HIGH DIMENSIONAL HAWKES PROCESSES

SYLVAIN DELATTRE, NICOLAS FOURNIER AND MARC HOFFMANN

Abstract. We generalise the construction of multivariate Hawkes processes to a possibly infinite network of counting processes on a directed graph \( G \). The process is constructed as the solution to a system of Poisson driven stochastic differential equations, for which we prove pathwise existence and uniqueness under some reasonable conditions.

We next investigate how to approximate a standard \( N \)-dimensional Hawkes process by a simple inhomogeneous Poisson process in the mean-field framework where each pair of individuals interact in the same way, in the limit \( N \to \infty \). In the so-called linear case for the interaction, we further investigate the large time behaviour of the process. We study in particular the stability of the central limit theorem when exchanging the limits \( N, T \to \infty \) and exhibit different possible behaviours.

We finally consider the case \( G = \mathbb{Z}^d \) with nearest neighbour interactions. In the linear case, we prove some (large time) laws of large numbers and exhibit different behaviours, reminiscent of the infinite setting. Finally we study the propagation of a single impulsion started at a given point of \( \mathbb{Z}^d \) at time 0. We compute the probability of extinction of such an impulsion and, in some particular cases, we can accurately describe how it propagates to the whole space.

Keywords: Point processes. Multivariate Hawkes processes. Stochastic differential equations. Limit theorems. Mean-field approximations. Interacting particle systems.

1. Introduction

1.1. Motivation. In several apparently different applied fields, a growing interest has been observed recently for a better understanding of stochastic interactions between multiple entities evolving through time. These include: seismology for modelling earthquake replicas (Helmstetter-Sornette [18], Kagan [24], Ogata [29], Bacry-Muzy [3]), neuroscience for modelling spike trains in brain activity (Grün et al. [13], Okatan et al. [30], Pillow et al. [31], Reynaud et al. [32, 33]), genome analysis (Reynaud-Schbath [32]), financial contagion (Ait-Sahalia et al. [1]), high-frequency finance (order arrivals, see Bauwens-Hautsch [6], Hewlett [19], market micro-structure see Bacry et al. [2] and market impact see Bacry-Muzy [3, 4]), financial price modelling across scales (Bacry et al. [3], Jaisson-Rosenbaum [21]), social networks interactions (Blundell et al. [7], Simma-Jordan [30], Zhou et al. [35]) and epidemiology like for instance viral diffusion on a network (Hang-Zha [37]), to name but a few. In all these contexts, observations are often represented as events (like spikes or features) associated to agents or nodes on a given network, and that arrive randomly through time but that are not stochastically independent.

In practice, we observe a multivariate counting process \((Z_1^t, \ldots, Z_N^t)_{t \geq 0}\), each component \(Z_i^t\) recording the number of events of the \(i\)-th component of the system during \([0,t]\), or equivalently the time stamps of the observed events. Under relatively weak general assumptions, a multivariate counting process \((Z_1^t, \ldots, Z_N^t)_{t \geq 0}\) is characterised by its intensity process \((\lambda_1^t, \ldots, \lambda_N^t)_{t \geq 0}\), informally defined by

\[
\Pr(Z_i^t \text{ has a jump in } [t, t + dt] \mid \mathcal{F}_t) = \lambda_i^t dt, \quad i = 1, \ldots, N,
\]
where \( \mathcal{F}_t \) denotes the sigma-field generated by \((Z^i)_{1 \leq i \leq N}\) up to time \( t \). For modelling the interactions, a particularly attractive family of multivariate point processes is given by the class of (mutually exciting) Hawkes processes (Hawkes [15], Hawkes-Oakes [16]), with intensity process given by

\[
\lambda^i_t = h_i \left( \sum_{j=1}^{N} \int_0^t \varphi_{ji}(t-s)dZ^j_s \right),
\]

where the causal functions \( \varphi_{ji} : [0, \infty) \to \mathbb{R} \) model how \( Z^j \) acts on \( Z^i \) by affecting its intensity process \( \lambda^i \). The nonnegative functions \( h_i \) account for some non-linearity, but if we set \( h_i(x) = \mu_i + x \) with \( \mu_i \geq 0 \), we obtain linear Hawkes processes where \( \mu_i \) can be interpreted as a baseline Poisson intensity. In the degenerate case \( \varphi_{ji} = 0 \), we actually retrieve standard Poisson processes.

Multivariate Hawkes processes have long been studied in probability theory (see for instance the comprehensive textbook of Daley-Vere-Jones [10] and the references therein, Brémaud-Massoulié [8] or the recent results of Zhu [39, 40]). Their statistical inference is relatively well understood too, from a classical parametric angle (Ogata [27]) together with recent significant advances in nonparametrics (Reynaud-Bouret-Schbath [32], Hansen et al. [17]). However, the frontier is progressively moving to understanding the case of large \( N \), when the number of components may become increasingly large or possibly infinite (see Galvez-Löcherbach [14] for some constructions in that direction). This context is potentially of major importance for future developments in the aforementioned applied fields. This is the topic of the present paper.

### 1.2. Setting

We work on a filtered probability space \((\Omega, \mathcal{F}, (\mathcal{F}_t)_{t \geq 0}, \mathbb{P})\). We say that \((X_t)_{t \geq 0}\) is a counting process if it is non-decreasing, càdlàg, integer-valued (and finite for all times), with all its jumps of height 1. For \((X_t)_{t \geq 0}\) a \((\mathcal{F}_t)_{t \geq 0}\)-adapted counting process, there is a unique non-decreasing predictable process \((\Lambda_t)_{t \geq 0}\), called compensator of \((X_t)_{t \geq 0}\), such that \((X_t - \Lambda_t)_{t \geq 0}\) is a \((\mathcal{F}_t)_{t \geq 0}\)-local martingale, see Jacod-Shiryaev [22] Chapter I.

We consider a countable directed graph \( G = (S, E) \) with vertices (or nodes) \( i \in S \) and (directed) edges \( e \in E \). We write \( e = (j, i) \in E \) for the oriented edge. We also need to specify the following parameters: a kernel \( \varphi = (\varphi_{ji}, (j, i) \in E) \) with \( \varphi_{ji} : [0, \infty) \to \mathbb{R} \), and a nonlinear intensity component \( h = (h_i, i \in S) \) with \( h_i : \mathbb{R} \to [0, \infty) \). The natural generalisation of finite-dimensional Hawkes processes is the following.

**Definition 1.** A Hawkes process with parameters \((G, \varphi, h)\) is a family of \((\mathcal{F}_t)_{t \geq 0}\)-adapted counting processes \((Z^i_t)_{i \in S, t \geq 0}\) such that

(i) almost surely, for all \( i \neq j \), \((Z_t^i)_{t \geq 0}\) and \((Z_t^j)_{t \geq 0}\) never jump simultaneously,

(ii) for every \( i \in S \), the compensator \((\Lambda_t^i)_{t \geq 0}\) of \((Z_t^i)_{t \geq 0}\) has the form \( \Lambda_t^i = \int_0^t \lambda_t^i ds \), where the intensity process \((\lambda_t^i)_{t \geq 0}\) is given by

\[
\lambda_t^i = h_i \left( \sum_{j=i}^{N} \int_0^t \varphi_{ji}(t-s)dZ^j_s \right),
\]

with the notation \( \sum_{j \to i} \) for summation over \( \{ j : (j, i) \in E \} \).

We say that a Hawkes process is linear when \( h_i(x) = \mu_i + x \) for every \( x \in \mathbb{R}, i \in S \), with \( \mu_i \geq 0 \) and when \( \varphi_{ji} \geq 0 \). We will give some general existence, uniqueness and approximation results for nonlinear Hawkes processes, but all the precise large-time estimates we will prove concern the linear case.
A Hawkes process \((Z_t^i)_{i \in S, t \geq 0}\) with parameters \((G, \varphi, h)\) behaves as follows. For each \(i \in S\), the rate of jump of \(Z_t^i\) is, at time \(t\), \(\lambda_i(t) = h_i(\sum_{j \neq i} \sum_{k \geq 1} \varphi_{ji}(t - T_k^i)1_{\{T_k^i \leq t\}})\), where \((T_k^i)_{k \geq 1}\) are the jump times of \(Z_t^i\). In other words, each time one of the \(Z_t^i\)’s has a jump, it excites its neighbours in that it increases their rate of jump (in the natural situation where \(h\) is increasing and \(\varphi\) is positive). If \(\varphi\) is positive and decreases to 0, the case of almost all applications we have in mind, the influence of a jump decreases and tends to 0 as time evolves.

1.3. Main results. In the case where \(G\) is a finite graph, under some appropriate assumptions on the parameters, the construction of \((Z_t^i)_{i \in S, t \geq 0}\) is standard. However, for an infinite graph, the situation is more delicate: we have to check, in some sense, that the interaction does not come from infinity.

The first part of this paper (Section 2) consists of writing a Hawkes process as the solution to a system of Poisson-driven S.D.E.s and of finding a set of assumptions on \(G\) and on the parameters \((\varphi, h)\) under which we can prove the pathwise existence and uniqueness for this system of S.D.E.s. Representing counting processes as solutions to S.D.E.s is classical, see Lewis-Shedler [26], Ogata, [28], Brémaud-Massoulié [8], Chevallier [9]. However, the well-posedness of such S.D.E.s is not obvious when \(G\) is an infinite graph.

In a second part (Section 3), we study the mean-field situation: we assume that we have a finite (large) number \(N \) of particles behaving similarly, with no geometry. In other words, \(S = \{1, \ldots, N\}\) is endowed with the set of all possible edges \(E = \{(i, j) : i, j \in S\}\), and there are two functions \(h\) and \(\varphi\) such that \(h_i = h\) and \(\varphi_{ij} = N^{-1}\varphi\) for all \(i, j \in S\). We show that, as \(N \to \infty\), Hawkes processes can be approximated by an i.i.d. family of inhomogeneous Poisson processes. Concerning the large-time behaviour, we discuss, in the linear case, the possible law of large numbers and central limit theorems as \((t, N) \to (\infty, \infty)\) and we observe some different situations according to the position of \(\int_0^\infty \varphi(t) dt\) with respect to 1 (the so-called critical case).

Finally, we consider in Section 4 the case where \(G\) is \(\mathbb{Z}^d\), endowed with the set of edges \(E = \{(i, j) : |i - j| = 0 \text{ or } 1\}\), where \(|\cdot|\) denotes the Euclidean distance. We study the large time behaviour, in the linear case where \(h_i(x) = \mu_i + x\) and when \(\varphi_{ij} = (2d + 1)^{-1}\varphi\) does not depend on \(i, j\). We first assume that \(\mu_i\) does not depend too much on \(i\) (consider e.g. the case where the \(\mu_i\) are random, i.i.d. and bounded) and show that (i) if \(\int_0^\infty \varphi(t) dt > 1\), then there is a law of large numbers and the interaction makes everything flat, in the sense that for all \(i \neq j\), \(Z_t^i \sim Z_t^j\) as \(t \to \infty\); (ii) if \(\int_0^\infty \varphi(t) dt < 1\), then there is again a law of large numbers, but the limiting value depends on \(i\). We also explain why these results are reminiscent of the infinite setting and of the interaction. Finally, we study the case where \(\mu_i = 0\) for all \(i\) but where there is an impulsion at time 0 at \(i = 0\). We compute the probability of extinction of such an impulsion and, in some particular cases, we study how it propagates to the whole space (when it does not blow out).

1.4. Notation. The Laplace transform of \(\varphi : [0, \infty) \to \mathbb{R}\) is defined, when it exists, by

\[
\mathcal{L}_\varphi(\alpha) = \int_0^\infty e^{-\alpha t} \varphi(t) dt.
\]

We also introduce the convolution of \(h, g : [0, \infty) \to \mathbb{R}\) as (if it exists) \((g \ast h)_i = \int_0^t g_{s} h_{t-s} ds = \int_0^t g_{t-s} h_{s} ds\). As is well-known, when everything makes sense, \(\mathcal{L}_{g \ast h}(\alpha) = \mathcal{L}_g(\alpha) \times \mathcal{L}_h(\alpha)\).
2. Well-posedness using a Poisson S.D.E.

We will study Hawkes processes through a system of Poisson-driven stochastic differential equations. This will allow us to speak of pathwise existence and uniqueness and to prove some propagation of chaos using some simple coupling arguments.

Consider, on a filtered probability space \((\Omega, F, (F_t)_{t \geq 0}, P))\), a family \((\pi^i(ds \, dz), i \in S)\) of i.i.d. \((F_t)_{t \geq 0}\)-Poisson measures with intensity measure \(ds \, dz\) on \([0, \infty) \times [0, \infty)\).

**Definition 2.** A family \((Z^i_t)_{i \in S, t \geq 0}\) of càdlàg \((F_t)_{t \geq 0}\)-adapted processes is called a Hawkes process with parameters \((G, \varphi, h)\) if a.s., for all \(i \in S\), all \(t \geq 0\)

\[
Z^i_t = \int_0^t \int_0^\infty 1\left\{z \leq h_i\left(\sum_{j \neq i} \int_0^{s-} \varphi_{ji}(s-u)dZ^j_u\right)\right\} \pi^i(ds \, dz).
\]

This formulation is consistent with Definition [1].

**Proposition 3.** (a) A Hawkes process in the sense of Definition 2 is also a Hawkes process in the sense of Definition 4.

(b) Consider a Hawkes process in the sense of Definition 2 (on some filtered probability space \((\Omega, F, (F_t)_{t \geq 0}, P))\), then we can build on a possibly enlarged probability space \((\tilde{\Omega}, \tilde{F}, (\tilde{F}_t)_{t \geq 0}, \tilde{P}))\), a family \((\pi^i(ds \, dz), i \in S)\) of i.i.d. \((\tilde{F}_t)_{t \geq 0}\)-Poisson measures with intensity measure \(ds \, dz\) on \([0, \infty) \times [0, \infty)\) such that \((\tilde{Z}^i_t)_{i \in S, t \geq 0}\) is a Hawkes process in the sense of Definition 4.

Point (a) is very easy: for a Hawkes process \((Z^i_t)_{i \in S, t \geq 0}\) in the sense of Definition 2 it is clear that for every \(i \in S\), the compensator of \(Z^i\) is \(\int_0^t \int_0^\infty 1\left\{z \leq h_i\left(\sum_{j \neq i} \int_0^{s-} \varphi_{ji}(s-u)dZ^j_u\right)\right\} dz ds\), which is equal to \(\int_0^t h_i(\sum_{j \neq i} \int_0^{s-} \varphi_{ji}(s-u)dZ^j_u) ds\). Furthermore, the independence of the Poisson random measures \((\pi^i(ds \, dz), i \in S)\) guarantees that for all \(i \neq j\), \((Z^i_t)_{t \geq 0}\) and \((Z^j_t)_{t \geq 0}\) a.s. never jump simultaneously.

Point (b) is more delicate but standard and a very similar result was given in Brémaud-Massoulié [8]. Their proof is based on results found in the book [20] of Jacod, of which one of the main goals is exactly this topic: prove the equivalence between martingale problems and S.D.E.s. We also refer to Chevalier [9] Section IV] where a very complete proof is given as well as a historical survey. Let us mention that the idea to integrate an indicator function with respect to a Poisson measure in order to produce an inhomogeneous Poisson process with given intensity was first introduced by Lewis-Shedler [26], and later extended by Ogata [28] in the case of a stochastic intensity.

The following set of assumptions will guarantee the well-posedness of 4.

**Assumption 4.** There are some nonnegative constants \((c_i)_{i \in S}\), some positive weights \((p_i)_{i \in S}\) and a locally integrable function \(\phi : [0, \infty) \mapsto [0, \infty)\) such that

(a) for every \(i \in S\), every \(x, y \in \mathbb{R}\), \(|h_i(x) - h_i(y)| \leq c_i |x - y|\),

(b) \(\sum_{i \in S} h_i(0)p_i < \infty\),

(c) for every \(s \in [0, \infty)\), every \(j \in S\), \(\sum_{i, (j,i) \in E} c_i p_i |\varphi_{ji}(s)| \leq p_j \phi(s)\).

Let us give a few examples of parameters \((G, \varphi, h)\) satisfying Assumption 4.

**Remark 5.** (i) If \(S\) is finite, then Assumption 7 holds true, with the choice \(p_i = 1\), as soon as \(h_i\) is Lipschitz continuous for all \(i \in S\) and \(\varphi_{ji}\) is locally integrable for all \((j, i) \in E\).
(ii) If $S = \mathbb{Z}^d$ is endowed with $E = \{(i, j) : |i - j| = 0 \text{ or } 1\}$, then Assumption 3 holds, with the choice $p_i = 2^{-|i|}$, if $\sum_{i,j} 2^{-|i|}|h_i(0)| < \infty$ and if there are $c > 0$ and $\varphi \in L_{\text{loc}}^1([0, \infty))$ such that $|h_i(x) - h_i(y)| \leq c|x - y|$ and $|\varphi_{jk}(t)| \leq \varphi(t)$ for all $i \in S$, $x, y \in \mathbb{R}$, $(j, k) \in E$ and $t \geq 0$. 

(iii) Consider next $S = \mathbb{Z}^d$ endowed with the set of all possible edges $E = \{(i, j) : i, j \in \mathbb{Z}^d\}$ and assume that there is $c > 0$ such that $|h_i(0)| \leq c$ and $|h_i(x) - h_i(y)| \leq c|x - y|$ for all $i \in S$, $x, y \in \mathbb{R}$. Assume that there are $\varphi \in L_{\text{loc}}^1([0, \infty))$ and a nonincreasing $a : [0, \infty) \to [0, \infty)$ such that $|\varphi_{jk}(t)| \leq a(|i - j|)\varphi(t)$ for all $(i, j) \in E$ and $t \geq 0$. Then if $\sum_{i \in \mathbb{Z}^d} a(|i|) < \infty$, Assumption 4 holds true.

(iv) Consider the (strongly oriented) graph $\mathbb{Z}^+_{\text{loc}}$ endowed with the set of edges $E = \{(i, i + 1) : i \in \mathbb{Z}^+\}$. Then Assumption 4 holds true as soon as there is $\varphi \in L_{\text{loc}}^1([0, \infty))$ such that for every $i \in \mathbb{Z}^+$, there are $c_i > 0$ and $a_i > 0$ such that $|h_i(x) - h_i(y)| \leq c_i|x - y|$ and $|\varphi_{ii+1}(t)| \leq a_i \varphi$. Points (ii) and (iii) of course extend to other graphs. In (iv), there is no growth condition on $|h_i(0)|$, $c_i$, and $a_i$. This comes from the fact that the interaction is directed: $Z^0$ is actually a Poisson process with rate $h_0(0)$, the intensity of $Z^1$ is entirely determined by that of $Z^0$, and so on. Hence this example is not very interesting. But we can mix e.g. points (ii) and (iv): informally, coefficients corresponding to edges directed to the origin have to be well-controlled, while coefficients corresponding to edges directed to infinity require less assumptions.

**Proof.** Point (i) is obvious. To check (ii), simply note that for all $j \in S$, $\sum_{i,j} 2^{-|i|} |\varphi_{ji}| \leq c_2 2^{-|j|} \sum_{i,j} 2^{|j|} \varphi_{ji} \leq c_2 (2d + 1) \varphi p_j$ and define $\phi = c_2 (2d + 1) \varphi$. Point (iv) holds with $(p_i)_{i \in \mathbb{Z}^+}$ defined by $p_0 = 1$ and, by induction, $p_{i+1} = \min \{2^{-i}/(1 + h_i(0)), p_i/(1 + a_i c_{i+1})\}$. This of course implies that $\sum_{i,j \in S} \varphi_{ji} p_i |h_i(0)| < \infty$ and that for all $j \geq 1$, $\sum_{i,j \in S} c_i p_i |\varphi_{ji}| = c_{j+1} p_{j+1} |\varphi_{j(j+1)}| \leq c_j p_j a_j \varphi \leq p_j \varphi$ as desired.

