chow–Robbins game; optimal stopping; upper bound; lower bound

2020 Mathematics Subject Classification: Primary 60G40
Secondary 60G50

1. Introduction

We repeatedly toss a fair coin. After each toss we can take the proportion of heads up to now as our reward, or continue. This is known as the Chow–Robbins game, first presented in 1965 [1]. As a stopping problem this can be formulated as

$$V^S(t, x) = \sup_{\tau} E\left[\frac{x + S_\tau}{t + \tau}\right],$$

where $S$ is a random walk. In the classical version $S$ has symmetric Bernoulli increments but it is possible to take different random walks as well. Chow and Robbins showed that an optimal stopping time exists in the Bernoulli case, and later [3] proved this for general centered independent and identically distributed (i.i.d.) increments with finite variance. But it was (and to some extent still is) difficult to see how that solution looks. Asymptotic results were given in [9], which showed that the boundary of the continuation set $\partial C$ can be written as a function $b: \mathbb{R}^+ \to \mathbb{R}$ with $\lim_{t \to \infty} \frac{b(t)}{\alpha \sqrt{t}} = 1$. Here, $\alpha \sqrt{t}$ is the boundary of the analogous stopping problem for a standard Brownian motion $W$ (see Lemma 1),

$$V^W(t, x) = \sup_{\tau} E\left[\frac{x + W_\tau}{t + \tau}\right].$$

In 2007, [6] gave a second-order approximation for the limit of \( b \), \( \lim_{t \to \infty} (\alpha \sqrt{t} - b(t)) = \frac{1}{2} \). Some approximation for values of \( b \) were also calculated by using the value function (2) [5], without constructing it as an upper bound; also given were some calculations for a random walk with standard normal increments.

A more rigorous computer analysis was given in [4]. Using backward induction from a time horizon \( T = 10^7 \), lower and upper bounds for \( V^S \) were calculated. For points reachable from \((0, 0)\), it was calculated whether they belong to the stopping or to the continuation set for all but seven points \((n, x)\) with \( n \leq 1000 \).

In this paper we give much sharper upper and lower bounds for \( V^S \). Using backward induction with these bounds, we are able to calculate all stopping and continuation points \((n, x) \in \mathbb{N} \times \mathbb{Z} \) with \( n \leq 10^5 \). We show that all seven points \((n, x) \in n \leq 1000 \) that were left open in [4] belong to the stopping set. In Section 2 we construct an upper bound for the value function (1) for random walks with sub-Gaussian increments. The main observation is that the value function (2) is an upper bound for \( V^S \). This is carried out in Section 2.1 on the Chow–Robbins game. In Section 2.2 we discuss how this kind of upper bound can be constructed for more general gain functions \( g \) and \( V^S(t, x) = \sup_x \mathbb{E} [g(t + \tau, x + S_\tau)] \). In Section 3 we construct a lower bound for \( V^S(T, x) \) in the Bernoulli case for a given time horizon \( T \). We show that there exist \( 0 < c < 1 \) and \( K > 0 \) such that \( K \int_0^\infty \exp \left[ a x - \frac{a^2}{2} T \right] da \leq V^S(T, x) \) for all \( x \leq b(T) \). We then show that the relative error of the bounds is of order \( O \left( \frac{1}{T} \right) \) for \( x \geq 0 \). In Section 5 we give computational results for the Chow–Robbins game in the Bernoulli case and give a detailed description of our methods. We calculate all integer-valued points in the stopping and continuation sets for \( n \leq 10^5 \), and give some examples of how \( V^S(t, x) \) and \( b(t) \) look for continuous \( t \) close to zero.

1.1. Notation

We introduce some notation that we will use. \( V \) denotes a value function, \( D = \{ V = g \} = \{ (t, x) \mid V(t, x) = g(t, x) \} \) the corresponding stopping set, and \( C = \{ V > g \} \) the continuation set. With \((t, x)\) we denote real variables, with \( n \) positive integers. With a superscript we denote which driving process is used, e.g. \( \hat{C} = \{ V^\hat{S} = g \}, C = \{ V^W = g \} \), etc. \( V_u \) and \( V_l \) denote upper and lower bounds respectively.

2. An upper bound for the value function \( V^S \)

We construct an upper bound for the value function \( V^S \) of the \( \frac{S_n}{n} \) problem, where \( S \) can be any random walk with sub-Gaussian increments. The classical Chow–Robbins game is a special case of these stopping problems.

**Definition 1. (Sub-Gaussian random variable)** Let \( \sigma^2 > 0 \). A real, centered random variable \( \xi \) is called \( \sigma^2 \)-sub-Gaussian (or sub-Gaussian with parameter \( \sigma^2 \)) if \( \mathbb{E}[e^{a \xi}] \leq \exp \left( \frac{\sigma^2 a^2}{2} \right) \) for all \( a \in \mathbb{R} \).

