ABSTRACT
Differential privacy (DP) has emerged as a de facto standard privacy notion for a wide range of applications. Since the meaning of data utility in different applications may vastly differ, a key challenge is to find the optimal randomization mechanism, i.e., the distribution and its parameters, for a given utility metric. Existing works have identified the optimal distributions in some special cases, while leaving all other utility metrics (e.g., usefulness and graph distance) as open problems. Since existing works mostly rely on manual analysis to examine the search space of all distributions, it would be an expensive process to repeat such efforts for each utility metric. To address such deficiency, we propose a novel approach that can automatically optimize different utility metrics found in diverse applications under a common framework. Our key idea is that, by regarding the variance of the injected noise itself as a random variable, a two-fold distribution may approximately cover the search space of all distributions. Therefore, we can automatically find distributions in this search space to optimize different utility metrics in a similar manner, simply by optimizing the parameters of the two-fold distribution. Specifically, we define a universal framework, namely, randomizing the randomization mechanism of differential privacy (R\(^2\)DP), and we formally analyze its privacy and utility. Our experiments show that R\(^2\)DP can provide better results than the baseline distribution (Laplace) for several utility metrics with no known optimal distributions, whereas our results asymptotically approach to the optimality for utility metrics having known optimal distributions. As a side benefit, the added degree of freedom introduced by the two-fold distribution allows R\(^2\)DP to accommodate the preferences of both data owners and recipients.

Differential Privacy; R\(^2\)DP Mechanism; Utility Metrics

1 INTRODUCTION
Significant amounts of individual information are being collected and analyzed today through a wide variety of applications across different industries [2]. Differential privacy has been widely recognized as the de facto standard notion [20, 23] in protecting individuals’ privacy during such data collection and analysis. On the other hand, since the privacy constraints (e.g., the degree of randomization) imposed by differential privacy may render the released data less useful for analysis, the fundamental trade-off between privacy and utility (i.e., analysis accuracy) has attracted significant attention in various settings [23, 25, 28, 54, 64, 67].

In this context, a key issue is to identify the optimal randomization mechanisms (i.e., distributions and their parameters) [4, 10, 31–33, 35, 38, 41]. While optimizing the parameters of a given distribution can be easily automated, identifying the optimal distribution for different utility metrics is more challenging, and typically requires manual analysis to examine the search space of all distributions. In fact, recent studies [4, 10, 31–33, 35, 38, 41] have only identified the optimal randomization mechanisms for a limited number of cases with specific utility metrics and queries. For instance, Ghosh et al. [35, 38] showed that an optimal randomization mechanism (adding a specific class of geometric noise) can be used to preserve differential privacy under the class of negative expected loss utility metrics for a single counting query. Subsequently, Geng et al. [33] showed that, under the \(\ell_1\) and \(\ell_2\) norms, the widely used standard Laplace mechanism is asymptotically optimal as \(\epsilon \to 0\), whereas the Staircase mechanism (which can be viewed as a geometric mixture of uniform probability distributions) performs exponentially better than the Laplace mechanism in cases of weaker privacy guarantees (a comprehensive literature review will be given in Section 6).

However, this has left the optimal distributions of many other utility metrics as open problems, e.g., usefulness (for machine learning applications [7]), entropy-based measures (for signal processing applications [17, 74], and semi-supervised learning [37]), and graph distance metrics (for social network applications [49]). As shown in the works of Ghosh et al. [35, 38] and Geng et al. [33], different utility metrics will likely lead to different optimal distributions. Moreover, since those existing works mostly rely on manual analysis to examine the search space of all distributions, it would be an expensive process to repeat such efforts for each utility metric. Consequently, many existing works simply employ a well-known distribution (e.g., Laplace noise with constant scale parameter or Gaussian noise with constant variance) without worrying about its optimality. Unfortunately, as our experimental results will show...
work that can automatically find the optimal distribution in the search space of all distributions, we would need a formulation to link the differential privacy guarantee to the parameters of different distributions (e.g., in Laplace mechanism, $\epsilon$ is proportionally related to the inverse of variance). However, it is a known fact that such a formulation varies for each distribution, which explains why existing works have to rely on manual efforts to cover the search space of all distributions, and it also becomes the main obstacle to finding a universal solution that works for all utility metrics employed in different applications.

As depicted in Figure 1, our key idea is that, although it is not possible to directly cover the search space of all distributions in an automated fashion, we can indirectly do so based on the following known fact in probability theory, i.e., a two-fold randomization over the exponential class of distributions may yield many other distributions to approximately cover the search space [16]. Since this class of distributions are all originated from one of the exponential family distributions, their differential privacy guarantee will become a unique function of the parameters of the second fold distribution. Therefore, these parameters can be used to automatically optimize utility w.r.t. different utility metrics through a universal framework, namely, randomizing the randomization mechanism in differential privacy ($R^2$DP). Furthermore, the two-fold distribution introduces an added degree of freedom, which allows $R^2$DP to incorporate the requirements of both data owners and data recipients.

### 1.2 Contributions

Specifically, we make the following contributions:

1. We define the $R^2$DP framework with several unique benefits. First, it provides the first universal solution that is applicable to different utility metrics, which makes it an appealing solution for applications whose utility metrics have no known optimal distributions (e.g., [7, 17, 49, 74]). Second, unlike most existing works which rely on manual analysis [35, 38], $R^2$DP can automatically identify a distribution that yields near-optimal utility, and hence is more practical for emerging applications. Third, $R^2$DP can incorporate the requirements of both data owners and data recipients, which addresses a practical limitation of most existing approaches, i.e., only the privacy budget $\epsilon$ is considered in designing the differentially private mechanisms.

2. We formally benchmark $R^2$DP under the well-studied Laplace mechanism. We tackle several key challenges related to the two-fold distribution in $R^2$DP. We then show that this mechanism yields a class of log-convex distributions for which the differential privacy guarantee can globally be given in terms of the PDFs' parameters. We also show that it can generate near-optimal results w.r.t. a variety of utility metrics whose optimality is known, e.g., staircase-shape distribution for large $\epsilon$ and Laplace itself for small $\epsilon$ [33].

3. We evaluate $R^2$DP using six different utility metrics, both numerically and experimentally on real data, using both statistical queries (e.g., count and average), and data analytics applications (e.g., machine learning and social network). The experimental results demonstrate that $R^2$DP can significantly increase the utility for those utility metrics with no known optimal distributions (compared to the baseline Laplace distribution). We also evaluate the optimality of $R^2$DP using utility metrics whose optimal distributions are known (e.g., staircase-shape for $\ell_1$ and $\ell_2$ norms [33]) and our results confirm that $R^2$DP can generate near-optimal results.

4. We discuss the potential of adapting $R^2$DP to improve a variety of other applications related to differential privacy.

The rest of the paper is organized as follows. Section 2 provides some related background. Section 3 defines the $R^2$DP framework. Section 4 formally studies the differential privacy guarantee and the utility of $R^2$DP. Section 5 presents the experiments. Section 6 reviews the related work, and Section 7 concludes the paper.

### 2 PRELIMINARIES

**Figure 1: $R^2$DP can automatically optimize different utility metrics which have no known optimal distributions.**

**1.1 $R^2$DP: A Universal Framework**

Our key observation is the following. To build a universal framework that can automatically find the optimal distribution in the search space of all distributions, we would need a formulation to link the differential privacy guarantee to the parameters of different distributions (e.g., in Laplace mechanism, $\epsilon$ is proportionally related to the inverse of variance). However, it is a known fact that such a formulation varies for each distribution, which explains why existing works have to rely on manual efforts to cover the search space of all distributions, and it also becomes the main obstacle to finding a universal solution that works for all utility metrics employed in different applications.

As depicted in Figure 1, our key idea is that, although it is not possible to directly cover the search space of all distributions in an automated fashion, we can indirectly do so based on the following known fact in probability theory, i.e., a two-fold randomization over the exponential class of distributions may yield many other distributions to approximately cover the search space [16]. Since this class of distributions are all originated from one of the exponential family distributions, their differential privacy guarantee will become a unique function of the parameters of the second fold distribution. Therefore, these parameters can be used to automatically optimize utility w.r.t. different utility metrics through a universal framework, namely, randomizing the randomization mechanism in differential privacy ($R^2$DP). Furthermore, the two-fold distribution introduces an added degree of freedom, which allows $R^2$DP to incorporate the requirements of both data owners and data recipients.

**1.2 Contributions**

Specifically, we make the following contributions:

1. We define the $R^2$DP framework with several unique benefits. First, it provides the first universal solution that is applicable to different utility metrics, which makes it an appealing solution for applications whose utility metrics have no known optimal distributions (e.g., [7, 17, 49, 74]). Second, unlike most existing works which rely on manual analysis [35, 38], $R^2$DP can automatically identify a distribution that yields near-optimal utility, and hence is more practical for emerging applications. Third, $R^2$DP can incorporate the requirements of both data owners and data recipients, which addresses a practical limitation of most existing approaches, i.e., only the privacy budget $\epsilon$ is considered in designing the differentially private mechanisms.

2. We formally benchmark $R^2$DP under the well-studied Laplace mechanism. We tackle several key challenges related to the two-fold distribution in $R^2$DP. We then show that this mechanism yields a class of log-convex distributions for which the differential privacy guarantee can globally be given in terms of the PDFs’ parameters. We also show that it can generate near-optimal results w.r.t. a variety of utility metrics whose optimality is known, e.g., staircase-shape distribution for large $\epsilon$ and Laplace itself for small $\epsilon$ [33].

3. We evaluate $R^2$DP using six different utility metrics, both numerically and experimentally on real data, using both statistical queries (e.g., count and average), and data analytics applications (e.g., machine learning and social network). The experimental results demonstrate that $R^2$DP can significantly increase the utility for those utility metrics with no known optimal distributions (compared to the baseline Laplace distribution). We also evaluate the optimality of $R^2$DP using utility metrics whose optimal distributions are known (e.g., staircase-shape for $\ell_1$ and $\ell_2$ norms [33]) and our results confirm that $R^2$DP can generate near-optimal results.

4. We discuss the potential of adapting $R^2$DP to improve a variety of other applications related to differential privacy.

The rest of the paper is organized as follows. Section 2 provides some related background. Section 3 defines the $R^2$DP framework. Section 4 formally studies the differential privacy guarantee and the utility of $R^2$DP. Section 5 presents the experiments. Section 6 reviews the related work, and Section 7 concludes the paper.
The following sensitivity concept plays an important role in the design of differentially private mechanisms [23].

**Definition 2.1.** The sensitivity of a query \( q : D \rightarrow \mathbb{R} \) is defined as
\[
s_q = \max_{d, d'} |q(d) - q(d')|.
\]

### 2.2 Laplace Mechanism

The Laplace mechanism [23] modifies a numerical query result by adding zero-mean noise (denoted as \( \text{Lap}(b) \)) distributed according to a Laplace distribution with mean zero and scale parameter \( b \). It has density \( p(x; b) = \frac{1}{2b} \exp(-|x|/b) \) and variance \( 2b^2 \).

**Theorem 2.1.** Let \( q : D \rightarrow \mathbb{R} \) be a query, \( \epsilon > 0 \). Then the mechanism \( M_q : D \times \Omega \rightarrow \mathbb{R} \) defined by \( M_q(d) = q(d) + \omega \), with \( \omega \sim \text{Lap}(b) \), where \( b \geq \frac{n}{\epsilon} \), is \( \epsilon \)-differentially private [23].

### 2.3 Utility Metrics

**\( \ell_p \) Metrics.** In penalized regression, “\( \ell_p \) penalty” refers to penalizing the \( \ell_p \) norm of a solution’s vector of parameter values (i.e., the sum of its absolute values, or its Euclidean length) [69]. In our privacy-utility setting, the \( \ell_p \) utility metric is defined as follows.

**Definition 2.2.** \((\ell_p)\). For a database mechanism \( M_q(D) \) the \( \ell_p \) utility metric is defined as \( \mathbb{E}(|M_q(D) - q(D)|^p)^{1/p} \).

**Usefulness.** Following Blum et al. [7], the following utility metric is commonly used for machine learning.

**Definition 2.3.** \((\text{Usefulness})\). A mechanism \( M_q \) is \((\gamma, \zeta)\)-useful if, with probability \( 1 - \zeta \), for any dataset \( d \subseteq D \), \( |M_q(d) - q(d)| \leq \gamma \).