To prove (iii), we work with the sup norm $|i| = |(i_1, \ldots, i_d)| = \max \{|i_1|, \ldots, |i_d|\}$. The delicate part consists in showing that there is $b : \mathbb{N} \to [0, \infty)$ and a constant $C > 0$ such that $\sum_{i \in \mathbb{Z}^d} b(|i|) < \infty$ and, for all $j \in \mathbb{Z}^d$, $\sum_{i,j \in \mathbb{Z}^d} b(|j|) a(|j - i|) \leq C b(|j|)$. Then the result will easily follow, with the choices $p_i = b(|i|)$ and $\phi = C \varphi$. We define $b$ recursively, by $b(0) = a(0)$ and $b(k+1) = \max \{a(k+1), (k+1)/(k+2)^{2d} b(k)\}$. Using that $a$ is nonincreasing, we easily check that $b$ is nonincreasing. We next check that $\sum_{i \in \mathbb{Z}^d} b(|i|) < \infty$, i.e. that $\sum_{k \geq 0} k^{d-1} b(k) < \infty$, knowing by assumption that $\sum_{k \geq 0} k^{d-1} a(k) < \infty$. We have, for $k \geq 0$,

$$b(k+1) - a(k+1) = ([k+1]/(k+2))^{2d} b(k) - a(k+1)) \leq ([k+1]/(k+2))^{2d} (b(k) - a(k)) + ([k+1]/(k+2))^{2d} a(k) - a(k+1)) \leq ([k+1]/(k+2))^{2d} (b(k) - a(k)) + (a(k) - a(k+1)).$$

Recalling that $b(0) = a(0)$, one gets $b(k) - a(k) \leq \sum_{\ell=1}^k (a(\ell-1) - a(\ell)) ([\ell+1]/(k+1))^{2d}$ by iteration. Hence

$$\sum_{k \geq 1} k^{d-1} (b(k) - a(k)) \leq \sum_{k \geq 1} k^{d-1} \sum_{\ell=1}^k (a(\ell-1) - a(\ell)) ([\ell+1]/(k+1))^{2d} = \sum_{\ell \geq 1} (a(\ell-1) - a(\ell)) ([\ell+1]/(k+1))^{2d} \sum_{k \geq \ell} k^{d-1} (k+1)^{-2d} \leq C \sum_{\ell \geq 1} (a(\ell-1) - a(\ell)) \ell^d.$$
This last quantity is nothing but $C \sum_{|i-j| \leq |j|/2} a(|i-j|) = C \sum_{|i-j| \geq |j|/2} b(|i-j|) + Cb(|j|)$. First, we claim that there is $C$ such that $b(k) \leq Cb(2k)$ for all $k \geq 0$. This is easily checked, iterating the inequality $b(k) \leq [(k+2)/(k+1)]^2b(k+1)$. Next we write, using that $a$ and $b$ are nonincreasing,

$$\sum_{i \in \mathbb{Z}^d} b(|i|) a(|i-j|) \leq \sum_{|i| < |j|/2} b(|i|) a(|i-j|) + \sum_{|i| \geq |j|/2} b(|i|) a(|i-j|) \leq a(|j|/2) \sum_{i \in \mathbb{Z}^d} b(|i|) + b(|j|/2) \sum_{i \in \mathbb{Z}^d} a(|i-j|) \leq Ca(|j|/2) + Cb(|j|/2).$$

By definition of $b$, we have $a(|j|/2) \leq b(|j|/2)$. And we have just seen that $b(|j|/2) \leq Cb(|j|)$. We finally have checked that $\sum_{i \in \mathbb{Z}^d} b(|i|) a(|i-j|) \leq Cb(|j|)$ as desired. 

Our well-posedness result is the following.

**Theorem 6.** Under Assumption 4 there exists a pathwise unique Hawkes process $(Z_t^i)_{i \in S, t \geq 0}$ such that $\sum_{i \in S} p_i \mathbb{E}[Z_t^i] < \infty$ for all $t \geq 0$.

Observe that this result is not completely obvious in the case of an infinite graph. In some sense, we have to check that the interaction does not come from infinity. Let us insist on the fact that, even in simple situations, a graphical construction is not possible: consider e.g. the case of $\mathbb{Z}$ endowed with the set of edges $\mathcal{E} = \{(i,j) : |i-j| = 0 \text{ or } 0 \text{ or } 1\}$, assume that $h_i(x) = 1 + x$ for all $i \in S$ and that $\varphi_{ij} = 1$ for all $(i,j) \in \mathcal{E}$. Then one easily gets convinced that we cannot determine the values of $(Z_t^i)_{i \in [0,T]}$ by observing the Poisson measures $\pi^i$ in a (random) finite box.

As a second comment, let us mention that we believe it is not possible, or at least quite difficult, to obtain the full uniqueness, i.e. uniqueness outside the class of processes satisfying $\sum_{i \in S} p_i \mathbb{E}[Z_t^i] < \infty$ (or something similar). Indeed, consider again the case of $\mathbb{Z}$ endowed with $\mathcal{E} = \{(i,j) : |i-j| = 0 \text{ or } 0 \text{ or } 1\}$, assume that $h_i(x) = 1 + x$ for all $i \in S$ and that $\varphi_{ij} = 1$ for all $(i,j) \in \mathcal{E}$. One easily checks that for $(Z_t^i)_{i \in S, t \geq 0}$ a Hawkes process, for $m_t^i = \mathbb{E}[Z_t^i]$ it holds that $m_t^i = t + \int_0^t (m_{s-}^i + m_{s+}^i) ds$ for every $i$. This infinite system of equations is of course closely related to the heat equation $\partial_t u(t,x) = 1 + \partial_x u(t,x)$ on $[0,\infty) \times \mathbb{R}$ and with initial condition $u(0,x) = 0$. As is well-known, uniqueness for this equation fails to hold true without imposing some growth conditions as $|x| \to \infty$. See e.g. Tychonov’s counterexample of uniqueness, which can be found in John 23 Chapter 7).

**Proof.** We first prove uniqueness. Let thus $(Z_t^i)_{i \in S, t \geq 0}$ and $(\tilde{Z}_t^i)_{i \in S, t \geq 0}$ be two solutions to (1) satisfying the required condition. Set

$$\Delta_t^i = \int_0^t |d(Z_s^i - \tilde{Z}_s^i)| \text{ for } i \in S, t \geq 0.$$ 

In other words, $\Delta_t^i$ is the total variation norm of the signed measure $d(Z_s^i - \tilde{Z}_s^i)$ on $[0,t]$. We also put $\delta_t^i = \mathbb{E}[\Delta_t^i]$ and first prove that

$$(2) \quad \delta_t^i \leq c_i \int_0^t \sum_{j=i}^t |\varphi_{ji}(t-s)| \delta_s^j ds.$$
We have
\[ \Delta^i_t = \int_0^t \int_0^\infty \left| 1_{\{s \leq h_i(\sum_{j \neq i} f_{ij}^- \varphi_{ij}(s-u) dZ_j^u)\}} - 1_{\{s \leq h_i(\sum_{j \neq i} f_{ij}^- \varphi_{ij}(s-u) dZ_j^u)\}} \right| \pi^i(ds \, dz). \]
Taking expectations, we deduce that
\[ \delta^i_t = \int_0^t \mathbb{E} \left[ \left| h_i \left( \sum_{j \neq i} \int_0^{s-} \varphi_{ij}(s-u) dZ_j^u \right) - h_i \left( \sum_{j \neq i} \int_0^{s-} \varphi_{ij}(s-u) dZ_j^u \right) \right| ds \right] \]
(3)
\[ \leq c_i \sum_{j \neq i} \mathbb{E} \left[ \int_0^t \int_0^{s-} |\varphi_{ij}(s-u)| \, d\Delta^j_u \, ds \right] \]
by Assumption 4(a). Using Lemma 22, we see that
\[ \int_0^t ds \int_0^{s-} |\varphi_{ij}(s-u)| \, d\Delta^j_u = \int_0^t |\varphi_{ij}(t-u)| \Delta^j_t \, du \]
which, plugged into (3), yields (2).

Set \( \delta_t = \sum_{i \in S} p_i \delta^i_t \), where the weights \( p_i \) were introduced in Assumption 4. By assumption, \( \delta_t \) is well-defined and finite. We infer by (2) that
\[ \delta_t \leq \int_0^t \sum_{i \in S} p_i c_i \sum_{j \neq i} |\varphi_{ij}(t-s)| \delta^j_s \, ds. \]
By Assumption 4(c),
\[ \delta_t \leq \int_0^t \sum_{j \in S} \delta^j_s \sum_{i, (j, s) \in E} c_i p_i |\varphi_{ij}(t-s)| \, ds \leq \int_0^t \sum_{j \in S} p_j \delta^j_s \phi(t-s) \, ds = \int_0^t \phi(t-s) \delta_s \, ds. \]
Lemma 23(i) thus implies that \( \delta_t = 0 \) identically, from which uniqueness follows.

We now quickly prove existence by a Picard iteration. Let \( Z^{i,0}_t = 0 \) and, for \( n \geq 0 \),
(4)
\[ Z^{i,n+1}_t = \int_0^t \int_0^\infty 1_{\{s \leq h_i(\sum_{j \neq i} f_{ij}^- \varphi_{ij}(s-u) dZ_j^u)\}} \pi^i(ds \, dz). \]
We define \( \delta^{i,n} = \mathbb{E} \left[ \int_0^t |dZ^{i,n+1}_t - dZ^{i,n}_t| \right] \) and \( \delta^n = \sum_{i \in S} p_i \delta^{i,n} \). As in the proof of uniqueness, we obtain, for \( n \geq 0 \),
(5)
\[ \delta^{n+1}_t \leq \int_0^t \phi(t-s) \delta^n_s \, ds. \]
Next, we put \( m^{i,n}_t = \mathbb{E}[Z^{i,n}_t] \). By Assumption 4(a), \( h_i(x) \leq h_i(0) + c_i |x| \), whence
\[ m^{i,n+1}_t \leq \mathbb{E} \left[ \int_0^t \left( h_i(0) + c_i \sum_{j \neq i} \int_0^{s-} |\varphi_{ij}(s-u)| \, dZ^j_u \right) ds \right] \leq \int_0^t \left( h_i(0) + c_i \sum_{j \neq i} |\varphi_{ij}(t-s)| m^{j,n}_s \right) ds, \]
where we used that, by Lemma 22, \( \int_0^t \int_0^{s-} |\varphi_{ij}(s-u)| \, dZ^j_u \, ds = \int_0^t |\varphi_{ij}(t-u)| \, dZ^j_u \, du \). Setting \( u^i_t = \sum_{i \in S} p_i m^{i,n}_t \) and using Assumption 4(b)-(c),
(6)
\[ u^{n+1}_t \leq t \sum_{i \in S} h_i(0) p_i + \int_0^t \sum_{i \in S} p_i c_i \sum_{j \neq i} |\varphi_{ij}(s-u)| m^{j,n}_s \, ds \leq Ct + \int_0^t \phi(t-s) u^n_s \, ds. \]
Since \( u^0 = 0 \) and \( \phi \) is locally integrable, we easily check by induction that \( u^n \) is locally bounded for all \( n \geq 0 \). Consequently, \( \delta^n \) is also locally bounded for all \( n \geq 0 \). Lemma 23(ii) implies that
for all $T \geq 0$, $\sum_{n \geq 1} \delta^n_T < \infty$. This classically implies that the Picard sequence is Cauchy and thus converges: there exists a family $(Z_t^i)_{i \in S, t \geq 0}$ of càdlàg nonnegative adapted processes such that for all $T \geq 0$, $\lim_n \sum_{i \in S} p_i \mathbb{E}[\int_0^T |dZ_t^i - dZ_t^{i,n}|] = 0$. It is then not hard to pass to the limit in (4) to deduce that $(Z_t^i)_{i \in S, t \geq 0}$ solves (1). Finally, Lemma 23-(iii) implies that $\sup_n u_t^N < \infty$ for all $t \geq 0$, from which $\sum_{i \in S} p_i \mathbb{E}[Z_t^i] < \infty$ as desired.

\[
\text{3. Mean-field limit}
\]

In this section, we work in the following setting.

**Assumption 7.** Let $h : \mathbb{R} \mapsto [0, \infty)$ be such that $|h|_{lip} = \sup_{x \neq y} |x - y|^{-1}|h(x) - h(y)| < \infty$ and let $\phi = [0, \infty) \mapsto \mathbb{R}$ be a locally square integrable function.

For each $N \geq 1$, we consider the complete graph $G_N$ with vertices $S_N = \{1, \ldots, N\}$ and edges $E_N = \{(i, j) : i, j \in S_N\}$, i.e. all pairs of points in $S_N$ are connected. We put $h^N_i = h$ for all $i \in S_N$ and $\phi^N_i = N^{-1} \phi$ for $(i, j) \in E_N$.

Under Assumption 7, the triplet $(G_N, \phi^N, h^N)$ satisfies Assumption 4 (the graph $G_N$ is finite) for each $N \geq 1$. Therefore, a Hawkes process $(Z_t^N, i, \ldots, Z_t^N, N)_{t \geq 0}$ with parameters $(G_N, \phi^N, h^N)$ is uniquely defined by Theorem 6.

Introduce the limit equation

\[
(Z_t) = \int_0^t \int_0^\infty 1 \{z \leq h(\int_0^s \phi(s - u)d\mathbb{E}[Z_u])\} \pi(ds dz), \quad \text{for every } t \geq 0,
\]

where $\pi(ds dz)$ is a Poisson measure on $[0, \infty) \times [0, \infty)$ with intensity measure $ds d\pi$. Also, $d\mathbb{E}[Z_u]$ is the measure on $[0, \infty)$ associated to the (necessarily) non-decreasing function $u \mapsto \mathbb{E}[Z_u]$. Note that a solution $(Z_t)_{t \geq 0}$, if it exists, is an inhomogeneous Poisson process on $[0, \infty)$ with intensity $\lambda_t = h(\int_0^t \phi(t - u)d\mathbb{E}[Z_u])$.

### 3.1. Propagation of chaos

The main result of this section reads as follows.

**Theorem 8.** Work under Assumption 7.

(i) There is a pathwise unique solution $(Z_t)_{t \geq 0}$ to (7) such that $(\mathbb{E}[Z_t])_{t \geq 0}$ is locally bounded.

(ii) It is possible to build simultaneously the Hawkes process $(Z_t^N, i, \ldots, Z_t^N, N)_{t \geq 0}$ with parameters $(G_N, \phi^N, h^N)$ and an i.i.d. family $(\mathbb{Z}_t)_{t \geq 0, i = 1, \ldots, N}$ of solutions to (7) in such a way that for all $T > 0$, all $i = 1, \ldots, N$,

\[
\mathbb{E}\left[\sup_{[0,T]} |Z_{t,i}^N - \mathbb{Z}_t^i|\right] \leq C_T N^{-1/2},
\]

the constant $C_T$ depending only on $h$, $\phi$ and $T$ (see Remark 4 below for some bounds of $C_T$ in a few situations).

(iii) Consequently, we have the mean-field approximation

\[
\frac{1}{N} \sum_{i=1}^N \delta_{(Z_t^N, i)}_{t \geq 0} \rightarrow \mathcal{L}((Z_t)_{t \geq 0}) \quad \text{in probability, as } N \rightarrow \infty,
\]

where $\mathcal{P}(\mathbb{D}([0, \infty), \mathbb{P}))$ is endowed with the weak convergence topology associated with the topology (on $\mathbb{D}([0, \infty), \mathbb{P})$) of the uniform convergence on compact time intervals.
Proof. For \((\mathbf{Z}_t)_{t \geq 0}\) a solution to (7), the equation satisfied by \(m_t = \mathbb{E}[\mathbf{Z}_t]\) writes

\begin{equation}
(8) \quad m_t = \int_0^t h\left(\int_0^s \varphi(s-u)dm_u\right) ds \quad \text{for every } t \geq 0.
\end{equation}

By Lemma 24, we know that this equation has a unique non-decreasing locally bounded solution, which furthermore is of class \(C^1\) on \([0, \infty)\). We now split the proof in several steps.

Step 1. Here we prove the well-posedness of (8). For \((\mathbf{Z}_t)_{t \geq 0}\) a solution to (8), its expectation \(m_t = \mathbb{E}[\mathbf{Z}_t]\) solves (8) and is thus uniquely defined. Thus the right hand side of (7) is uniquely determined, which proves uniqueness. For the existence, consider \(m\) the unique solution to (8) and put \(Z_t = \int_0^t \int_0^\infty 1\{z \leq h(f_0^- \varphi(s-u)dm_u)\} \pi(ds) dz\). We thus only have to prove that \(\mathbb{E}[Z_t] = m_t\). But \(\mathbb{E}[Z_t] = \int_0^t h(f_0^- \varphi(s-u)dm_u) ds\), which is nothing but \(m_t\) since \(m\) solves (8).

Step 2. We next introduce a suitable coupling. Let \((\pi_i(ds)dz))_{i \geq 1}\) be an i.i.d. family of Poisson measures with common intensity measure \(ds dz\) on \([0, \infty) \times [0, \infty)\). For each \(N \geq 1\), we consider the Hawkes process \((Z^{N,i}_t)_{t \geq 0}\)

\[Z^{N,i}_t = \int_0^t \int_0^\infty 1\{z \leq h(f_0^- \varphi(s-u)dm_u)\} \pi_i(ds) dz.\]

Next, still denoting by \(m\) the unique solution to (8), we put, for every \(i \geq 1\),

\[\mathbf{Z}^i_t = \int_0^t \int_0^\infty 1\{z \leq h(f_0^- \varphi(s-u)dm_u)\} \pi_i(ds) dz.\]

Clearly, \(((\mathbf{Z}^i_t)_{t \geq 0})_{i \geq 1}\) is an i.i.d. family of solutions to (7).

