A SPECTRAL CHARACTERIZATION OF SKELETAL MAPS

TARAS BANAKH, ANDRZEJ KUCHARSKI, AND MARTA MARTYNENKO,

ABSTRACT. We prove that a map between two realcompact spaces is skeletal if and only if it is homeomorphic to the limit map of a skeletal morphism between \( \omega \)-spectra with surjective limit projections.

In this paper we present two characterizations of skeletal maps between realcompact topological spaces. All maps considered in this paper are continuous and all spaces are Tychonoff. For a subset \( A \) of a topological space \( X \) by \( \cl A \) we shall denote the closure of \( A \) in \( X \).

A map \( f : X \to Y \) is called skeletal if for each nowhere dense subset \( A \subseteq Y \) the preimage \( f^{-1}(A) \) is nowhere dense in \( X \). This is equivalent to saying that for each non-empty open set \( U \subseteq X \) the closure \( \cl f(U) \) has non-empty interior in \( Y \), see [4].

The latter definition can be localized as follows. A map \( f : X \to Y \) between two topological spaces is called

- skeletal at a point \( x \in X \) if for each neighborhood \( U \subseteq X \) of \( x \) the closure \( \cl_Y(f(U)) \) of \( f(U) \) has non-empty interior in \( Y \);
- skeletal at a subset \( A \subseteq X \) if \( f \) is skeletal at each point \( x \in A \).

It is clear that a map \( f : X \to Y \) is skeletal if and only if \( f \) is skeletal at each point \( x \in X \).

1. Characterizing skeletal maps between metrizable Baire spaces

It is clear that each open map is skeletal. For closed maps between metrizable Baire spaces this implication can be partly reversed. Let us recall that a topological space \( X \) is Baire if for any sequence \((U_n)_{n \in \omega}\) of open dense subsets \( U_n \subseteq X \) the intersection \( \bigcap_{n \in \omega} U_n \) is dense in \( X \).

We shall say that a map \( f : X \to Y \) between topological spaces is

- open at a point \( x \in X \) if for each neighborhood \( U \subseteq X \) of \( x \) the image \( f(U) \) is a neighborhood of \( f(x) \);
- open at a subset \( A \subseteq X \) if \( f \) is open at each point \( x \in A \);
- densely open if \( f \) is open at some dense subset \( A \subseteq X \).

It is easy to see that each densely open map is skeletal. The converse is true for skeletal maps between metrizable compacta, and more generally, for closed skeletal maps defined on metrizable Baire spaces.

**Theorem 1.1.** For a closed map \( f : X \to Y \) defined on a metrizable Baire space \( X \) the following conditions are equivalent:

1. \( f \) is skeletal;
2. \( f \) is skeletal at a dense subset of \( X \);
3. \( f \) is densely open;
4. \( f \) is open at a dense \( G_\delta \)-subset of \( X \).

**Proof.** The implications (4) \( \Rightarrow \) (3) \( \Rightarrow \) (2) \( \Rightarrow \) (1) are trivial and hold without any conditions on \( f \).

To prove the implication (1) \( \Rightarrow \) (4), fix a metric \( d \) generating the topology of the metrizable space \( X \). For every \( n \in \mathbb{N} \) consider the family \( \mathcal{U}_n \) of all non-empty open subsets \( U \subseteq X \) such that \( \text{diam}(U) < 1/n \) and \( f(U) \) is open in \( f \). The skeletal property of \( f \) implies that the union \( \bigcup \mathcal{U}_n \) is dense in \( X \). Since the space \( X \) is Baire, the intersection \( A = \bigcap_{n=1}^{\infty} \bigcup \mathcal{U}_n \) is a dense \( G_\delta \)-set in \( X \). It is clear that \( f \) is open at the set \( A \).

The following simple example shows that the metrizability of \( X \) is essential in Theorem 1.1 and cannot be weakened to the first countability.

**Example 1.2.** The projection \( \text{pr} : A \to [0,1] \) from the Aleksandrov “two arrows” space \( A = [0,1) \times \{0\} \cup (0,1] \times \{1\} \) onto the interval is skeletal. Yet it is open at no point \( x \in A \).
2. Skeletal and densely open squares

In this section the notions of skeletal and densely open maps are generalized to square diagrams. These generalized properties will be used in the spectral characterization of skeletal maps given in the next section.

**Definition 2.1.** Let $\mathcal{D}$ be a commutative diagram

\[
\begin{array}{ccc}
\tilde{X} & \xrightarrow{f} & \tilde{Y} \\
\downarrow{p_X} & & \downarrow{p_Y} \\
X & \xrightarrow{f} & Y
\end{array}
\]

consisting of continuous maps between topological spaces. The commutative square $\mathcal{D}$ is called

- **open at a point** $x \in X$ if for each neighborhood $U \subset X$ of $x$ the point $f(x)$ has a neighborhood $V \subset Y$ such that $V \subset f(U)$ and $p_Y^{-1}(V) \subset \tilde{f}(p_X^{-1}(U))$;
- **open at a subset** $A \subset X$ if $\mathcal{D}$ is open at each point $x \in A$;
- **densely open** if it is open at some dense subset $A \subset X$;
- **skeletal at a point** $x \in X$ if for each neighborhood $U \subset X$ of $x$ there is a non-empty open set $V \subset Y$ such that $V \subset \text{cl} f(U)$ and $p_Y^{-1}(V) \subset \text{cl} \tilde{f}(p_X^{-1}(U))$;
- **skeletal at a subset** $A \subset X$ if $\mathcal{D}$ is skeletal at each point $x \in A$;
- **skeletal** if $\mathcal{D}$ is skeletal at $X$.