Some examples of sub-Gaussian random variables are:

- \( X \) with \( P(X_i = -1) = P(X_i = 1) = \frac{1}{2} \) is \( 1 \)-sub-Gaussian.
- The normal distribution \( \mathcal{N}(0, \sigma^2) \) is \( \sigma^2 \)-sub-Gaussian.
- The uniform distribution on \([-a, a]\) is \( a^2 \)-sub-Gaussian.
- Any random variable \( Y \) with values in a compact interval \([a, b]\) is \( \frac{1}{4}(b - a)^2 \)-sub-Gaussian.
In the following we show that the value function $V^W$ of the continuous-time problem (2) is an upper bound for the value function $V^S$ whenever $S$ is a random walk with 1-sub-Gaussian increments. We first state the solution of (2).

Let

$$h(t, x) := (1 - \alpha^2) \int_0^\infty \exp \left[ ax - \frac{a^2}{2} t \right] da = (1 - \alpha^2) \frac{1}{t} \Phi_t(x),$$

where $\Phi_t(x) = \Phi(x/\sqrt{t})$ denotes the cumulative distribution function of a centered normal distribution with variance $\sigma^2 = t$, $\varphi_t$ is the corresponding density function, and $\alpha \approx 0.839\,923\,675\,692\,373$ is the unique solution to $\alpha \varphi(\alpha) = (1 - \alpha^2) \Phi(\alpha)$.

**Lemma 1.** The stopping problem (2) is solved by $\tau_s = \inf\{ t \mid x + W_t \geq \alpha \sqrt{s + t} \}$ with value function

$$V^W(t, x) = \begin{cases} h(t, x) & \text{if } x \leq \alpha \sqrt{t}, \\ \frac{x}{t} & \text{otherwise}. \end{cases}$$

$V^W(t, x)$ is differentiable (smooth fit), and $h(t, x) \geq g(t, x) = \frac{x}{t}$ for all $t > 0$ and $x \in \mathbb{R}$.

This result was proved independently in [9, 10].

We now prove that $V^W$ is an upper bound for $V^S$. We know from general theory that $V^S$ is the smallest superharmonic function dominating the gain function $g$ (see, e.g., [8]). If we find a superharmonic function dominating $g$ we have an upper bound for $V^S$.

**Lemma 2.** Let $X_i$ be i.i.d. 1-sub-Gaussian random variables, and $S_n = \sum_{i=1}^n X_i$. The function $h: \mathbb{R}^+ \times \mathbb{R}^+ \rightarrow \mathbb{R}^+$ such that $(t, x) \mapsto (1 - \alpha^2) \int_0^\infty \exp \left[ ax - \frac{a^2}{2} t \right] da$ is $S$-superharmonic.

**Proof.** We first show the claim for fixed $a \in \mathbb{R}$ and $f(t, x) = e^{ax - \frac{a^2}{2} t}$. We need to show that $\mathbb{E}[f(t + 1, x + X_1)] \leq f(t, x)$ for all $t > 0$ and $x \in \mathbb{R}$, and calculate

$$\mathbb{E} \left[ \exp \left\{ a(x + X_1) - \frac{a^2}{2} (t + 1) \right\} \right] \leq \exp \left\{ ax - \frac{a^2}{2} t \right\}$$

$$\iff \exp \left\{ ax - \frac{a^2}{2} (t + 1) \right\} \mathbb{E}[e^{aX_1}] \leq \exp \left\{ ax - \frac{a^2}{2} t \right\}$$

$$\iff e^{-\frac{a^2}{2}} \mathbb{E}[e^{aX_1}] \leq 1$$

$$\iff \mathbb{E}[e^{aX_1}] \leq e^{\frac{a^2}{2}}. \quad (3)$$

The last inequality (3) is just the defining property of a 1-sub-Gaussian random variable. By integration over $a$ and multiplication by $1 - \alpha$, the result follows. \hfill \Box

**Theorem 1.** (An upper bound for $V^S$) Let $W$ be a standard Brownian motion, $S$ a random walk with 1-sub-Gaussian increments, and

$$V^S(t, x) = \sup_{\tau} \mathbb{E} \left[ \frac{x + S_{\tau}}{t + \tau} \right], \quad V^W(t, x) = \sup_{\tau} \mathbb{E} \left[ \frac{x + W_{\tau}}{t + \tau} \right].$$