Step 3. Here we introduce \(\Delta_N^i(t) = \int_0^t |d(\mathbf{Z}^i_u - Z^{N,i}_u)|\) and \(\delta_N(t) = \mathbb{E}[\Delta_N(t)]\), which obviously does not depend on \(i\) (by exchangeability). Observe that

\begin{equation}
(9) \quad \sup_{[0,t]} |\mathbf{Z}^i_u - Z^{N,i}_u| \leq \Delta_N^i(t), \quad \text{whence } \mathbb{E}\left[\sup_{[0,t]} |\mathbf{Z}^i_u - Z^{N,i}_u|\right] \leq \delta_N(t).
\end{equation}

We show in this step that for all \(t > 0\),

\begin{equation}
(10) \quad \delta_N(t) \leq |h|_{lip} N^{-1/2} \int_0^t \left(\int_0^s \varphi^2(s-u)dm_u\right)^{1/2} ds + |h|_{lip} \int_0^t |\varphi(t-s)|\delta_N(s)ds.
\end{equation}

First, \(\Delta_N^i(t)\) equals

\[\int_0^t \int_0^\infty \left|1\{z \leq h(f_0^- \varphi(s-u)dm_u)\} - 1\{z \leq h(f_0^- \varphi(s-u)dm_u)\}\right| \pi_i(ds) dz.\]

Taking expectations, we find

\[\delta_N(t) = \int_0^t \mathbb{E}\left[|h(\int_0^s \varphi(s-u)dm_u) - h(N^{-1} \sum_{j=1}^N \int_0^s \varphi(s-u)dz^{N,j}_u)|\right] ds,
\]
whence
\[
\delta_N(t) \leq |h|_{lip} \int_0^t \mathbb{E} \left[ \left| \int_0^s \varphi(s-u)dm_u - N^{-1} \sum_{j=1}^N \int_0^s \varphi(s-u)dZ_u^j \right| \right] ds
\]
\[
+ |h|_{lip} \int_0^t \mathbb{E} \left[ \left| N^{-1} \sum_{j=1}^N \int_0^s \varphi(s-u)d[Z_u^j - Z_u^N] \right| \right] ds
\]
\[
= |h|_{lip}(A + B).
\]
Using exchangeability and Lemma 22
\[
B \leq \int_0^t \mathbb{E} \left[ \int_0^s |\varphi(s-u)|d\Delta_N^1(u) \right] ds = \int_0^t |\varphi(t-u)|\delta_N(u)du.
\]
Next, we use that \( X_s^j = \int_0^s \varphi(s-u)dZ_u^j \) are i.i.d. with mean \( \int_0^s \varphi(s-u)dm_u \), whence
\[
\int_0^s \int_0^\infty 1_{\{z \leq h(\int_0^s \varphi(u-r)dm_u)\}} \varphi(s-u)\pi^1(du\,dz).
\]
Since the integrand is deterministic, denoting by \( \tilde{\pi}^1 \) the compensated Poisson measure,
\[
X_s^1 - \mathbb{E}[X_s^1] = \int_0^s \int_0^\infty 1_{\{z \leq h(\int_0^s \varphi(u-r)dm_u)\}} \varphi(s-u)\tilde{\pi}^1(du\,dz).
\]
Recalling Assumption 7 we find
\[
\text{Var} X_s^1 = \int_0^s \varphi^2(s-u)h(\int_0^u \varphi(u-r)dm_u)ds = \int_0^s \varphi^2(s-u)dm_u.
\]
We used (8) for the last inequality. Gathering (11), (12), (13) and (14) completes the step.

**Step 4.** Here we conclude that for all \( T \geq 0 \), sup\( _{[0,T]} \delta_N(t) \leq C_T N^{-1/2} \). This will end the proof of (ii) by (9). This is not hard: it suffices to start from (10), to apply Lemma 23 (i) and to observe that
\[
\int_0^1 \left( \int_0^s \varphi^2(s-u)dm_u \right)^{1/2} ds
\]
is locally bounded (which follows from the assumption that \( \varphi \) is locally square integrable and the fact that \( m \) is \( C^1 \) on \([0,\infty)\)).

**Step 5.** Finally, (iii) follows from (ii): by Sznitman [35, Proposition 2.2], it suffices to check that for each fixed \( \ell \geq 1 \), \((Z_t^{N,1})_{t \geq 0}, \ldots, (Z_t^{N,\ell})_{t \geq 0}\) goes in law, as \( N \to \infty \), to \( \ell \) independent copies of \((\mathcal{Z}_t)_{t \geq 0}\) (for the uniform topology on compact time intervals). This clearly follows from (ii).

We now want to show that the constant \( C_T \) we get can be quite satisfactory.

**Remark 9.** Work under Assumption 7

(a) Assume that \( |h|_{lip} \int_0^\infty |\varphi(s)|ds < 1 \) (subcritical case) and that \( \int_0^\infty \varphi^2(s)ds < \infty \). Then (ii) of Theorem 8 holds with \( C_T = C \), for some constant \( C > 0 \). This is a satisfactory slow growth.

(b) Assume that \( h(x) = \mu + x \) for some \( \mu > 0 \) and that \( \varphi(t) = ae^{-bt} \) for some \( a > b > 0 \) (if \( a < b \), then point (a) applies). Then \( m_t = \mathbb{E}[\mathcal{Z}_t] \sim \mu(a-b)^{-2}e^{(a-b)t} \) as \( t \to \infty \) and (ii) of Theorem 8 holds with \( C_T = Ce^{(a-b)T} \), for some constant \( C > 0 \). This is again quite satisfactory: the error is of order \( N^{-1/2}m_T \).
Proof. We start with (a). Using the notation of the previous proof, it suffices (see (9)) to show that $\delta_N(t) \leq C T N^{-1/2}$. Setting $\Lambda = |h|_{lip} \int_0^\infty |\varphi(s)|ds < 1$, starting from (10) and observing that $\delta_N$ is non-decreasing, we find $\delta_N(t) \leq |h|_{lip} N^{-1/2} \int_0^t \varphi^2(s-u)dm_u + \delta_N(t)$, whence $\delta_N(t) \leq CN^{-1/2} \int_0^t \varphi^2(s-u)dm_u$. We thus only have to check that $\int_0^t \varphi^2(s-u)dm_u$ is bounded on $[0, \infty)$. Since $\int_0^\infty \varphi^2(s)ds < \infty$, it suffices to prove that $m'_t$ is bounded on $[0, \infty)$. But $m'_t = h(\int_0^t \varphi(t-u)m'_u du) \leq h(0) + |h|_{lip} \int_0^t |\varphi(t-u)|m'_u du$, whence $\sup_{[0,T]} m'_t \leq h(0) + \Lambda \sup_{[0,T]} m'_t$, and thus $\sup_{[0,T]} m'_t \leq h(0) / (1 - \Lambda)$ for any $T > 0$.

We next check (b). First, (8) rewrites $m_t = \mu t + a \int_0^t \int_0^s e^{-h(s-u)}dm_u ds$, with unique solution

$$m_t = -\frac{\mu b t}{a - b} + \frac{\mu a (e^{(a-b)t} - 1)}{(a-b)^2} = \frac{\mu a}{(a-b)^2} e^{(a-b)t}.$$

Next, using (10) and the explicit expressions of $h$, $\varphi$ and $m$, we find

$$\delta_N(t) \leq N^{-1/2} \int_0^t \left( \int_0^s \varphi^2(s-u)dm_u \right)^{1/2} ds + \int_0^t \varphi(t-s)\delta_N(s)ds \leq CN^{-1/2} e^{(a-b)t/2} + a \int_0^t e^{-h(t-s)}\delta_N(s)ds.$$

Setting $u_N(t) = \delta_N(t)e^{bt}$, we get $u_N(t) \leq CN^{-1/2} e^{(a+b)t/2} + a \int_0^t u_N(s)ds$. By Grönwall’s lemma, $u_N(t) \leq CN^{-1/2} e^{(a+b)t/2} + a \int_0^t CN^{-1/2} e^{(a+b)\delta N(s)}ds$. On easily deduces, since $a > b$, that $u_N(t) \leq CN^{-1/2} e^{at}$ so that $\delta_N(t) \leq CN^{-1/2} e^{(a-b)t}$. The use of (9) ends the proof. \qed

3.2. Large time behaviour. We now address the important problem of the large time behaviour. Since the solution $(Z_t)_{t \geq 0}$ to (7) is nothing but an inhomogeneous Poisson process, its large-time behaviour is easily and precisely described, provided we have sufficiently information on the solution to (8). The question is thus: can we use the large time estimates of the mean-field limit to describe the large-time behaviour of the true Hawkes process with a large number of particles? To fix the ideas, we consider the linear case.

We treat separately the subcritical and supercritical cases.

**Theorem 10.** Work under Assumption 7 with $\varphi$ nonnegative and $h(x) = \mu + x$ for some $\mu > 0$. Assume also that $\Lambda = \int_0^\infty \varphi(s)ds < 1$. For each $N \geq 1$, consider the Hawkes process $(Z_t^{N,1}, \ldots, Z_t^{N,N})_{t \geq 0}$ with parameters $(G_N, \varphi^N, h^N)$. Consider also the unique solution $(m_t)_{t \geq 0}$ to (8).

1. We have $m_t \sim a t$ as $t \to \infty$, where $a_0 = \mu/(1 - \Lambda)$.
2. For any fixed $i \geq 1$, $Z_t^{N,i}/m_t$ tends to 1 in probability as $t \to \infty$, uniformly in $N$. More precisely, $\mathbb{E}[|Z_t^{N,i}/m_t - 1|] \leq C m_t^{-1/2}$ for some constant $C$.
3. For any fixed $\ell \geq 1$ $(m_t^{1/2}(Z_t^{N,i}/m_t - 1))_{i=1,...,\ell}$ goes in law to $N(0, I_\ell)$ as $(t, N) \to (\infty, \infty)$ (without condition on the regime).

**Theorem 11.** Work under Assumption 7 with $\varphi$ nonnegative and $h(x) = \mu + x$ for some $\mu > 0$. Assume also that $\Lambda = \int_0^\infty \varphi(s)ds \in (1, \infty]$. Assume finally that $t \to \int_0^t |d\varphi(s)|$ has at most polynomial growth. For each $N \geq 1$, consider the Hawkes process $(Z_t^{N,1}, \ldots, Z_t^{N,N})_{t \geq 0}$ with parameters $(G_N, \varphi^N, h^N)$. Consider also the unique solution $(m_t)_{t \geq 0}$ to (8).
1. We have $m_t \sim a_0 e^{a_0 t}$ as $t \to \infty$, where $a_0 > 0$ is determined by $L_{\varphi}(a_0) = 1$ and where $a_0 = \mu_0^{-2} (\int_0^\infty \varphi(t) e^{-\alpha_0 t} dt)^{-1}$. 

2. For any fixed $i \geq 1$, $Z_t^{N,i}/m_t$ tends to 1 in probability as $(t, N) \to (\infty, \infty)$. More precisely, there is a constant $C$ such that $\mathbb{E}[|Z_t^{N,i}/m_t - 1|] \leq m_t^{-1/2} + CN^{-1/2}(1 + m_t^{-1})$. 

3. For any fixed $\ell \geq 1$,
   (i) $(m_t^{1/2}(Z_t^{N,i}/m_t - 1))_{i=1,\ldots,\ell}$ goes in law to $N(0, I_\ell)$ if $t \to \infty$ and $N \to \infty$ with $m_t/N \to 0$; 
   (ii) $(N^{1/2}(Z_t^{N,i}/m_t - 1))_{i=1,\ldots,\ell}$ goes in law to $(X, \ldots, X)$, if $t \to \infty$ and $N \to \infty$ with $m_t/N \to \infty$. Here $X$ is a $N(0, \sigma^2)$-distributed random variable, where $\sigma^2 = \alpha_0^2 \mu^{-2} \int_0^\infty e^{-2\alpha_0 s} m_t^2 ds$.

Let us summarize. At first order (law of large numbers), the mean-field approximation is always good for large times. At second order (central limit theorem), the mean field approximation is always good for large times in the subcritical case, but fails to be relevant for too large times (depending on $N$) in the supercritical case: the independence property breaks down.

In the supercritical case, we have the technical condition that $t \mapsto \int_0^t |d\varphi(s)|$ has at most polynomial growth. This is useful to have some precise estimates of the solution $m$ to (3). This is, e.g., always satisfied when $\varphi$ is bounded and non-increasing, as is often the case in applications. It is slightly restrictive however, since it forces $\varphi(0)$ to be finite.

It should be possible to study also the critical case, but then the situation is more intricate: many regimes might arise. With a little more work, we could also study, in the supercritical case, the regime where $m_t/N \to x \in (0, \infty)$.

In order to prove Theorems 10 and 11 we will use the following central limit theorem for martingales.

**Lemma 12.** Let $\ell \geq 1$ be fixed. For $N \geq 1$, consider a family $(M_t^{N,1, \ldots, M_t^{N,\ell}})_{t \geq 0}$ of $\ell$-dimensional local martingales satisfying $M_0^{N,1} = \cdots = M_0^{N,\ell} = 0$. Assume that all their jumps are uniformly bounded and that $[M^{N,i}, M^{N,j}]_t = 0$ for every $N \geq 1$, $i \neq j$ and $t \geq 0$. Assume also that there is a continuous increasing function $(v_i)_{i \geq 1} : (0, \infty) \mapsto (0, \infty)$ such that for all $i = 1, \ldots, \ell$, $\lim_{t \to \infty} [M^{N,i}, M^{N,j}]_t = 1$ in probability. In the case where $v_\infty = \lim_{t \to \infty} v_t < \infty$, assume moreover that for all $i = 1, \ldots, \ell$, all $t_0 > 0$, uniformly in $t \geq t_0$, $\lim_{N \to \infty} [M^{N,i}, M^{N,j}]_t = v_t^2$ in probability.

Then $v_t^{-1}(M_t^{N,1}, \ldots, M_t^{N,\ell})$ converges in law to the Gaussian distribution $\mathcal{N}(0, I_\ell)$ as $(t, N) \to (\infty, \infty)$, where $I_\ell$ is the $\ell \times \ell$ identity matrix.

**Proof.** Let $(t_N)_{N \geq 1}$ be a sequence of positive numbers such that $t_N \to \infty$. We want to prove that $v_t^{-1}(M_t^{N,1}, \ldots, M_t^{N,\ell})$ converges in law to $\mathcal{N}(0, I_\ell)$ for all $t \in [0, 1]$, set $\tau_u^N = \inf\{t \geq 0 : v_t^2 \geq u v_{t_N}^2\}$.

Since $v$ is increasing and continuous, $\tau_u^N$ is also continuous and increasing for each $N$. We also clearly have $v_{t_N}^2 = u v_{t_N}^2$ for all $u \in [0, 1]$ and $\tau_1^N = t_N$. Finally, for each $u > 0$ fixed, the sequence $\tau_u^N$ is increasing.

For all $u \in [0, 1]$, $\lim_{N} v_{\tau_u^N}^{-2}[M^{N,i}, M^{N,j}]_{\tau_u^N} = 1$ in probability. Indeed, in the case $v_\infty = \infty$, this follows from the facts that $\lim_{N} v_{\tau_u^N}^{-2}[M^{N,i}, M^{N,j}]_{\tau_u^N} = 1$. When $v_\infty < \infty$, the additional assumption (uniformity in $t \geq t_0$ of the convergence as $N \to \infty$) clearly suffices, since the sequence $\tau_u^N$ is increasing and thus bounded from below.
We define the martingales \((L_u^{N,i})_{u \in [0, 1]}\) by \(L_u^{N,i} = v_{t_u}^{-1} M_{t_u}^{N,i}\). All their jumps are uniformly bounded (because those of \(M^{N,i}\) are assumed to be uniformly bounded and because \(\sup_N v_{t_u}^{-1} < \infty\) since \(v\) is increasing). We also have \([L^{N,i}, L^{N,j}]_u = 0\) for all \(i \neq j\), all \(u \in [0, 1]\). Furthermore, using that \(v_{t_u}^2 = u v_{t_u}^2\),
\[
[L^{N,i}, L^{N,j}]_u = \frac{[M^{N,i}, M^{N,j}]_{t_u}}{v_{t_u}^2} = \frac{[M^{N,i}, M^{N,j}]_{t_u}}{u v_{t_u}^2} u \to u
\]
in probability. Therefore, according to Jacod-Shiryaev \cite{22} (Theorem VIII-3.11), the process \((L_u^{N,1}, \ldots, L_u^{N,N})_{u \in [0, 1]}\) converges in law to \((B_u^1, \ldots, B_u^N)_{u \in [0, 1]}\) where the \(B^i\) are independent standard Brownian motions. In particular, \((L_u^{N,1}, \ldots, L_u^{N,N})\) goes in law to \(\mathcal{N}(0, I_N)\). To conclude the proof, it thus suffices to observe that \(L^{N,i} = v_{t_u}^{-1} M^{N,i}_u\). □

We can now give the

**Proof of Theorem 10.** In the present (linear) case, we can rewrite \(8\) as \(m_t = f_0^t (\mu + f_s^t \varphi(t-s) m_u) ds = \mu + \int_0^t \varphi(t-s) m_u ds\) by Lemma \(22\). This equation is studied in details in Lemma \(25\) recalling that \(\Lambda = \int_0^\infty \varphi(s) ds < 1\), we have \(m_t' \sim a_0\) and \(m_t \sim a_0 t\) as \(t \to \infty\), where \(a_0 = \mu/(1-\Lambda)\), which proves point (i). The proof is now divided in several steps. Step 1 will also be used in the supercritical case.

**Step 1.** Recall that, for some i.i.d. family \((\pi^i(ds dz))_{i \geq 1}\) of Poisson measures on \([0, \infty) \times [0, \infty)\) with intensity measure \(ds dz\),
\[
Z_t^{N,i} = \int_0^t \int_0^\infty \{z \leq \mu + N^{-1} \sum_{j=1}^N f_0^s \varphi(s-u) d\mathcal{Z}_u^{N,j}\} \pi^i(ds dz).
\]
We have \(E[Z_t^{N,i}] = m_t\). Indeed, by exchangeability, we see that \(E[Z_t^{N,i}] = E[Z_t^{N,1}]\) and that
\[
E[Z_t^{N,1}] = \int_0^t \left(\mu + N^{-1} \sum_{j=1}^N \int_0^s \varphi(s-u) dE[Z_u^{N,j}]\right) ds = \int_0^t \left(\mu + \int_0^s \varphi(s-u) dE[Z_u^{N,1}]\right) ds,
\]
whence \((E[Z_t^{N,1}])_{i \geq 0}\) solves \(8\), of which the unique solution is \((m_t)_{t \geq 0}\) by Lemma \(24\).

We next introduce \(U_t^{N,i} = Z_t^{N,i} - m_t\) and the martingales (here \(\pi^i(ds dz) = \pi_t(ds dz) - ds dz\))
\[
M_t^{N,i} = \int_0^t \int_0^\infty \{z \leq \mu + N^{-1} \sum_{j=1}^N f_0^s \varphi(s-u) d\mathcal{Z}_u^{N,j}\} \tilde{\pi}^i(ds dz).
\]
We consider the mean processes \(\mathcal{Z}_t^N = N^{-1} \sum_1^N \mathcal{Z}_t^{N,i}, \mathcal{U}_t^N = N^{-1} \sum_1^N U_t^{N,i}\) and finally \(\mathcal{M}_t^N = N^{-1} \sum_1^N M_t^{N,i}\). An easy computation using \(8\) and Lemma \(22\) shows that
\[
U_t^{N,i} = M_t^{N,i} + \int_0^t N^{-1} \sum_{j=1}^N \int_0^s \varphi(s-u) d\mathcal{Z}_u^{N,j} ds - m_t
\]
\[
= M_t^{N,i} + \int_0^t \int_0^s \varphi(s-u) \left(N^{-1} \sum_{j=1}^N d\mathcal{Z}_u^{N,j} - dm_u\right) ds
\]
\[
= M_t^{N,i} + \int_0^t \varphi(t-s) \left(N^{-1} \sum_{j=1}^N \mathcal{Z}_s^{N,j} - m_s\right) ds,
\]
so that

\[(15) \quad U_t^{N,i} = M_t^{N,i} + \int_0^t \varphi(t-s)U_s^N \, ds.\]

This directly implies that

\[(16) \quad U_t^N = M_t^N + \int_0^t \varphi(t-s)U_s^N \, ds.\]

Next, we observe that \([M^{N,i}, M^{N,j}]_t = 0\) for all \(i \neq j\) (because these martingales a.s. never jump simultaneously) and that \([M^{N,i}, M^{N,j}]_t = Z_t^{N,i}.\) Hence \([\bar{M}^N, \bar{M}^N]_t = N^{-1}Z_t^N.\) We thus have 

\[\mathbb{E}[(M_t^{N,i})^2] = \mathbb{E}[Z_t^{N,i}] = m_t \quad \text{and} \quad \mathbb{E}((\bar{M}_t^N)^2) = N^{-1}\mathbb{E}[Z_t^N] = N^{-1}m_t.\]

**Step 2.** Recalling (10) and using that \(\Lambda = \int_0^\infty \varphi(s)\, ds < 1,\) we observe that \(\sup_{[0,t]} |U_s^N| \leq \sup_{[0,t]} |\bar{M}_s^N| + \Lambda \sup_{[0,t]} |\bar{U}_s^N|\). Consequently,

\[\mathbb{E}\left[\sup_{[0,t]} |U_t^N|\right] \leq (1 - \Lambda)^{-1} \mathbb{E}\left[\sup_{[0,t]} |\bar{M}_s^N|\right] \leq CN^{-1/2}m_t^{-1/2}\]

by the Doob and Cauchy-Schwarz inequalities. We easily deduce that

\[\mathbb{E}\left[\int_0^t \varphi(t-s)|U_s^N|\, ds\right] \leq \Lambda \mathbb{E}\left[\sup_{[0,t]} |U_s^N|\right] \leq CN^{-1/2}m_t^{1/2},\]

whence finally, recalling (15),

\[m_t^{-1} \mathbb{E}[U_t^{N,i}] \leq m_t^{-1} \mathbb{E}[|M_t^{N,i}|] + Cm_t^{-1}N^{-1/2}m_t^{1/2} \leq Cm_t^{-1/2}.