**Remark 2.2.** If the square $\mathcal{D}$ is skeletal (at a point $x \in X$), then the map $f$ is skeletal (at the point $x$).

**Remark 2.3.** A map $f : X \to Y$ is skeletal (resp. open) at a subset $A \subset X$ if and only if the square

\[
\begin{array}{ccc}
X & \xrightarrow{f} & Y \\
\downarrow{\text{id}_X} & & \downarrow{\text{id}_Y} \\
X & \xrightarrow{f} & Y
\end{array}
\]

is skeletal (resp. open) at the subset $A$.

It is easy to see that each densely open square is skeletal. Under some conditions the converse is also true. The following proposition is a “square” counterpart of the characterization Theorem 2.4.

**Proposition 2.4.** Let $\mathcal{D}$ be a commutative diagram

\[
\begin{array}{ccc}
\tilde{X} & \xrightarrow{f} & \tilde{Y} \\
\downarrow{p_X} & & \downarrow{p_Y} \\
X & \xrightarrow{f} & Y
\end{array}
\]

consisting of continuous maps between topological spaces such that the map $\tilde{f} : \tilde{X} \to \tilde{Y}$ is closed, the projection $p_Y$ is surjective, and the space $X$ is metrizable and Baire. Then the following conditions are equivalent:

1. the square $\mathcal{D}$ is skeletal;
2. $\mathcal{D}$ is skeletal at a dense subset of $X$;
3. $\mathcal{D}$ is densely open;
4. $\mathcal{D}$ is open at a dense $G_δ$-subset of $X$.

**Proof.** The implications $(4) \Rightarrow (3) \Rightarrow (2) \Rightarrow (1)$ are trivial and hold without any conditions on $\mathcal{D}$.

To prove the implication $(1) \Rightarrow (4)$, assume that the square $\mathcal{D}$ is skeletal. First let us prove two auxiliary claims.

**Claim 2.5.** For each non-empty open subset $U \subset X$ there is a non-empty open set $V \subset Y$ such that $V \subset f(U)$ and $p_Y^{-1}(V) \subset \tilde{f}(p_X^{-1}(U))$. 
Proof. Using the regularity of the space $X$, find a non-empty open subset $W \subset X$ whose closure $\overline{W}$ lies in the open set $U$. Since the square $\mathcal{D}$ is skeletal, for the set $W$ there is a non-empty open set $V \subset Y$ such that $p_Y^{-1}(V) \subset \text{cl} \hat{f}(p_X^{-1}(W))$. Taking into account that the map $\hat{f}$ is closed, we see that the set $\hat{f}(p_X^{-1}(W))$ is closed in $Y$ and hence
\[
p_Y^{-1}(V) \subset \text{cl} \hat{f}(p_Y^{-1}(V)) \subset \hat{f}(p_X^{-1}(W)) \subset \hat{f}(p_X^{-1}(U)).
\]
Applying to these inclusions the surjective map $p_Y$, we get the inclusion
\[
V = p_Y(p_Y^{-1}(V)) \subset p_Y \circ \hat{f}(p_X^{-1}(U)) = f \circ p_X(p_X^{-1}(U)) \subset f(U).
\]
\[
\square
\]

Claim 2.6. Each non-empty open set $U \subset X$ contains a non-empty open set $W \subset U$ such that $f(W)$ is open in $Y$ and $f(p_X^{-1}(W)) = p_Y^{-1}(f(W))$.

Proof. By Claim 2.5, there is a non-empty open set $V \subset Y$ such that $V \subset f(U)$ and $p_Y^{-1}(V) \subset \hat{f}(p_X^{-1}(U))$. Then the open set $W = U \cap f^{-1}(V)$ has the required properties. Indeed, its image $f(W) = V$ is open in $Y$. Also the inclusion $p_Y^{-1}(V) \subset \hat{f}(p_X^{-1}(U))$ implies
\[
\hat{f}(p_X^{-1}(W)) = \hat{f}(p_X^{-1}(U) \cap f^{-1}(V)) = \hat{f}(p_X^{-1}(U) \cap p_X^{-1}(f^{-1}(V))) = \hat{f}(p_X^{-1}(U) \cap \hat{f}(p_Y^{-1}(V))) = \hat{f}(\hat{f}(p_X^{-1}(U)) \cap p_Y^{-1}(V)) = p_Y^{-1}(V) = p_Y^{-1}(f(W)).
\]
\[
\square
\]