Then $V^W(t, x) \geq V^S(t, x)$ for all $t > 0$, $x \in \mathbb{R}$. 
Proof. Let $h(t, x) = (1 - \alpha^2) \int_0^\infty \exp \left[ ax - \frac{a^2}{2} t \right] da$ as in Lemma 1. We know that $h \geq g$ (Lemma 1), $h$ is $S$-superharmonic (Lemma 2), and $V^w = h_1 c^w + g_1 d^w$. $V^S$ is the smallest superharmonic function dominating $g$, therefore $V^S \leq h$. We know from Lemma 1 that $V^w(t, \sqrt{t}) = h(t, \sqrt{t}) = g(t, \sqrt{t})$, and therefore $g(t, \sqrt{t}) \geq V^S(t, \sqrt{t}) \leq h(t, \sqrt{t}) = g(t, \sqrt{t})$. Hence, $V^S(t, \sqrt{t}) = g(t, \sqrt{t})$ and $(t, \sqrt{t}) \in D^S$. The boundary $\partial C^S$ is the graph of a function, therefore $(t, x) \in D^S$ for all $x \geq \sqrt{t}$. It follows that $C^S \subset C^w$ and that $V^S(t, x) \leq V^w(t, x)$ for all $t > 0$, $x \in \mathbb{R}$.

\textbf{Corollary 1.} From the proof, we see that $C^S \subset C^w$, and $b(t) \leq \alpha \sqrt{t}$ for all $t > 0$.

\textbf{2.1. The Chow–Robbins game}

Let $X_1, X_2, \ldots$ be i.i.d. random variables with $P(X_i = -1) = P(X_i = 1) = \frac{1}{2}$ and $S_n = \sum_{i=1}^n X_i$. The classical Chow–Robbins problem is given by

$$V^S(t, x) = \sup_{\tau} \mathbb{E} \left[ \frac{x + S_\tau}{t + \tau} \right].$$

The $X_i$ are 1-sub-Gaussian with variance 1. An almost surely (a.s.) finite stopping time $\tau_*$ exists that solves (4) (see [3]). By Theorem 1 we get that $V^S(t, x) \leq V^w(t, x) = h(x, t) 1_{\{x \leq \sqrt{t}\}} + \frac{1}{\sqrt{t}} 1_{\{x > \sqrt{t}\}}$. We will see later that this upper bound is very tight. We will construct a lower bound for $V^S$ in the next section and give a rigorous computer analysis of the problem in Section 5.

\textbf{Example 1.} For some time it was unclear whether it is optimal to stop in $(8, 2)$ or not. It was first shown in [7] and later confirmed in [4] that $(8, 2) \in D^S$ (in [4] this is written as 5–3, 5 heads–3 tails). We show here how to immediately prove this with our upper bound. We choose the time horizon $T = 9$, set $V^S_u(T, x) = V^w(T, x)$, and calculate with one-step backward induction $V^S_u(8, 2)$ as an upper bound for $V^S(8, 2)$: $V^S(9, 3) = \frac{3}{9} = \frac{1}{3}$ (since $3 > \alpha \sqrt{9}$), $V^S_u(9, 1) = h(9, 1) \approx 0.1642$, and we get

$$V^S(8, 2) \leq V^S_u(8, 2) = \max \left\{ \frac{2}{8}, \frac{V^S_u(9, 3) + V^S_u(9, 1)}{2} \right\},$$

$$\frac{V^S_u(9, 3) + V^S_u(9, 1)}{2} = \frac{1}{6} + \frac{0.1642}{2} = 0.2488 < \frac{2}{8}.$$

Hence, we have $V^S(8, 2) \leq g(8, 2) = \frac{2}{5}$, and it follows that $(8, 2)$ is in the stopping set. For a detailed description of the method see Section 5.

\textbf{2.2. Generalizations}

In the proof of Theorem 1 we did not use the specific form of the gain function $g(t, x) = \frac{x}{\sqrt{t}}$. All we needed was that:

- The value function of the stopping problem

$$V^w(t, x) = \sup_{\tau} \mathbb{E} \left[ g(t + \tau, x + W_\tau) \right]$$

is on $C$ of the form $V^w \vert_{c}(t, x) = \int_{\mathbb{R}} \exp \left[ ax - \frac{a^2}{2} t \right] d\mu(a)$ for a measure $\mu$. 

The function \( h(t, x) = \int_\mathbb{R} \exp \left[ ax - \frac{1}{2} d^2 t \right] d\mu(a) \) dominates \( g \) on \( \mathbb{R}^+ \times \mathbb{R} \).

The boundary of the continuation set \( \partial C^S \) of the stopping problem \( V^S(t, x) = \sup_{\tau} \mathbb{E} \left[ g(t + \tau, x + S_\tau) \right] \) is the graph of a function \( b: \mathbb{R}^+ \to \mathbb{R} \). (This requirement can easily be relaxed to the symmetric case, where \( \partial C^S = \text{Graph}(b) \cup \text{Graph}(-b) \).)