This says that \(\mathbb{E}[|Z_t^{N,i}/m_t - 1|] \leq Cm_t^{-1/2}\) and thus proves point 2.

**Step 3.** We then fix \(\ell \geq 1\) and use (15) to write, for \(i = 1, \ldots, \ell,\)

\[m_t^{1/2}(Z_t^{N,i}/m_t - 1) = m_t^{-1/2}M_t^{N,i} = m_t^{-1/2}M_t^{N,i} + m_t^{-1/2} \int_0^t \varphi(t-s)U_s^N \, ds.\]

First, \(\mathbb{E}[m_t^{-1/2} \int_0^t \varphi(t-s)|U_s^N|\, ds] \leq CN^{-1/2},\) which tends to 0 as \((t, N) \to (\infty, \infty),\) by the estimate proved in Step 2. To conclude the proof of point 3, we thus only have to prove that \((m_t^{-1/2}M_t^{N,i})_{i=1,\ldots,\ell}\) goes to law in \(\mathcal{N}(0, I_\ell)\) as \((t, N) \to (\infty, \infty).\) To this end, we apply Lemma 12. The jumps of the martingales \(M_t^{N,i}\) are uniformly bounded (by 1) and we have seen that \([M^{N,i}, M^{N,j}]_t = 0\) for all \(i \neq j.\) The function \((m_t)_{t \geq 0}\) is continuous and increases to infinity. It thus suffices to check that, as \((t, N) \to (\infty, \infty),\) \(m_t^{-1}[M_t^{N,i}, M_t^{N,j}] \to 1\) in probability. Since \([M_t^{N,i}, M_t^{N,j}]_t = Z_t^{N,i},\) this is an immediate consequence of point 2. \(\square\)

We now turn to the supercritical case.

**Proof of Theorem 17.** We rewrite (8) as \(m_t = \int_0^t (\mu + \int_0^s \varphi(s-u) \, du) \, ds = \mu t + \int_0^t \varphi(t-s) \, ds\) by Lemma 22. This equation is studied in details in Lemma 26. There is a unique \(\alpha_0 > 0\) such that \(L_\varphi(\alpha_0) = 1\) and, defining \(\alpha_0 \in (0, \infty)\) as in the statement, we have \(m_t \sim a_0 e^{\alpha_0 t}\) and \(m'_t \sim a_0 a_0 e^{\alpha_0 t}\) as \(t \to \infty,\) which proves point 1. We also know that \(\Gamma(t) = \sum_{n \geq 1} \varphi^n(t) \sim (a_0 a_0 / \mu) e^{\alpha_0 t},\) that \(\Theta(t) = \int_0^t \Gamma(s) \, ds \sim (a_0 a_0 / \mu) e^{\alpha_0 t}\) and further properties of \(m, m', \Gamma, \Theta\) are proved in Lemma 26.

**Step 1.** We adopt the same notation as in the proof of Theorem 10. Step 1, of which all the results remain valid in the present case. Point 1 follows from Lemma 26(a).
Step 2. First, (16) says exactly that \( \mathbb{U}^N = \mathbb{M}^N + \varphi \ast \mathbb{U}^N \). Using Lemma 26\((e)\), we deduce that \( \mathbb{U}^N = \mathbb{M}^N + \Gamma \ast \mathbb{M}^N \) (the processes \( \mathbb{U}^N \) and \( \mathbb{M}^N \) are clearly a.s. càdlàg and thus locally bounded). Since \( \mathbb{E}(\|\mathbb{M}^N_t\|^2) = N^{-1}m_t \) by Step 1,
\[
\mathbb{E}(\|\mathbb{U}^N_t\|) \leq \mathbb{E}(\|\mathbb{M}^N_t\|) + \int_0^t \mathbb{E}(\|\mathbb{M}^N_s\|)ds
\]
\[
\leq N^{-1/2}m_t^{1/2} + \int_0^t \mathbb{E}(\|\mathbb{M}^N_s\|)ds
\]
\[
\leq CN^{-1/2}(1 + m_t).
\]
The last inequality easily follows from Lemma 26\((b)\).

Using (16) again, we see that \( \int_0^t \varphi(t-s)\mathbb{U}^N_s ds = \mathbb{U}^N_t - \mathbb{M}^N_t \), whence
\[
\mathbb{E}
\[
\mathbb{E}(\|\mathbb{U}^N_t\|) \leq \mathbb{E}(\|\mathbb{M}^N_t\|) \leq N^{-1/2}m_t^{1/2} + CN^{-1/2}(1 + m_t) \leq CN^{-1/2}(1 + m_t).
\]

On the other hand, we know from Step 1 that \( \mathbb{E}(\|\mathbb{M}^N_t\|^2) = m_t \). Using (15), we conclude that
\[
\mathbb{E}(\|\mathbb{M}^N_t\|^2) = m_t \leq CN^{-1/2}(1 + m_t)
\]
which ends the proof of 2.

Step 3. We then fix \( \ell \geq 1 \) and write, for \( i = 1, \ldots, \ell \), by (15),
\[
\mathbb{E}(\|Z^{N,i}_t/m_t - 1\|) = m_t^{-1} \mathbb{E}(\|\mathbb{U}^{N,i}_t\|) \leq m_t^{-1} + CN^{-1/2}(1 + m_t).
\]

Step 3.1. We first consider the regime \( (t, N) \to (\infty, \infty) \) with \( m_t/N \to 0 \) and study
\[
m_t^{1/2}(Z^{N,i}_t/m_t - 1) = m_t^{-1/2} \mathbb{M}^{N,i}_t + \int_0^t \varphi(t-s)\mathbb{U}^N_s ds.
\]
The second term tends to 0 in probability, because we can bound, using Step 2, its \( L^1 \)-norm by \( Cm_t^{-1/2}N^{-1/2}(1 + m_t) \), which tends to 0 in the present regime. We thus just have to prove that \( (m_t^{-1/2} \mathbb{M}^{N,i}_t)_{i=1,\ldots,\ell} \) goes in law to \( N(0, I_\ell) \). We use Lemma 12 the martingales \( \mathbb{M}^{N,i}_t \) uniformly bounded \((by 1)\) jumps and we have seen that \( \mathbb{M}^{N,i}_t = \varphi(t-s)\mathbb{U}^N_s ds \).

Step 3.2. We finally consider the regime \( (t, N) \to (\infty, \infty) \) with \( m_t/N \to 0 \) and study
\[
N^{1/2}(Z^{N,i}_t/m_t - 1) = N^{1/2}m_t^{-1} \mathbb{M}^{N,i}_t + N^{1/2}m_t^{-1} \int_0^t \varphi(t-s)\mathbb{U}^N_s ds.
\]
First, \( N^{1/2}m_t^{-1} \mathbb{M}^{N,i}_t \to 0 \) in probability, because its \( L^1 \)-norm is bounded by \( N^{1/2}m_t^{-1/2} \) (recall that \( \mathbb{E}(\|\mathbb{M}^{N,i}_t\|^2) = m_t \)), which tends to 0 in the present regime. Since \( V^{N}_{t} := N^{1/2}m_t^{-1} \int_0^t \varphi(t-s)\mathbb{U}^N_s ds \) does not depend on \( i \), it only remains to prove that \( V^{N}_t \) goes in law to \( N(0, \sigma^2) \). We write, using (16), recalling that \( \mathbb{U}^N = \mathbb{M}^N + \Gamma \ast \mathbb{M}^N \) (see Step 2) and integrating by parts (recall that \( \Upsilon(t) = \int_0^t \Upsilon(s)ds \))
\[
V^{N}_{t} = N^{1/2}m_t^{-1}(\mathbb{U}^N_t - \mathbb{M}^N_t) = N^{1/2}m_t^{-1} \int_0^t \Gamma(t-s)\mathbb{M}^N_s ds = N^{1/2}m_t^{-1} \int_0^t \Upsilon(t-s)d\mathbb{M}^N_s.
\]

HIGH DIMENSIONAL HAWKES PROCESSES 15
Introduce $W_t^N = (\alpha_0/\mu) N^{-1/2} \int_0^t e^{-\alpha_0 s} dM_s^N$ and observe that, since $E[|M_s^N, M_s^N|] = N^{-1} m_t$, \[ E[(V_t^N - W_t^N)^2] = E\left[ N \int_0^t (m_t^{-1} Y(t-s) - (\alpha_0/\mu)e^{-\alpha_0 s})^2 d|M_s^N, M_s^N|_s \right] \]
\[ = \int_0^t (m_t^{-1} Y(t-s) - (\alpha_0/\mu)e^{-\alpha_0 s})^2 m'_t ds. \]

Lemma 26 (c) tells us that this tends to 0 as $t \to \infty$. We thus only have to prove that $W_t^N$ goes in law to $\mathcal{N}(0, \sigma^2)$ as $(t, N) \to (\infty, \infty)$.

This follows again from Lemma 12 (with $\ell = 1$): the jumps of the martingale $(W_t^N)_{t \geq 0}$ are bounded by $(\alpha_0/\mu) N^{-1/2}$ (because those of $M_t^N$ are bounded by $N^{-1}$). The function $v_t = (\alpha_0/\mu)(\int_0^t e^{-2\alpha_0 s} m'_s ds)^{1/2}$ is continuous and increasing to the finite limit $v_\infty = \sigma$ (which was defined in the statement). We thus only have to prove that (a) $v_t^{-2}[W_t^N, W_t^N]_t \to 1$ in probability as $(t, N) \to (\infty, \infty)$, (b) for all $t > 0$, uniformly in $t \geq t_0$, $v_t^{-2}[W_t^N, W_t^N]_t \to 1$ in probability as $N \to \infty$. By Lemma 12, we will deduce that $v_t^{-1} W_t^N$ goes in law to $\mathcal{N}(0, 1)$ as $(t, N) \to (\infty, \infty)$, which of course implies that $W_t^N$ goes in law to $\mathcal{N}(0, \sigma^2)$ as desired.

We have, since $|M_s^N, M_s^N|_t = N^{-1} Z_t^N$, \[ [W_t^N, W_t^N]_t = (\alpha_0/\mu)^2 N \int_0^t e^{-2\alpha_0 s} d[M_s^N, M_s^N]_s = (\alpha_0/\mu)^2 \int_0^t e^{-2\alpha_0 s} dZ_s^N. \]
Using that $Z_t^N = U_t^N + m_t$ and performing an integration by parts, we see that \[ [W_t^N, W_t^N]_t = v_t^2 + (\alpha_0/\mu)^2 \int_0^t e^{-2\alpha_0 s} dU_s^N \]
\[ = v_t^2 + (\alpha_0/\mu)^2 e^{-2\alpha_0 t} U_t^N + 2(\alpha_0^3/\mu^2) \int_0^t e^{-2\alpha_0 s} U_s^N ds. \]
Recalling that $E[|U_t^N|] \leq CN^{-1/2}(1 + m_t)$, we infer \[ E\left[ ((\alpha_0/\mu)^2 e^{-2\alpha_0 t} U_t^N + 2(\alpha_0^3/\mu^2) \int_0^t e^{-2\alpha_0 s} U_s^N ds \right] \]
\[ \leq \frac{C}{N^{1/2}} \left( e^{-2\alpha_0 t}(1 + m_t) + \int_0^t e^{-2\alpha_0 s}(1 + m_s) ds \right), \]
which is bounded by $CN^{-1/2}$ by Lemma 26. We have proved that $\sup_{t \geq 0} E[[W_t^N, W_t^N]_t - v_t^2]] \leq CN^{-1/2}$, from which points (a) and (b) above immediately follow. The proof is complete. □

4. Nearest neighbour model

We consider here the case where $G$ is a regular grid, on which particles interact (directly) only if they are neighbours. We will work on $\mathbb{Z}^d$, endowed with the set of edges \[ \mathcal{E} = \{(i, j) \in (\mathbb{Z}^d)^2 : |i - j| = 0 \text{ or } 1\}, \]
where $|(i_1, \ldots, i_d)| = (\sum_{r=1}^d i_r^2)^{1/2}$. Thus each point has $2d + 1$ neighbours (including itself). We hesitated to include self-interaction, but this avoids some needless complications due to the periodicity of the underlying random walk on $\mathbb{Z}^d$. 
Assumption 13. (i) The graph $G = (S, E)$ is $S = \mathbb{Z}^d$ (for some $d \geq 1$) endowed with the above set of edges $E$.

(ii) There is a nonnegative locally integrable function $\varphi : [0, \infty) \to [0, \infty)$ such that for all $(j, i) \in E$, $\varphi_{ji} = (2d + 1)^{-1}\varphi$.

(iii) For all $i \in \mathbb{Z}^d$, there is $\mu_i \geq 0$ such that $h_i(x) = \mu_i + x$. The family $(\mu_i)_{i \in \mathbb{Z}^d}$ is bounded.

We next introduce a few notation. In the whole section, we call vector (and write in bold) a family of numbers indexed by $\mathbb{Z}^d$. We call matrix a family indexed by $\mathbb{Z}^d \times \mathbb{Z}^d$. The identity matrix $I$ is of course defined as $I(i, j) = 1_{(i=j)}$. We will often use the product of a matrix and a vector. The matrix $A = (A(i, j))_{i,j \in \mathbb{Z}^d}$ defined by

$$A(i, j) = (2d + 1)^{-1}1_{(i,j) \in E}$$

will play an important role. Since $A$ is a stochastic matrix, we can define, for any $\Lambda \in (0, 1)$,

$$Q_{\Lambda}(i, j) = \sum_{n \geq 0} \Lambda^n A^n(i, j).$$

4.1. Large-time behaviour. Under Assumption 13 we can use Theorem 6 (with $p_i = 2^{-|i|}$, see Remark 2(ii)): there is a unique Hawkes process $(Z^i_t)_{i \in \mathbb{Z}^d, t \geq 0}$ with parameters $(G, \varphi, h)$ such that $\sum_{i \in \mathbb{Z}^d} 2^{-|i|}E[Z^i_t] < \infty$. Let us state the first results of this section. As usual, we treat separately the subcritical and supercritical cases.

Theorem 14. Work under Assumption 13 and assume further that $\Lambda = \int_0^\infty \varphi(t)dt < 1$. Consider the unique Hawkes process $(Z^i_t)_{i \in \mathbb{Z}^d, t \geq 0}$ with parameters $(G, \varphi, h)$. For all $i \in \mathbb{Z}^d$, $t^{-1}Z^i_t$ goes in probability, as $t \to \infty$, to $\sum_{j \in \mathbb{Z}^d} Q_{\Lambda}(i, j)\mu_j$.

Theorem 15. Work under Assumption 13 and assume further that $\Lambda = \int_0^\infty \varphi(t)dt \in (1, \infty]$ and that $t \mapsto \int_0^t |d\varphi(s)|$ has at most polynomial growth. Consider $\alpha_0 > 0$ uniquely defined by $\mathcal{L}_\varphi(\alpha_0) = 1$. Assume finally that the “mean value”

$$\mu = \lim_{t \to \infty} \frac{1}{\#\{i \in \mathbb{Z}^d : |i| \leq t\}} \sum_{|i| \leq t} \mu_i$$

exists and is positive.

Consider the unique Hawkes process $(Z^i_t)_{i \in \mathbb{Z}^d, t \geq 0}$ with parameters $(G, \varphi, h)$. Then for all $i \in \mathbb{Z}^d$, $e^{-\alpha_0 t}Z^i_t$ goes in probability, as $t \to \infty$, to $a_0 = \mu \alpha_0^{-2} (\int_0^\infty t\varphi(t)e^{-\alpha_0 t}dt)^{-1}$.

Let us comment on these results. In the subcritical case, the parameter $\mu = (\mu_i)_{i \in \mathbb{Z}^d}$ is strongly present in the limiting behaviour: the limit of $t^{-1}Z^i_t$ depends on a certain mean of $\mu$ around the site $i$ and thus depends on $i$. In the supercritical case, the behaviour is very different: the limit value of $e^{-\alpha_0 t}Z^i_t$ does not depend on $i$, and depends on $\mu = (\mu_i)_{i \in \mathbb{Z}^d}$ only through a global mean value. Observe also that for a finite-dimensional (e.g. scalar) Hawkes process, there is no law of large numbers: one can get a limit of something like $e^{-\alpha_0 t}Z^1_t$, but the limit is random, see Zhu [41] Section 5.4 (in particular Theorem 23 and Corollary 1). In that sense, we can say that in the supercritical case, the law of large number is reminiscent of the infinite dimension and of the interaction.

We will need a precise approximation for $A^n(i, j)$ where $A$ is defined by (17). It is given by the local central limit theorem, since $A$ is the transition matrix of an aperiodic symmetric random walk on $\mathbb{Z}^d$ with bounded jumps. Precisely, we infer from Lawler-Limic [25] Theorem 2.1.1 and
On the one hand, using that
\[ \sum_n \sum \]
Similarly, we have
From (20), the first sum is bounded by
\[ p_n(x) = \frac{(2d + 1)^{d/2}}{4\pi t} \exp \left( -\frac{(2d + 1)|x|^2}{4t} \right). \]
To apply [23] Theorem 2.1.1], we needed to compute the covariance matrix \( \Gamma \) corresponding to our random walk, we found \( \Gamma = 2.2(2d + 1)^{-1}I_d \), \( I_d \) being the \( d \times d \) identity matrix.

**Lemma 16.** Consider the matrix \( (A(i, j))_{i,j \in \mathbb{Z}^d} \) defined by (17).

(i) It holds that \( \varepsilon_n = \sum_{j \in \mathbb{Z}^d} (A^n(i, j))^2 \) does not depend on \( i \in \mathbb{Z}^d \) and tends to 0 as \( n \to \infty \).

(ii) Let \( \mu = (\mu_i)_{i \in \mathbb{Z}^d} \) be bounded and satisfy (19). Then for all \( i \in \mathbb{Z}^d \), \( \lim_{n \to \infty} (A^n \mu)_i = \mu \).

**Proof.** In the following we denote by \( C \) a constant depending only on \( d \).

Point (i) is easy: since \( A^n(i, j) = A^n(0, j - i) \) and since \( A \) is stochastic, one has \( \varepsilon_n = \sum_{j \in \mathbb{Z}^d} (A^n(0, j))^2 \leq \sup_{j \in \mathbb{Z}^d} A^n(0, j) \). Moreover, by (20), \( A^n(0, j) \leq p_n(j) + Cn^{-(d+1)/2} \leq Cn^{-d/2} \). We conclude that \( \varepsilon_n \leq Cn^{-d/2} \to 0 \) as desired.