Let $\mathcal{W}$ be the family of all non-empty open sets $W \subset X$ such that $f(W)$ is open in $Y$ and $p_Y^{-1}(f(W)) = \hat{f}(p_X^{-1}(W))$. Fix any metric $d$ generating the topology of the metrizable space $X$ and for every $n \in \omega$ consider the subfamily $\mathcal{W}_n = \{W \in \mathcal{W} : \text{diam}(W) < 2^{-n}\}$. By Claim 2.6 the union $\bigcup \mathcal{W}_n$ is an open dense subset of $X$. Since $X$ is a Baire space, the intersection $A = \bigcap_{n \in \omega} \mathcal{W}_n$ is a dense $G_\delta$-set in $X$. To finish the proof, observe that the diagram $\mathcal{D}$ is open at the dense $G_\delta$-set $A$. \[
\square
\]

3. Skeletal squares and inverse spectra

In this section we detect morphisms between inverse spectra, inducing skeletal maps between their limit spaces. At first we need to recall some standard information about inverse spectra, see [3 §2.5] and [2 Ch.1] for more details.

For an inverse spectrum $\mathcal{S} = \{X_\alpha, p^\beta_\alpha, A\}$ consisting of topological spaces and continuous bonding maps, by
\[
\text{lim}_\alpha \mathcal{S} = \{ (x_\alpha)_{\alpha \in A} \in \prod_{\alpha \in A} X_\alpha : \forall \alpha \leq \beta \ p^\beta_\alpha (x_\beta) = x_\alpha \}
\]
we denote the limit of $\mathcal{S}$ and by $p_\alpha : \text{lim}_\alpha \mathcal{S} \to X_\alpha, p_\alpha : x \mapsto x_\alpha$, the limit projections.

Let $S_X = \{X_\alpha, p^\beta_\alpha, A\}$ and $S_Y = \{Y_\alpha, \pi^\beta_\alpha, A\}$ be two inverse spectra indexed by the same directed partially ordered set $A$. A morphism $\{f_\alpha\}_{\alpha \in A} : S_X \to S_Y$ between these spectra is a family of maps $\{f_\alpha : X_\alpha \to Y_\alpha\}_{\alpha \in A}$ such that $f_\alpha \circ p^\beta_\alpha = \pi^\beta_\alpha \circ f_\beta$ for any elements $\alpha \leq \beta$ in $A$.

Each morphism $\{f_\alpha\}_{\alpha \in A} : S_X \to S_Y$ of inverse spectra induces a limit map
\[
\text{lim}_\alpha f : \text{lim}_\alpha S_X \to \text{lim}_\alpha S_Y, \quad \text{lim}_\alpha f : (x_\alpha)_{\alpha \in A} \mapsto (f_\alpha(x_\alpha))_{\alpha \in A}
\]
between the limits of these inverse spectra.

For indices $\alpha \leq \beta$ in $A$ the commutative squares
\[
\begin{array}{ccc}
X_\alpha & \xrightarrow{f_\alpha} & Y_\alpha \\
p_\alpha \downarrow & & \downarrow \pi_\alpha \\
X_\beta & \xrightarrow{f_\beta} & Y_\beta
\end{array}
\quad \text{and} \quad
\begin{array}{ccc}
X_\alpha & \xrightarrow{f_\alpha} & Y_\alpha \\
p_\alpha \downarrow & & \downarrow \pi_\alpha \\
X_\beta & \xrightarrow{f_\beta} & Y_\beta
\end{array}
\]
are called respectively the limit $\downarrow_\alpha$-square and the bonding $\downarrow^\beta_\alpha$-square of the morphism $\{f_\alpha\}$.

We shall say that the morphism $\{f_\alpha\}_{\alpha \in A} : S_X \to S_Y$ has
\begin{itemize}
\item is skeletal if each map $f_\alpha : X_\alpha \to Y_\alpha, \alpha \in A$, is skeletal;
\item has skeletal limit squares if for every index $\alpha \in A$ the limit $\downarrow_\alpha$-square is skeletal;
\end{itemize}
• has skeletal bonding squares if for every indices $\alpha \leq \beta$ in $A$ the bonding $\downarrow_{\alpha}^{\beta}$-square is skeletal.

Our aim is to find conditions on a morphism $\{f_\alpha\} : S_X \to S_Y$ of spectra implying the skeletality of the limit map $f = \lim f_\alpha : \lim S_X \to \lim S_Y$.

**Proposition 3.1.** For a morphism $\{f_\alpha\} : S_X \to S_Y$ between inverse spectra $S_X = \{X_\alpha, p_\alpha^\beta, A\}$ and $S_Y = \{X_\beta, \pi_\beta^\alpha, A\}$ with surjective limit projections, the limit map $\lim f_\alpha : \lim S_X \to \lim S_Y$ is skeletal if the morphism $\{f_\alpha\}$ has skeletal limit squares.

**Proof.** We need to show that the limit map $f = \lim f_\alpha : X \to Y$ is skeletal, where $X = \lim S_X$, $Y = \lim S_Y$. Given any non-empty open set $U \subset X$, we need to find a non-empty open set $V \subset Y$ such that $V \subset \text{cl} f(U)$.