These requirements are not very restrictive, and there are many other gain functions and associated stopping problems for which this kind of upper bound can be constructed. A set of examples which fulfill these requirements and for which (5) is explicitly solvable can be found in [8]. Some of these are:

\[
\begin{align*}
g(t, x) &= \frac{x^{2d-1}}{t^q} \quad \text{with } d \in \mathbb{N} \text{ and } q > d - \frac{1}{2}, \\
g(t, x) &= |x| - \beta \sqrt{t} \quad \text{for some } \beta \geq 0, \\
g(t, x) &= \frac{|x|}{t}.
\end{align*}
\]

### 3. A lower bound for \( V^S \)

In this section we want to give a lower bound for the value function of the Chow–Robbins game (4). Here, \( S \) will always be a symmetric Bernoulli random walk. The basis of our construction is the following lemma.

**Lemma 3.** (A lower bound for \( V \)) Let \( X \) be a random walk, \( g \) a gain function, \( V(t, x) = \sup_{\tau} \mathbb{E}[g(\tau + t, X_\tau + x)] \), and \( h: \mathbb{R}^+ \times \mathbb{R} \to \mathbb{R} \) measurable. For a given point \((t_0, x_0)\) let \( \tau \) be a stopping time such that the stopped process \((h(t + \tau + t_0, X_\tau + x_0))_{\tau \geq 0}\) is a submartingale and \( h(\tau + t_0, X_\tau + x_0) \leq g(\tau + t_0, X_\tau + x_0) \) a.s. Then \( h(t_0, x_0) \leq V(t_0, x_0) \).

**Proof.** Since \( h(\tau, X_\tau) \leq g(\tau, X_\tau) \) we can use the optional sampling theorem and obtain \( h(t_0, x_0) \leq \mathbb{E}[h(\tau + t_0, X_\tau + x_0)] \leq \mathbb{E}[g(\tau + t_0, X_\tau + x_0)] \leq V(t_0, x_0) \). \( \square \)

We modify the function \( h(t, x) = (1 - a^2) \int_0^\infty \exp \left[ ax - \frac{a^2 t}{2} \right] da \) from Lemma 1 slightly to

\[
h_c(t, x) := K \int_0^\infty \exp \left[ ax - \frac{c a^2 t}{2} \right] da
\]
for some \( 0 < c < 1 \) and \( K > 0 \) to match the assumptions of Lemma 3. As a stopping time we choose \( \tau_0 = \inf \{ n \geq 0 \mid x + S_n \geq \alpha \sqrt{t + n - 1} \} \). Unfortunately there is no \( c \) such that (6) is globally \( S \)-subharmonic, and hence we have to choose \( c \) depending on the time horizon \( T \). This makes the following result a bit technical.

**Theorem 2.** (A lower bound for \( V^S \)) Let

\[
h_c(t, x) := K \int_0^\infty \exp \left[ ax - \frac{c a^2 t}{2} \right] da = K \frac{1}{ct} \Phi_c(x), \quad K = \alpha \frac{\phi_c(\alpha)}{\Phi_c(\alpha)}.
\]

Given a time horizon \( T > 0 \), let \( c_1 \) be the biggest solution smaller than 1 to \( \frac{1}{2} (h_c(T + 1, \alpha \sqrt{T} - 1) + h_c(T + 1, \alpha \sqrt{T} + 1)) = h_c(T, \alpha \sqrt{T}) \), \( c_2 \) the unique positive solution of

\[
h_c(T, \alpha \sqrt{T} - 1) = \frac{\alpha \sqrt{T} - 1}{T},
\]

\( n = \int_0^\infty \exp \left[ ax - \frac{a^2 t}{2} \right] da \)
and \( c = \min\{c_1, c_2\} \). Let \( a_0 \) be the unique positive solution (in \( a \)) to 
\[
\frac{1}{2} \left( e^a + e^{-a} \right) e^{-\frac{c^2 a^2}{2}} = 1.
\]
If 
\[
T \geq \left( \frac{\alpha}{a_0 c} \right)^2,
\]
then \( h_c(t, x) \) is a lower bound for \( V^S(t, x) \) for all \( t \geq T \) and \( x \leq \alpha \sqrt{T} \).

**Remark 1.** Our numerical evaluations suggest that for \( T \geq 4 \) (8) is always satisfied, and for \( T \geq 200 \) we always have \( c = c_1 \).

**Proof.** We divide the proof into three parts. First, we show that the stopped process \( h_c(t \land \tau_0, x + S_{t \land m}) \) is a submartingale; second, we calculate \( K \); and third, we show that \( h(\tau_0, x + S_0) \leq g(\tau_0, x + S_0) \) \( P_{T, x} \) a.s. and use Lemma 3 to prove the statement. An illustration of the setting is given in Figure 1.