Now we turn to the proof of (ii). Let \( i \in \mathbb{Z}^d \). First we show that \( \lim_n [(A^n \mu)_i - \sum_{j \in \mathbb{Z}^d} p_n(j)\mu_j] = 0 \). Since \( (A^n \mu)_i = \sum_{j \in \mathbb{Z}^d} A^n(i, j)\mu_j = \sum_{j \in \mathbb{Z}^d} A^n(0, j - i)\mu_j \) and since the family \( (\mu_j)_{j \in \mathbb{Z}^d} \) is bounded, it suffices to prove that \( v_n = \sum_{j \in \mathbb{Z}^d} |A^n(0, j - i) - p_n(j)| \to 0 \). We write
\[
v_n \leq \sum_{|j| \leq n^{1/2+1/4d}} |A^n(0, j - i) - p_n(j)| + \sum_{|j| > n^{1/2+1/4d}} (A^n(0, j - i) + p_n(j)) = v_n^1 + v_n^2.
\]

On the one hand, using that \( \sum_{j \in \mathbb{Z}^d} |j|^2 A^n(0, j) \leq Cn \) (the variance of the random walk at time \( n \) is of order \( n \)), so that \( \sum_{j \in \mathbb{Z}^d} |j|^2 A^n(0, j - i) = \sum_{k \in \mathbb{Z}^d} |i + k|^2 A^n(0, k) \leq C(|i|^2 + n) \) and thus
\[
\sum_{|j| > n^{1/2+1/4d}} |j|^2 A^n(0, j - i) \leq Cn^{-1/2d} \sum_{j \in \mathbb{Z}^d} |j|^2 A^n(0, j - i) \leq Cn^{-1/2d}(|i|^2 + n).
\]

Similarly, we have \( \sum_{j \in \mathbb{Z}^d} |j|^2 p_n(j) \leq Cn \) and thus
\[
\sum_{|j| > n^{1/2+1/4d}} p_n(j) \leq n^{-1/2d} \sum_{j \in \mathbb{Z}^d} |j|^2 p_n(j) \leq Cn^{-1/2d}.
\]

Consequently \( \lim_n v_n^2 = 0 \). On the other hand,
\[
v_n^1 \leq \sum_{|j| \leq n^{1/2+1/4d}} |A^n(0, j - i) - p_n(j - i)| + \sum_{|j| \leq n^{1/2+1/4d}} |p_n(j - i) - p_n(j)|.
\]

From [23], the first sum is bounded by \( Cn^{-(d+1)/2} \# \{ j \in \mathbb{Z}^d : |j| \leq n^{1/2+1/4d} \} \leq Cn^{-3/4} \to 0 \).

For the second sum, we use that, with \( c_d = (2d + 1)/4 \),
\[
|p_n(j - i) - p_n(j)| = p_n(j) \left[ 1 - \exp \left( -\frac{c_d}{n} |i|^2 + \frac{2c_d}{n} |i| \right) \right].
\]

Hence for \( |j| \leq n^{1/2+1/4d} \) and for \( n \) large enough (e.g. so that \( |i|n^{-1/2+1/4d} \leq 1 \)),
\[
|p_n(j - i) - p_n(j)| \leq C p_n(j)(|i|^2 n^{-1} + |i|n^{-1/2+1/4d}) \leq C p_n(j)(1 + |i|^2)n^{-1/4}.
\]

Thus \( \sum_{|j| \leq n^{1/2+1/2d}} |p_n(j - i) - p_n(j)| \leq C(1 + |i|^2)n^{-1/4} \) and we deduce that \( \lim_n v_n^1 = 0 \).
We have shown that \( \lim v_n = 0 \). It only remains to check that \( \lim_n \sum_{j \in \mathbb{Z}^d} \mu_j p_n(j) = \mu \). Let \( \{r_k\}_{k \geq 0} \) be the increasing sequence of nonnegative numbers such that \( \{r_k\}_{k \geq 0} = \{|j| : j \in \mathbb{Z}^d\} \) and observe that

\[
\sum_{j \in \mathbb{Z}^d} \mu_j p_n(j) = \sum_{k \geq 0} p_n(r_k) \sum_{|j|=r_k} \mu_j.
\]

A discrete integration by parts shows that

\[
\sum_{j \in \mathbb{Z}^d} \mu_j p_n(j) = \sum_{k \geq 0} (p_n(r_k) - p_n(r_{k+1})) \sum_{|j|\leq r_k} \mu_j = \sum_{k \geq 0} v(r_k)(p_n(r_k) - p_n(r_{k+1})) \frac{1}{v(r_k)} \sum_{|j|\leq r_k} \mu_j,
\]

where \( v(r) = \#\{j \in \mathbb{Z}^d : |j| \leq r\} \). We easily conclude that \( \lim_n \sum_{j \in \mathbb{Z}^d} \mu_j p_n(j) = \mu \) as desired, because

(a) \( \lim_{k \to \infty} \frac{1}{v(r_k)} \sum_{|j|\leq r_k} \mu_j = \mu \);

(b) for all \( k \geq 0 \) fixed, \( \lim_n v(r_k)(p_n(r_k) - p_n(r_{k+1})) = 0 \);

(c) \( \lim_{n \to \infty} \sum_{k=0}^\infty v(r_k)(p_n(r_k) - p_n(r_{k+1})) = 1 \).

Point (a) follows from our condition (14) on \( \mu \), point (b) is obvious (because \( |v(r_k)(p_n(r_k) - p_n(r_{k+1}))| \leq v(r_k) \sup_{i \in \mathbb{Z}^d} p_n(i) \leq C v(r_k) n^{-d/2} \to 0 \)). To check (c), we write \( \sum_{k=0}^\infty v(r_k)(p_n(r_k) - p_n(r_{k+1})) = \sum_{j \in \mathbb{Z}^d} p_n(j) = \sum_{j \in \mathbb{Z}^d} A^n(0, j) + \sum_{j \in \mathbb{Z}^d} (p_n(j) - A^n(0, j)) = 1 + \sum_{j \in \mathbb{Z}^d} (p_n(j) - A^n(0, j)) \) and this tends to 1, because \( \lim_n \sum_{j \in \mathbb{Z}^d} (p_n(j) - A^n(0, j)) = 0 \), as seen in the first part of the proof (this is \( v_n \) in the special case where \( i = 0 \)).

Let us now give the

**Proof of Theorem 14.** We split the proof into several steps. We assume that there is at least one \( i \in \mathbb{Z}^d \) such that \( \mu_i > 0 \), because else the result is obvious (because then \( Z_i^t = 0 \) for all \( i \in \mathbb{Z}^d \), all \( t \geq 0 \)). The first step will also be used in the supercritical case.

**Step 1.** We write as usual, for some i.i.d. family \( (\pi^i(ds \, dz))_{i \geq 1} \) of Poisson measures on \( [0, \infty) \times [0, \infty) \) with intensity measure \( ds \, dz \),

\[
Z_i^t = \int_0^t \int_0^\infty 1_{\{s \leq \mu_i + (2d+1)^{-1} \sum_{j \neq i} \varphi(s-u)dz\}} \pi^i(ds \, dz).
\]

Let us put \( m_i^t = \mathbb{E}[Z_i^t] \) and \( m_i = (m_i^t)_{i \in \mathbb{Z}^d} \). A simple computation (using one more time Lemma 22) gives us, for all \( i \in \mathbb{Z}^d \),

\[
m_i^t = \mu_i t + \int_0^t (2d+1)^{-1} \sum_{j \neq i} \varphi(t-s)m_j^s \, ds.
\]

Using the vector formalism, this rewrites \( m_i = \mu t + \int_0^t \varphi(t-s)(Am^s)ds \). We furthermore know (from Theorem 6) that for all \( t \geq 0 \), \( \sum_{j \in \mathbb{Z}^d} 2^{-|j|} m_j^t < \infty \). Applying Lemma 27 we see that \( m^t \) is of class \( C^1 \) on \( [0, \infty) \) for each \( i \in \mathbb{Z}^d \), that

\[
m_i^t = \mu + \int_0^t \varphi(t-s)Am^s ds
\]

and that

\[
m_i = (I + \sum_{n \geq 1} A^n \int_0^t \varphi^n(s) ds) \mu.
\]
Lemma 27 also tells us that \( u_t = \sup_{i \in \mathbb{Z}^d} \sup_{[0,t]} (m^i_s)' \) is locally bounded, which of course implies that \( \sup_{i \in \mathbb{Z}^d} \sup_{[0,t]} m^i_s \) is also locally bounded (because \( m^i_0 = 0 \) for all \( i \in \mathbb{Z}^d \)), and that

\[
(24) \quad u_t \leq C + \int_0^t \varphi(t-s) u_s ds.
\]

We introduce the martingales, for \( i \in \mathbb{Z}^d \), (we use a tilde for compensation),

\[
M^i_t = \int_0^t \int_0^\infty 1 \{ z \leq \mu_i + (2d+1)^{-1} \sum_{j \neq i} \int_0^z \varphi(s-w) dZ^j_w \} \tilde{\mathbb{P}}^i(ds,dz)
\]

and observe as usual that \(|M^i, M^j|_t = 0\) when \( i \neq j \) (because these martingales a.s. never jump at the same time) while \([M^i, M^i]_t = Z^i_t\). We finally introduce \( U^i_t = Z^i_t - m^i_t \), the vectors \( U_t = (U^i_t)_{i \in \mathbb{Z}^d} \) and \( M_t = (M^i_t)_{i \in \mathbb{Z}^d} \) and observe that

\[
(25) \quad U_t = M_t + \int_0^t \varphi(t-s) A U_s ds.
\]

Indeed, for every \( i \in \mathbb{Z}^d \), using Lemma 22 and the equation satisfied by \( m^i_t \), we find

\[
U^i_t = M^i_t + \int_0^t (2d+1)^{-1} \sum_{j \neq i} \varphi(t-s)(Z^j_s - m^j_s) ds = M^i_t + \int_0^t \varphi(t-s)(AU_s)_i ds.
\]

Equation (25) can be solved as usual as

\[
(26) \quad U_t = \left( M_t + \sum_{n \geq 1} \int_0^t \varphi^n(t-s) A^n M_s ds \right).
\]

Finally, we easily check that \( v_t = \sup_{i \in \mathbb{Z}^d} \sup_{[0,t]} \mathbb{E}[|U^i_t|] \) is locally bounded (because \( \mathbb{E}[|U^i_t|] \leq \mathbb{E}[|Z^i_t|] + m^i_t \leq 2m^i_t \)) and satisfies (start from (25), use that \( \mathbb{E}[|M^i_t|] \leq \mathbb{E}[|M^i, M^i|_t]^{1/2} = \mathbb{E}[Z^i]^{1/2} = (m^i)^{1/2} \leq (\int_0^t u_s ds)^{1/2} \) and that \( A \) is stochastic)

\[
(27) \quad v_t \leq \left( \int_0^t u_s ds \right)^{1/2} + \int_0^t \varphi(t-s) v_s ds.
\]

**Step 2.** Here we prove that there is a constant \( C \) such that for all \( i \in \mathbb{Z}^d \), \( (m^i_t)' \leq C \) (and thus also \( m^i_t \leq Ct \)). This follows from (24), which implies that \( u_t \leq C + \Lambda u_t \), whence \( u_t \leq C/(1-\Lambda) \).

**Step 3.** For all \( i \in \mathbb{Z}^d \), \( (m^i_t)' \sim (Q_{i, \mu})_t \), whence also \( m^i_t \sim (Q_{i, \mu})_t \), as \( t \to \infty \). Indeed, starting from (23), using the monotone convergence theorem and that \( \int_0^\infty \varphi(s) ds = \int_0^\infty \varphi(s) ds^n = \Lambda^n \),

\[
\lim_{t \to \infty} (m^i_t) = \left( (I + \sum_{n \geq 1} \Lambda^n A^n) \right) \mu = (Q_{i, \mu}).
\]

**Step 4.** There is a constant \( C \) such that for all \( i \in \mathbb{Z}^d \), all \( t \geq 0 \), \( \mathbb{E}[|U^i_t|] \leq Ct^{1/2} \). Indeed, this follows from (27) and Step 2, which imply that \( v_t \leq Ct^{1/2} + \Lambda v_t \), whence \( v_t \leq Ct^{1/2}/(1-\Lambda) \).

**Step 5.** The conclusion follows immediately, writing

\[
\mathbb{E}\left[ \frac{Z^i_t}{t} - (Q_{i, \mu})_t \right] \leq \mathbb{E}\left[ \left| \frac{U^i_t}{t} \right| + \left| \frac{m^i_t}{t} - (Q_{i, \mu})_t \right| \right],
\]

which tends to 0 as \( t \to \infty \) by Steps 3 and 4. \( \square \)

We now turn to the supercritical case.
Proof of Theorem 12. We consider \( m \) (not to be confused with \( m \)) the unique solution to \( m_t = \mu t + \int_0^t \varphi(t-s)m_s ds \), where \( \mu \) is the mean value defined by (19). This equation is studied in details in Lemma 26 with \( a_0 \) and \( a_1 \) defined in the statement, we have \( m_t \sim a_0 e^{\alpha t} \) and \( m_0' \sim a_0 a_0 e^{\alpha t} \) as \( t \to \infty \), as well as \( \Gamma(t) = \sum_{n \geq 1} \varphi^n(t) \sim (a_0 \alpha_0^2/\mu) e^{\alpha t} \) and \( \Upsilon(t) = \int_0^t \Gamma(s) ds \sim (a_0 \alpha_0/\mu) e^{\alpha t} \).

Step 1. We adopt the notation introduced in Step 1 of the proof of Theorem 14.

Step 2. Here we check that that there is \( C \) such that for all \( i \in \mathbb{Z}^d \), \( (m_i')' \leq C e^{\alpha t} \) (and thus \( m_i' \leq C e^{\alpha t} \)). This follows from (24), which tells us that \( u_t = sup_i \in \mathbb{Z}^d (m_i')' \) is locally bounded and satisfies \( u_t \leq C + \int_0^t \varphi(t-s) u_s ds \). Setting \( h_t = u_t - \int_0^t \varphi(t-s) u_s ds \), we see that \( h_t \) is locally bounded (from above and from below), because \( u \) is locally bounded and \( \varphi \) is locally integrable. We furthermore have \( u = h + u * \varphi \). Applying Lemma 26 (e), we deduce that \( u \leq h + \Gamma \). But \( h \) is bounded from above by \( C \). Consequently, \( u \leq C + C * \Gamma = C(1 + \Upsilon) \), where \( \Upsilon \) was defined in Lemma 26. The conclusion follows from Lemma 26 (b).

Step 3. We now show that for all \( i \in \mathbb{Z}^d \), \( (m_i')' \sim (m_i')' \) (whence \( m_i' \sim m_t \)) as \( t \to \infty \). Let us fix \( i \in \mathbb{Z}^d \) and set \( r_i' := (m_i')' - (m_i')' \), which satisfies \( r_i' = \mu_i - \mu + \sum_{n \geq 1} ((A^n \mu_i - \mu) \int_0^t \varphi^n(s) ds \). We know from Lemma 16 (ii) that \( \gamma_n = (A^n \mu_i - \mu) \) tends to 0 as \( n \to \infty \). Consequently, Lemma 26 (d) tells us that \( e^{-\alpha t} \sum_{n \geq 1} ((A^n \mu_i - \mu) \int_0^t \varphi^n(s) ds \) tends to 0 as \( t \to \infty \). Hence \( e^{-\alpha t} r_i' \to 0 \) as \( t \to \infty \). Using finally that \( m_i' \sim a_0 a_0 e^{\alpha t} \) as \( t \to \infty \), we conclude that \( m_i'^t/m_i' = 1 + r_i'/m_i' \sim 1 + (a_0 a_0)^{-1} e^{-\alpha t} r_i' \to 1 \) as desired.

Step 4. Here we check that for every \( i \in \mathbb{Z}^d \), \( e^{-\alpha t} E[U_i^t] \) tends to 0 as \( t \to \infty \). We start from (20) to write

\[
|U_i^t| \leq |M_i^t| + \sum_{n \geq 1} \int_0^t \varphi^n(t-s)(A^n M_s)_i ds.
\]

But \( E[M_i^t] \leq E[Z_i^t]^{1/2} = (m_i')^{1/2} \leq C e^{\alpha t/2} \) by Step 2 and \( E[(A^n M_i)_s^2] \leq C e^{\alpha t} \sum_j (A^n(i,j))^2 m_j \leq C e^{\alpha t} \sum_j (A^n(i,j))^2 \leq C e^{\alpha t} \varepsilon_n \) by Lemma 16 (i), with \( \varepsilon_n \to 0 \) as \( n \to \infty \). Consequently,

\[
e^{-\alpha t} E[U_i^t] \leq C e^{-\alpha t/2} + C e^{-\alpha t} \sum_{n \geq 1} E[\varphi^n(t-s)e^{\alpha s/2} ds].
\]

Lemma 26 (d) allows us to conclude.

Step 5. The conclusion follows, writing

\[
E\left[ \left| \frac{Z_i^t}{a_0 e^{\alpha t}} - 1 \right| \right] \leq E\left[ \left| \frac{U_i^t}{a_0 e^{\alpha t}} \right| \right] + \left| \frac{m_i}{a_0 e^{\alpha t}} - 1 \right|,
\]

and using Steps 3, 4, and that \( m_t \sim a_0 e^{\alpha t} \) by Lemma 26 (a). \( \square \)

4.2. Study of an impulsion. Here we want to study how an impulsion at time 0 at \( i = 0 \) propagates. To this end, we work under Assumption 13 with \( \mu_i = 0 \) for all \( i \in \mathbb{Z}^d \), but we assume that \( Z^0 \) has a jump at time 0. Such a study is of course important: it allows us to measure, in some sense, the range of the interaction.

We first define precisely the process under study.

Definition 17. We work under Assumption 15 (i)-(ii) and consider a family \( (\pi^i(ds dz), i \in \mathbb{Z}^d) \) of i.i.d. \( (\mathcal{F}_t)_{t \geq 0} \)-Poisson measures on \( [0, \infty) \times [0, \infty) \) with intensity measure \( ds dz \). We say that a
family \((Z^i_t)_{i \in \mathbb{Z}^d, t \geq 0}\) of \((\mathcal{F}_t)_{t \geq 0}\)-adapted counting processes is an impulse Hawkes process if

\[
\forall \ i \in \mathbb{Z}^d, \quad Z^i_t = \int_0^t \int_\infty^0 1_{\{z \leq \sum_{j \neq i} (2d + 1)^{-1} \int_0^s \varphi(s - u) dZ^j_u + \varphi(s)1_{\{j = 0\})\}} \pi^i(ds \, dz).
\]

As said previously, the term \(\sum_{j \neq i} \varphi(s)1_{\{j = 0\}}\) is interpreted as an excitation due to a forced jump of \(Z^0\) at time \(0\): simply rewrite it as \(1_{\{0 \rightarrow i\}} \int_0^s \varphi(s - u) \delta_u(ds)\).

The following proposition is easy.

**Proposition 18.** Adopt the assumptions and notation of Definition 17. There exists a pathwise unique impulse Hawkes process \(((Z^i_t)_{i \in \mathbb{Z}^d, t \geq 0}\) such that \(\sum_{i \in \mathbb{Z}^d} E[Z^i_t] < \infty\) for all \(t \geq 0\).