By the definition of the topology of the limit space $X = \lim S_X$, there is an index $\alpha \in A$ and a non-empty open set $U_\alpha \subset X_\alpha$ such that $U \supset p_\alpha^{-1}(U_\alpha)$. Since the limit $\downarrow_{\alpha}$-square

$$
\begin{array}{ccc}
X & \xrightarrow{f} & Y \\
\downarrow{p_\alpha} & & \downarrow{\pi_\alpha} \\
X_\alpha & \xrightarrow{f_\alpha} & Y_\alpha
\end{array}
$$

is skeletal, for the open set $U_\alpha \subset X_\alpha$ there exists a non-empty open set $V_\alpha \subset Y_\alpha$ such that the open set $V = \pi_\alpha^{-1}(V_\alpha)$ lies in the closure of the set $f(p_\alpha^{-1}(U_\alpha))$, which lies in the closure of the set $f(U)$. \hfill \square

It turns out that in some cases the skeletality of squares is preserved by limits.

A partially ordered set $A$ is called $\kappa$-directed for a cardinal number $\kappa$ if each subset $K \subset A$ of cardinality $|K| \leq \kappa$ has an upper bound in $A$.

For a topological space $X$ by $\pi w(X)$ we denote the $\pi$-weight of $X$, that is, the smallest cardinality $|B|$ of a $\pi$-base $B$ for $X$. We recall that a family $B$ of non-empty open subsets of $X$ is called a $\pi$-base for $X$ if each non-empty open subset of $X$ contains a set $U \in B$.

**Proposition 3.2.** Let $\{f_\alpha\}_{\alpha \in A} : S_X \to S_Y$ be a morphism between inverse spectra $S_X = \{X_\alpha, p_\alpha^\beta, A\}$ and $S_Y = \{X_\beta, \pi_\beta^\alpha, A\}$ with surjective limit projections. If for some $\alpha \in A$ and the cardinal $\kappa = \pi w(Y_\alpha)$ the index set $A$ is $\kappa$-directed, then the limit $\downarrow_{\alpha}$-square is skeletal provided that for any $\beta \geq \alpha$ in $A$ the bonding $\downarrow_{\alpha}^{\beta}$-square is skeletal.

**Proof.** Assuming that the limit $\downarrow_{\alpha}$-square is not skeletal, we can find a non-empty open set $U_\alpha \subset X_\alpha$ such that for any non-empty open set $V_\alpha \subset Y_\alpha$ we get $\pi_\alpha^{-1}(V_\alpha) \not\subset \text{cl} f(U)$ where $U = p_\alpha^{-1}(U_\alpha)$ and $f = \lim f_\alpha$ is the limit map. Fix a $\pi$-base $B$ for the space $Y_\alpha$ having cardinality $|B| = \pi w(Y_\alpha) \leq \kappa$. For every set $V \in B$ the open set $\pi_\alpha^{-1}(V) \setminus \text{cl} f(U)$ is not empty and hence contains a set of the form $\pi_{\alpha V}^{-1}(W_V)$ for some index $\alpha V \geq \alpha$ in $A$ and some non-empty open set $W_V \subset Y_{\alpha V}$. Since the index set $A$ is $\kappa$-directed, the set $\{\alpha V : V \in B\}$ has an upper bound $\beta \in A$.

By our hypothesis, the bonding $\downarrow_{\alpha}^{\beta}$-square is skeletal. Then for the open subset $U_\beta = (p_\beta^\alpha)^{-1}(U_\alpha)$ of $X_\beta$ we can find a non-empty open set $V \subset Y_\alpha$ such that $(\pi_\beta^\alpha)^{-1}(V) \subset \text{cl} f_\beta(U_\beta)$. We lose no generality assuming that $V \in B$. In this case the choice of the set $W_V$ guarantees that $\pi_\alpha^{-1}(W_V) \subset \pi_\alpha^{-1}(V) \setminus f(U)$. Then the open subset $W_\beta = (\pi_{\alpha V}^\beta)^{-1}(W_V) = \pi_\beta(\pi_{\alpha V}^{-1}(W_V))$ of $(\pi_\alpha^\beta)^{-1}(V)$ does not intersect the set $\pi_\beta \circ f(U) = f_\beta \circ p_\beta(U) = f_\beta(U_\beta)$ and hence cannot lie in $\text{cl} f_\beta(U_\beta)$. This contradiction shows that the limit $\downarrow_{\alpha}$-square is skeletal. \hfill \square

**Corollary 3.3.** Let $\{f_\alpha\}_{\alpha \in A} : S_X \to S_Y$ be a morphism between inverse spectra $S_X = \{X_\alpha, p_\alpha^\beta, A\}$ and $S_Y = \{X_\beta, \pi_\beta^\alpha, A\}$ with surjective limit projections. If for the cardinal $\kappa = \sup(\pi w(Y_\alpha) : \alpha \in A)$ the index set $A$ is $\kappa$-directed, then the morphism $\{f_\alpha\}_{\alpha \in A}$ has skeletal limit squares provided it has bonding limit squares.

For $\pi\tau$-spectra, Proposition 3.1 can be partly reversed. First let us introduce the necessary definitions.