**Theorem 2.2.** The Laplace Mechanism is \((\frac{\Delta q}{\epsilon}, \ln \frac{1}{\epsilon} + \zeta)\)-useful, or equivalently, the Laplace Mechanism is \((\gamma, e^{\frac{\Delta q}{\epsilon}})\)-useful [13].

**Mallows Metric.** The Mallows metric has been applied for evaluating the private estimation of the degree distribution of a social network [42]. It is defined to test if two samples are from the same distribution. Given two random variables \( X \) and \( Y \), we have Mallows\((X, Y) = 1 - \frac{1}{n} \sum_{i=1}^{n} (X_i - Y_i)^2 / p \) (similar to \( p \)-norm).

**Relative Entropy (Rényi Entropy).** The relative entropy, also known as the Kullback-Leibler (KL) divergence, measures the distance between two probability distributions [17]. Formally, given two probability distributions \( p(x) \) and \( q(x) \) over a discrete random variable \( x \), the relative entropy given by \( D(p||q) \) is defined as follows:
\[
D(p||q) = \sum_{x \in X} p(x) \log \frac{p(x)}{q(x)}.
\]
Further generalization came from Rényi [36, 68], who introduced an indexed family of generalized information and divergence measures akin to the Shannon entropy and KL divergence. Rényi introduced the entropy of order \( \alpha \) as \( I_\alpha(p) = \frac{1}{1-\alpha} \log \left( \sum_{x \in X} p(x)^\alpha \right) \), \( \alpha > 0 \) and \( \alpha \neq 1 \).

### 3 THE R\(^2\)DP FRAMEWORK

In this section, we define the R\(^2\)DP framework and its main building block which is the Utility-maximized PDF finder.

#### 3.1 Notions and Notations

In probability and statistics, a random variable (RV) that is distributed according to some parameterized PDFs, with (some of) the parameters of that PDFs themselves being random variables, is known as a mixture distribution [16] when the underlying RV is discrete (or a compound distribution when the RV is continuous). Compound (or mixture) distributions have been applied in many contexts in the literature [66] and arise naturally where a statistical population contains two or more sub-populations.

**Definition 3.1.** Let \((\Omega, \mathcal{F}, \mathbb{P})\) be a probability space and let \( X \) be a RV that is distributed according to some parameterized distribution \( f(\theta) \in \mathcal{F} \) with an unknown parameter \( \theta \) that is again distributed according to some other distribution \( g \). The resulting distribution \( h \) is said to be the distribution that results from compounding \( f \) with \( g \),
\[
h(X) = \int_{\Omega} f(X|\theta)g(\theta)\,d\theta
\]
Then for any Borel subset \( B \) of \( \mathbb{R} \),
\[
\mathbb{P}(X \in B) = \int_{\mathbb{R}} \int_{B} f(X|\theta)g(\theta)\,d\theta\,dx
\]
In general, we call any differentially private query answering mechanisms that leverage two-fold probability distribution functions in their randomization, an R\(^2\)DP mechanism.

**Definition 3.2.** \((R^2DP\text{ Mechanism})\). Let \( M_q(d, u) = q(d) \oplus \omega(u) \) be a mechanism randomizing the answer of a query \( q \) using a random oracle \( \omega(u) \), where \( u \) is the set of parameters (mean, variance, etc.) of the PDF of \( \omega \) and \( \oplus \) stands for the corresponding operator. Denote by \( \mathcal{F} \) the space of PDFs, we call \( M_q(d, u) \) an R\(^2\)DP mechanism if at least one of the parameters \( u_i \in u \), \( i \leq |u| \) is /are chosen randomly w.r.t. a specified probability distribution \( f_{u_i} \in \mathcal{F} \).

In particular, the R\(^2\)DP Laplace mechanism will modify the answer to a numerical query by adding zero-mean noise distributed according to a compound Laplace distribution with the scale parameter \( b \) itself distributed according to some distribution \( f_b \).

**Example 3.1.** Suppose that the scale parameter \( b \) in a Laplace mechanism is randomized as follows:
\[
b = \begin{cases} b_1 \quad \text{w.p.} \; p, \\
b_2 \quad \text{w.p.} \; 1-p. \\
\end{cases}
\]
Then, the perturbed result \( q(D) + \text{Lap}(b) \) is an example R\(^2\)DP Laplace mechanism using a Bernoulli distribution.

**Definition 3.3.** Let \( q : D \rightarrow \mathbb{R} \) be a query and suppose \( f_b \in \mathcal{F} \) is a probability density function of the scale parameter \( b \). Then, the mechanism \( M_q : D \times \Omega \rightarrow \mathbb{R} \) defined by \( M_q(d, b) = q(d) + \text{Lap}(b) \) is an R\(^2\)DP Laplace mechanism that utilizes PDF \( f_b \).

#### 3.2 The Framework

As shown in Figure 2, R\(^2\)DP framework include the following steps.

**R\(^2\)DP Computation:**

- **Step 1:** The data owner specifies the differential privacy budget \( \epsilon \) and the data recipient specifies his/her query of interest together with its required utility metric.
- **Step 2:** Given the input triplets \((\epsilon, q, \text{metric})\), the utility-maximized PDF computing module computes the provably optimal probability density function and its parameters for the variance of the additive noise. For example, in Figure 2,
the PDF computing module returns a lower tail truncated Gaussian distribution for the specified inputs.

- **Step 3:** The variance sampler module randomly samples (w.r.t. the PDF found in Step 2) one standard deviation $\sigma_i$ of the noise to be eventually added.

### Baseline DP Randomization:

- **Step 4:** Next, the computed standard deviation $\sigma_i$ is used to generate a noise $\omega(\sigma_i)$ for the baseline DP mechanism, which is a DP mechanism of exponential order, e.g., Laplace, Gaussian and exponential mechanisms.

- **Step 5:** The computed noise $\omega(\sigma_i)$ is added to the query result $q(D)$ to provide a utility-maximized DP result to the data recipient.

The most important module of the $\text{R}^2\text{DP}$ framework is the utility-maximized PDF computing module (Step 2) which will be described in more details in the following. Furthermore, to make our discussions more concrete, we instantiate the $\text{R}^2\text{DP}$ framework based on the well studied Laplace mechanism, namely, the $\text{R}^2\text{DP}$ Laplace mechanism, where other baseline DP mechanisms will be discussed in Appendix F due to space limitation (from now on, we will simply refer to the $\text{R}^2\text{DP}$ Laplace mechanism as $\text{R}^2\text{DP}$). Particularly, we show that, with a two-fold Laplace distribution, an infinite-size class of log-convex distributions can be identified. This class of distributions pertains a differential privacy guarantee which can globally be given in terms of the PDFs’ parameters, and hence is automatically optimizable under the differential privacy constraint.

### 3.3 Computing Utility-Maximized PDF

In Figure 2, to compute the utility-maximized PDF (Step 2), a key challenge is to establish the search space of automatically optimizable PDFs, from which the utility-maximized PDF is computed. Ideally, the search space of an $\text{R}^2\text{DP}$ mechanism can be defined as the collection of all two-fold distributions, e.g., with Laplace and exponential as the first and second fold distributions, respectively. However, the key challenge here is that a mixture of distributions is itself a distribution which does not necessarily provide a global differential privacy guarantee in terms of the resulting PDFs’ parameters (automatically optimizable under the differential privacy constraint). To address this issue, the Moment Generating Function (MGF) [30] of the second fold distribution could be utilized, e.g., given the first fold as Laplace distribution. Specifically, MGF of a random variable is an alternative specification of its probability distribution, and hence provides the basis of an alternative route to analytical results compared with directly using probability density functions or cumulative distribution functions [30]. In particular, the MGF of a random variable is a log-convex function of its probability distribution which can provide a global differential privacy guarantee [30] (see Theorem 4.1).

**Definition 3.4.** (Moment Generating Function [30]). The moment-generating function of a random variable $x$ is $M_X(t) = \mathbb{E}[e^{tx}], t \in \mathbb{R}$ wherever this expectation exists. The moment-generating function is the expectation of the random variable $e^{tx}$.

**Theorem 3.1.** We can write the CDF of the output of an $\text{R}^2\text{DP}$ mechanism in terms of the Moment Generating Function (MGF) [30] of the probability distribution $f_X$, where $b$ is the randomized scale parameter (see Appendix A and C for the details and the proof).

Thus, for a PDF with non-negative support (since scale parameter is always non-negative), the $\text{R}^2\text{DP}$ mechanism outputs another PDF using the MGF (where CDF is the moment and PDF is its derivative, as shown in Equation 10 in Appendix C). Moreover, since MGF is a bijection function [29], the $\text{R}^2\text{DP}$ mechanism can in fact generate a search space as large as the space of all PDFs with non-negative support and an existing MGF. However, the next challenge is that not all random variables have moment generating functions (MGFs), e.g., Cauchy distribution [12]. Fortunately, MGFs possess an appealing composability property between independent probability distributions [16], which can be used to provide a search space of all linear combinations of a set of popular distributions with known MGFs (infinite number of RVs).

**Theorem 3.2 (MGF of Linear Combination of RVs).** If $x_1, \ldots, x_n$ are $n$ independent RVs with MGFs $M_{x_i}(t) = \mathbb{E}[e^{tx_i}]$ for $i = 1, \ldots, n$, then the MGF of the linear combination $Y = \sum_{i=1}^{n} a_i x_i$ is $\prod_{i=1}^{n} M_{x_i}(a_i t)$.

Consequently, we define the search space of the $\text{R}^2\text{DP}$ mechanism as all possible linear combinations of a set of independent RVs with existing MGF (Section 4.2.2 will provide more details on how to choose the set of independent RVs). Although this search
space is only a subset of all two-fold distributions, we will show through both numerical results (in Section E) and experiments with real data (Section 5) that this search space is indeed sufficient to generate near-optimal utility w.r.t. all utility metrics (universality).

4 PRIVACY AND UTILITY

In this section, we analyze the privacy and utility of the R²DP, and then discuss extensions for improving and implementing R²DP.

4.1 Privacy Analysis

We now show the R²DP mechanism provides differential privacy guarantee. By Theorem 3.1, the DP bound of the R²DP is

$$\epsilon = \max_{x \in R} \left\{ \frac{-M_x(-|x-q(d)|)}{E_x(\frac{1}{\epsilon})} \right\}$$

Hence, the value of $\epsilon^*$ only depends on the distribution of reciprocal of the scale parameter $b$, i.e., $f^*_b$. Moreover, an MGF is positive and log-convex [30] where the latter property is desirable in defining various natural logarithm upper bounds, e.g., DP bound. In the following theorem, our MGF-based formula for the probability $P ((q(d) + \text{Lap}(b)) \in S)$ can be easily applied to calculate the differential privacy guarantee (see Appendix C for the proof).

**Theorem 4.1.** The R²DP mechanism $M_q(d, b)$ is differentially private.

Moreover, Theorem 3.2 can be directly applied to calculate the differential privacy guarantee of any RV from the search space defined in Section 3.3 (i.e., all linear combinations of a set of independent RVs with known MGFs).

**Corollary 4.2 (Differential Privacy of Combined PDFs). If $x_1, \cdots, x_n$ are independent random variables with respective MGFs $M_{x_i}(t) = E(e^{t x_i})$ for $i = 1, \cdots, n$, then the R²DP mechanism $M_q(d, b)$ where $\frac{b}{2}$ is defined as the linear combination $d = \sum_{i=1}^n a_i x_i$ is $\epsilon$-differentially private, where

$$\epsilon = \ln \left[ \frac{\sum_{j=1}^n a_j \cdot E_{x_j}(\frac{1}{\epsilon})}{\sum_{j=1}^n a_j \cdot M_{x_j}( -a_j \cdot \Delta q) \prod_{i=1}^n M_{x_i}( -a_i \cdot \Delta q)} \right]$$

Therefore, we have established a search space of probability distributions with a universal formulation for their differential privacy guarantees, which is the key enabler for the universality of R²DP. Next, we characterize the utility of R²DP mechanisms.

