Keywords: non-steroidal anti-inflammatory drugs (NSAIDs), mitochondrial metabolism, mitochondrial dynamics, gastropathy, oxidative stress, gastric cancer, apoptosis, inflammation, kinase signaling, dynamin-related protein 1 (DRP1)

Abstract

The subcellular mechanism by which non-steroidal anti-inflammatory drugs (NSAIDs) induce apoptosis in gastric cancer and normal mucosal cells is elusive because of the diverse cyclooxygenase-independent effects of these drugs. Using human gastric carcinoma cells (AGSs) and a rat gastric injury model, here we report that the NSAID indomethacin activates the protein kinase C zeta (PKCζ)-p38 MAP kinase (P38)-dynamin-related protein 1 (DRP1) pathway and thereby disrupts the physiological balance of mitochondrial dynamics by promoting mitochondrial hyper-fission and dysfunction leading to apoptosis. Notably, DRP1 knockdown or SB203580-induced P38 inhibition reduced indomethacin-induced damage to AGSs. Indomethacin impaired mitochondrial dynamics by promoting fissogenic activation and mitochondrial recruitment of DRP1 and down-regulating fusogenic optic atrophy 1 (OPA1) and mitofusins in rat gastric mucosa. Consistent with OPA1 maintaining cristae architecture, its down-regulation resulted in EM-detectable cristae deformity. Deregulated mitochondrial dynamics resulting in defective mitochondria were evident from enhanced Parkin expression and mitochondrial proteome ubiquitination. Indomethacin ultimately induced mitochondrial metabolic and bioenergetic crises in rat stomach, indicated by compromised fatty acid oxidation, reduced complex I-associated electron transport chain activity, and ATP depletion. Interestingly, Mdivi-1, a fission-preventing mito-protective drug, reversed indomethacin-induced DRP1 phosphorylation on Ser-616, mitochondrial proteome ubiquitination, and mitochondrial metabolic crisis. Mdivi-1 also prevented indomethacin-induced mitochondrial macromolecular damage, caspase activation, mucosal inflammation, and gastric mucosal injury. Our results identify mitochondrial hyper-fission as a critical and common subcellular event triggered by indomethacin that promotes apoptosis in both gastric cancer and normal mucosal cells, thereby contributing to mucosal injury.

Introduction

Non-steroidal anti-inflammatory drugs (NSAIDs) are the most effective medicines for treating pain and inflammation (1-2). In addition to their anti-nociceptive action, NSAIDs are also gaining significant importance owing to their
anti-neoplastic effects against wide spectrum of cancers. In fact prolonged NSAID users are at lower risk of developing cancers (3-4) and these non canonical anti-cancer drugs are now included in combination-chemotherapy regimen as they potentiate chemotherapy and radiotherapy (5). Although prostaglandin depletion due to cyclooxygenase (COX) inhibition is primarily responsible for both anti-inflammatory as well as cytotoxic anti-cancer action of NSAIDs (6), COX-independent targets including cGMP phosphodiesterase, PPARs, Retinoid X receptor, IKKβ, AMP kinase and other targets of these drugs as well as their metabolites (7) help to trigger cell death by apoptosis while blocking proliferation. Hence NSAIDs are gaining immense importance and have been under exploration in various diseases including cancer (7-10). In spite of their multidimensional health benefits, the toxic actions of NSAIDs are observed against various normal cells of the body that compromise metabolic homeostasis and tissue integrity (6,11-12). Of the several organs affected by long term NSAID-usage (13-16), the gastro-intestinal system and predominantly stomach is the most prominent target which suffer severe gastric mucosal injury, bleeding and abdominal pain (10,17). All these effects strongly discourage their rampant usage and warrants for thorough mechanistic studies to reveal precise subcellular effects of NSAIDs, which in turn can lead to better and rational therapeutic exploitation of these drugs, bypassing their side effects.

Mitochondrial structural and functional integrity underlies the maintenance of bioenergetic homeostasis and cellular health. Constant dynamic equilibrium (18) between extended filamentous network and small punctate particles (19) play vital role in the mitigation of myriad metabolic duties including ATP production, intracellular [Ca^{2+}] regulation, endoplasmic reticulum-assisted [Ca^{2+}] buffering and cell death. At any instance the predominance of a particular structural form determines the status of cellular health. Moreover, changes in cellular microenvironment and pathogenic conditions in turn pose significant effect on mitochondrial structure including fission-fusion dynamics and turnover (18). While filamentous mitochondria are frequently associated with enhanced cellular respiration, mitochondrial ATP production, distribution of metabolites and mitochondrial gene products all over the organelle (20), fragmented mitochondria either characterize cell division or elimination of damaged mitochondria during stress and diseases (21-25). Damaged and fragmented mitochondria are selectively culled from the cell by a process of specialized organellar autophagy called mitophagy (26) to prevent their incorporation back into the healthy mitochondrial pool during acute and persistent damage. However, excess mitochondrial fragmentation coupled with mitophagy and proteasomal degradation result in severe bioenergetic deficit and consequent tissue damage (27).