First, we have to show that \( \frac{1}{2} (h_c(t + 1, x - 1) + h_c(t + 1, x + 1)) \geq h_c(t, x) \) for every \( t \geq T \) and \( x \leq \alpha \sqrt{T} - 1 \); we will even show that it applies for all \( x \leq \alpha \sqrt{T} \). The constant \( K \) has no influence on this inequality, so we set it to 1 for now. We have

\[
f_c(t, x) := \frac{1}{2} (h_c(t + 1, x - 1) + h_c(t + 1, x + 1)) - h_c(t, x)
\]
\[
= \int_0^\infty \frac{1}{2} \exp \left[ a(x - 1) - \frac{c}{2} a^2 (t + 1) \right] da + \int_0^\infty \frac{1}{2} \exp \left[ a(x + 1) - \frac{c}{2} a^2 (t + 1) \right] da
\]
\[
- \int_0^\infty \exp \left[ ax - \frac{c}{2} a^2 t \right] da
\]
\[
= \int_0^\infty \exp \left[ ax - \frac{c}{2} a^2 t \right] \left[ \frac{1}{2} (e^a + e^{-a}) e^{-\frac{c^2 a^2}{2}} - 1 \right] da.
\]

(9)
The function \( \lambda(a) := \frac{1}{2}(e^{a} + e^{-a})e^{-\frac{a^{2}}{2}} - 1 \) has a unique positive root \( a_{0} \); for \( a \in [0, a_{0}] \) we have \( \lambda(a) \geq 0 \), and for \( a \geq a_{0}, \lambda(a) \leq 0 \). Suppose, for given \((t, x)\), we have \( f_{c}(t, x) \geq 0 \). Let \( \delta \geq 0, \varepsilon \in \mathbb{R} \); we have

\[
f_{c}(t + \delta, x + \varepsilon) = \int_{0}^{a_{0}} \exp \left[ ax - \frac{c}{2} a^{2} t \right] \lambda(a) \exp \left[ \varepsilon a - \delta \frac{c}{2} a^{2} \right] da \\
+ \int_{a_{0}}^{\infty} \exp \left[ ax - \frac{c}{2} a^{2} t \right] \lambda(a) \exp \left[ \varepsilon a - \delta \frac{c}{2} a^{2} \right] da \\
\geq \int_{0}^{a_{0}} \exp \left[ ax - \frac{c}{2} a^{2} t \right] \lambda(a) \exp \left[ \varepsilon a_{0} - \delta \frac{c}{2} a_{0}^{2} \right] da \\
+ \int_{a_{0}}^{\infty} \exp \left[ ax - \frac{c}{2} a^{2} t \right] \lambda(a) \exp \left[ \varepsilon a_{0} - \delta \frac{c}{2} a_{0}^{2} \right] da \\
= \exp \left[ \varepsilon a_{0} - \delta \frac{c}{2} a_{0}^{2} \right] f_{c}(t, x) \geq 0.
\]

Here, \((*)\) is true if \( \varepsilon a - \delta \frac{c}{2} a^{2} \geq \varepsilon a_{0} - \delta \frac{c}{2} a_{0}^{2} \) for \( a \leq a_{0} \) and \( \varepsilon a - \delta \frac{c}{2} a^{2} \leq \varepsilon a_{0} - \delta \frac{c}{2} a_{0}^{2} \) for \( a \geq a_{0} \), which is the case if

\[
\varepsilon \leq a_{0} \delta \frac{c}{2}.
\]

By assumption, we have \( f_{c}(T, \alpha \sqrt{T}) \geq 0 \). (If \( c = c_{1} \) as in all our computational examples, this is clear. If \( c = c_{2} < c_{1} \), inspection of \( f_{c} \) in (9) shows that \( f_{c} > f_{c_{1}} \).) The function \( \alpha \sqrt{t} \) is concave and

\[
\frac{\partial}{\partial t} \alpha \sqrt{t} = \frac{\alpha}{2 \sqrt{t}},
\]

so for \( t \geq T \) and \( x \leq \alpha \sqrt{t} \) with \((t, x) = (T + \delta, \alpha \sqrt{T} + \varepsilon)\) we have

\[
\varepsilon \leq \delta \frac{\alpha}{2 \sqrt{T}}.
\]

Putting this into (10) we get the condition

\[
\delta \frac{\alpha}{\sqrt{T}} \leq a_{0} \delta c, \text{ i.e. } T \geq \left( \frac{\alpha}{a_{0} c} \right)^{2},
\]

which is true by assumption. That concludes the first part of the proof.