4.2 Utility Analysis

We now characterize the utility of the R²DP mechanism. To make concrete discussions, we focus on the usefulness metric (see Section 2.3), and a similar logic can also be applied to other metrics.

4.2.1 Characterizing the Utility. Denote by $U(\epsilon, \Delta q, \gamma)$ the usefulness of an R²DP mechanism for all $\epsilon > 0$, sensitivity $\Delta q$ and error bound $\gamma$. The optimal usefulness is then given as the answer of the following optimization problem over the search space of PDFs.

$$\max_{f \in \mathcal{F}} \{ U(\epsilon, \Delta q, \gamma) \} = \max_{f \in \mathcal{F}} \left\{ \frac{1}{\epsilon} \cdot \left[ -M_x(-|x-q(d)|) q(d) + \max_{f \in \mathcal{F}} \{ U(\epsilon, \Delta q, \gamma) \} \right] \right\}$$

subject to $\epsilon = \ln \left[ \frac{\mathbb{E}(\frac{1}{\epsilon})}{\frac{dM_x(t)}{dt} \bigg|_{t=-\Delta q}} \right]$

where the utility function is the probability of generating $\epsilon$-DP query results within a distance of $\gamma$-error (using Theorem 3.1). Note that $\epsilon$ and $\Delta q$ do not directly impact the usefulness but they do so indirectly through the differential privacy constraint. Furthermore, as shown in Theorem 4.1, the differential privacy guarantee $\epsilon$ over the established search space is a unique function of the parameters of the second-fold distribution.

**Corollary 4.3.** Denote by $u$, the set of parameters for a probability distribution $f^*_b$, and by $M_{f(u)}$ its MGF. Then, the optimal usefulness of an R²DP mechanism utilizing $f^*_b$, at each triplet $(\epsilon, \Delta q, \gamma)$ is

$$U_f(\epsilon, \Delta q, \gamma) = \max_{u \in \mathcal{U}} \left\{ \frac{1}{\epsilon} \cdot \left[ -M_f(u)(-|x-q(d)|) q(d) + \max_{u \in \mathcal{U}} \{ U_f(\epsilon, \Delta q, \gamma) \} \right] \right\}$$

subject to $\epsilon = \ln \left[ \frac{\mathbb{E}(\frac{1}{\epsilon})}{\frac{dM_f(t)}{dt} \bigg|_{t=-\Delta q}} \right]$

Since MGFs are positive and log-convex, with $M(0) = 1$, we have $U_f(\epsilon, \Delta q, \gamma) = 1 - \min_{u \in \mathcal{U}} M_{f(u)}(-\gamma)$. Thus, for usefulness metric, the optimal distribution for $\epsilon$ is the one with the minimum MGF evaluated at $\gamma$. In particular, for a set of privacy/utility parameters, we can find the optimal PDF using the Lagrange multiplier [6], i.e.,

$$\mathcal{L}(u, \lambda) = M_{f(u)}(-\gamma) + \lambda \cdot \left( \ln \left[ \frac{\mathbb{E}(\frac{1}{\epsilon})}{\frac{dM_f(t)}{dt} \bigg|_{t=-\Delta q}} \right] - \epsilon \right)$$

Moreover, Theorem 3.2 can be directly applied to design a utility-maximizing R²DP mechanism with a sufficiently large search space (with an infinite number of different random variables).

**Corollary 4.4 (Optimal Utility for Combined RVs). If $x_1, x_2, \cdots, x_n$ are independent random variables with respective MGFs $M_{x_i}(t) = E(e^{t x_i})$ for $i = 1, 2, \cdots, n$, then for the linear combination

$$Y = \sum_{i=1}^n a_i x_i$$

the optimal usefulness (similar relation holds for other
metrics) under $\epsilon$-differential privacy constraint is given as

$$U_\gamma(\epsilon, \Delta q, y) = 1 - \min_{\mathcal{A}, \mathcal{U}} \left\{ \prod_{i=1}^{n} M_{x_i}(-a_iy) \right\}$$

subject to

$$\epsilon = \ln \left[ \frac{\sum_{j=1}^{n} a_j \cdot E_{\mathcal{U}}(\frac{1}{b})}{\sum_{j=1}^{n} a_j \cdot M_{x_j}(-a_j \cdot \Delta q) \cdot \prod_{i=1}^{n} M_{x_i}(-a_i \cdot \Delta q)} \right]$$

where $\mathcal{A} = \{a_1, a_2, \cdots, a_n\}$ is the set of the coefficients and $\mathcal{U} = \{u_1, u_2, \cdots, u_n\}$ is the set of parameters of the probability distributions of RVs $x_i$, $\forall i \leq n$.

Similar to the case of a single RV, we can compute the optimal solution for this optimization problem using the Lagrange multiplier function in Equation 6.

4.2.2 Finding Utility-Maximizing Distributions. Since not all second-fold probability distributions can boost the utility of the baseline Laplace mechanism, leveraging all RVs into our search space would only result in redundant computation by the utility-maximized PDF computing module. Accordingly, in this section, we first derive a necessary condition on the differential privacy guarantee of $R^2$DP to boost the utility of the baseline Laplace mechanism (refer to Appendix C for the proof). Using this necessary condition, we can easily filter out those probability distributions that cannot deliver any utility improvement.

Theorem 4.5. The utility of $R^2$DP with $\epsilon \geq \ln \left[ \frac{\mathbb{E}_\frac{1}{b} [e^{\epsilon(b)}]}{M_{\frac{1}{b}}(-\Delta q)} \right]$ is always upper bounded by the utility of the $\epsilon$-differentially private baseline Laplace mechanism. Equivalently, for an $R^2$DP mechanism to boost the utility, the following relation is necessarily true.

$$e^\epsilon = \frac{\mathbb{E}_\frac{1}{b} [e^{\epsilon(b)}]}{M_{\frac{1}{b}}(-\Delta q)} < M_{\frac{1}{b}}(\Delta q)$$

We note that $\epsilon = \ln \left[ \frac{\mathbb{E}_\frac{1}{b} [e^{\epsilon(b)}]}{M_{\frac{1}{b}}(-\Delta q)} \right]$ provides a tight upper bound since it gives the overall $e^\epsilon$ of an $R^2$DP mechanism as the average of differential privacy leakage. Next, we examine a set of well-known PDFs as second-fold distribution to identify the distribution that offers a significantly improved utility compared with the bound given in Theorem 4.5. Promisingly, our analytic evaluations for three of these distributions, i.e., Gamma, uniform and truncated Gaussian distributions demonstrate such a payoff (Appendix B theoretically analyzes several case study PDFs). We note that those chosen distributions are general enough to cover many of other probability distributions (e.g., Exponential, Erlang, and Chi-squared distributions are special cases of Gamma distribution).

4.2.3 Deriving Error Bounds. The error bounds of the $R^2$DP mechanism under some well-known utility metrics are shown in Table 1. The key idea in deriving these results is to calculate the mean of each utility metric over the PDF of RV $1/b$ (which is the linear combination of RV's in multiple PDFs). Specifically, given the error bound $e_L(b)$ for deterministic variance (i.e., Laplace mechanism), the total error bound of an $R^2$DP mechanism will be the mean $\int_0^\infty e_L(b)f_b(b)db$. The results shown in Table 1 can be easily applied to optimize those metrics in corresponding applications (e.g., $\ell_1$ for private record matching [44], $\ell_2$ for location privacy [8], usefulness for machine learning [7], Mallows for social network analysis [42], and relative entropy (with a degree $\alpha$) for semi-supervised learning [37]).

| Metric | Dependency to Prior | $R^2$DP Error Bound |
|--------|---------------------|----------------------|
| $\ell_1$ | independent | $\int \frac{M_{\frac{1}{b}}(-\Delta q)}{\mathbb{E}_\frac{1}{b} [e^{\epsilon(b)}]}$ |
| $\ell_2$ | independent | $\sqrt{\frac{2}{\pi}} \int \frac{M_{\frac{1}{b}}(-\Delta q)}{\mathbb{E}_\frac{1}{b} [e^{\epsilon(b)}]}$ |
| Usefulness | independent | $1 - \frac{M_{\frac{1}{b}}(-\Delta q)}{\mathbb{E}_\frac{1}{b} [e^{\epsilon(b)}]}$ |
| Mallows ($p$) | dependent | $\left( \sum_{i=1}^{n} |N_i - [M_{\frac{1}{b}}(-\Delta q)/\mathbb{E}_\frac{1}{b} [e^{\epsilon(b)}]] | p_i \right)/p_i$ |
| Relative Entropy ($\alpha$) | dependent | $\int \frac{\mathbb{E}_\frac{1}{b} [e^{\epsilon(b)}]}{M_{\frac{1}{b}}(-\Delta q)} - \log(p(x) - p(x)) \sim M_{\frac{1}{b}}(-\Delta q)/2$ |

In this context, the $\ell_1$, $\ell_2$ and usefulness metrics (as defined in Section 2.3) are independent to the prior (i.e., not depending on the distribution of the true results). The metrics will be evaluated based on the deviation between the true and noisy results (which does not change regardless of the prior). On the contrary, some other metrics (e.g., Mallows and relative entropy) depend on the prior distribution of the true results [37, 42]. In such cases, the metrics will be evaluated based on the deviation between the true and noisy results w.r.t. the prior in specific experimental settings (we will discuss those specific priors used in the experiments in Section 5).

In addition to the error bounds given in Table 1, an analyst can derive error bounds for more advanced queries, e.g., those pertaining to learning algorithms [22, 47, 71, 84]. Given the error bound of Laplace mechanism in an application (e.g., Linear SVM [47]), the error bound of the $R^2$DP framework for this application can be derived by taking average of the Laplace's result over the PDF of $\frac{1}{b}$. In particular, Table 2 demonstrates the error bounds of $R^2$DP for some learning algorithms (as shown in Section 5, those learning algorithms can benefit from integrating $R^2$DP instead of Laplace).

To derive the error bounds shown in Table 1 and Table 2, the noise parameter(s) and the PDFs used in $R^2$DP can be released to a downstream analyst. This will not cause any privacy leakage because, similar to other differential privacy mechanisms, the privacy protection of $R^2$DP comes from the (first-fold) randomization (whose generated random noises are never disclosed), which will not be affected even if all the noise parameter(s) and the PDFs are disclosed (see Section 4.1 and Appendix C for the formal privacy analysis and proof). We note that, although $R^2$DP replaces the fixed variance of a standard differential privacy mechanism with a random variance, this second-fold randomization is not meant to keep the generated parameters (e.g., the variance) secret, but designed to cover a larger search space (as detailed in Section 3.3).

4.3 $R^2$DP Algorithm

Algorithm 1 details an instance of the $R^2$DP framework using linear combination of three different PDFs. In particular, the algorithm with $e$-DP finds the best second-fold distribution using the Lagrange multiplier function (see Appendix D) that optimizes the utility
Bayesian Inference (statistician) and described in [77]. MERL has collected motion sensor data contains over 30 million raw motion records. To illustrate the query mechanism carried out in the Mitsubishi Electric Research Laboratories (MERL) and described in [77]. MERL has collected motion sensor data from a network of over 200 sensors for a year and the dataset contains over 30 million raw motion records. To illustrate the query performance with different sensitivities, we create the queries based on a subset of the data including aggregated events that are recorded by closely located sensors over 5-minute intervals. We formed in this way 10 input signals corresponding to 10 spatial zones (each zone is covered by a group of sensors). Since each individual can activate several sensors and travel through different zones, we define moving average functions with arbitrary sensitivity values, e.g., $\Delta q \in [0.1, 5]$. For instance, we could be interested in the summation of the moving averages over the past 30 min for zones 1 to 4. We apply $^{2}$DP w.r.t. usefulness, $\ell_1$, $\ell_2$, entropy, and Rénýi metrics, respectively.

### 5.1.1 Statistical Queries
In the first set of our experiments, we examine the benefits of $^{2}$DP using basic statistical functions, i.e., count and average. The dataset comes from a sensor network experiment carried out in the Mitsubishi Electric Research Laboratories (MERL) and described in [77]. MERL has collected motion sensor data from a network of over 200 sensors for a year and the dataset contains over 30 million raw motion records. To illustrate the query

#### Algorithm 1: The Ensemble $^{2}$DP Algorithm

Some advanced applications (e.g., workload queries) that integrate $^{2}$DP to improve their utility are discussed in Appendix G.