Let $\tau$ be an infinite cardinal number. We shall say that an inverse spectrum $S = \{X_\alpha, p_\alpha^\beta, A\}$ is a $\pi\tau$-spectrum (resp. a $\tau$-spectrum) if

• each space $X_\alpha$, $\alpha \in A$, has $\pi$-weight $\pi w(X_\alpha) \leq \tau$ (resp. weight $w(X_\alpha) \leq \tau$);
• the index set $A$ is $\tau$-directed in the sense that each subset $B \subset A$ of cardinality $|B| \leq \tau$ has an upper bound in $A$;
• the index set $A$ is $\omega$-complete in the sense that each countable chain $C \subset A$ has the smallest upper bound $\sup C$ in $A$;

• has skeletal bonding squares if for every indices $\alpha \leq \beta$ in $A$ the bonding $\downarrow_{\alpha}^{\beta}$-square is skeletal.
the spectrum $S$ is $\tau$-continuous in the sense that for any directed subset $C \subset A$ with $\gamma = \sup C$ the limit map $\lim p_\alpha^\gamma : X_\gamma \to \lim \{X_\alpha, p_\alpha^\gamma, C\}$ is a homeomorphism.

A subset $C$ of a directed poset $A$ is called

- cofinal if for any $\alpha \in A$ there is an index $\beta \in C$ with $\alpha \leq \beta$;
- $\tau$-closed if for each directed subset $D \subset C$ that has the lowest upper bound $\sup D$ in $A$ we get $\sup D \in C$;
- $\tau$-stationary if $C$ has no cofinal $\tau$-closed subset of $A$.

**Theorem 3.4.** Let $\{f_\alpha\}_{\alpha \in A} : S_X \to S_Y$ be a morphism between two $\pi\tau$-spectra $S_X = \{X_\alpha, p_\alpha^\beta, A\}$ and $S_Y = \{Y_\alpha, \pi_\alpha^\beta, A\}$ with surjective limit projections. If the limit map $\lim f_\alpha : \lim S_X \to \lim S_Y$ is skeletal, then for some cofinal $\tau$-closed subset $B \subset A$ the morphism $\{f_\alpha\}_{\alpha \in B}$ is skeletal and has skeletal bonding and limit squares.

**Proof.** To simplify denotations, let $X = \lim S_X$, $Y = \lim S_Y$, and $f = \lim f_\alpha : X \to Y$. First we show that the set

$$B = \{\alpha \in A : \text{the limit } \downarrow_\alpha\text{-square is skeletal}\}$$

is cofinal and $\tau$-closed in $A$. For this we shall prove an auxiliary statement:

**Claim 3.5.** For every $\alpha \in A$ there is $\beta \in B$, $\beta \geq \alpha$, such that for any non-empty open set $U \subset X_\alpha$ there is a non-empty open set $V \subset Y_\beta$ such that $\pi_\beta^{-1}(V) \subseteq \text{cl } (p_\alpha^{-1}(U))$.

**Proof.** Fix any index $\alpha_0 \in A$. Using Claim 3.5, by induction we can construct a non-decreasing sequence $(\alpha_n)_{n \in \omega}$ in $A$ such that for any non-empty open set $U \subset X_{\alpha_n}$, $n \in \omega$, there is a non-empty open set $V \subset Y_{\alpha_{n+1}}$ with $\pi_{\alpha_{n+1}}^{-1}(V) \subseteq \text{cl } f(p_{\alpha_n}^{-1}(U))$.

Since the set $A$ is $\omega$-complete, the set $(\alpha_n)_{n \in \omega}$ has the smallest upper bound $\beta = \sup \{\alpha_n\}_{n \in \omega} \in A$. The proof of Claim 3.6 will be complete as soon as we check that $\beta \in B$, which means that the limit $\downarrow_\beta$-square is skeletal.

Given any non-empty open set $U_\beta \subset X_\beta$ we need to find a non-empty open set $V_\beta \subset Y_\beta$ such that $\pi_\beta^{-1}(V_\beta) \subseteq \text{cl } f(p_\beta^{-1}(U))$. Since the spectrum $S_X$ is $\tau$-continuous, the space $X_\beta$ can be identified with the limit of the inverse system $\{X_{\alpha_n}, p_{\alpha_n}^{-1}, \omega\}$ and hence for the open set $U_\beta \subset X_\beta$ there are an index $n \in \mathbb{N}$ and a non-empty open set $U \subset X_{\alpha_n}$ such that $(p_{\alpha_n}^{-1})^{-1}(U) \subset U_\beta$. By the construction of the sequence $(\alpha_k)$, for the set $U \subset X_{\alpha_n}$ there is a non-empty open set $V \subset Y_{\alpha_{n+1}}$ such that $\pi_{\alpha_{n+1}}(V) \subseteq \text{cl } f(p_{\alpha_n}^{-1}(U))$.

Consider the open set $V_\beta = (\pi_{\alpha_{n+1}}^{-1})^{-1}(V) \subset Y_\beta$. Taking into account that the limit projections $p_\beta$ and $\pi_\beta$ are surjective, we conclude that

$$V_\beta = \pi_\beta(\pi_{\alpha_{n+1}}^{-1}(V)) \subseteq \pi_\beta(\text{cl } f(p_{\alpha_n}^{-1}(U))) \subseteq \text{cl } \pi_\beta \circ f(p_{\alpha_n}^{-1}(U)) =$$

$$\text{cl } f_\beta \circ p_\beta(p_{\alpha_n}^{-1}(U)) \subseteq \text{cl } f_\beta((p_{\alpha_n}^{-1})^{-1}(U)) \subseteq \text{cl } f_\beta(U_\beta),$$

witnessing that $\beta \in B$.