Second, we want to choose \( K \) such that \( h_{c}(t, \alpha \sqrt{t}) = g(t, \alpha \sqrt{t}) = \frac{\alpha}{\sqrt{t}} \). We first show that this is possible, and then calculate \( K \). We have

\[
h_{c}(t, x) = K \int_{0}^{\infty} \exp \left[ ax - \frac{c}{2} a^{2} t \right] da = K \frac{1}{c t} \Phi_{ct}(x),
\]

\[
h_{c}(t, \alpha \sqrt{t}) = K \frac{1}{c t} \Phi_{c \sqrt{ct}}(\alpha \sqrt{t}) = K \frac{1}{c \sqrt{t}} \Phi_{c}(\alpha),
\]

which depends only on \( \frac{1}{\sqrt{t}} \). Solving \( h_{c}(t, \alpha \sqrt{t}) = \frac{\alpha}{\sqrt{t}} \) we get

\[
K = \alpha c \frac{\Phi_{c}(\alpha)}{\Phi_{c}(\alpha)}.
\]
Third, we chose \( \tau_0 = \inf \{ n \geq 0 \mid x + S_n \geq \alpha \sqrt{t + n} - 1 \} \) and need to show that 
\[ h_c(\tau_0, S_{\tau_0}) \leq g(\tau_0, S_{\tau_0}). \]
It is clear that \( S_{\tau_0} \in [\alpha \sqrt{\tau_0} - 1, \alpha \sqrt{\tau_0}] \). By the construction of \( K \) in the second part, we know that \( h_c(\tau, \alpha \sqrt{\tau}) = g(\tau, \alpha \sqrt{\tau}) \). Since \( h_c \) has strictly positive curvature, we know that \( h_c(\cdot, \cdot \sqrt{\tau}) \) has exactly one more intersection with \( g(\cdot, \cdot \sqrt{\tau}) \), which we denote by \( \alpha \sqrt{\tau} - d(\cdot) \).

We will see that \( d(\tau) \geq 1 \) for \( \tau \geq T \) and hence \( h_c(\tau, x) \leq g(\tau, x) \) for \( x \in [\alpha \sqrt{\tau} - d(\tau), \alpha \sqrt{\tau}] \).

We saw in the second part that \( \sqrt{\tau} \cdot h_c(\tau, \alpha \sqrt{\tau}) \) is constant for any \( \beta > 0 \). If, for some \( x_0 \), 
\[ h_c(T, x_0) \leq g(T, x_0) = \frac{x_0}{\sqrt{T}}, \]
we set \( \beta := \frac{x_0}{\sqrt{T}} \) and see that, for all \( \tau > T \),

\[ h_c(\tau, \frac{x_0}{\sqrt{T}} \sqrt{\tau}) \leq g(\tau, \frac{x_0}{\sqrt{T}} \sqrt{\tau}) = \frac{1}{\sqrt{T}} \frac{x_0^2}{\sqrt{T}}. \]

If \( x_0 \leq \alpha \sqrt{T} - 1 \), then \( \frac{x_0}{\sqrt{T}} \sqrt{\tau} \leq \alpha \sqrt{\tau} - 1 \). If \( d(\tau) \geq 1 \) then we set \( x_0 := \alpha \sqrt{T} - d(\tau) \). We can now conclude that for \( \tau \geq T \) we have \( d(\tau) \geq 1 \), hence it is enough to show that \( d(\tau) \geq 1 \). For \( c = c_2 \) this is true by assumption. In general \( c \leq c_2 \), and we have \( \frac{\partial}{\partial x} h_c(\tau, x) \leq \frac{\partial}{\partial x} h_{c_2}(\tau, x) \). Since \( h_{c_2}(T, \alpha \sqrt{T}) = h_{c_2}(T, \alpha \sqrt{T}) \) we have

\[ h_c(T, \alpha \sqrt{T} - 1) \leq h_{c_2}(T, \alpha \sqrt{T} - 1) = \frac{\alpha \sqrt{T} - 1}{T} \]

and the statement follows. Now \( h_c \) and \( \tau_0 \) fulfill the conditions of Lemma 3. This completes the proof. \( \square \)

**Remark 2.** The only properties of \( S \) we used in the proof are that \( S \) has limited jump sizes upwards and that \( m_S(a) = \mathbb{E}[e^{aS_1}] \) has only one positive intersection with \( e^{\frac{1}{2}a^2} \) (i.e. \( \frac{1}{2}(e^a + e^{-a})e^{-\frac{1}{2}a^2} - 1 \) has only one positive root). This kind of lower bound can be constructed for any random walk with increments that fulfill these two conditions. This would of course result in different values for \( c \).

Some values for \( c \) are given in Table 1.

### 4. Error of the bounds

We want to show that the relative error of the constructed bounds is of order \( O\left( \frac{1}{T} \right) \) for \( x \geq 0 \). First, we show that \( c = c(T) \geq \frac{T - 1}{T} \) for \( T \) large enough. Indeed, for \( c_1 \), evaluating (9) for \( c = \frac{T}{T + 1} \) yields

\[ f_{\frac{T}{T + 1}}(T, x) = \int_0^\infty \exp \left[ ax - \frac{1}{2}a^2 T \right] \left[ \frac{1}{2} (e^a + e^{-a}) - e^{\frac{1}{2}a^2} \right] da, \]
which can be seen to be positive for $T$ large enough, yielding $c_1 \geq \frac{T}{T+1} \geq T^{-1}$. We evaluate (7) for $c = \frac{T-1}{T}$ and get, with elementary estimates,