### 5.2 Basic Statistical Queries
We validate the effectiveness of $^{2}$DP using two basic statistical queries: count (sensitivity=1) and moving average with different sensitivities, we create the queries based on a subset of the data including aggregated events that are recorded by closely located sensors over 5-minute intervals. We formed in this way 10 input signals corresponding to 10 spatial zones (each zone is covered by a group of sensors). Since each individual can activate several sensors and travel through different zones, we define moving average functions with arbitrary sensitivity values, e.g., $\Delta q \in [0.1, 5]$. For instance, we could be interested in the summation of the moving averages over the past 30 min for zones 1 to 4. We apply $^{2}$DP w.r.t. usefulness, $\ell_1$, $\ell_2$, entropy, and Rénýi metrics, respectively.

#### 5.1.2 Social Network.
Social network degree distribution is performed on a Facebook dataset [55]. They consist of “circles” and “friends lists” from Facebook by representing different individuals as nodes (47,538 nodes) and friend connections as edges (222,887 edges). Recall that the Mallows metric is frequently used for social network (graph-based) applications [49]. We thus apply $^{2}$DP w.r.t. the Mallows metric in this group of experiments.

#### 5.1.3 Machine Learning.
Naive Bayes classification is performed on two datasets: Adult dataset (in the UCI ML Repository) [51] and KDDCup99 dataset [70]. First, the Adult dataset includes the demographic information of 48,842 different adults in the US (14 features). It can be utilized to train a Naive Bayes classifier to predict whether an individual is earns over $50k$, or not. Second, the KDD competition dataset was utilized to build a network intrusion detector (given 24 training attack types) by classifying “bad” connections and “good” connections. Recall that the usefulness metric is commonly used for machine learning [7]. We thus apply $^{2}$DP w.r.t. the usefulness in this group of experiments.

### 5.2 Basic Statistical Queries

| Linear SVM [47] | Bayesian Inference (statistician) [84] | Robust Linear Regression [22] | Naive Bayes [71] |
|----------------|----------------------------------------|-----------------------------|-----------------|
| $O(\log(1/\delta)/\alpha^2 + \frac{\Delta}{\epsilon \alpha e})$ | $O(\min \log(n) \{1 - \exp(-\frac{\Delta}{\epsilon 2\alpha e})\}$ | $O(\Delta^{-\alpha})$ | $O(\Delta^{-\alpha})$ |
| $^{2}$DP | $O(\log(1/\delta)/\alpha^2 + E(\frac{b}{\alpha} + \frac{\Delta}{\epsilon \alpha e}))$ | $O(\min \log(n) \{1 - M_{\epsilon}^{-1}(\frac{n}{\Delta})\})$ | $O(\Delta^{-\alpha})$ |

#### Table 2: $^{2}$DP compared to Laplace w.r.t. error bounds for learning algorithms

#### Table 2: $^{2}$DP compared to Laplace w.r.t. error bounds for learning algorithms

In this section, we experimentally evaluate the performance of $^{2}$DP using six different utility metrics, i.e., $\ell_1$, $\ell_2$, entropy, usefulness, Mallows and Rénýi divergence. Furthermore, we investigate the tightness of $^{2}$DP under Rénýi differential privacy (RDP in short) [62] which provides a universal formulation of the privacy losses of various DP mechanisms, as shown in Appendix F.2.2 (facilitating the comparison between different mechanisms). Our objective is to verify the following two properties about the performance of the $^{2}$DP framework w.r.t. all seven utility and privacy metrics: (1) $^{2}$DP produces near-optimal results and (2) $^{2}$DP performs strictly better than well-known baseline mechanisms, e.g. Laplace and Staircase mechanisms, in settings where an optimal PDF is not known, e.g., usefulness utility metric or Rénýi differential privacy.
Figure 3: Usefulness metric: $R^2$DP (with five PDFs, i.e., Gamma, Uniform, Truncated Gaussian, Noncentral Chi-squared and Rayleigh distributions) strictly outperforms Laplace and Staircase mechanisms for statistical queries, where the ratio of improvement depends on the values of $\Delta q, y$ and $\epsilon$.

Figure 4: $\ell_1$ and $\ell_2$ metrics: $R^2$DP compared to Laplace and Staircase mechanisms for statistical queries (with five PDFs, i.e., Gamma, Uniform, Truncated Gaussian, Noncentral Chi-squared and Rayleigh distributions). of the $R^2$DP mechanism. Furthermore, we observe that the Laplace and the staircase mechanisms are not optimal (w.r.t. usefulness) for
very small and large values of $\epsilon$, respectively, even though they are
known to be optimal under other utility metrics (e.g., [34]).

5.2.2 $\ell_1$ and $\ell_2$ Metrics. We compare $R^2$DP with the baseline Laplace
and Staircase mechanisms [38], by varying the privacy budget $\epsilon$
and for four different sensitivities $\Delta q \in \{0.1, 0.5, 1, 1.5\}$. Our re-
results validate the findings of Geng et al. [34], i.e., in the low privacy
regime ($\epsilon \to \infty$), the Staircase mechanism is optimal while in the
high privacy regime ($\epsilon \to 0$), the Laplace mechanism is optimal.

More importantly, our evaluations show that, for medium regime
of privacy budgets (which could be more desirable in practice), the
class of optimal noise can be totally different. In fact, as shown
in Geng et al. [34], the lower-bound of $\epsilon$ at which the Staircase
distribution performs better than the Laplace distribution is some-
where around $\epsilon = 3$ for both $\ell_1$ and $\ell_2$ metrics. As illustrated in
Figure 4, in contrast to $\ell_1$ metric (for which the results of laplace
and staircase are relatively tight), $R^2$DP can find a class of noises
with significantly improved $\ell_2$ metric for $\epsilon < 3$ (a logarithmic X
axis is used to illustrate the performance in this region). The PDF
of this class of noises is mostly two-fold distributions with Laplace
distribution as the first fold, and Gamma distribution as the second
fold. This finding is in line with the optimal class of noise proposed
by Koufogiannis et al. [52], i.e., $f(v) = e^{\frac{\Delta q}{2}v^2 + 1} \pi^{2\alpha} \Gamma(n + 1)$.
Fur-
thermore, our results suggest different classes of optimal noises
(than those found in the literature) for different parameters, sensi-
tivity, $\epsilon$ and $p$ (index of $\ell$ norm). In particular, a larger $p$ tends to
provide larger search spaces for $R^2$DP optimization, which results
in further improved results for $\epsilon < 3$ (Figure 4 (a,b,e,f) vs. (c,d,g,h)).

5.2.3 Relative Entropy Metric. As Wang et al [75] has already
shown that the output entropy of $\epsilon$-DP randomization mechanisms
is lower bounded by $1 - \ln(\epsilon/2)$ (for count queries) and the optimal
result is achieved with Laplace mechanism, we focus our entropy
metric evaluation on relative entropy metrics, i.e., KL and Rényi
divergences. To define the prior distribution for this group of ex-
periments, we have created a histogram with 50 bins of our data
and calculated the probability mass function (pmf) of the bins. 1
As illustrated in Figure 5, we can draw similar observations for the KL
entropy metric. In particular, we observe that $R^2$DP performs better
for smaller sensitivity due to the larger search space of PDFs used
in optimization. Similarly the Rényi entropy depicted in Figure 6
shows a similar trend with different $\alpha$ (the index of the divergence).

Summary. The $R^2$DP mechanism can generate better results than
most of the well-known distributions for utility metrics without
known optimal distributions (e.g., usefulness), and our results asym-
potically approach to the optimal for utility metrics with known
optimal distributions (e.g., $\ell_1$ and $\ell_2$). In particular, even though
$R^2$DP is not specifically designed to optimize $\ell_1$ and $\ell_2$ metrics, we
observe very similar performance between the $R^2$DP results and the optimal Staircase results, e.g., the multiplicative gain com-
pared to the Laplace results. We note that using a larger number

of independent RVs drawn from different PDFs as the search space
generator may further improve the results.

5.3 Tightness of $R^2$DP under Rényi DP

Rényi differential privacy [62] is a recently proposed as a relaxed
notion of DP which effectively quantifies the bad outcomes in ($\epsilon, \delta$-
DP mechanisms and consequently evaluates how such mechanisms
behave under sequential compositions (see Appendix F.2.2 for de-
tails on Rényi DP). We now evaluate how the privacy loss of $R^2$DP
behaves under Rényi DP.

Specifically, this group of experiments is conducted to provide
insights about the privacy loss of $R^2$DP and other well-known
mechanisms. In particular, Figure 7 (a-d) depicts the Rényi differen-
tial privacy of the $R^2$DP and two basic mechanisms for counting
queries: random response and Laplace mechanisms. These results
are based on the privacy guarantees depicted in Table 3. Our results
demonstrate that fine tuning $R^2$DP can generate strictly more pri-
vate results compared to the other two $\epsilon$-DP mechanisms when the
definition of the privacy notion is relaxed. Furthermore, the level of
such tightness depends on the Rényi differential privacy index
where a smaller value of $\alpha$ pertains to a relatively tighter $R^2$DP
mechanism. On the other hand, all three mechanisms behave more
similarly as $\alpha$ increases. Ultimately, at $\alpha \to \infty$, where Rényi differ-
ential privacy becomes equivalent to the classic notion of $\epsilon$-DP, all
three mechanisms’ privacy guarantees converge to $\epsilon$.

Table 3: Summary of Rényi DP parameters for four mecha-
nisms based on Theorem F.4

| Mechanism | Differential Privacy | Rényi Differential Privacy for $\alpha$ |
|-----------|----------------------|--------------------------------------|
| Laplace   | $\frac{1}{\pi}$      | $a > 1 : \frac{1}{2\pi} \log \frac{e^{\frac{\Delta q}{2}}}{\frac{\Delta q}{2} + 1} + \frac{\Delta q}{2} + 1$ |
| Random Response | $\frac{1}{\pi}$ | $a > 1 : \frac{1}{2\pi} \log \frac{e^{\frac{\Delta q}{2}}}{\frac{\Delta q}{2} + 1} + \frac{\Delta q}{2} + 1$ |
| $R^2$DP   | $M'_0(0)/M'_{-1}(0)$ | $a > 1 : \frac{1}{2\pi} \log \frac{e^{\frac{\Delta q}{2}}}{\frac{\Delta q}{2} + 1} + \frac{\Delta q}{2} + 1$ |
| Gaussian  | $\infty$           | $a > 1 : \frac{1}{2\pi} \log \frac{e^{\frac{\Delta q}{2}}}{\frac{\Delta q}{2} + 1} + \frac{\Delta q}{2} + 1$ |

In the next set of experiments, we compare the $R^2$DP mecha-
nism and Gaussian mechanism in terms of privacy guarantee to
understand how exactly the bad outcomes probability ($\delta$) affects
the privacy robustness of a privatized mechanism. Figure 7 (e-h) gives
such a comparison. Specifically, since Rényi differential privacy at
each $\alpha$ can be seen as higher-order moments as a way of bounding
the tails of the privacy loss variable [62], we observe that each
value of $\alpha$ reveals a snapshot of such a privacy loss. As a tangible
observation, we conclude that the class of optimal $\epsilon$-differential
privacy mechanisms benefits from a very smaller privacy loss at
smaller moments (which are more decisive in overall protection)
and larger privacy loss at bigger moments.

5.4 Social Network Analysis

We conduct experiments to compare the performance of $R^2$DP,
Laplace and two staircase mechanisms based on PINQ queries in
social network analysis. Figure 8 compares the degree distribution

---

12 millions records fall into 50 bins (e.g., equal range for each bin). Then, any counting
and moving average query (with different sensitivities) can be performed within each
of the 50 bins to generate the distribution. Finally, the distance between the original
and noisy distributions can be measured using the relative entropy metrics.
for a real Facebook dataset using Mallows metric (the prior, i.e., \( n = 47,538 \) nodes, and \( p = 1 \) or 2 for computing the distribution distance using Mallows metric). Again, our results confirm that R^2DP can effectively generate PDFs to maximize this utility metric suitable for social networking analysis. Note that, since the definition of this metric is similar to \( \ell_p \) metric (Mallows is more empirical, depending on the number of nodes in the dataset), the results for this metric display a similar pattern to those for \( \ell_p \) metric depicted in Figure 4.