**Claim 3.7.** The set $B$ is $\tau$-closed in $A$.

**Proof.** Let $C \subset B$ be a directed subset of cardinality $|C| \leq \tau$ having the lowest upper bound $\gamma = \sup C$ in $A$. We need to show that $\gamma \in B$, which means that the limit $\gamma$-square is skeletal. Fix a non-empty open subset $U_\gamma \subset X_\gamma$. Since the spectrum $S_X$ is $\tau$-continuous, the space $X_\gamma$ can be identified with the limit space of the inverse spectrum $\{X_\alpha, p_\alpha^\gamma, C\}$. Then the open set $U_\gamma \subset X_\gamma$ contains the preimage $(p_\alpha^\gamma)^{-1}(U_\alpha)$ of some non-empty open set $U_\alpha \subset X_\alpha$, $\alpha \in C$. Since $\alpha \in C \subset B$, the limit $\downarrow_\alpha$-square is skeletal. Consequently, for the
set $U_α$ there is a non-empty open set $V_α \subseteq Y_α$ such that $π_α^{-1}(V_α) \subseteq \text{cl } f(p_α^{-1}(U_α))$. Then for the open subset $V_γ = (π_α^{-1}(V_α))^{-1}(V_α)$ in $X_γ$ we get

$$π_γ^{-1}(V_γ) = π_α^{-1}(V_α) \subseteq \text{cl } f(p_α^{-1}(U_α)) = \text{cl } f(p_γ^{-1}((π_α^{-1}(V_α))^{-1}(U_α))) \subseteq \text{cl } f(p_γ^{-1}(U_γ)),$$

witnessing that the limit $\downarrow γ$-square is skeletal.

\textbf{Claim 3.8.} For any indices $α ≤ β$ in $B$ the bonding $\downarrow α^{−β}$-square is skeletal.

\textbf{Proof.} To show that the bonding $\downarrow α^{−β}$-square is skeletal, fix any open non-empty subset $U_α \subseteq X_α$. Since $α ∈ B$, the limit $\downarrow α$-square is skeletal and hence there exists open non-empty subset $V_α \subseteq Y_α$ such that $π_α^{-1}(V_α) \subseteq \text{cl } f(p_α^{-1}(U_α))$. Since the limit projections $p_β$ and $π_β$ are surjective, we get

$$(π_α^{−β})^{-1}(V_α) = π_β(π_α^{-1}(V_α)) \subseteq π_β(\text{cl } f(p_α^{-1}(U_α))) \subseteq \text{cl } f_β(π_α^{-1}(V_α)) \subseteq \text{cl } f_β(\text{cl } p_α^{-1}(U_α)) = \text{cl } f_β(p_α^{-1}(U_β)).$$

The definition of the set $B$ and Remark 2.2 imply our last claim, which completes the proof of Theorem 3.4.

\textbf{Claim 3.9.} For every $α ∈ B$ the map $f_α : X_α → Y_α$ is skeletal and hence the morphism $\{f_α\}_{α ∈ B}$ is skeletal.

\textbf{Theorem 3.10.} Let $\{f_α\}_{α ∈ A} : S_X → S_Y$ be a morphism between two $πτ$-spectra $S_X = \{X_α, p_α^0, A\}$ and $S_Y = \{Y_α, π_α^1, A\}$ with surjective limit projections. If the limit map $\lim f_α : \text{lim } S_X → \text{lim } S_Y$ is not skeletal, then the set

$$B = \{α ∈ A : f_α is not skeletal\}$$

is $ω$-stationary in $A$.

\textbf{Proof.} Assume that the limit map $f = \lim f_α : X → Y$ between the limit spaces $X = \text{lim } S_X$ and $Y = \text{lim } S_Y$ is not skeletal. Then the space $X$ contains a non-empty open set $U ⊆ V$ whose image $f(U)$ is nowhere dense in $Y$. We lose no generality assuming that the set $U$ is of the form $U = p_β^{-1}(U_β)$ for some index $β ∈ A$ and some non-empty open set $U_β ⊆ X_β$.

To prove our theorem, we need to check that the set $B$ meets each cofinal $ω$-closed subset $C$ of $A$.

\textbf{Claim 3.11.} For any index $α ∈ C$, $α ≥ α$, there is an index $β ∈ C$, $β ≥ α$, such that for any non-empty open set $V_α ⊆ Y_α$ there is a non-empty open set $W_β \subset Y_β$ such that $π_β^{-1}(W_β) \subset π_α^{-1}(V_α) \setminus f(U)$.

\textbf{Proof.} Fix a $π$-base $B$ for the space $Y_α$ having cardinality $|B| = πω(Y_α) ≤ κ$. Since the set $f(U)$ is nowhere dense, for every set $V ∈ B$ the open subset $π_α^{-1}(V) \setminus \text{cl } f(U)$ of $Y$ is not empty and hence contains a set of the form $π_α^{-1}(W_β)$ for some index $α_β ≥ α$ in $A$ and some non-empty open set $W_β \subset Y_β$. Since the index set $A$ is $κ$-directed and the set $C$ is cofinal in $A$, the set $\{α_β : V ∈ B\}$ has an upper bound $β ∈ C$. It is easy to see that the index $β$ has the required property.