$$h_{T-1}(T, \alpha \sqrt{T} - 1) = \frac{K}{\sqrt{T} - 1} \frac{\Phi\left(\frac{\alpha \sqrt{T} - 1}{\sqrt{T}}\right)}{\varphi\left(\frac{\alpha \sqrt{T} - 1}{\sqrt{T}}\right)}$$

$$\leq \frac{K}{\sqrt{T} - 1} \left( \frac{\Phi\left(\frac{\alpha \sqrt{T}}{\sqrt{T}}\right) - \frac{1}{\sqrt{T-1}} \varphi\left(\frac{\alpha \sqrt{T}}{\sqrt{T}}\right)}{\varphi\left(\frac{\alpha \sqrt{T} - 1/2}{\sqrt{T}}\right)} \right)$$

$$= \exp\left[ -\frac{\alpha \sqrt{T} - 1}{T-1} \right] \left( \frac{\alpha}{\sqrt{T}} - \frac{K}{T-1} \right) = \frac{c}{\sqrt{T} - 1} \leq \frac{\alpha \sqrt{T} - 1}{T}$$

for $T$ large enough, so that $c_2 \geq \frac{T-1}{T}$. We obtain $c = \min\{c_1, c_2\} \geq \frac{T-1}{T}$. We now calculate the asymptotic relative error between $V_0$ and $V_1$ in $x = 0$:

$$\frac{V_u(T, 0)}{V_l(T, 0)} - 1 = \frac{h(T, 0)}{h_c(T, 0)} - 1 = \frac{1 - \alpha^2}{K} \varphi\left(\frac{1}{\sqrt{T}}\right) - 1 = \frac{1 - \alpha^2 \Phi\left(\frac{\alpha}{\sqrt{T}}\right)}{\varphi\left(\frac{\alpha}{\sqrt{T}}\right)} - 1.$$

We use the approximation

$$\frac{\Phi\left(\frac{\alpha}{\sqrt{T}}\right)}{\varphi\left(\frac{\alpha}{\sqrt{T}}\right)} \approx \exp\left[ -\frac{\alpha^2(c - 1)}{2c} \right] \left( \Phi(\alpha) + \frac{\alpha(1 - \sqrt{c})}{\sqrt{c}} \right)$$

$$= \exp\left[ -\frac{\alpha^2(c - 1)}{2c} \right] \left( \frac{\alpha}{1 - \alpha^2} + \frac{\alpha(1 - \sqrt{c})}{\sqrt{c}} \right)$$

and get, with $c = \frac{T-1}{T}$,

$$\frac{h(T, 0)}{h_c(T, 0)} - 1 \approx \exp\left[ -\frac{\alpha^2(c - 1)}{2c} \right] \left( 1 + \frac{\alpha(1 - \sqrt{c})}{\sqrt{c}} \right) - 1$$

$$= \exp\left[ -\frac{\alpha^2}{2T-2} \right] \left( 1 + \alpha \left( \sqrt{\frac{T-1}{T}} - 1 \right) \right) - 1 = O\left(\frac{1}{T}\right).$$

It is now straightforward to check that, for $\alpha \sqrt{T} \geq x \geq 0$,

$$\frac{h(T, 0)}{h_c(T, 0)} - 1 \geq \frac{h(T, x)}{h_c(T, x)} - 1.$$

This yields

$$\frac{V(T, x)}{V_l(T, x)} - 1 = O\left(\frac{1}{T}\right), \quad \frac{V(T, x)}{V_u(T, x)} - 1 = O\left(\frac{1}{T}\right),$$

for all $\alpha \sqrt{T} \geq x \geq 0$.

_[On the $\frac{S_n}{\sqrt{n}}$ problem]_
5. Computational results

In this section we show how to compute the continuation and stopping set for the Chow–Robbins game. In 2013, Häggström and Wästlund [4] computed stopping and continuation points starting from (0, 0). They used another unsymmetric notation for the problem. We give their bounds transformed into our setting. They chose a, rather large, time horizon of \( T = 10^7 \), and set \( V_1^S(T, x) = \max \left\{ \frac{x}{T}, 0 \right\} \) as a lower bound and

\[
V_u^S(T, x) = \max \left\{ \frac{x}{T}, 0 \right\} + \min \left\{ \frac{\pi}{\sqrt{T}}, \frac{1}{|x|} \right\}
\]

as an upper bound. Then they used backward induction to calculate \( V_i^S(n, x) \) for \( n < T \) and \( i \in \{u, l\} \) with \( V_i^S(n, x) = \max \left\{ \frac{x}{n}, \mathbb{E}[V_i^S(n + 1, x + X_i)] \right\} \). If \( V_u(n, x) = \frac{x}{n} \) then \((n, x) \in D\); if \( V_l(n, x) > \frac{x}{n} \) then \((n, x) \in C\). In this way they were able to decide for all but seven points \((n, x) \in \mathbb{N} \times \mathbb{Z}\) with \( n \leq 1000 \) whether they belong to \( C \) or \( D \).