**Proof.** The proof resembles much that of Theorem 6, so we only sketch it. We start with uniqueness and thus consider two impulse Hawkes processes \((Z^i_t)_{i \in \mathbb{Z}^d, t \geq 0}\) and \((\tilde{Z}^i_t)_{i \in \mathbb{Z}^d, t \geq 0}\) such that \(\sum_{i \in \mathbb{Z}^d} E[Z^i_0 + \tilde{Z}^i_0] < \infty\). We set \(\Delta^i_t = \int_0^t d(Z^i_s - \tilde{Z}^i_s), \delta^i_t = E[\Delta^i_t]\) and \(\delta_t = \sum_{i \in \mathbb{Z}^d} \delta^i_t\) (which is locally bounded by assumption). We may check that \(\delta_t \leq (2d + 1)^{-1} \int_0^t \sum_{i \neq j} \varphi(t - s) \delta_s ds\) exactly as in the proof of Theorem 6. Summing in \(i\) and recalling that each site has \(2d + 1\) neighbours, we find \(\delta_t \leq \int_0^t \varphi(t - s) \delta_s ds\). Lemma 23(i) tells us that \(\delta_t = 0\) for all \(t\), whence pathwise uniqueness.

Existence follows from a Picard iteration. Let us only check an *a priori* estimate implying that \(\sum_{i \in \mathbb{Z}^d} E[Z^i_0] < \infty\) for all \(t \geq 0\). Set \(m^i_t = E[Z^i_t]\) and \(m_t = \sum_{i \in \mathbb{Z}^d} m^i_t\). A direct computation using Lemma 22 shows that \(m^i_t = (2d + 1)^{-1} \int \sum_{j \neq i} \int_0^t \varphi(t - s) m^j_s ds + 1_{\{j = 0\}} \int_0^t \varphi(s) ds\) [\(\int_0^t \varphi(s) ds\) is locally bounded], we deduce that \(\sup_{[0,T]} m_t \leq C(T, \varphi)\) as desired. \(\square\)

We next compute the probability of the extinction event. Point 1 is a noticeable property that makes the result very easy and precise.

**Theorem 19.** Adopt the assumptions and notation of Definition 17 and consider the impulse Hawkes process \(((Z^i_t)_{i \in \mathbb{Z}^d, t \geq 0}\).

1. The process \(Z_t = \sum_{i \in \mathbb{Z}^d} Z^i_t\) is a scalar impulse Hawkes process with excitation function \(\varphi\).

In other words, \((Z_t)_{t \geq 0}\) is a counting process with compensator \(A_t = \int_0^t \lambda_s ds\), where

\[
\lambda_t = \varphi(t) + \int_0^t \varphi(t - s) dZ_s.
\]

2. We introduce the extinction event defined by \(\Omega_e = \{\lim_{t \to \infty} \sum_{i \in \mathbb{Z}^d} Z^i_t = \infty\}\). Setting \(\Lambda = \int_0^\infty \varphi(s) ds\), we have (i) \(Pr(\Omega_e) = 0\) if \(\Lambda = \infty\); (ii) \(Pr(\Omega_e) = \exp(-\gamma \Lambda)\) if \(\Lambda \in (1, \infty)\), where \(\gamma \Lambda \in (0, 1)\) is characterised by \(\gamma \Lambda + \log(1 - \gamma \Lambda) = 0\); (iii) \(Pr(\Omega_e) = 1\) if \(\Lambda \in (0, 1)\).

Of course, we can sometimes use this theorem, by a simple comparison argument, if \(\varphi_{ji}\) depends on \(i, j\). For example, to guarantee non-extinction with probability one, it suffices that all the \(\varphi_{ji}\) are bounded below by some \((2d + 1)^{-1} \varphi\) such that \(\int_0^\infty \varphi(s) ds = \infty\).
Proof. Point 1 is immediate: the compensator of the counting process \((Z_t)_{t \geq 0}\) is

\[
A_t = \int_0^t \sum_{i \in \mathbb{Z}^d} \sum_{j \to i} (2d + 1)^{-1} \left[ \int_0^{s-} \varphi(s - u) dZ_u^i + \varphi(s) \mathbf{1}_{\{j = 0\}} \right] ds
\]

\[
= \int_0^t \sum_{j \in \mathbb{Z}^d} \left[ \int_0^{s-} \varphi(s - u) dZ_u^j + \varphi(s) \mathbf{1}_{\{j = 0\}} \right] ds
\]

\[
= \int_0^t \left[ \varphi(s) + \int_0^{s-} \varphi(s - u) dZ_u \right] ds.
\]

We next prove point 2. It is well-known Folklore that a scalar impulsion Hawkes process can be related to a Poisson Galton-Watson process with Poisson(\(\Lambda\)) reproduction law, but we give a direct proof for the sake of completeness. If \(\Lambda = \infty\), it suffices to note that \(\Pr(\Omega_{\infty}) = \Pr(Z_\infty < \infty) = \Pr(\Lambda_{\infty} < \infty) \leq \Pr(\int_0^\infty \varphi(s) ds < \infty) = 0\). When \(\Lambda < \infty\), we introduce the martingale, for \(\gamma \in (0,1)\), \(N_t^\gamma = -\gamma(Z_t - A_t) = -\gamma Z_t + \gamma \int_0^t \varphi(s) ds + \gamma \int_0^t \varphi(t-s) Z_s ds\) by Lemma \(22\). We denote by \(M_t^\gamma = \mathcal{E}(N_t^\gamma) = e^{\gamma A_t} \prod_{s \leq t} (1 - \gamma \Delta Z_s)\) its Doléans-Dade exponential, see Jacod-Shiryaev [22, Chapter 1, Section 4f]. Since \(Z\) is a counting process, we see that

\[
M_t^\gamma = \exp \left( \gamma \int_0^t \varphi(s) ds + \gamma \int_0^t \varphi(t-s) Z_s ds + \log(1 - \gamma) Z_t \right).
\]

If \(\gamma \Lambda + \log(1 - \gamma) \leq 0\) then \(M_t^\gamma\) is bounded (because \(\gamma \int_0^t \varphi(s) ds + \gamma \int_0^t \varphi(t-s) Z_s ds + \log(1 - \gamma) Z_t \leq \gamma \Lambda + (\gamma \Lambda + \log(1 - \gamma)) Z_t \leq \gamma \Lambda\)), and thus converges in \(L^1\). Consequently, \(\mathbb{E}[M_{\infty}^\gamma] = 1\) and (one easily verifies, using that \(Z\) is non-decreasing, that \(\lim_{t \to \infty} \int_0^t \varphi(t-s) Z_s ds = \Lambda Z_\infty\))

\[
\mathbb{E}\left[ \exp \left( \gamma \Lambda + \log(1 - \gamma) + \gamma \Lambda \right) Z_\infty \right] = 1.
\]

But for all \(x > 0\), there is a unique \(\gamma(x) \in (0,1)\) such that \(\gamma(x) \Lambda + \log(1 - \gamma(x)) = -x\), whence

\[
\mathbb{E}\left[ \exp(-x Z_\infty) \right] = \exp(-\Lambda \gamma(x)).
\]

Consequently,

\[
\Pr(\Omega_{\infty}) = \Pr(Z_\infty < \infty) = \lim_{x \to 0^+} \mathbb{E}\left[ \exp(-x Z_\infty) \right] = \exp(-\Lambda \gamma(0^+)).
\]

If \(\Lambda \in (0,1)\), we see that \(\gamma(0^+) = 0\), so that \(\Pr(\Omega_{\infty}) = 1\). If now \(\Lambda > 1\), \(\gamma(0^+)\) is the unique solution in \((0,1)\) to \(\gamma(0^+) \Lambda + \log(1 - \gamma(0^+)) = 0\).

We next study more deeply, in the super-critical case, how the impulsion propagates. Unfortunately, the computations are really tedious: we decided to restrict ourselves to a particular case (\(\varphi\) is an exponential function) where some computations are explicit. We believe that the result below can be extended to a general class of functions \(\varphi\), but a difficult technical lemma is required.

**Theorem 20.** Work under Assumption [**Z3**](i)-(ii), with \(\varphi(t) = ae^{-bt}\), for some \(a > b > 0\).

Consider the impulsion Hawkes process \((Z_t)_{t \in \mathbb{Z}^d, t \geq 0}\). Since \(\int_0^\infty \varphi(s) ds = a/b > 1\), we know from Theorem [19] that \(\Pr(\Omega_{\infty}) \in (0,1)\). We set \(\alpha_0 = a/b\) (for which \(\mathcal{L}_\varphi(\alpha_0) = 1\)) and we recall that the Gaussian density \(p_t(x)\) is defined by \(21\).

(i) There are some constants \(C > 0\) and \(t_0 > 0\) and a random variable \(H \geq 0\) such that for all \(i \in \mathbb{Z}^d\), all \(t \geq t_0\),

\[
\mathbb{E}\left[ \left| Z_t^i - H p_{at}(i) e^{\alpha_0 t} \right| \right] \leq \frac{C e^{\alpha_0 t}}{t^{d/2+1/3}}.
\]
(ii) For all $x \in \mathbb{R}^d$, $t^{d/2} e^{-\alpha_0 t} Z_i e^{t^{1/2}} \rightarrow H_p(\alpha t) \text{ in probability as } t \rightarrow \infty$. Here, we define the “integer part” of $y = (y_1, \ldots, y_d) \in \mathbb{R}^d$, by $[y] = ([y_1], \ldots, [y_d]) \in \mathbb{Z}^d$.

(iii) The random variable $H$ is positive on the event $\Omega^*_d$.

This result describes quite precisely how an impulsion propagates. Conditional on non extinction, and the process $(Z_i)_{i \in \mathbb{Z}^d}$ resembles a Gaussian profile, with height $t^{-d/2} H e^{\alpha_0 t}$ and radius $\sqrt{t}$, for some positive random variable $H$.

Compared to the previous result (Theorem 15), the growth is only very slightly slower: a single impulsion at the site 0 produces a growth in $t^{-d/2} e^{\alpha_0 t}$, while we have $e^{\alpha_0 t}$ when all the sites are regularly excited (as is e.g. the case when $\mu_i = 1$ for all $i$).

Finally, it is important to note that, even if the growth “near 0” of the process is very fast (exponential), the spatial propagation is quite slow (of order $\sqrt{t}$).

We start with some preliminary computations.

**Lemma 21.** Adopt the notation and assumptions of Theorem 20. Introduce also, for $i \in \mathbb{Z}^d$ and $t \geq 0$, $\Gamma(i, t) = \sum_{n \geq 1} A^n(0, i) \varphi^{*n}(t)$.

(i) For all $n \geq 1$, $\varphi^{*n}(t) = (at)^{n-1} e^{-bt} / (n-1)!$.

(ii) For all $t \geq 0$, $\sum_{i \in \mathbb{Z}^d} \Gamma(i, t) = e^{\alpha_0 t}$.

(iii) There is $C$ such that for all $t \geq 0$, $\sum_{i \in \mathbb{Z}^d} |i|^2 \Gamma(i, t) \leq C (1 + t) e^{\alpha_0 t}$.

(iv) There are some constants $C$ and $t_0 > 0$ such that for all $t \geq t_0$, $\sum_{i \in \mathbb{Z}^d}$

\begin{align}
|\Gamma(i, t) - p_{\alpha t}(i) e^{\alpha_0 t}| &\leq \frac{C e^{\alpha_0 t}}{t^{d/2+1/3}}, \\
|\int_0^t \Gamma(i, s) ds - \frac{1}{\alpha} p_{\alpha t}(i) e^{\alpha_0 t}| &\leq \frac{C e^{\alpha_0 t}}{t^{d/2+1/3}}.
\end{align}

**Proof.** Point (i) is well-known and can be checked recursively. Using that $A^n$ is a stochastic matrix, we see that $\sum_{i \in \mathbb{Z}^d} \Gamma(i, t) = \sum_{n \geq 1} \varphi^{*n}(t)$. Hence (ii) follows from (i).

Next, we recall that $A$ is the transition matrix of a symmetric random walk on $\mathbb{Z}^d$ (with bounded jumps), so that there is a constant $C$ such that for all $n \geq 0$, $\sum_{i \in \mathbb{Z}^d} |i|^2 A^n(0, i) \leq C n$ (its variance at time $n$ is of order $n$). Consequently,

\begin{align}
\sum_{i \in \mathbb{Z}^d} |i|^2 \Gamma(i, t) &\leq C \sum_{n \geq 1} n \varphi^{*n}(t) = C \sum_{n \geq 1} \frac{n (at)^{n-1} e^{-bt}}{(n-1)!} = C \left[ \sum_{n \geq 1} \frac{(at)^{n-1} e^{-bt}}{(n-1)!} + \sum_{n \geq 2} \frac{(at)^{n-1} e^{-bt}}{(n-2)!} \right].
\end{align}

This is easily computed: it gives $Ce^{\alpha_0 t}[1 + at]$.

Point (iv) is more complicated. First, we need the Gaussian approximation of $A^n(0, i)$ given by 20. We will also need the following result, which can be found e.g. in [12 Lemma 9-(d)] (plus the fact that for $x \in (0, 1)$, $(x+1) \log(x+1) - x \geq x^2/4$): for any $\lambda > 0$, for $X$ a Poisson($\lambda$)-distributed random variable, for any $x \in (0, 1)$,

\begin{align}
\Pr(|X - \lambda| \geq \lambda x) \leq 2 \exp(-\lambda x^2/4).
\end{align}
We now turn to our problem. Observing that \( \sum_{n \geq 1} \varphi^n(t) = e^{at} \), we write
\[
\Delta(i, t) = \left| \Gamma(i, t) - p_{at}(i)e^{at} \right| = \left| \sum_{n \geq 1} \varphi^n(t)(A^n(0, i) - p_{at}(i)) \right| .
\]

We now assume that \( t \) is large enough so that \( p_{t/a}(i) \leq 1 \) for all \( i \) and we write
\[
\begin{align*}
\Delta(i, t) &\leq \sum_{n \geq 1} \varphi^n(t)1_{\{[(n-1)-at]>(at)^{2/3}\}} + \sum_{n \geq 1} \varphi^n(t)1_{\{[(n-1)-at]\leq(at)^{2/3}\}|A^n(0, i) - p_{at}(i)|} \\
&\quad + \sum_{n \geq 1} \varphi^n(t)1_{\{[(n-1)-at]>(at)^{2/3}\}|p_{at}(i) - p_{at}(i)|} \\
&= \Delta_1(i, t) + \Delta_2(i, t) + \Delta_3(i, t).
\end{align*}
\]

First, using point (i) and (30) (with \( \lambda = at \) and \( x = (at)^{-1/3} \), we see that (if \( t \) is large enough so that \( at > 1 \))
\[
\Delta_1(i, t) \leq e^{at} \sum_{n \geq 1} e^{-at(\frac{n-1}{(n-1)!}1_{\{[(n-1)-at]>(at)^{2/3}\}}} \leq 2e^{at}e^{-(at)^{1/3}/4}.
\]

We next use (20) and assume that \( t \) is large enough so that \( |(n-1)-at| \leq (at)^{2/3} \) implies \( n \geq at/2 \):
\[
\Delta_2(i, t) \leq C \sum_{n \geq 1} n^{-(d+2)/2} \varphi^n(t)1_{\{[(n-1)-at]\leq(at)^{2/3}\}} \leq C(at)^{-(d+2)/2} \sum_{n \geq 1} \varphi^n(t) \leq Ct^{-(d+2)/2}e^{at}.
\]

Finally, we observe that \( |\partial_i p_{at}(x)| \leq C t^{-d/2-1} \), so that, if \( t \) is sufficiently large, \( |(n-1)-at| \leq (at)^{2/3} \) implies \( |p_n(i) - p_{at}(i)| \leq C t^{-d/2-1/3} \). Consequently,
\[
\Delta_3(i, t) \leq C t^{-d/2-1/3} \sum_{n \geq 1} \varphi^n(t) \leq C t^{-d/2-1/3}e^{at}.
\]

We have proved that there are \( C \) and \( t_0 \) such that for all \( t \geq t_0 \), all \( i \in \mathbb{Z}^d \),
\[
|\Gamma(i, t) - p_{at}(i)e^{at}| \leq 2e^{at}e^{-(at)^{1/3}/4} + Ct^{-(d+2)/2}e^{at} + Ct^{-d/2-1/3}e^{at} \leq Ct^{-d/2-1/3}e^{at},
\]
which is (28).

It remains to deduce (29) from (28). We write
\[
\delta(t, i) = \left| \int_0^t \Gamma(i, s)ds - p_{at}(i)e^{at}/\alpha_0 \right| \\
\leq \int_0^{t-t^{1/2}} \Gamma(i, s)ds + \int_{t-t^{1/2}}^t |\Gamma(i, s) - p_{as}(i)e^{as}|ds \\
\quad + \int_{t-t^{1/2}}^t |p_{as}(i)e^{as} - p_{at}(i)e^{as}|ds + p_{at}(i) \int_{t-t^{1/2}}^t e^{as}ds - e^{at}/\alpha_0 | \\
= \delta_1(t, i) + \delta_2(t, i) + \delta_3(t, i) + \delta_4(t, i).
\]

First, point (ii) implies that
\[
\delta_1(t, i) \leq \int_0^{t-t^{1/2}} e^{as}ds \leq Ce^{at(t-t^{1/2})}.
\]
Next, [25] tells us, if $t$ is sufficiently large (so that $t - t^{1/2} > t_0$ and $t - t^{1/2} > t/2$), that

$$
\delta_2(t, i) \leq C \int_{t-t^{1/2}}^{t} s^{-d/2-1/3} e^{\alpha_0 s} ds \leq Ct^{-d/2-1/3} e^{\alpha_0 t}.
$$

Recalling that $|\partialtp_t(x)| \leq Ct^{-d/2-1}$, we get (still for $t$ large enough so that $t - t^{1/2} > t/2$)

$$
\delta_3(t, i) \leq C \int_{t-t^{1/2}}^{t} s^{-d/2-1}(t-s)e^{\alpha_0 s} ds \leq Ct^{-d/2-1/3} e^{\alpha_0 t}.
$$

Finally, if $t$ is sufficiently large, we can bound $p_{at}(i)$ by 1 (for all $i$), whence

$$
\delta_4(t, i) \leq \alpha_0^{-1}|e^{\alpha_0 t} - e^{\alpha_0(t-t^{1/2})} - e^{\alpha_0 t}| \leq C e^{\alpha_0 t}.
$$

All in all, we have proved that for all $t$ large enough, all $i \in \mathbb{Z}^d$,

$$
\left| \int_0^t \Gamma(i, s) ds - p_{at}(i)e^{\alpha_0 t}/\alpha_0 \right| \leq C e^{\alpha_0(t-t^{1/2})} + Ct^{-d/2-1/3} e^{\alpha_0 t} + Ct^{-d/2-1/2} e^{\alpha_0 t} \leq Ct^{-d/2-1/3} e^{\alpha_0 t}
$$

as desired. □

We finally can give the

**Proof of Theorem 29.** We divide the proof in several steps.

**Step 1.** As usual, we write

$$
Z_i^t = \int_0^t \int_0^\infty \mathbf{1}_{\{z \leq (2d+1)^{-1} \sum_{j \neq i} [\int_0^s \varphi(s-u)dz + \varphi(s)1_{(s=0)}]\}} \pi^i(ds \, dz),
$$

we set $m_i^t = E[Z_i^t]$ and $m_t = (m_i^t)_{i \in \mathbb{Z}^d}$. A simple computation, using Lemma 22 shows that

$$
m_i^t = \int_0^t (2d+1)^{-1} \sum_{j \neq i} \varphi(t-s)m_j^s ds + 1_{(i \neq j)} (2d+1)^{-1} \int_0^t \varphi(s) ds.
$$

Using the vector formalism and introducing $\delta = (\delta_i)_{i \in \mathbb{Z}^d}$ defined by $\delta_i = 1_{(i=0)}$, this rewrites $m_i^t = (A\delta)\int_0^t \varphi(s) ds + \int_0^t \varphi(s) ds + (Am_i^t)\varphi(s) ds$. Differentiating this formula (see Lemma 27 for the justification of a very similar differentiation), we find $m_i' = (A\delta)\varphi(t) + \int_0^t \varphi(t-s)Am_i^s ds$, which can be solved as (see Lemma 27 again) $m_i' = \sum_{n \geq 1} \varphi^*(n)(t)A^n \delta$. Hence for all $i \in \mathbb{Z}^d$,

$$
(\text{31}) \quad (m_i')^n = \sum_{n \geq 1} A^n(0, i)\varphi^*(n)(t).
$$

We introduce the martingales, for $i \in \mathbb{Z}^d$, (we use a tilde for compensation),

$$
M_i^t = \int_0^t \int_0^\infty \mathbf{1}_{\{z \leq (2d+1)^{-1} \sum_{j \neq i} [\int_0^s \varphi(s-u)dz + \varphi(s)1_{(s=0)}]\}} \tilde{\pi}^i(ds \, dz)
$$

and observe as usual that $[M_i^t, M_j^t]_t = 0$ when $i \neq j$ (because these martingales a.s. never jump at the same time) while $[M_i^t, M_i^t]_t = Z_i^t$. We will use several times that for any family $(\alpha_i)_{i \in \mathbb{Z}^d}$,

$$
E[(\sum_{i \in \mathbb{Z}^d} \alpha_i M_i^t)^2] = \sum_{i \in \mathbb{Z}^d} \alpha_i^2 m_i^t.
$$
We finally introduce $U_t^i = Z_t^i - m_t^i$, the vectors $U_t = (U_t^i)_{i \in \mathbb{Z}^d}$ and $M_t = (M_t^i)_{i \in \mathbb{Z}^d}$ and observe, exactly as in the proof of Theorem 14, that $U_t = M_t + \sum_{n \geq 1} A^n \int_0^t \varphi^n(t-s) U_s ds$, whence $U_t = \left( M_t + \sum_{n \geq 1} A^n \int_0^t \varphi^n(t-s) M_s ds \right)$ and thus, for all $i \in \mathbb{Z}^d$,

$$Z_t^i = m_t^i + M_t^i + \sum_{j \in \mathbb{Z}^d} \sum_{n \geq 1} \int_0^t \varphi^n(t-s) A^n(i,j) M_s^j ds = m_t^i + M_t^i + W_t^i,$$

the last equality defining $W_t^i$.