5.5 Machine Learning

We obtain our baseline results by applying the Naive Bayes classifier on the Adult dataset (45K training records and 5K testing records), the precision and recall results are derived as 0.814 and 0.825, respectively. Then, we evaluate the precision and recall of R^2DP and Laplace-based naive classification \([72]\) by varying the privacy budget for each PINQ query \( \epsilon \in [0.1, 10] \) (sensitivity=1) where two different error bounds \( \gamma = 0.05, 0.1 \) are specified for R^2DP. We have the following observations:

- As shown in Figure 9(a) and 9(b), the R^2DP-based classification is more accurate than the Laplace and staircase mechanisms with the same total privacy budget for all the PINQ queries \( \epsilon \). As the privacy budget \( \epsilon \) increases, following our statistical query experiments, R^2DP offers a far better precision/recall compared to the Laplace-based classification (close to the results without privacy consideration) since it approaches to the optimal PDF.

- Among the precision/recall results derived with two different \( \gamma \) in R^2DP-based classification, for each \( \epsilon \), one out of the two specified error bounds (e.g., \( \gamma = 5\% \)) may reach the highest accuracy (not necessarily the result with the smaller \( \gamma \)).

- As shown in Figure 9(c) and 9(d), we can draw similar observations from the KDDCup99 dataset.

The above experimental results have validated the effectiveness of integrating R^2DP to improve the output utility for classification while ensuring \( \epsilon \)-differential privacy. In summary, all the experiments conducted in both statistical queries and real-world applications have validated the practicality of the R^2DP framework.

6 RELATED WORK

Differential privacy \([23]\) is a model for preserving privacy while releasing the results of various useful functions, such as contingency tables, histograms and means \([20]\). Many existing works focus on improving the utility based on different mechanisms.

**Noise Perturbation.** Based on the general utility maximization framework from Ghosh et al. \([35]\), Gupta and Sundararajan \([38]\) further study the optimal noise probability distributions for single count queries. Later, Geng et al. \([32, 35]\) demonstrate the optimal
Rényi Differential Privacy

\[ (a) \alpha = 1 \quad (b) \alpha = 3 \quad (c) \alpha = 4 \quad (d) \alpha = 5 \]

Figure 7: Rényi Differential Privacy: (a-d) R\(^2\)DP compared to Laplace and Random Response mechanisms, and (e-h) R\(^2\)DP compared to Gaussian mechanism.

\[ (a) p = 1, \Delta q = 0.5 \quad (b) p = 1, \Delta q = 1 \quad (c) p = 2, \Delta q = 0.5 \quad (d) p = 2, \Delta q = 1 \]

Figure 8: Mallows metric: R\(^2\)DP compared to Laplace and Staircase mechanisms for degree distribution (Facebook dataset).

noise distribution has a Staircase-shaped PDF for Laplace mechanism. Furthermore, Balle and Wang \cite{balle2018gaussian} develop an optimal Gaussian mechanism in high privacy regime to minimize the noise and increase the utility for queries. Geng et al. \cite{geng2022minimizing} further show the optimal noise distribution is a uniform distribution over Gaussian mechanism. Moreover, Hardt et al. \cite{hardt2014beating} study the privacy-utility trade-off for answering a set of linear queries over a histogram, where the error is defined as the worst expectation of the \(l_2\)-norm (identical to variance) of the noise among all possible outputs. Subsequently, Brenner et al. \cite{brenner2015privacy} show that, for general query functions, no universally optimal DP mechanisms exist.

**Sampling and Aggregation.** Sampling and aggregation frameworks mostly split the database into chunks, and aggregate the result using a DP algorithm after querying each chunk \cite{balle2018gaussian}. To expand the applicability of output perturbation, Nissim et al. \cite{nissim2017differentially} propose a framework to formally analyze the effect of instance-based noise. Observing the highly compressible nature of many real-life data, researchers propose lossy compression techniques to add noise calibrated to the compressed data. Acs et al. \cite{acs2018dp} propose an optimization of Fourier perturbation algorithm that clusters and exploits the redundancy between bins. Instead of directly adding noise to histogram counts, it first lossily compresses the data, then adds noise calibrated to the data. Li et al. \cite{li2017privacy} propose an algorithm to partitions a data domain into uniform regions and adapts the strategy to fit the specific set of range queries to achieve a lower error rate. Zhang et al. \cite{zhang2018differentially} improve the clustering mechanism by sorting histogram bins based on the noisy counts.
Data Composition. Barak et al. [5] propose transforming the data into the Fourier domain, which could avoid the violation of consistency for low-order marginals in database tables. As efficiency is the main bottleneck for this approach when the number of attributes is large, Hay et al. [43] ensure that the error rate does not grow with the size of a database. The proposed hierarchical histogram method also achieves a lower error for a fixed domain. Different from one-dimensional datasets solution proposed by Hay et al. [43], Xiao et al. [79] propose Privleve that improves accuracy on datasets with arbitrary dimensions, which could reduce error to 25% compared to 70% as baseline error rate. Cormode et al. [18] apply quadtrees and kd-trees as new techniques for parameter setting to improve the accuracy on spatial data. Ding et al. [19] introduce a general noise-control framework based on data cubes. Li et al. [58] unify the two range queries over histograms into one framework. Other techniques, such as principal component analysis (PCA), linear discriminant analysis (LDA) [48], and random projection [15, 80] are also used to lower the data dimension for reducing the errors. Cormode et al. [18] apply quadtrees (data-independent) and kd-trees (data-dependent) to add noise to a histogram output.

Adaptive Queries. In this technique, the improvement of utilities takes advantage of a known set of queries, for example, Dwork et al. [27] propose Boosting for Queries algorithm to obtain a better accuracy of learning algorithms. Hardt et al. [39, 40] present multiplicative weights mechanism to improve the efficiency of interactive queries. Instead of polynomial running time [25], this work achieves a nearly linear running time with a relaxed utility requirement. Yuan et al. [81, 82] propose low-rank mechanism (LRM) to further improve the adaptive queries. Other techniques such as correlated noise [63] and sparse vector technique (SVD) [60] are also used in adaptive queries.

Applications. Many researchers also work on improving the utility for different types of data, such as, the Fourier Perturbation Algorithm (FPAK) [67] in time-series data (e.g., location traces, web history, and personal health), kd-trees on spatial data [18], and matrix-valued query [14].

Summary. Our R^2DP framework provides a complementary approach to those existing works by providing the opportunity of searching for the maximal utility along an extra dimension. This framework also enables data recipients to specify their utility requirements and the computed parameter could be incorporated into existing solutions to further improve utility.

7 CONCLUSION

This paper has proposed the R^2DP framework as a universal solution for optimizing a variety of utility metrics requested in different applications. It can automatically identify a distribution that yields near-optimal utility, and hence is more practical for emerging applications. Specifically, we have shown that a differentially private mechanism could be defined based on a random variable which is itself distributed according to some parameterized distributions. We have also shown that such a mechanism could explicitly take into account both the privacy requirements and the utility requirements specified by the data owner and data recipient, respectively. We have formally analyzed the privacy guarantee of R^2DP based on the well-known Laplace mechanism and formally proved the improvement of utility over the baseline Laplace mechanism. Furthermore, we discuss the potential of applying R^2DP to advanced algorithms. Finally, our experimental results based on six different utility metrics for statistical queries, machine learning and social network, as well as one privacy metric, have demonstrated that R^2DP could significantly improve the utility of differentially private solutions for a wide range of applications.

APPENDIX

A DEMONSTRATION OF THEOREM 3.1

A Laplace distribution is of a \((e^x \cdot e^{x^{-t}})\) order, where \(x\) is the inverse of the scale parameter. Second, since \(e^{x^{-t}} = \frac{de^{x^{-t}}}{dt} = \text{cumulative distribution function (CDF)}\) resulted from randomizing \(x\) can be expressed in terms of the expectation \(E[e^{x^{-t}}]\). We note that from now on, we will simply refer to \(RD\) with Laplace distribution as the first fold PDF as the \(RD\) DP mechanism.

**Figure 10:** The term in the parenthesis is the derivative of \(E[e^{x^{-t}}]w.r.t. -|w|\), and hence the above probability can be expressed in terms of the expectation

**Example A1.** Following Example 3.1, for a Bernoulli distributed scale parameter \(b\), Figure 10 illustrates the above finding (see Appendix C for proof). It can be verified that the term inside the braces is the derivative of \(E[e^{x^{-t}}]w.r.t. -|w|\), and hence the above probability can be expressed in terms of the expectation.
B CASE STUDY PDFS

B.0.1 Discrete Probability Distributions. First, we consider two different mixture Laplace distributions that can be applied for constructing $R^2$DP with discrete probability distribution $f_b$.

1. Degenerate distribution. A degenerate distribution is a probability distribution in a (discrete or continuous) space with support only in a space of lower dimension [9]. If the degenerate distribution is uni-variate (involving only a single random variable), it will be a deterministic distribution and takes only a single value. Therefore, the degenerate distribution is identical to the baseline Laplace mechanism as it also assigns the mechanism one single value.

2. Bernoulli distribution. The probability mass function of this distribution, over possible outcomes $k$, is

$$f_B(k; p) = \begin{cases} p & \text{if } k = 1, \\ 1 - p & \text{if } k = 0. \end{cases}$$

Note that the binary outcomes $k = 0$ and $k = 1$ can be mapped to any two outcomes $X_0$ and $X_1$, respectively. Therefore, we consider the following Bernoulli outcomes

$$f_{B, X_0, X_1}(X; p) = \begin{cases} p & \text{if } X = X_1, \\ 1 - p & \text{if } X = X_0. \end{cases}$$

The MGF for Bernoulli distribution $f_{B, X_0, X_1}(X; p) = M_B(t) = p \cdot e^{t \cdot 0} + (1 - p) \cdot e^{t \cdot 1}$ [12]. We now derive the precise differential privacy guarantee of an $R^2$DP mechanism with its scale parameter randomized according to a Bernoulli distribution.

Theorem B.2. The $R^2$DP mechanism $M_B(d, e), e \sim f_B(\cdot; \beta), it satisfies $\Delta q$-differential privacy.

This bound is exactly the mean of $\epsilon^{(b)}$ given in Theorem 4.5.

B.0.2 Continuous Probability Distributions. We now investigate three compound Laplace distributions.

1. Gamma distribution. The gamma distribution is a two-parameter family of continuous probability distributions with a shape parameter $k > 0$ and a scale parameter $\theta$. Besides the generality, the gamma distribution is the maximum entropy probability distribution (both w.r.t. a uniform base measure and w.r.t. a 1/x base measure) for a random variable $X$ for which $\mathbb{E}(X) = k \theta = \alpha / \beta$ is fixed and greater than zero, and $\mathbb{E}(|X|) = \psi(k + \ln(\theta) = \psi(x) - \ln(\beta)$ is fixed ($\psi$ is the digamma function). Therefore, it may provide a relatively higher privacy-utility trade-off in comparison to the other candidates [45, 50]. A random variable $X$ that is gamma-distributed with shape $\alpha$ and rate $\beta$ is denoted by $X \sim \Gamma(k, \theta)$ and the corresponding PDF is

$$f_T(X; k, \theta) = \frac{x^{k-1} e^{-\frac{x}{\theta}}}{\Gamma(k)} \cdot \frac{\theta^k}{\theta^{x}}$$

for $X > 0$ and $k, \theta > 0$,

where $\Gamma(x)$ is the gamma function. We now investigate the differential privacy guarantee provided by assuming that the reciprocal of the scale parameter $b$ in Laplace mechanism is distributed according to the gamma distribution (see Appendix C for the proof).

Theorem B.3. The $R^2$DP mechanism $M_{\gamma}(d, e), e \sim f_T(\cdot; k, \theta)$, satisfies $(k + 1) \cdot \ln(1 + \Delta q \cdot \theta)$ differential privacy.

We now apply the necessary condition given in Equation 8 (see Appendix C for the proof).

Lemma B.4. $R^2$DP using Gamma distribution can satisfy the necessary condition in Equation 8.