Using Claim 3.11 by induction construct a non-decreasing sequence $(α_n)_{n ∈ ω}$ in $C$ such that $α_0 ≥ α$ and for any non-empty open set $V ⊆ Y_{α_n}$, $n ∈ ω$, there is a non-empty open set $W ⊆ Y_{α_{n+1}}$ such that $π_{α_{n+1}}^{-1}(W) \subset π_{α_n}^{-1}(V) \setminus f(U)$.

Since the set $C$ is $ω$-closed in the $ω$-complete set $A$ the chain $\{α_n\}_{n ∈ ω} ⊆ C$ has an lowest upper bound $β ∈ A$, which belongs to the $ω$-closed set $C$.

\textbf{Claim 3.12.} $β ∈ B ∩ C$.

\textbf{Proof.} We need to show that the map $f_β : X_β → Y_β$ is not skeletal. Assuming the opposite, for the non-empty open subset $U_β = (p_β^0)^{-1}(U_β) = p_β(U_β)$ of $X_β$, we can find a non-empty open set $V_β ⊆ Y_β$ that lies in the closure $\text{cl } f_β(U_β)$. Since the spectrum $S_Y$ is $ω$-continuous, the space $Y_β$ can be identified with the limit space of the inverse spectrum $\{Y_{α_n}, π_{α_n}^ω, ω\}$. Therefore, we lose no generality assuming that the set $V_β$ is of the form $V_β = (π_{α_n}^{−β})^{-1}(V)$ for some open set $V ⊆ Y_{α_n}$, $n ∈ ω$. By the choice of $α_n$, there is a non-empty open set
$W \subset Y_{\alpha+1}$ such that $\pi_{\alpha+1}^{-1}(W) \subset \pi_{\alpha}^{-1}(V) \setminus f(U)$. Applying to this inclusion the surjective map $\pi_\beta$, we obtain that the non-empty open subset

$$(\pi_{\alpha+1}^{-1}(W))^{-1}(W) = \pi_{\beta}(\pi_{\alpha+1}^{-1}(W)) \subset \pi_{\beta}(\pi_{\alpha}^{-1}(V) \setminus f(U)) =$$

$$= \pi_{\beta}(\pi_{\alpha}^{-1}(V)) \setminus \pi_{\beta} \circ f(U) = (\pi_{\alpha}^{-1}(V) \setminus f_{\beta} \circ p_{\beta}(U)) = V_{\beta} \setminus f_{\beta}(U_{\beta})$$

of $V$ does not intersect the set $f_{\beta}(U_{\beta})$ and hence cannot lie in its closure. This contradiction shows that the map $f_{\beta}$ is not skeletal and hence $\beta \in B \cap C$. 

4. A SPECTRAL CHARACTERIZATION OF SKELETAL MAPS BETWEEN REALCOMPACT SPACES

In this section we prove Theorem 4.1 which characterizes skeletal maps between realcompact spaces and is the main result of this paper. This characterization has been applied in the paper [1] detecting functors that preserve skeletal maps between compact Hausdorff spaces.

Let us recall that a Tychonoff space $X$ is called realcompact if each $C$-embedding $f : X \to Y$ into a Tychonoff space $Y$ is a closed embedding. An embedding $f : X \to Y$ is called a $C$-embedding if each continuous function $\varphi : f(X) \to \mathbb{R}$ has a continuous extension $\varphi : Y \to \mathbb{R}$. By Theorem 3.11.3 [3], a topological space is realcompact if and only if it is homeomorphic to a closed subspace of some power $\mathbb{R}^\kappa$ of the real line, see [3], §3.11. By [3] 3.11.12], each Lindelöf space is realcompact.

We say that two maps $f : X \to Y$ and $f' : X' \to Y'$ are homeomorphic if there are homeomorphisms $h_X : X \to X'$ and $h_Y : Y \to Y'$ such that $f' \circ h_Y = h_X \circ f$. It is clear that a map $f : X \to Y$ is skeletal if and only if it is homeomorphic to a skeletal map $f' : X' \to Y'$.

**Theorem 4.1.** For a map $f : X \to Y$ between Tychonoff spaces the following conditions are equivalent:

1. $f$ is skeletal and the spaces $X, Y$ are realcompact.
2. $f$ is homeomorphic to the limit map $\lim_{\alpha} f_{\alpha} : \lim_{\alpha} S_X \to \lim_{\alpha} S_Y$ of a skeletal morphism $\{f_{\alpha}\} : S_X \to S_Y$ between two $\omega$-spectra $S_X = \{X_{\alpha}, p_{\alpha}^0, A\}$ and $S_Y = \{Y_{\alpha}, \pi_{\alpha}^0, A\}$ with surjective limit projections.
3. $f$ is homeomorphic to the limit map $\lim_{\alpha} f_{\alpha} : \lim_{\alpha} S_X \to \lim_{\alpha} S_Y$ of a morphism $\{f_{\alpha}\} : S_X \to S_Y$ with skeletal limit squares between two $\omega$-spectra $S_X = \{X_{\alpha}, p_{\alpha}^0, A\}$ and $S_Y = \{Y_{\alpha}, \pi_{\alpha}^0, A\}$ with surjective limit projections.
4. $f$ is homeomorphic to the limit map $\lim_{\alpha} f_{\alpha} : \lim_{\alpha} S_X \to \lim_{\alpha} S_Y$ of a morphism $\{f_{\alpha}\} : S_X \to S_Y$ with skeletal bonding squares between two $\omega$-spectra $S_X = \{X_{\alpha}, p_{\alpha}^0, A\}$ and $S_Y = \{Y_{\alpha}, \pi_{\alpha}^0, A\}$ with surjective limit projections.