**Step 2.** Here we treat the terms $m_t^i$, $M_t^i$, and collect a few more information. Recall that $\Gamma(t, i) = \sum_{n \geq 1} A^n(0,i) \varphi^n(t)$. Starting from (31), we see that $m_t^i = \int_0^t \Gamma(i, s) ds$ and deduce from Lemma 21(iv) that there are $C$ and $t_0 \geq 0$ such that for all $i \in \mathbb{Z}^d$, all $t \geq t_0$,

$$|m_t^i - \frac{1}{\alpha_0} p_{at}(i)e^{\alpha_0 t}| \leq \frac{C e^{\alpha_0 t}}{t^{d/2+1/3}}.$$

Next, Lemma 21(ii)-(iii) imply that $\sum_{i \in \mathbb{Z}^d} m_t^i = \int_0^t \Gamma(i, s) ds \leq C e^{\alpha_0 t}$ and $\sum_{i \in \mathbb{Z}^d} |i|^2 m_t^i \leq C \int_0^t (1 + s) e^{\alpha_0 s} ds \leq C(1 + t) e^{\alpha_0 t}$. Finally, we observe that

$$\mathbb{E}[|M_t^i|] \leq \langle m_t^i \rangle^{1/2} \leq \left( \sum_{j \in \mathbb{Z}^d} m_t^j \right)^{1/2} \leq C e^{\alpha_0 t/2}.$$

**Step 3.** We introduce

$$X = \sum_{j \in \mathbb{Z}^d} \int_0^t e^{-\alpha_0 s} M_s^j ds$$

and show that there are $C > 0$ and $t_0 > 0$ such that for all $i \in \mathbb{Z}^d$, all $t \geq t_0$, 

$$\mathbb{E}[|W_t^i - p_{at}(i)e^{\alpha_0 t} X|] \leq \frac{C e^{\alpha_0 t}}{t^{d/2+1/3}}.$$

We observe that since $A^n(i,j) = A^n(0, i-j)$, it holds that $W_t^i = \sum_{j \in \mathbb{Z}^d} \int_0^t \Gamma(i - j, t - s) M_s^j ds$. We also introduce the auxiliary processes

$$\overline{W}_t = \sum_{j \in \mathbb{Z}^d} \int_0^{t^{1/2}} \Gamma(i - j, t - s) M_s^j ds,$$

$$\widetilde{W}_t = \sum_{j \in \mathbb{Z}^d} \int_0^{t^{1/2}} p_{at-s}(i-j) e^{\alpha_0 (t-s)} M_s^j ds,$$

$$\hat{W}_t = \sum_{j \in \mathbb{Z}^d} \int_0^{t^{1/2}} p_{at}(i) e^{\alpha_0 (t-s)} M_s^j ds.$$

**Step 3.1.** Here we show that $\mathbb{E}[|W_t^i - \overline{W}_t|] \leq C \exp(\alpha_0 t - (\alpha_0/2)t^{1/2})$. By definition of $\Gamma$ and using (32),

$$\mathbb{E}[|W_t^i - \overline{W}_t|] \leq \int_0^t \sum_{n \geq 1} \varphi^n(t-s) \mathbb{E}[\sum_{j \in \mathbb{Z}^d} A^n(i,j) M_s^j] ds \leq \int_0^t \sum_{n \geq 1} \varphi^n(t-s) \left( \sum_{j \in \mathbb{Z}^d} (A^n(i,j))^2 m_s^j \right)^{1/2} ds.$$
Using that $A^n(i,j)$ is bounded by 1 and that $\sum_{\mathbb{Z}^d} m^j_t \leq C e^{\alpha t}$ (see Step 2), we see that $\sum_{j \in \mathbb{Z}^d} (A^n(i,j))^2 m^j_t \leq C e^{\alpha s/2}$. Next, the explicit expression of $\varphi^n$ (see Lemma 21(i)) gives $\sum_{n \geq 1} \varphi^n(t-s) = e^{\alpha(t-s)}$. We finally find

$$E[|\bar{W}^i_t - \bar{W}^i_t|] \leq C \int_{t^{1/2}}^t e^{\alpha(t-s)} e^{\alpha s/2} ds \leq C e^{\alpha t} e^{-\alpha t^{1/2}/2}.$$

**Step 3.2.** We next check that $E[|\bar{W}^i_t - \bar{W}^i_t|] \leq C t^{-d/2-1/3} e^{\alpha t}$. Using (22), we get

$$E[|\bar{W}^i_t - \bar{W}^i_t|] \leq \int_0^{t^{1/2}} \left( \sum_{j \in \mathbb{Z}^d} m^j_t (\Gamma(i-j, t-s) - p_{a(t-s)}(i-j) e^{\alpha(t-s)})^2 \right)^{1/2} dt ds.

Using Lemma 21(iv), $|\Gamma(i-j, t-s) - p_{a(t-s)}(i-j) e^{\alpha(t-s)}| \leq C(t-s)^{-d/2-1/3} e^{\alpha(t-s)}$ if $t-s$ is large enough (which is the case for all $s \in [0, t^{1/2}]$ if $t$ is large enough). Since furthermore $\sum_{i \in \mathbb{Z}^d} m^i_t \leq C e^{\alpha t}$ (see Step 2), we find

$$E[|\bar{W}^i_t - \bar{W}^i_t|] \leq C e^{\alpha t} \int_{0}^{t^{1/2}} e^{\alpha s/2} ds = C t^{-d/2-1/3} e^{\alpha t}.

For $t$ large enough, we clearly have $(t-s)^{-d/2-1/3} \leq 2 t^{-d/2-1/3}$ for all $s \in [0, t^{1/2}]$, whence

$$E[|\bar{W}^i_t - \bar{W}^i_t|] \leq C t^{-d/2-1/3} e^{\alpha t} \int_{0}^{t^{1/2}} e^{\alpha s/2} ds \leq C t^{-d/2-1/3} e^{\alpha t}.

**Step 3.3.** We now prove that $E[|\bar{W}^i_t - \bar{W}^i_t|] \leq C t^{-d/2-1/2} e^{\alpha t}$. As usual, we start with

$$E[|\bar{W}^i_t - \bar{W}^i_t|] \leq \int_0^{t^{1/2}} \left( \sum_{j \in \mathbb{Z}^d} m^j_t (p_{a(t-s)}(i-j) - p_{a(t)}(i))^2 \right)^{1/2} e^{\alpha(t-s)} ds.

But an easy computation (using that $|\partial_x p_t(x)| \leq C t^{-d/2-1}$ and $|\nabla_x p_t(x)| \leq C t^{-d/2-1}$) shows that for all $t > 0$, all $h \in (0, t/2)$, all $x, y \in \mathbb{R}^d$, $|p_{t-h}(x-y) - p_t(x)| \leq C h t^{-d/2-1} + |y| t^{-d/2-1}$. Hence if $t$ is large enough so that $t-t^{1/2} \geq t/2$, we can write

$$E[|\bar{W}^i_t - \bar{W}^i_t|] \leq C \int_0^{t^{1/2}} \left( \sum_{j \in \mathbb{Z}^d} m^j_t (st^{-d/2-1} + |j| t^{-d/2-1})^2 \right)^{1/2} e^{\alpha(t-s)} ds
\leq C t^{-d/2-1/2} \int_0^{t^{1/2}} \left( \sum_{j \in \mathbb{Z}^d} m^j_t \right)^{1/2} e^{\alpha(t-s)} ds + C t^{-d/2-1/2} \int_0^{t^{1/2}} \left( \sum_{j \in \mathbb{Z}^d} j^2 m^j_t \right)^{1/2} e^{\alpha(t-s)} ds.

Finally, we know from Step 2 that $\sum_{j \in \mathbb{Z}^d} m^j_t + \sum_{j \in \mathbb{Z}^d} |j|^2 m^j_t \leq C(1+s) e^{\alpha s}$, whence

$$E[|\bar{W}^i_t - \bar{W}^i_t|] \leq C t^{-d/2-1/2} \int_0^{t^{1/2}} (1+s)^{1/2} e^{\alpha(s/2)} e^{\alpha(t-s)} ds \leq C t^{-d/2-1/2} e^{\alpha t}.

**Step 3.4** We finally verify that $E[|\bar{W}^i_t - p_{a(t)} e^{\alpha t} X|] \leq C e^{\alpha t - (\alpha/2) t^{1/2}}$. We note that

$$\bar{W}^i_t - p_{a(t)} e^{\alpha t} X = p_{a(t)} e^{\alpha t} \sum_{j \in \mathbb{Z}^d} \int_{t^{1/2}}^t e^{-\alpha s} M^j ds.$$
For $t$ large enough (not depending on $i$), we can bound $p_{at}(i)$ by 1. Hence, we infer from (32) and the fact that $\sum_{j \in \mathbb{Z}^d} m_j \leq C e^{-\alpha s}$ that

$$E[|\hat{W}_t - p_{at}(i)e^{a t} X|] \leq C e^{-\alpha s} \left( \sum_{j \in \mathbb{Z}^d} m_j \right)^{1/2} ds \leq C e^{-\alpha s} \int_{t/2}^{\infty} e^{-\alpha s/2} ds,$$

from which the conclusion follows.

**Step 3.5.** Gathering Steps 3.1 to 3.4, we conclude that indeed, there are $C > 0$ and $t_0 > 0$ such that for all $t \geq t_0$, all $i \in \mathbb{Z}^d$, $E[|\hat{W}_t - p_{at}(i)e^{a t} X|] \leq C \alpha^{-d/2 - 1/3}.$

**Step 4.** Define the random variable $H = \alpha_0^{-1} + X$. Recall (33) and write $Z_i - p_{at}(i)e^{a t} H = [m_i - \alpha_0^{-1} p_{at}(i)e^{a t}] + [W_i - p_{at}(i)e^{a t} X]$. Gathering Steps 2 and 3, we see that there are $C > 0$ and $t_0 > 0$ such that for all $t \geq t_0$, all $i \in \mathbb{Z}^d$,

$$E[|Z_i - p_{at}(i)e^{a t} H|] \leq C e^{a t} + C e^{a t/2} \leq C e^{a t}.$$

To prove that $H$ is nonnegative, it suffices to use the above inequality with $i = 0$, divided by $p_{at}(0)e^{a t}$. Recalling that $p_{at}(0) = e^{-a t/2}$ for some constant $c$, we deduce that $E[|H - Z_i^0 e^{-a t}/p_{at}(0)|] \leq C t^{-1/3}.$ Consequently, $H$ is the limit (in $L^1$) of $Z_i^0 e^{-a t}/p_{at}(0)$, and is thus nonnegative. This ends the proof of (i).

**Step 5.** We now check (ii), which follows from (i): for $x \in \mathbb{R}^d$, and $t \geq t_0$,

$$E[|H_{p_{at}}(x)|] \leq t^{d/2} e^{-a t} E\left[\left|Z_t^{[x t^{1/2}]} - H_{p_{at}}(x)\right|^2\right] + E[|H|] t^{d/2} p_{at}(\{x t^{1/2}\}) - p_{at}(x).$$

The first term on the RHS is bounded, by (i), by $C t^{-1/3}$, which tends to 0 as $t \to \infty$. The second term also tends to 0, simply because

$$t^{d/2} p_{at}(\{x t^{1/2}\}) = p_{at}(t^{-1/2} \{x t^{1/2}\}) \to p_{at}(x) \quad \text{as} \quad t \to \infty.$$

**Step 6.** It remains to prove (iii). First note that $H = \lim_{t \to \infty} e^{-a t} Z_t$ in $L^1$, where $Z_t = \sum_{i \in \mathbb{Z}^d} Z_i^t$. Indeed, recalling (33)

$$Z_t = \sum_{i \in \mathbb{Z}^d} m_i + \sum_{i \in \mathbb{Z}^d} M_i + \sum_{i \in \mathbb{Z}^d} W_i.$$

We have $\sum_{i \in \mathbb{Z}^d} m_i = \int_0^t e^{-a s} ds = \alpha_0^{-1} e^{a t} - 1$ by Step 2. (32) implies that $E[(\sum_{i \in \mathbb{Z}^d} M_i^2)]^2 = \sum_{i \in \mathbb{Z}^d} m_i$ and finally $\sum_{i \in \mathbb{Z}^d} W_i = e^{a t} \int_0^t e^{-a s} \sum_{i \in \mathbb{Z}^d} M_i^2 ds$, therefore $e^{-a t} Z_t$ converges to $\alpha_0^{-1} + 0 + X = H$ as $t \to \infty$ in $L^1$. We also note that $E[H] = \alpha_0^{-1} > 0$ since $E[X] = 0$.

Next, we recall that by Theorem (15)(i), $(Z_t)_{t \geq 0}$ is a scalar impulsion Hawkes process: its compensator is given by $A_t = \int_0^t \varphi(s) + \int_{\mathbb{R}^d} \varphi(s - u) dZ_u ds$. We claim that $(Z_t)_{t \geq 0}$ has the same law as $(\tilde{Z}_t)_{t \geq 0}$ built as follows:

- consider a Poisson process $N_t \geq 0$ with intensity $\varphi(t)dt$, observe that $N_\infty$ is Poisson($\Lambda$)-distributed, denote by $0 < T_1 < \cdots < T_N$ its times of jump (we adopt the convention that $T_i = \infty$ for $i > N_\infty$),

- consider an i.i.d. family $(\tilde{Z}_t^k)_{t \geq 0}$ of scalar impulsion Hawkes process with same law as $(Z_t)_{t \geq 0}$,

- put $\tilde{Z}_t = N_t + \sum_{i=1}^{N_\infty} \tilde{Z}_t^{k_i} 1_{\{t \geq T_k\}}$. 
Indeed, \((\tilde{Z}_t)_{t \geq 0}\) is a counting process with compensator

\[
\int_0^t [\varphi(s) + \sum_{i \geq 1} 1_{\{s > T_i\}}(\varphi(s-T_i) + \int_{0}^{s-T_i} \varphi(s-T_k-u)d\tilde{Z}_u^i)]ds = \int_0^t [\varphi(s) + \int_0^s \varphi(s-u)d\tilde{Z}_u]ds.
\]

We define \(\tilde{H} = \lim_{t \to \infty} e^{-\alpha t} \tilde{Z}_t\) and, for each \(k \geq 1\), \(\tilde{H}_k = \lim_{t \to \infty} e^{-\alpha t} \tilde{Z}_t^k\). We obviously have \(\tilde{H} = \sum_{k=1}^{\infty} e^{-\alpha T_k} \tilde{H}_k\). Denoting by \(p = \Pr(H = 0)\) (which also equals \(\Pr(\tilde{H} = 0)\) and \(\Pr(\tilde{H}_k = 0)\) for all \(k \geq 1\)), we deduce by independence of the family \((\tilde{H}_k)_{k \geq 1}\), that \(p = \sum_{n \geq 1} \Pr(N_n = n)p^n\).

Appendix: convolution equations

We collect here some technical results about convolution equations. We start with an identity of constant use in the paper.

**Lemma 22.** Let \(\varphi : [0, \infty) \to \mathbb{R}\) be locally integrable and let \(\alpha : [0, \infty) \to \mathbb{R}\) have finite variations on compact intervals and satisfy \(\alpha(0) = 0\). Then for all \(t \geq 0\),

\[
\int_0^t \int_0^s \varphi(s-u)d\alpha(u)ds = \int_0^t \int_0^s \varphi(s-u)d\alpha(u)ds = \int_0^t \varphi(t-s)\alpha(s)ds.
\]

**Proof.** First, we clearly have that \(\int_0^s \varphi(s-u)d\alpha(u) = \int_0^s \varphi(s-u)d\alpha(u)\) for almost every \(s \geq 0\), whence \(\int_0^t \int_0^s \varphi(s-u)d\alpha(u)ds = \int_0^t \int_0^s \varphi(s-u)d\alpha(u)ds\). Using twice the Fubini theorem,

\[
\int_0^t \left( \int_0^s \varphi(s-u)d\alpha(u) \right)ds = \int_0^t \left( \int_u^t \varphi(s-u)d\alpha(u) \right)ds = \int_0^t \left( \int_0^{t-u} \varphi(v)d\alpha(u) \right)dv = \int_0^t \varphi(t-v)d\alpha(u)dv = \int_0^t \alpha(t-v)\varphi(v)dv,
\]

from which the conclusion follows, using the substitution \(s = t - v\). \(\square\)

We carry on with a generalized Grönwall-Picard lemma, which is more or less standard.

**Lemma 23.** Let \(\varphi : [0, \infty) \to [0, \infty)\) be locally integrable and \(g : [0, \infty) \to [0, \infty)\) be locally bounded.

(i) Consider a locally bounded nonnegative function \(u\) such that for all \(t \geq 0\), \(u_t \leq g_t + \int_0^t \varphi(t-s)u_s ds\) for all \(t \geq 0\). Then \(\sup_{[0,T]} u_t \leq C_T \sup_{[0,T]} g_t\), for some constant \(C_T\) depending only on \(T > 0\) and \(\varphi\).