We use backward induction from a finite time horizon as well, but use the much sharper bounds given in Sections 2 and 3. For our upper bound this has a nice intuition. We play the Chow–Robbins game up to the time horizon \( T \), then we change the game to the favorable \( \frac{W_T}{n} \) game, which slightly rises our expectation.

With a time horizon of \( T = 10^6 \) we are able to calculate all the stopping and continuation points \((n, x) \in \mathbb{N} \times \mathbb{Z}\) with \( n \leq 489241 \). We show that all open points in [4] belong to \( D \).

Unlike [4] we use the symmetric notation. Let \( X_i \) be i.i.d. random variables with \( P(X_i = -1) = P(X_i = 1) = \frac{1}{2} \) and \( S_n = \sum_{i=1}^{n} X_i \). We choose a time horizon \( T \) and use \( V_W^S \) given in Lemma 1 as an upper bound, \( V_u^S(T, x) = V_W^S(T, x) \), and \( h_c \) given in Theorem 2 as a lower bound, \( V_l^S(T, x) = h_c(T, x) \), for \( x \in \mathbb{Z} \) with \( x \leq \alpha \sqrt{T} \). For \( i \in \{u, l\} \) we now recursively calculate \( V_i^S(n, x) = \max \left\{ \frac{x}{n}, \frac{1}{2} \left( V_u^S(n + 1, x + 1) + V_l^S(n + 1, x - 1) \right) \right\} \). If \( V_l(n, x) > \frac{x}{n} \), then \((n, x) \in C\). To check if \((n, x) \in D\) we use, instead of \( V_u(n, x) = \frac{x}{n} \), the slightly stronger, but numerically easier to evaluate, condition \((n, x) \in D\) if \( \frac{1}{2} \left( V_u^S(n + 1, x + 1) + V_l^S(n + 1, x - 1) \right) < \frac{x}{n} \). We use \( T = 10^6 \) to calculate \( V(0, 0) \) and the integer thresholds \( \hat{b}(n) := \lfloor b(n) \rfloor \). For 34 values of \( n \leq 10^6 \) the exact value \( b(n) \) cannot be determined this way; the smallest such value is \( n = 489242 \).

Theorem 3. For the stopping problem (4) starting in \((0, 0)\), the stopping boundary \( \hat{b} \) for \( n \leq 489241 \) is given by

\[
\hat{b}(n) = \left\lceil \frac{\alpha \sqrt{n}}{2} + 1 + \frac{1}{7.9 + 4.54 \sqrt{n}} \right\rceil \quad (11)
\]

with the eight exceptions shown in Table 2. For the value function we have

\[
0.585\ 907\ 012\ 8172 \leq V^S(0, 0) \leq 0.585\ 907\ 012\ 8182.
\]
Häggström and Wästlund used a different notation (denoted with a ′ here), with \( P(X'_i = 0) = P(X'_i = 1) = \frac{1}{2} \). Our functions and values translate to \( V(n, x) = 2V'(n, \frac{x+n}{2}) - 1 \), \( b'(n) = \left\lceil \frac{\alpha \sqrt{n} + n}{2} - \rho'(n) \right\rceil \) with \( \rho'(n) = \frac{1}{4} - \frac{1}{15.8 + 9 \sqrt{n}} \), and

\[
0.792\,953\,506\,4086 \leq V'(0, 0) \leq 0.792\,953\,506\,4091.
\]

The value of \( V(0, 0) \) is calculated with \( T = 2 \cdot 10^6 \). 

**Remark 3.** The function \( (7.9 + 4.54 \sqrt{n})^{-1} \) is constructed from our computed data. It is an interesting question whether it is indeed possible to show that \( \alpha \sqrt{t} - b(t) = \frac{1}{2} - O(t^{-\frac{1}{4}}) \). A method to show that \( \lim_{t \to \infty} \alpha \sqrt{t} - b(t) = \frac{1}{2} \) was introduced in [6]. This is reflected nicely in our calculations.

We also calculated \( V^S \) and \( b \) for non-integer values. We did this by choosing an integer \( D \) and then calculating \( V^S \) on \( \frac{1}{D} \mathbb{N} \times \frac{1}{D} \mathbb{Z} \) with the method described above; for most plots we used \( D = 300 \). Some plots of \( b \) and \( V^S \) are given in Figures 2–4. The method enables us to get very detailed impressions of \( b \) and \( V^S \) that inspire further analytical research. In [2] the authors showed that \( V^S \) is not differentiable on a dense subset of \( C^S \), and that \( C^S \) is not convex.