**Proof.** We shall prove the implications $(1) \Rightarrow (4) \Rightarrow (3) \Rightarrow (2) \Rightarrow (1)$.

$(1) \Rightarrow (4)$ Assume that the spaces $X, Y$ are realcompact. Then Proposition 1.3.4 and 1.3.5 of [2] imply that the map $f$ is homeomorphic to the limit map $\lim_{\alpha} f_{\alpha} : \lim_{\alpha} S_X \to \lim_{\alpha} S_Y$ of a morphism $\{f_{\alpha}\}_{\alpha \in A}$ between two $\omega$-spectra $S_X = \{X_{\alpha}, p_{\alpha}^0, A\}$ and $S_Y = \{Y_{\alpha}, \pi_{\alpha}^0, A\}$ with surjective limit projections. If the map $f$ is skeletal, then Theorem 3.4 yields a cofinal $\omega$-bounded subset $B \subset A$ such that the morphism $\{f_{\alpha}\}_{\alpha \in B}$ has skeletal bonding squares. Since the set $B$ is cofinal in $A$, $f$ is homeomorphic to the limit map $\lim_{\alpha} f_{\alpha}$ induced by the morphism $\{f_{\alpha}\}_{\alpha \in B}$ with skeletal bonding squares between the inverse $\omega$-spectra $\{X_{\alpha}, p_{\alpha}^0, B\}$ and $\{Y_{\alpha}, \pi_{\alpha}^0, B\}$.

The implications $(4) \Rightarrow (3)$ and $(3) \Rightarrow (2)$ follow from Corollary 3.3 and Remark 2.2, respectively.

The final implication $(2) \Rightarrow (1)$ follows from Theorem 3.10 and Proposition 1.3.5 [2] saying that a Tychonoff space is homeomorphic to the limit space of an $\omega$-spectrum (with surjective limit projections) if and only if it is realcompact.

Let us observe that Theorem 4.1 does not hold for arbitrary spectra. Just take any non-skeletal map $f : X \to Y$ between zero-dimensional (metrizable) compacta and apply the following lemma.

**Lemma 4.2.** Each continuous map $f : X \to Y$ from a topological space $X$ to a realcompact space $Y$ of covering topological dimension $\dim(Y) = 0$ is homeomorphic to the limit map $\lim f_{\alpha} : \lim S_X \to S_Y$ of a skeletal morphism $\{f_{\alpha}\}_{\alpha \in A} : S_X \to S_Y$ between inverse spectra $S_X = \{X_{\alpha}, p_{\alpha}^0, A\}$ and $S_Y = \{Y_{\alpha}, \pi_{\alpha}^0, A\}$.

**Proof.** By Lemma 6.5.4 of [2], the zero-dimensional realcompact space $Y$ is homeomorphic to a closed subspace of the power $\mathbb{N}^\tau$ for some cardinal $\tau$. Let $A = [\tau]^\omega$ be the family of finite subsets of $\tau$, partially ordered by the inclusion relation. For every $\alpha \in A$ let $Y_{\alpha}$ be the projection of the space $Y \subset \mathbb{N}^\tau$ onto the face $\mathbb{N}^\alpha$.
and $\pi_\alpha : Y \to Y_\alpha$ be the corresponding projection map. For any finite sets $\alpha \subset \beta$ let $\pi_\beta^\alpha : Y_\beta \to Y_\alpha$ be the corresponding bonding projection. Then the space $Y$ can be identified with the limit $\lim S_Y$ of the inverse spectrum $S_Y = \{Y_\alpha, \pi_\beta^\alpha, A\}$ consisting of discrete spaces $Y_\alpha$, $\alpha \in A$.

The space $X$ can be identified with the limit of the trivial spectrum $S_X = \{X_\alpha, p_\beta^\alpha, A\}$ consisting of spaces $X_\alpha = X$ and identity bonding maps $\pi_\beta^\alpha : X_\beta \to X_\alpha$. Then the map $f$ is homeomorphic to the limit map $\lim f : \lim S_X \to \lim S_Y$ of the skeletal morphism $\{f_\alpha\}_{\alpha \in A} : S_X \to S_Y$ consisting of the maps $f_\alpha = \pi_\alpha \circ f : X_\alpha = X \to Y_\alpha$, $\alpha \in A$. Here we remark that each map $f_\alpha : X_\alpha \to Y_\alpha$ is skeletal because the space $Y_\alpha$ is discrete. $\square$