Alteration in mitochondrial dynamics and predominance of abnormal phenotypes involving either excessively fragmented mitochondria or hyper-fused elongated tubules are exclusively disease specific (21-25,28-31). At the same time inhibition of mitochondrial fission may prove detrimental (32-34) due to its importance in clearance of damaged organelles or segregation of mitochondria during cell division (35). Interestingly, all these pathologies have oxidative stress as a common etiologic factor wherein mitochondrial oxidative stress (MOS) and consequent apoptosis act as major perpetrators governing the severity of diseases associated with mitochondrial functional derangement (36). Although much explored in various pre-clinical models, the putative role of aberrant mitochondrial dynamics in gastropathy and the impact of NSAIDs therein are still lacking.

In the present study we have studied the effect of NSAIDs on mitochondrial dynamics using indomethacin as the representative NSAID owing to its efficacy in expanding the life span of cancer patients with metastasis (37). We report that indomethacin activates PKCζ-p38-DRP1 pathway to trigger mitochondrial hyper fission in both gastric cancer cell and normal mucosal cells. The activation of mitochondrial hyper fission is a common subcellular event involved in antineoplastic and gastro-damaging activities of this NSAID.

### Results

**Indomethacin (an NSAID) interferes with human gastric carcinoma cells (AGS) proliferation and induces mitochondrial hyper fission**

Initially, the optimum concentration required for anti-proliferative activity of indomethacin was determined by following [³H]-thymidine uptake
and cellular dehydrogenase activity in AGS cells. Data indicated that indomethacin concentration-dependently reduced AGS cell proliferation (Table 1). Indomethacin at a concentration of 0.5 mM significantly reduced the DNA content (≈ 81%) while inhibited cell viability (≈ 50%) as evident from [3H]-thymidine incorporation and cellular dehydrogenase assays respectively. At further higher dose (0.8 mM and 1.5 mM), the cytotoxic effects were extremely high. Because we wanted to check the subtle sub-cellular alterations induced by indomethacin on gastric cancer cells, we deliberately used the IC₅₀ concentration (0.5 mM) for all the subsequent in vitro studies. Next we were keen to check any plausible cytoarchitectural alterations that indomethacin might cause to the AGS cells. Direct visualization of control and indomethacin treated cells by phase contrast microscopy revealed a remarkable deterioration of cellular architecture starting early at the 6th hour of treatment (Fig. 1A). At 12 hr and 24 hr, indomethacin induced apoptotic changes in the cells as evident from cytoplasmic shrinkage, membrane blebbings and pinching off of cellular structures (indicated by red arrows) (Fig. 1A). An early detrimental change in the cytoarchitecture further warranted for the examination of mitochondrial structure. Confocal microscopy revealed that indomethacin time-dependently rendered the transformation of uniformly distributed filamentous mitochondria into clumped, peri-nuclearly clustered and fragmented puncta. Insets containing magnified portions of the micrographs clearly indicated abundance of tubular mitochondrial structures in control cells, compared to indomethacin-treated cells enriched in fragmented mitochondria (Fig. 1B). Further, to explore the status of the molecular regulators of fission, subcellular localization of dynamin related protein 1 (DRP1, pro-fission master-switch) was checked along with other fission mediators by immunoblotting (Fig. 1C). Densitometric analyses of the immunoblots indicated that DRP1 level was found to be significantly high in the mitochondrial fractions implying mitochondrial translocation (Fig. 1C). Moreover, the level of pDRP1Ser616, a marker for fissogenic activation of DRP1, was found to be significantly increased in the indomethacin treated cells compared to control. In addition, mitochondrial fission factor (MFF), which is one of the predominant DRP1 adapters on mitochondrial surface was also upregulated upon indomethacin treatment (Fig. 1C). The data were fairly supported by confocal super resolution (STED) immunocytographs, which pin pointed focal localization of DRP1 (green) on mitochondria (red) along with the extent of mitochondrial translocation under the influence of indomethacin (r = 0.61) in indomethacin treated cells compared to control where r = 0.43 (Fig. 1D). Immunocytochemistry of MFF similarly revealed upregulation with high mitochondrial colocalization (r = 0.55) upon indomethacin treatment (Fig. 1E). In accordance with the expressional pattern of the fission mediators, mitochondrial fusion mediators including the outer mitochondrial membrane (OMM) fusion mediator mitofusin 1 (MFN1) and inner mitochondrial membrane (IMM) fusion regulator optic atrophy 1 (OPA1) exhibited depleted expression in presence of indomethacin. The band patterns in the immunoblot data of OPA1 were indicative of relative depletion of higher molecular weight isoforms of OPA1 (Fig. 1F). Next, it was imperative to check the effect of altered structural dynamics on mitochondrial integrity. Data indicated that indomethacin induced moderate mitochondrial depolarization even after 6 hrs of treatment (Fig. 2A). Depolarization was however severely elevated at the 24th hour post treatment with indomethacin indicating compromised mitochondrial integrity. Next, to check the effect of indomethacin on mitochondrial metabolic status, oxygen consumption ratio was measured. Data indicated that mitochondrial metabolic parameters were severely compromised upon indomethacin treatment compared to control (Table 2). Basal respiration considerably reduced along with severely compromised ATP production in presence of indomethacin. The effect was further reflected in decreased maximal respiration and loss of cellular reserve capacity (Table 2). Collective effect of all these metabolic crises led to gradual mitochondrial depolarization and induction of apoptosis, which initiated at 6 hr after indomethacin treatment and significantly increased by the 24th hour (Fig. 2A-B). We were next eager to check the status of mitochondrial fission at this early time point (6 hr), when mitochondria were metabolically compromised yet apoptosis had not set in significantly. Therefore, we followed the status of DRP1, pDRP1Ser616 and OPA1 as major markers of fission and fusion respectively. Data indicated that DRP1 activation already started at 6 hrs
after indomethacin treatment and it further increased till 24 hrs (Fig. 2C) as evident from immunoblot data performed using total cell lysates. Notably, down-regulation of OPA1 was also initiated after 6 hrs of indomethacin treatment and the level remained low at 24 hrs as well.