(ii) Consider a sequence of locally bounded nonnegative functions \(u^n\) such that for all \(t \geq 0\), all \(n \geq 0\), \(u_{t+1}^n \leq \int_0^t \varphi(t-s)u^n_s ds\). Then \(\sup_{[0,T]} \sum_{n \geq 0} u^n_t \leq C_T\), for some constant \(C_T\) depending only on \(T > 0\), \(u^0\) and \(\varphi\).
(iii) Consider a sequence of locally bounded nonnegative functions \( u^n \) such that for all \( t \geq 0 \), all \( n \geq 0 \), \( u^{n+1}_t \leq g_t + \int_0^t \phi(t-s)u^n_s ds \). Then for all \( T \geq 0 \), \( \sup_{[0,T]} \sup_{n \geq 0} u^n_t \leq C_T \), for some constant \( C_T \) depending only on \( T > 0 \), \( u^0 \), \( g \) and \( \phi \).

Proof. We start with point (i). Fix \( T > 0 \) and consider \( A > 0 \) such that \( \int_0^T \phi(s)1_{\{\phi(s) \geq A\}} ds \leq 1/2 \). Then for all \( t \in [0,T] \),

\[
u_t \leq g_t + \int_0^t 1_{\{\phi(t-s) \leq A\}} \phi(t-s)u_s ds + \int_0^t 1_{\{\phi(t-s) > A\}} \phi(t-s)u_s ds \leq g_t + A \int_0^t u_s ds + sup_{[0,t]} u_s/2.
\]

from which we deduce that \( \sup_{[0,t]} u_s \leq 2 \sup_{[0,t]} g_s + 2A \int_0^t u_s ds \). We then can apply the standard Grönwall Lemma to get \( \sup_{[0,t]} u_s \leq 2(\sup_{[0,T]} \phi_s) e^{2AT} \).

To check point (iii), put \( v^n_t = sup_{k=0,...,n} u^k_t \). One easily checks that for all \( n \geq 0 \), \( v^n_t \leq u^n_0 + g_t + \int_0^t \phi(t-s)v^n_s ds \). By point (i), \( \sup_{[0,T]} v^n_t \leq C_T \sup_{[0,T]} (g_t + u^n_0) \). Letting \( n \) increase to infinity concludes the proof.

Point (ii) follows from point (iii), since \( v^n_t = \sum_{k=0}^n u^k_t \) satisfies \( v^{n+1}_t \leq u^n_t + \int_0^t \phi(t-s)v^n_s ds \).

We next prove an easy well-posedness result for a general convolution equation.

Lemma 24. Let \( h : \mathbb{R} \mapsto [0,\infty) \) be Lipschitz-continuous and \( \varphi : [0,\infty) \mapsto \mathbb{R} \) be locally integrable. The equation

\[
m_t = \int_0^t h(\int_0^s \varphi(s-u)dm_u) ds
\]

has a unique non-decreasing locally bounded solution. Furthermore, \( m \) is of class \( C^1 \) on \( [0,\infty) \).

If \( h(x) = \mu + x \) for some \( \mu > 0 \) and if \( \varphi \) is nonnegative, Equation (34) rewrites as

\[
m_t = \mu t + \int_0^t \varphi(t-s)m_s ds.
\]

Proof. Let \( m \) and \( \tilde{m} \) be two such solutions. Since \( h \) is Lipschitz-continuous,

\[
v_t = \int_0^t |d(m_u - \tilde{m}_u)| \leq C \int_0^t ds \int_0^s |\varphi(s-u)||d(m_u - \tilde{m}_u)| = C \int_0^t |\varphi(t-u)| v_u du.
\]

The last inequality follows from Lemma 23. Lemma 23(i) allows us to conclude that \( v_t = 0 \) for all \( t \geq 0 \) (because \( v_t \leq m_t + \tilde{m}_t \) is locally bounded), whence \( m_t = \tilde{m}_t \) for all \( t \geq 0 \). For the existence, we consider the sequence of non-decreasing functions \( m^n_t = 0 \) and \( m^{n+1}_t = \int_0^t h(\int_0^s \varphi(s-u)dm^n_u) ds \) for every \( n \geq 0 \). We easily check that \( m^{n+1}_t \leq h(0)t + |h|_{lip}\int_0^t |\varphi(t-u)| m^n_u du \), so that \( sup_{n \geq 0} m^n_t \) is locally bounded by Lemma 23(iii). Setting, for \( n \geq 0 \), \( \delta^n_t = \int_0^t |d(m^{n+1}_u - m^n_u)| \), one readily gets \( \delta^{n+1}_t \leq |h|_{lip}\int_0^t |\varphi(s-u)|\delta^n_u du \) for all \( n \geq 0 \). Lemma 23(ii) thus implies that \( \sum_{n \geq 0} \delta^n_t < \infty \). All this classically implies the existence of a locally bounded non-decreasing \( m \) such that for all \( t \geq 0 \), \( \lim_{n \to \infty} \int_0^t |d(m_u - m^n_u)| = 0 \). Checking that \( m \) solves (34) is routine.

To prove that \( m \) is \( C^1 \), we use the previous Picard Iteration. One easily sees, by induction, that \( m^n \) is \( C^1 \) for all \( n \geq 0 \) and that \( (m^{n+1}_t)' = h(\int_0^t \varphi(t-u)(m^n_u)' du) \) (indeed, \( t \mapsto \int_0^t \varphi(t-u)(m^n_u)' du = \int_0^t \varphi(u)(m^n_{t-u})' du \) is continuous because \( \varphi \) is locally integrable and because \( (m^n_u)' \) is continuous by the inductive assumption). Next, a direct computation shows that \( |(m^{n+1}_t)' - (m^n_t)'| \leq C \int_0^t |\varphi(t-
Lemma 26. We now divide the proof into several steps. \( \Gamma(n) \) has a unique non-decreasing locally bounded solution \( (m_t)_{t \geq 0} \), which is furthermore of class \( C^1 \). It holds that \( m_t' \sim a_0 \) and \( m_t \sim a_0 t \) as \( t \to \infty \), where \( a_0 = \mu/(1 - \Lambda) > 0 \).

Proof. We rather use \( \Theta \), which writes \( m_t = \mu t + \int_0^t \int_0^s \varphi(s-u)m'_u du ds \). Differentiating this expression, we find \( m'_t = \mu + \int_0^t \varphi(t-s)m'_s ds \). We first introduce \( u_t = \sup_{[0,t]} m'_s \). We have \( u_t \leq \mu + \Lambda u_t \), whence \( u_t \leq \mu/(1 - \Lambda) \) for all \( t \geq 0 \) and thus \( \limsup_{t \to \infty} m'_t \leq \mu/(1 - \Lambda) \). We next introduce \( v_t = \inf_{s \geq t} m'_s \), which is non-decreasing and thus has a limit \( \ell \in (0,\infty) \). We have \( v_t \geq \mu + \int_{t/2}^t \varphi(s)ds \to \mu + \Lambda \ell \) as \( t \to \infty \). Consequently \( \ell \geq \mu + \Lambda \ell \), whence \( \ell \geq \mu/(1 - \Lambda) \) and finally \( \liminf_{t \to \infty} m'_t \geq \mu/(1 - \Lambda) \). All this proves that \( m'_t \sim a_0 \) and this implies that \( m_t \sim a_0 t \). \( \square \)

We now turn to the supercritical case.

Lemma 25. Consider \( \mu > 0 \) and a function \( \varphi : (0,\infty) \to [0,\infty) \) such that \( \Lambda = \int_0^\infty \varphi(s)ds < 1 \). By Lemma 24 \( \Theta \) has a unique non-decreasing locally bounded solution \( (m_t)_{t \geq 0} \), which is of class \( C^1 \). Assume furthermore that \( t \mapsto \int_0^t |d\varphi(s)| \) has at most polynomial growth. Let 
\( \Gamma(t) = \sum_{n \geq 1} \varphi^{*n}(t) \) and \( \Upsilon(t) = \int_0^t \varphi(s)ds \).

(a) There is a unique \( a_0 > 0 \) such that \( \mathcal{L}_\varphi(a_0) = 1 \). The function \( \Gamma \) is locally bounded. Setting \( a_0 = \mu(a_0^2/\mu)e^{a_0t} \), we have, as \( t \to \infty \),
\[
\Gamma(t) \sim \frac{a_0^2}{\mu} e^{a_0t}, \quad \Upsilon(t) \sim \frac{a_0 a_0/\mu}{e^{a_0t}}, \quad m_t \sim a_0 e^{a_0t}, \quad m'_t \sim a_0 a_0 e^{a_0t}.
\]

(b) There are some constants \( 0 < c < C \) such that for all \( t \geq 0 \), \( c e^{a_0t} \leq \Gamma(t) + 1 \leq C e^{a_0t} \), \( c e^{a_0t} \leq \Upsilon(t) + 1 \leq C e^{a_0t} \), \( c e^{a_0t} \leq m_t + 1 \leq C e^{a_0t} \) and \( e^{a_0t} \leq m'_t + 1 \leq C e^{a_0t} \).

(c) We also have
\[
\lim_{t \to \infty} \int_0^t \left( \frac{\Upsilon(t-s)}{m_t} - \frac{a_0}{\mu} e^{-a_0s} \right)^2 m'_s ds = 0.
\]

(d) Consider a real sequence \( (\eta_n)_{n \geq 1} \) such that \( \lim_{n \to \infty} \eta_n = 0 \). Then we have the property that
\[
\lim_{n \to \infty} e^{-a_0t} \sum_{n \geq 1} \eta_n \int_0^t \varphi^{*n}(t-s) e^{a_0s/2} ds = 0.
\]

(e) For any pair of locally bounded functions \( u, h : (0,\infty) \to \mathbb{R} \) such that \( u = h + u \ast \varphi \), there holds \( u = h + h \ast \Gamma \).

Proof. We easily deduce from our assumptions on \( \varphi \) that there is some constants \( C > 0, p > 0 \) such that for all \( t \geq 0 \), \( \varphi(t) \leq C(1 + t)^p \) (in particular, \( \varphi \) is locally bounded). Hence its Laplace transform is clearly well-defined on \( (0,\infty) \), of class \( C^\infty \), and \( \lim_{a \to \infty} \mathcal{L}_\varphi(a) = 0 \). Furthermore, \( \mathcal{L}_\varphi(0) = \int_0^\infty \varphi(t) dt \in (1,\infty) \). Hence, there indeed exists a unique \( a_0 > 0 \) such that \( \mathcal{L}_\varphi(a_0) = 1 \). We now divide the proof into several steps.

Step 1. We first prove that \( \Gamma \) is locally bounded. To this end, we introduce \( \Gamma_n = \sum_{k=1}^n \varphi^{*k}(t) \) and observe that \( \Gamma_{n+1} = \varphi + \Gamma_n \ast \varphi \). Since \( \varphi \) is locally bounded, Lemma 24 \( \Theta \) allows us to conclude that \( \sup_n \Gamma_n \) is locally bounded, whence the result.
Step 2. Here we prove (e). Since $h$ is locally bounded and since $\varphi$ is locally integrable, we easily deduce from Lemma 27(i) that the equation $v = h + v \ast \varphi$ (with unknown $v$) has at most one locally bounded solution. Since both $u$ and $h + h \ast \Gamma$ are locally bounded solutions, the conclusion follows.

Step 3. The aim of this step is to verify that $\Gamma(t) \sim (a_0 a_0^2 / \mu)e^{\alpha t}$ as $t \to \infty$. Observe that $\Gamma$ solves $\Gamma = \varphi + \Gamma \ast \varphi$ and introduce $u(t) = \Gamma(t)e^{-\alpha t}$ and $f(t) = \varphi(t)e^{-\alpha t}$. One easily checks that $u = f + u \ast f$. We now apply Theorem 4 of Feller [11]. We have $\int_0^t f(t)dt = 1$ by definition of $a_0$. We set $b_1 = \int_0^\infty tf(t)dt = \int_0^\infty t \varphi(t)e^{-\alpha t}dt$ and $b_2 = \int_0^\infty t^2 f(t)dt = \int_0^\infty t^2 \varphi(t)e^{-\alpha t}dt$, which clearly both converge, since $\varphi(t) \leq C(1 + t)^p$. Finally, it is not difficult to check that $f(t)$, $t^2 f(t)$ and $t^2 f(t)$ have a bounded total variation on $[0, \infty)$ since we have assumed that $t \to \int_0^t d\varphi(s)$ has at most polynomial growth. Thus Feller [11] Theorem 4 tells us that $u(t) \to 1/b_1$ as $t \to \infty$, which gives $\Gamma(t) \sim e^{\alpha t}/b_1$. This ends the proof, since $1/b_1 = a_0 a_0^2 / \mu$ by definition of $a_0$.

Step 4. We now conclude the proof of (a) and (b). Recall that $m_t = \mu t + \int_0^t \int_0^\infty \varphi(s-u)m_s'duds$, so that $m_t = \mu + \varphi \ast m'$, so that $m' = \mu + \varphi \ast m'$. Applying (e), we deduce that $m_t = \mu + \mu \ast \Gamma = \mu(1 + \Upsilon)$, by Step 3.

Step 5. We then introduce $\varepsilon_k = \sup_{n \geq k} |\eta_n|$, which decreases to 0 as $k \to \infty$, and write, for any $k \geq 1$,

$$\limsup_{t \to \infty} e^{-\alpha t} \sum_{n \geq 1} |\eta_n| \int_0^t \varphi^n(t-s)e^{\alpha s/2}ds \leq \limsup_{t \to \infty} e^{-\alpha t} \sum_{n=1}^k |\eta_n| \int_0^t Cn(t-s)^p e^{\alpha s/2}ds$$

$$\quad + \varepsilon_k \limsup_{t \to \infty} e^{-\alpha t} \sum_{n=k+1}^\infty \int_0^t \varphi^n(t-s)e^{\alpha s/2}ds.$$}

The first term on the RHS is of course 0 (for any fixed $k$). We can bound the second one, using (b), by

$$\varepsilon_k \limsup_{t \to \infty} e^{-\alpha t} \int_0^t \Gamma(t-s)e^{\alpha s/2}ds \leq C\varepsilon_k \limsup_{t \to \infty} e^{-\alpha t} \int_0^t e^{2(t-s)}e^{\alpha s/2}ds \leq C\varepsilon_k.$$}

Letting $k$ tend to infinity concludes the proof.

Step 6. It only remains to check point (c). We use the Lebesgue dominated convergence theorem. Define $h_s^t = (\Upsilon(t-s)/m_t - a_0 e^{-\alpha s}/\mu)^2 m'_t 1_{s \leq t}$. We have to prove that $\lim_{t \to \infty} \int_0^\infty h_s^t ds = 0$.

First, it is obvious from (a) that for $s > 0$ fixed, $\lim_{t \to \infty} h_s^t = 0$. Next, we use (b) to write (for $t$ large enough so that $m_t \geq ce^{\alpha t}$) $h_s^t \leq C(e^{-\alpha t})^2 e^{\alpha s} \leq Ce^{-\alpha s}$, which does not depend on $t$ and is integrable on $(0, \infty)$. □

We next consider briefly a vector convolution equation.

**Lemma 27.** Consider a family $\mu = (\mu_i)_{i \in \mathbb{Z}^d}$ of real numbers such that $0 \leq \mu_i \leq C$ for all $i \in \mathbb{Z}^d$, the stochastic matrix $(A(i,j))_{i,j \in \mathbb{Z}^d}$ defined by (17), and a locally integrable function $\varphi : (0, \infty) \to [0, \infty)$. The equation $m_t = \mu t + \int_0^t \varphi(t-s)Am_sds$ with unknown $m = (m_i)_{i \in \mathbb{Z}^d}$ has a unique solution such that for all $t \geq 0$, $\sum_{i \in \mathbb{Z}^d} 2^{-||i||} \sup_{[0,t]} m_i < \infty$. Furthermore, $m_i$ is of class $C^1$ on $[0, \infty)$ for all $i \in \mathbb{Z}^d$, and it holds that $m'_i = \mu + \int_0^t \varphi(t-s)Am_i'sds$ and $m'_i = \ldots$
\[
(I + \sum_{n \geq 1} A^n \int_0^t \varphi^* (s) ds) \mu. \] Finally, \( u_t = \sup_{t \in \mathbb{Z}^d} \sup_{[0,t]} (m^t_x)' \) is finite for all \( t \geq 0 \) and it holds that \( u_t \leq C + \int_0^t \varphi(t-s) u_s ds. \)

Proof. We proceed in a few steps.

Step 1. We first note that for any vector \( x = (x_i)_{i \in \mathbb{Z}^d} \), it holds that \( \sum_{i \in \mathbb{Z}^d} 2^{-|i|} |(Ax)_i| \leq 2 \sum_{i \in \mathbb{Z}^d} 2^{-|i|} |x_i|. \) This easily follows from the explicit form of \( A \).

Step 2. We next check uniqueness. Consider two solutions \( m \) and \( \tilde{m} \) satisfying the required condition and put \( h_t = \sum_{i \in \mathbb{Z}^d} 2^{-|i|} \sup_{[0,t]} |m^i_t - \tilde{m}^i_t| \). We have \( h_t \leq \sum_{i \in \mathbb{Z}^d} 2^{-|i|} \int_0^t \varphi(t-s)(A(m^i_s - \tilde{m}^i_s))ds \). Using Step 1, we deduce that \( h_t \leq 2 \int_0^t \varphi(t-s) h_s ds \) and thus \( h_t = 0 \) by Lemma 23 (i).

Step 3. We define \( m'_t = (I + \sum_{n \geq 1} A^n \int_0^t \varphi^* (s) ds) \mu. \) Using that \( A \) is stochastic and that \( \mu \)

is bounded (by \( C \)), we easily deduce that for all \( i \in \mathbb{Z}^d \), \( (m'_t)^i \leq C(1 + \sum_{n \geq 1} \int_0^t \varphi^* (s) ds) \). This function is locally bounded because \( \varphi \) is locally integrable: use that \( \Upsilon_k(t) = \sum_{n=1}^k \int_0^t \varphi^* (s) ds \) satisfies \( \Upsilon_k(t) \leq \int_0^t \varphi(s) ds + \int_0^t \varphi(t-s) \Upsilon_k(s) ds \) and use Lemma 23 (iii), which provides a uniform (in \( k \)) bound. Consequently, \( u_t = \sup_{t \in \mathbb{Z}^d} \sup_{[0,t]} (m'_t)' \) is finite for all \( t \geq 0 \). Similar arguments show that \( (m'_t)^i \) is continuous on \([0, \infty)\), because \( |(m_{t+h}^i)' - (m_t^i)| \leq C \sum_{n \geq 1} \int_t^{t+h} \varphi^* (s) ds \).

Step 4. A straightforward consequence of the definition of \( m'_t \) is that it solves \( m'_t = \mu + \int_0^t \varphi(t-s) A m'_s ds. \) Using that \( A \) is stochastic and that \( \mu \)

is bounded, we immediately deduce that \( u_t \leq C + \int_0^t \varphi(t-s) u_s ds. \) We finally define, for each \( i \in \mathbb{Z}^d \), \( m^i_t = \int_0^t (m'_s)^i ds. \) Integrating the equation satisfied by \( m'_t \) and using Lemma 22 we find that \( m = (m^i_t)_{i \in \mathbb{Z}^d, t \geq 0} \) is indeed a solution to \( m_t = \mu + \int_0^t \varphi(t-s) A m_s ds. \) It only remains to check that \( \sum_{i \in \mathbb{Z}^d} 2^{-|i|} \sup_{[0,t]} m^i_t < \infty \) for all \( t \geq 0 \), but this obviously follows from the facts that \( u_t \) is locally bounded and that \( m_0 = 0 \). □