Therefore, Gamma distribution may improve over the baseline, and this can be computed by optimizing the privacy-utility trade-off using the Lagrange multiplier function in Equation 6. Also, our numerical results show that, this distribution is more effective for large $\epsilon$ (weaker privacy guarantees).

2. Uniform distribution. In probability theory and statistics, the continuous uniform distribution or rectangular distribution is a family of symmetric probability distributions such that for each member of the family, all intervals of the same length on the support of the distribution are equally probable. The support is defined by the two parameters, $a$ and $b$, which are the minimum and maximum values. The distribution is often abbreviated as $U(a, b)$, which is the maximum entropy probability distribution for a random variable $X$ under no constraint; other than that, it is contained in the distribution’s support [45, 50]. The MGF for $U(a, b)$ is

$$M_X(t) = \begin{cases} \frac{e^{tb} - e^{ta}}{(b-a)} & \text{for } t \neq 0, \\ 1 & \text{for } t = 0. \end{cases}$$

Using Theorem 4.1, we now drive the precise differential privacy guarantee of an $R^2$DP mechanism for uniform distribution $U(a, b)$.

Theorem B.5. The $R^2$DP mechanism $M_{U}(d, e), e \sim f_{U}(\cdot; a, b)$, it satisfies $\max_{a^2 - b^2} - \frac{\Delta q}{\ln(1 + \Delta q \cdot \theta)}$ differential privacy, where $a = a \cdot \Delta q$ and $\beta = b \cdot \Delta q$.

We now apply the necessary condition given in Equation 8. One can easily verify that the inequality holds for an infinite number of settings, e.g., $a = 0.5, b = 9$ and $\Delta q = 1.2$.

Lemma B.6. $R^2$DP using uniform distribution can satisfy the necessary condition in Equation 8.

Therefore, $R^2$DP using uniform distribution may improve over the baseline, and this can be computed by optimizing the privacy-utility trade-off using the Lagrange multiplier function in Equation 6. Also, our numerical results show that, this distribution can also be effective for both small and large $\epsilon$.

3. Truncated Gaussian distribution. The last distribution we consider is the Truncated Gaussian distribution. This distribution
is derived from that of a normally distributed random variable by bounding the random variable from either below or above (or both). Therefore, we can benefit from the numerous useful properties of Gaussian distribution, by truncating the negative region of the Gaussian distribution. Suppose \( X \sim N(\mu, \sigma^2) \) has a Gaussian distribution and lies within the interval \( X \in (a, b) \), \(-\infty < a < b \leq \infty \). Then, \( X \) conditional on \( a < X < b \) has a truncated Gaussian distribution with the following probability density function

\[
 f_{N|T}(x; \mu, \sigma, a, b) = \frac{\phi\left(\frac{x - \mu}{\sigma}\right)}{\sigma \cdot (\Phi(\frac{b - \mu}{\sigma}) - \Phi(\frac{a - \mu}{\sigma}))} \quad \text{for } a \leq x \leq b
\]

and by \( f_{N|T} = 0 \) otherwise. Here, \( \phi(x) = \frac{1}{\sqrt{2\pi}} e^{-\frac{x^2}{2}} \) and \( \Phi(x) = 1 - Q(x) \) are PDF and CDF of the standard Gaussian distribution, respectively. Next, using Theorem 4.1, we give the differential privacy guarantee provided by the mechanism assuming that the reciprocal of \( b \) is distributed according to the truncated Gaussian distribution.

**Theorem B.7.** The \( R^2\)DP mechanism \( \mathcal{M}_q(d, \epsilon, \sigma) \), \( \epsilon \sim f_{N|T}(\epsilon; \mu, \sigma, a, b) \), satisfies \( \epsilon_{N|T} \)-differential privacy, where

\[
\epsilon_{N|T} = \ln \left( \frac{\mu + \sigma \cdot (\phi(\alpha) - \phi(\beta))}{\Phi(\beta) - \Phi(\alpha)} \right) \frac{dM_{N|T}(t)}{dt} \bigg|_{t = -\Delta q}
\]

in which \( \phi(\cdot) \) is the probability density function of the standard normal distribution, \( \Phi(\cdot) \) is its cumulative distribution function and \( \alpha = \frac{a - \mu}{\sigma} \) and \( \beta = \frac{b - \mu}{\sigma} \).

**Lemma B.8 (see Appendix C for the proof).** \( R^2\)DP using truncated Gaussian distribution can satisfy the necessary condition in Equation 8.

Therefore, truncated Gaussian distribution may improve over the baseline, and this can be computed by optimizing the privacy-utility trade-off using the Lagrange multiplier function in Equation 6. In particular, our numerical results show that, this distribution can also be effective for smaller \( \epsilon \) (stronger privacy guarantees).

**C PROOFS**

**Example A.1.** Following Example 3.1, for a Bernoulli distributed scale parameter \( b \), we have

\[
\mathbb{P}(\mathcal{M}_q(d, b) \in S) = \int_{\mathbb{R}} \frac{p}{2b_1} \cdot \mathbbm{1}_S\{q(d) + w\} e^{\frac{i\omega q}{2}} + \frac{1 - p}{2b_2} \cdot \mathbbm{1}_S\{q(d) + w\} e^{\frac{i\omega d}{2b}} d\omega
\]

\[
= \int_{\mathbb{R}} \left( \frac{p}{2b_1} e^{\frac{i\omega q}{2}} + \frac{1 - p}{2b_2} e^{\frac{i\omega d}{2b}} \right) \mathbbm{1}_S\{q(d) + w\} d\omega
\]

where \( \mathbbm{1}_{\{\cdot\}} \) denotes the indicator function. It can be verified that the term in the braces is the derivative of \( \mathbb{E}[e^{\frac{i\omega q}{2}}] \) w.r.t. \( -|\omega| \), and hence the above probability can be expressed in terms of the expectation.

**Theorem 3.1.** For an \( R^2\)DP Laplace mechanism and \( \forall S \subset \mathbb{R} \) measurable and dataset \( d \in D \), we have

\[
\mathbb{P}(\mathcal{M}_q(d, b) \in S) = \int_{\mathbb{R}} f(b) \left( \frac{1}{2b_1} \int_{\mathbb{R}} \mathbbm{1}_S\{q(d) + w\} e^{\frac{i\omega q}{2}} d\omega \right) db
\]

\[
= \int_{\mathbb{R}} \frac{g(u)}{2} \left( \int_{\mathbb{R}} \mathbbm{1}_S\{q(d) + w\} e^{-|\omega| u} d\omega \right) du
\]

\[
= \int_{\mathbb{R}} \mathbbm{1}_S\{q(d) + w\} \left( \int_{\mathbb{R}} g(u) e^{-|\omega| u} d\omega \right) du
\]

\[
= \int_{\mathbb{R}} \mathbbm{1}_S\{q(d) + w\} \left( \int_{\mathbb{R}} g(u) \frac{u}{2} e^{-|\omega| u} d\omega \right) du
\]

\[
= \int_{\mathbb{R}} \left( \frac{dM_\mu(t)}{dt} \right) \mathbbm{1}_S\{q(d) + w\} \left|_{\omega = -|\omega|} \right. d\omega
\]

\[
= \frac{1}{2} \int_{\mathbb{R}} \left. \frac{dM_\mu(t)}{dt} \right|_{\omega = -|\omega|} d\omega
\]

\[
= \frac{1}{2} \left[ -M_u\left(-|\omega - q(d)|\right) \right|_{\omega = q(d)} + M_u\left(-|\omega - q(d)|\right) \right|_{\omega = q(d)}
\]

(11)

where \( u = b^{-1} \), is reciprocal of random variable \( b \) and \( g(u) = \frac{u}{2} \cdot f(\frac{1}{u}) \). Note that \( M_\mu(t) \) is the MGF of random variable \( u \) which is identical with \( M_\mu(t) \).

**Theorem 4.1.** To prove this theorem, we first need to give two lemmas on the properties of \( R^2\)DP Laplace mechanism and MGFs.

**Lemma C.1.** The \( R^2\)DP mechanism \( \mathcal{M}_q(d, b) \), is

\[
\ln \left( \max_{\forall x \in \mathbb{R}} \left( \frac{dM_\mu(t)}{dt} \bigg|_{\omega = -|\omega - q(d)|} \right) \right) \text{-differentially private. (12)}
\]

**Proof.** According to Equation 10,

\[
\mathbb{P}(\mathcal{M}_q(d, b) \in S) = \frac{1}{2} \int_{\mathbb{R}} \frac{dM_\mu(t)}{dt} \bigg|_{\omega = -|\omega - q(d)|} d\omega
\]

\[
= \frac{1}{2} \int_{\mathbb{R}} \frac{dM_\mu(t)}{dt} \left|_{\omega = -|\omega - q(d)|} \right. \left. \bigg|_{\omega = |\omega - q(d)|} \right. d\omega
\]

Denote by

\[
e^e = \sup \left( \frac{dM_\mu(t)}{dt} \bigg|_{\omega = -|\omega - q(d)|}, \forall x \in S \right)
\]

and the choice of \( S = \mathbb{R} \) concludes the proof.

Next, we show the log-convexity property of the first derivative of moment generating functions.

**Lemma C.2.** First derivative of a moment generating function defined by \( \frac{dM_\mu(t)}{dt} = \mathbb{E}(z \cdot e^{zt}) \) is log-convex.

**Proof.** For real- or complex-valued random variables \( X \) and \( Y \), Hölder’s inequality [1] reads: \( \mathbb{E}(XY) \leq \mathbb{E}(X)^p \frac{1}{p} + \mathbb{E}(Y)^q \frac{1}{q} \) for any \( 1 < p, q < \infty \) with \( 1/p + 1/q = 1 \). Next, for all \( \theta \in (0, 1) \)
and \(0 \leq x_1, x_2 < \infty\), define \(Z = z^{1-\theta} \cdot e^{x_1} x_2 z\). \(Y = z^{1-\theta} \cdot e^{x_1} x_2 z\) and \(p = 1/\theta, q = 1/(1 - \theta)\). Therefore, we have \(E(z \cdot e^{(x_1 + (1-\theta)x_2)z}) \leq E(z \cdot e^{x_1} x_2 z) \cdot E(z \cdot e^{(1-\theta)x_2} z)^{1-\theta}\) which shows the definition of log-convexity holds for \(M'(t)\). □

Back to the original proof, following the DP guarantee in Lemma C.1, and using triangle inequality, we have

\[
e^\epsilon = \max_{Y \geq 0} \left\{ \frac{E(e^{-|x-qd'|/b})}{E(e^{-|x-qd'|/b})} \right\} \leq \max_{Y \geq 0} \left\{ \frac{E(e^{t(-\Delta q)})}{E(e^{t(-\Delta q)})} \right\}
\]

Next, we show that \(f(t) = \frac{E(e^{t(-\Delta q)})}{E(e^{t(-\Delta q)})}\) is non-decreasing w.r.t. \(t\). For this purpose, we must show that

\[
f'(t) = \frac{M''(t) \cdot M'(t - \Delta q) - M'(t) \cdot M''(t - \Delta q)}{M''(t - \Delta q)}
\]

is non-negative. However, this is equivalent to show that \(M''(t) \cdot M'(t - \Delta q) \geq M'(t) \cdot M''(t - \Delta q)\) or more generally \(M''(t) \cdot M'(t - \Delta q)\) is not-decreasing. However, following the log-convexity of first \(M'(t)\), the logarithmic derivative of \(M'(t)\) denoted by \(M''(t)\) is non-decreasing. Thus, for all \(t < 0, f(t) \leq f(0)\), and evaluating \(e^\epsilon(t)\) at \(t = 0\), concludes our proof. □

**Theorem 4.5.** Following Theorem 2.2, an \(\epsilon\)-DP Laplace mechanism is \((\gamma, e^{\gamma(\epsilon)})\)-useful for all \(\gamma \geq 0\), where \(b(e) = \frac{\Delta q}{\epsilon} \). Therefore, for the usefulness of the baseline Laplace mechanism at \(\epsilon = \ln[E_{\frac{\gamma}{\Delta q}}(e^{\gamma})]\), we have

\[
e^\gamma \frac{1}{\Delta q} \leq E(e^{\gamma \frac{\Delta q}{\epsilon}}) \leq E(e^{\gamma \frac{\Delta q}{\epsilon}})
\]

where the last inequality relation is verified by Jensen inequality [46] as \(g(x) = x^{\frac{\gamma}{\Delta q}}\) is a convex function. Recall the following Jensen inequality: Let \((\Omega, \mathcal{F}, P)\) be a probability space, \(X\) an integrable real-valued random variable and \(g\) a convex function. Then \(g(E[X]) \leq E(g(X))\)

Therefore,

\[
e^\gamma \frac{1}{\Delta q} \geq 1 - E \left( \frac{e^{-\gamma \frac{\Delta q}{\epsilon}}} E \right) U(\ln[E_{\frac{\gamma}{\Delta q}}(e^{\gamma})], \Delta q, \gamma)
\]

This completes the proof. □

**Theorem B.1.** For \(\frac{1}{b} \sim \text{Gamma}(\frac{1}{b}, \theta)\), the MGF is given by \(M_{\frac{1}{b}}(t) = e^{\frac{t}{b}} \). Following Theorem C.1, one can write

\[
e^\epsilon = \max_{Y \geq 0} \left\{ \frac{1}{\epsilon} e^{-\frac{|x-qd'|}{b}} \right\} \leq \max_{Y \geq 0} \left\{ \frac{1}{\epsilon} e^{-\frac{|x-qd'|}{b}} \right\} \leq \max_{Y \geq 0} \left\{ \frac{1}{\epsilon} e^{\frac{\Delta q}{\epsilon}} \right\} = e^{\frac{\Delta q}{\epsilon}}
\]

where the last inequality is from triangle inequality. □

**Theorem B.2.** The \(R^2\)-DP Laplace mechanism \(M_{\varphi}(d, b), \frac{1}{b} \sim \text{Gamma}(\frac{1}{b}, \theta)\), returns with probability \(p\), a Laplace mechanism with scale parameter \(b_1\), and with probability \(1 - p\) another Laplace mechanism with scale parameter \(b_2\). To this end, we are looking for

\[
e^\epsilon = \max_{Y \geq 0} \left\{ \frac{1}{\epsilon} e^{-\frac{|x-qd'|}{b}} \right\} \leq \max_{Y \geq 0} \left\{ \frac{1}{\epsilon} e^{-\frac{|x-qd'|}{b}} \right\} \leq \max_{Y \geq 0} \left\{ \frac{1}{\epsilon} e^{\frac{\Delta q}{\epsilon}} \right\} = e^{\frac{\Delta q}{\epsilon}}
\]

Therefore, using triangle inequality, we have

\[
e^\epsilon = \max_{Y \geq 0} \left\{ \frac{1}{\epsilon} e^{-\frac{|x-qd'|}{b}} \right\} \leq \max_{Y \geq 0} \left\{ \frac{1}{\epsilon} e^{\frac{\Delta q}{\epsilon}} \right\} = e^{\frac{\Delta q}{\epsilon}}
\]

Let us make the substitutions \(X = e^{-\frac{|x-qd'|}{b}}\), \(a = \frac{\Delta q}{\epsilon}\) and \(k = \frac{\Delta q}{\epsilon} > 1\).

Hence, we have

\[
e^\epsilon = \max_{X \geq 0} \left\{ \frac{1}{\epsilon} e^{-\frac{|x-qd'|}{b}} \right\} \leq \max_{X \geq 0} \left\{ \frac{1}{\epsilon} e^{\frac{\Delta q}{\epsilon}} \right\} = e^{\frac{\Delta q}{\epsilon}}
\]

To obtain \(e^\epsilon\), we need to find all the critical points of \(e^\epsilon(X) = \frac{1}{\epsilon} e^{-\frac{|x-qd'|}{b}}\). However, the critical points of a fractional function are the roots of the numerator of its derivative. Hence, suppose

\[
\frac{d e^\epsilon(X)}{dX} = N(X) \frac{D(X)}{D(\varphi)}
\]

then

\[
\Rightarrow N(X) = (p \cdot a + (1 - p) \cdot k \cdot a \cdot (a \cdot X)^{k-1})
\]

\[
\cdot (p \cdot X + (1 - p) \cdot X^k) - (p + (1 - p) \cdot k \cdot (a \cdot X)^{k-1})
\]

\[
\cdot (p \cdot a \cdot X + (1 - p) \cdot (a \cdot X)^k)
\]

\[
= p \cdot (1 - p) \cdot (k - 1) \cdot (a^{k-1} - 1) \cdot X^k
\]

However, all the terms in the last expression are strictly positive. Therefore, the only critical points are \(X = 0\) and \(X = 1\) as the function is strictly increasing.

\[
e^\epsilon \leq e^\epsilon(1) = p \cdot a + (1 - p) \cdot (a)^k
\]

\[
= p \cdot \frac{\Delta q}{\epsilon} + (1 - p) \cdot e^{\frac{\Delta q}{\epsilon}}
\]

which is the bound in the Theorem. □

**Theorem B.3.** For a Gamma distribution with shape parameters \(k\) and scale parameters \(\theta\), the MGF at point \(t\) is given as \((1 - \theta \cdot t)^{-k}\). Since \(\frac{1}{b} \sim \text{Gamma}(\frac{1}{b}, \theta)\), following Theorem C.1, one can write

\[
e^\epsilon = \max_{Y \geq 0} \left\{ \frac{1}{\epsilon} e^{-\frac{|x-qd'|}{b}} \right\} \leq \max_{Y \geq 0} \left\{ \frac{1}{\epsilon} e^{\frac{\Delta q}{\epsilon}} \right\} = e^{\frac{\Delta q}{\epsilon}}
\]

to find the maximum of the \(\ln\) term, denote by \(X = 1 + \theta \cdot |x-qd'| \). Moreover, since \(|x - qd'| \leq |x - qd'| + \Delta q\), we have

\[
\Rightarrow e^\epsilon \leq \max_{X \geq 1} \left\{ \frac{X + \Delta q \cdot \theta}{X} \right\}
\]
However, since
\[ \forall X \geq 1, \quad \frac{X + \Delta q \cdot \theta}{X} \]
is strictly decreasing, we have
\[ \Rightarrow \epsilon = (k + 1) \cdot \ln \left(1 + \theta \cdot \Delta q\right) \]
This completes the proof. \(\square\)

**Lemma B.4.** We need to show that there exist \(k\) and \(\theta\) such that
\[ (k + 1) \cdot \ln(1 + \Delta q \cdot \theta) < -k \cdot \ln(1 - \Delta q \cdot \theta), \quad \theta < \frac{\Delta q}{\Delta q} \]
Given \(\theta = \frac{1}{2\Delta q}\), we need to show that \(\exists k, k \cdot \ln(2) > (k + 1) \cdot \ln(1.5)\), which always holds for all \(k > 1.4094\).
\(\square\)

**Lemma B.8.** Using exhaustive search, suppose \(\mu = 0.5223, \sigma = 1.5454\), a = 0.5223 and for \(\epsilon = 1.1703\) and \(\Delta q = 0.6\), we will get
\[ \ln(M_{\Delta q}(\Delta q)) = 1.2417. \]

\(\square\)

## D LAGRANGE MULTIPLIER FUNCTION

The Lagrange Multiplier Function (all possible linear combinations of the Gamma, uniform and truncated Gaussian distributions) is:

\[
\mathcal{L}(a_1, a_2, a_3, k, \theta, a_u, b_u, \mu, \sigma, a_{\mathcal{N}^T}, b_{\mathcal{N}^T}, \lambda) = M_k(\theta)(-a_1 y) \cdot M_U(a_u, b_u)(-a_2 y) \\
\cdot M_{\mathcal{N}^T}(\mu, \sigma, a_{\mathcal{N}^T}, b_{\mathcal{N}^T})(-a_3 y) + \lambda \cdot (\ln N - D) - \epsilon
\]

where the numerator and the denominator \(N, D\) are

\[
N = \\
(a_1 \cdot k \cdot \theta) + (a_2 \cdot \frac{\sigma \cdot \Delta q}{\lambda}) + (a_3 \cdot (\mu + \frac{\sigma \cdot \phi(\mu) - \phi(\mu)}{\Phi(\mu) - \Phi(\mu)}))
\]

\[
D = a_1 \cdot M_k(\theta)(-a_1 \cdot \Delta q) \cdot M_U(a_u, b_u)(-a_2 \cdot \Delta q) \\
\cdot M_{\mathcal{N}^T}(\mu, \sigma, a_{\mathcal{N}^T}, b_{\mathcal{N}^T})(-a_3 \cdot \Delta q) \\
+ a_2 \cdot M_k(\theta)(-a_1 \cdot \Delta q) \cdot M_U(a_u, b_u)(-a_2 \cdot \Delta q) \\
\cdot M_{\mathcal{N}^T}(\mu, \sigma, a_{\mathcal{N}^T}, b_{\mathcal{N}^T})(-a_3 \cdot \Delta q) \\
+ a_3 \cdot M_k(\theta)(-a_1 \cdot \Delta q) \cdot M_U(a_u, b_u)(-a_2 \cdot \Delta q) \\
\cdot M_{\mathcal{N}^T}(\mu, \sigma, a_{\mathcal{N}^T}, b_{\mathcal{N}^T})(-a_3 \cdot \Delta q)
\]

## E NUMERICAL ANALYSIS

We also demonstrate the effectiveness of \(R^2\)DP through numerical results based on Algorithm 1 (the ensemble \(R^2\)DP algorithm). In particular, Figure 11 depicts the corresponding usefulness (the probability of the results to be within a pre-specified error bound) of the \(R^2\)DP, the Laplace and the Staircase mechanisms. Figure 11 clearly demonstrates the fact that the \(R^2\)DP mechanism can significantly improve both already considered to be competing mechanisms. In particular, we observe the power of the \(R^2\)DP mechanism in generating very high utility results, e.g., results with more than 0.8 probability fallen inside only \(\gamma = 0.1\) error-bound, owing to automatically searching a large search space of PDFs.

## F \(R^2\)DP AND OTHER DP MECHANISMS

In this section we briefly discuss the application of the \(R^2\)DP framework in two other well-known baseline DP mechanisms.

### F.1 \(R^2\)DP Exponential Mechanism

The exponential mechanism was designed for situations in which we wish to choose the best response but adding noise directly to the computed quantity can completely destroy its value, such as setting a price in an auction, where the goal is to maximize revenue, and adding a small amount of positive noise to the optimal price (in order to protect the privacy of a bid) could dramatically reduce the resulting revenue [26]. The exponential mechanism is the natural building block for answering queries with arbitrary utilities (and arbitrary non-numeric range), while preserving differential privacy. Given some arbitrary range \(R\), the exponential mechanism is defined with respect to some utility function \(u : \mathbb{R}^{[\mathcal{X}]} \times \mathcal{R} \rightarrow \mathbb{R}\), which maps database/output pairs to utility scores. Intuitively, for a fixed database \(x\), the user prefers that the mechanism outputs some element of \(R\) with the maximum possible utility score. Note that when we talk about the sensitivity of the utility score \(u : \mathbb{R}^{[\mathcal{X}]} \times \mathcal{R} \rightarrow \mathbb{R}\), we care only about the sensitivity of \(u\) with respect to its database argument; it can be arbitrarily sensitive in its range argument:

\[
\Delta u \equiv \max_{r \in R} \max_{x, y} \|x - y\| \leq 1 |u(x, r) - u(y, r)|.
\]

The intuition behind the exponential mechanism is to output each possible \(r \in R\) with probability proportional to \(\exp(u(x, r))/\Delta u\) and so the privacy loss is approximately:

\[
\ln \left(\frac{\exp(u(x, r))/\Delta u}{\exp(u(y, r))/\Delta u}\right) = |u(x, r) - u(y, r)/\Delta u| \leq \epsilon
\]

The exponential mechanism is a canonical \(\epsilon\)-DP mechanism, meaning that it describes a class of mechanisms that includes all possible differentially private mechanisms. However, the exponential mechanism can define a complex distribution over a large arbitrary domain, and so it may not be possible to implement the exponential mechanism efficiently when the range of \(u\) is super-polynomially large in the natural parameters of the problem [26]. This is the main restrictive aspect of the exponential mechanism against leveraging different accuracy metrics. However, the exponential mechanism can benefit from the additional randomization of privacy budget, to handle the complexity (excessive sharpness) of the defined probability distribution. In particular, as we mentioned earlier, compound (or mixture) distributions arise naturally where a statistical population contains two or more sub-population which is the case for the exponential mechanism. Thus, we motivate the application of the \(R^2\)DP framework in designing exponential mechanisms with rather smooth but accurate distributions around each element in the range of \(u\). However, further discussion on \(R^2\)DP exponential mechanism requires formal analysis, e.g., deriving the DP guarantee of such a mechanism.

### F.2 \(R^2\)DP and Differential Privacy Relaxations

\(R^2\)DP can also be studied under various relaxations of differential privacy, e.g., \((\epsilon, \delta)\)-differential privacy or Rényi Differential
Privacy [62] which is a privacy notion based on the Rényi divergence [73]. These relaxations allow suppressing the long tails of the mechanism’s distribution where pure $\epsilon$-differential privacy guarantees may not hold. Instead, they offer asymptotically smaller cumulative loss under composition and allow greater flexibility in the selection of privacy preserving mechanisms [62]. In the following, we briefly discuss the application of $R^2$DP in two of such relaxed notions of the differential privacy.

**F.2.1 $R^2$DP Gaussian Mechanism.** A relaxation of $\epsilon$-differential privacy allows an additional bound $\delta$ in its defining inequality:

**Definition F.1 ($\epsilon$,$\delta$)-Differential Privacy [21].** A randomized mechanism $M : D \times \Omega \rightarrow R$ is ($\epsilon$,$\delta$)-differentially private if for all adjacent $d, d' \in D$, we have

$$
\mathbb{P}(M(d) \in S) \leq e^{\epsilon \delta} \mathbb{P}(M(d') \in S) + \delta, \quad \forall S \subset R. \tag{15}
$$

This definition quantifies the allowed deviation ($\delta$) for the output distribution of an $\epsilon$-differentially private mechanism, when a single individual is added or removed from a dataset. A differentially private mechanism proposed in [21] modifies an answer to a numerical query by adding the independent and identically distributed $\sigma$-Gaussian noise. Given the definition of the $Q$-function $Q(x) := \frac{1}{\sqrt{2\pi}} \int_x^{+\infty} e^{-u^2/2} du$, we have the following theorem [21, 53].

**Theorem F.1.** Let $q : D \rightarrow \mathbb{R}$ be a query and $\epsilon > 0$. Then the Laplace mechanism $M^q_\epsilon : D \times \Omega \rightarrow R$ defined by $M^q_\epsilon(d) = q(d) + w$, with $w \sim \mathcal{N}(0, \sigma^2)$, where $\sigma \geq \frac{\Delta_q}{2\epsilon}(K + \sqrt{K^2 + 2\epsilon})$ and $K = Q^{-1}(\delta)$, satisfies ($\epsilon$,$\delta$)-DP.

Figure 11: The $R^2$DP mechanism significantly outperforms the competing Laplace and the staircase mechanisms in maximizing the usefulness metric (an example of a utility metric with no known optimal PDF).

We define $\kappa_{\Delta, \epsilon} = \frac{1}{\epsilon^2}(K + \sqrt{K^2 + 2\epsilon})$, then the standard deviation $\sigma$ in Theorem F.1 can be written as $\sigma(\delta, \epsilon) = \kappa_{\Delta, \epsilon} \Delta q$. It can be shown that $\kappa_{\Delta, \epsilon}$ behaves roughly as $O(\ln(1/\delta)^{1/2}/\epsilon)$. For example, to ensure $\epsilon$,$\delta$-differential privacy with $\epsilon = \ln(2)$ and $\delta = 0.05$, the standard deviation of the injected Gaussian noise should be about 2.65 times the $\ell_1$-sensitivity of $q$.

**Theorem F.2.** The Gaussian Mechanism in Theorem F.1 is $(\gamma, 2 \cdot Q(\frac{\gamma}{\kappa_{\Delta, \epsilon}}))$-useful.

Similar to our $R^2$DP Laplace mechanism, we can formulate an optimization problem for the $R^2$DP model using Gaussian mechanism. Therefore, using Theorems F.1 and F.2, we have the following.

**Corollary F.3.** Denote by $u$, the set of parameters for a probability distribution $f_u$. Then, the optimal usefulness of an $R^2$DP Gaussian mechanism utilizing $f_u$, at each quadruplet $(\epsilon, \delta, \Delta q, \gamma)$ is

$$
U_f(\epsilon, \delta, \Delta q, \gamma) = \max_{u \in \mathbb{U}} \left(1 - 2 \cdot \mathbb{E}_\sigma(Q(\frac{\gamma}{\kappa_{\Delta, \epsilon}}))\right)
$$

subject to

$$
\max_{\gamma \in \kappa_{\Delta, \epsilon}} \left\{\mathbb{P}(\Delta_q(\sigma, \epsilon) \leq \gamma) \right\} = \epsilon,
$$

$$
\mathbb{E}_\sigma(Q(\epsilon \sigma - \frac{\gamma}{\kappa_{\Delta, \epsilon}})) = \delta.
$$

**F.2.2 $R^2$DP and Rényi Differential Privacy.** Despite its notable advantages in numerous applications, the definition of ($\epsilon$,$\delta$)-differential privacy has the following two limitations.

First, ($\epsilon$,$\delta$)-differential privacy was applied to the analysis of the Gaussian mechanism [21]. In contrast to the Laplace mechanism (whose privacy guarantee is characterized tightly and accurately...
by ϵ-differential privacy), a single Gaussian mechanism satisfies a curve of (ε(δ), δ)-differential privacy definitions [21]. Picking any one point on this curve may leave out important information about the mechanism’s actual behavior [62].

Second, (ε, δ)-differential privacy also has limitations on the composition of differential privacy [61]. By relaxing the guarantee to (ε, δ)-differential privacy, advanced composition allows tighter analyses for compositions of (pure) differentially private mechanisms. Iterating this process, however, quickly leads to a combinatorial explosion of parameters, as each application of an advanced composition theorem leads to a wide selection of possibilities for (ε(δ), δ)-differentially private guarantees.

To address these shortcomings, Rényi differential privacy was proposed as a natural relaxation of differential privacy in [62].

**Definition F.2 ((α, ε)-RDP).** A randomized mechanism \( M : D \times \Omega \to R \) is said to have \( ε \)-Rényi differential privacy of order \( α \), or \( (α, ε) \)-RDP for short, if for all \( d, d' \in D \), we have

\[
D_α(M(d)||M(d')) \leq e^ε, \text{ where } D_α(\cdot) \text{ is the (parameterized) Rényi divergence. [73].}
\]

Compared to (ε, δ)-differential privacy, Rényi differential privacy is a strictly stronger privacy definition. It offers an operationally convenient and quantitatively accurate way of tracking cumulative privacy loss throughout execution of a standalone differentially private mechanism and across many such mechanisms [62]. Next, we give the Rényi differential privacy guarantee of our R\(^2\)DP mechanism and show that the privacy loss of R\(^2\)DP under Rényi DP can significantly (asymptotically for small \( α \)) outperform Laplace, Gaussian and Random Response mechanisms.

**Theorem F.4.** If real-valued query \( q \) has sensitivity 1, then the R\(^2\)DP mechanism \( M_q \), leveraging MGF \( M \), satisfies

\[
(α, \frac{1}{α-1} \log \left( \frac{aM(α-1)+(α-1)M(α-2)}{2α-1} \right) ) - \text{RDP}. \quad \text{if } α > 1
\]

\[
(1, M'(0) + M(-1) - 1) - \text{RDP}. \quad \text{if } α = 1
\]

**Proof.** The above RDP guarantee follows Corollary 2 in [62] on the RDP guarantee of the classic Laplace mechanism. In particular, the above equations are derived using the following substitutions

\[
\text{exp}(t/b) \rightarrow M(t) \text{ and } 1/b \rightarrow M'(0) \text{ due to the second-fold randomization of } b. \quad \Box
\]

### G OTHER APPLICATIONS OF R\(^2\)DP

R\(^2\)DP represents a very general concept which could potentially be applied in a broader range of contexts. In general, applying R\(^2\)DP to design more application-aware mechanisms may further improve the utility of many existing solutions [64]. We now briefly discuss some of the potential applications as follows.

**R\(^2\)DP and Query-Workload Answering [59].** Given a workload (aka. a batch of queries), the matrix mechanism generates a different set of queries, called strategy queries, which are answered using a standard Laplace or Gaussian mechanism. The noisy answers to the workload queries can then be derived from the noisy answers to the strategy queries [57]. This two-stage process can result in a correlated noise distribution that preserves differential privacy and also increases utility.

Given a triplet (ε, query, metric), R\(^2\)DP can be applied to replace the Laplace or Gaussian mechanism for answering the strategy queries of the matrix mechanism. As a result, R\(^2\)DP will provide additional improvement in utility (in terms of the TotalError as defined in [57]) over the improvement already provided by the matrix mechanism. More specifically, we compare the total errors of Laplace and R\(^2\)DP mechanisms in Table 4 for specific workloads of interest (similar to those considered in [57]). These two workloads were analyzed in [57] using two \( n \)-sized query strategies, each of which can be envisioned as a recursive partitioning of the domain based on the Haar wavelet [78]. We denote by \( f(ε, δq) \) the improvement in the TotalError for applying an R\(^2\)DP noise instead of a Laplace noise in the matrix mechanism. For instance, leveraging the results of R\(^2\)DP (w.r.t. \( f_2 \) or \( f_3 \)) shown in Section 5.2.2, for a workload of size \( n = 6 \), at \( ε = 2.3 \), the improvement for range queries (\( δq = 36 \)) and predicate queries (\( δq = 64 \)) are \( ~20\% \) and \( ~10\% \), respectively.

#### Table 4: Total error of matrix mechanisms comparison (with R\(^2\)DP vs. Laplace) – two workloads and two query strategies

|                      | Total Error | Matrix Strategies |
|----------------------|-------------|-------------------|
|                       | Laplace     | R\(^2\)DP          |
| **Laplace**          |             |                   |
| Range Queries        | Θ(\( n^2 \log(n)/ε^2 \)) | Θ(\( n^2 \log(n)/ε^2 \)) |
| Predicate Queries    | Θ(\( n^2 \log(n)/ε^2 \)) | Θ(\( n^2 \log(n)/ε^2 \)) |
| **R\(^2\)DP**        |             |                   |
| Range Queries        | Θ(\( f(ε, 2^3 n^2 \log(n)/ε^2) \)) | Θ(\( f(ε, 2^3 n^2 \log(n)/ε^2) \)) |
| Predicate Queries    | Θ(\( f(ε, 2^5 n^2 \log(n)/ε^2) \)) | Θ(\( f(ε, 2^5 n^2 \log(n)/ε^2) \)) |

**R\(^2\)DP and Composition.** R\(^2\)DP may be applied for reducing the privacy leakage due to sequential or parallel querying over a dataset, of which the objective will be to maximize the number of compositions under a specified ε-differential privacy constraint. 

**R\(^2\)DP and Local Differential Privacy.** In this context, R\(^2\)DP can be regarded as a new randomized response model. In particular, the randomized response scheme presented in [76] can be produced using R\(^2\)DP for the Bernoulli distribution when \( b_0 \to 0 \) and \( b_1 \to ∞ \). Therefore, designing more efficient local differential privacy schemes using R\(^2\)DP is an interesting future direction.

**R\(^2\)DP for Continual Observation Applications.** Providing differential privacy guarantees on data streams represents another important future direction for R\(^2\)DP. As an example, the multi-input multi-output (MIMO) systems process streams of signals originated from many sensors capturing privacy-sensitive events about individuals, and statistics of interest need to be continuously published in real time [24, 53], e.g., privacy-preserving traffic monitoring over multi-lane roads [11]. In this context, R\(^2\)DP can leverage the constraint related to the number of inputs and the number of outputs (e.g., the sensitivity of the output of MIMO filter \( G \) with \( m \) inputs and \( p \) outputs is proportional to the \( \mathcal{H}_2 \) norm of \( G \) which itself is an increasing function of \( m \) and \( p \) [65]) into its model to build more efficiently differential private mechanisms for the MIMO scenarios.