**Activation of PKCζ-p38 MAPK-DRP1 pathway by indomethacin to stimulate excess mitochondrial fission**

We next focused to identify the plausible upstream mediators that regulate DRP1 activation by indomethacin. Data indicated that indomethacin activated p38 MAPK as evident from phosphorylation of p38 (Fig. 2D). The event was concurrent with DRP1-Ser 616 phosphorylation. Further exploration revealed that p38 MAPK activation was positively associated with phosphorylation of the atypical protein kinase C (PKC) isoform, PKC zeta, PKCζ (Fig. 2D). To check the effect of MAPK inhibition on indomethacin-induced pathology we pre-treated cells with a p38 specific inhibitor, SB203580 or a PKCζ pseudo substrate inhibitor peptide (PKCζ-PSI) prior to indomethacin treatment. The activation by phosphorylation and expression level of p38 and PKCζ were monitored in presence and absence of the respective inhibitors (Fig. 2E-F) used at an optimum dose. Furthermore, to check the role of DRP1 in indomethacin-induced pathology, DRP1 was knocked down and the expression level of DRP1 was monitored (Fig. 2G). Interestingly, pre-treatment with p38 specific inhibitor, SB203580, rescued cells from indomethacin-mediated deterioration in mitochondrial structural and functional integrity to a considerable extent as evident from reduction of ΔΨm collapse measured by flow cytometry (Fig. 3A) and reduction in mitochondrial fragmentation as observed by live cell imaging (Fig. 3B). A similar effect was observed by blocking PKCζ activation by PKCζ-PSI or DRP1 knock down (DRP1 KD) prior to indomethacin administration (Fig. 3A-B). Cell death by indomethacin was also reduced by SB203580 and PKCζ-PSI as evident from flow cytometric analysis of apoptosis (Fig. 3C). Furthermore, the protective effect of SB203580 and siDRP1 pre-treatment on indomethacin-induced metabolic crisis was further reflected from the preservation of dehydrogenase activity, mitochondrial respiration, oxygen consumption, and ATP production (Table 2). In addition, immunoblot analysis indicated that indomethacin-induced OPA1 depletion and increased p38 phosphorylation were both rectified by SB203580 pre-treatment or PKCζ-PSI pre-treatment (Fig. 4A-B). Reduction in indomethacin-induced fissogenic DRP1 activation was also clearly evident from the depletion of pDRP1Ser616 level upon pre-treatment with SB203580 or PKCζ-PSI as revealed by immunocytochemical analysis (Fig. 4C). However, being downstream in the signaling pathway, siDRP1 offered negligible protection against indomethacin induced PKCζ and p38 activation by phosphorylation (Fig. 4D); although the reduced OPA1 level was moderately rectified. Overall in the present model, an association of PKCζ-p38 signaling with mitochondrial fission, was evident from the fact that considerable rescue effect was observed upon PKCζ-PSI treatment which moderately inhibited indomethacin-induced p38 and DRP1 activation (Fig. 4B-C).

**Indomethacin negatively modulates mitochondrial structural dynamics and functional integrity in rat gastric mucosa**

After checking the effect of indomethacin on gastric carcinoma cells *in vitro*, we were keen to see whether it also targets mitochondrial dynamics in gastric mucosa *in vivo*. Therefore, gastric mucosal cells isolated from control and indomethacin-treated rats were stained with mitotracker red, and observed under high resolution confocal microscope. Data indicated that while the control cells displayed uniformly distributed mitochondria throughout the cells, cells from indomethacin-treated rat stomachs displayed clumped and punctate mitochondrial particles (Fig. 5A). We next zoomed deeper into the gastric mucosal ultra-structure, *in situ*, to visualize the finer structural alterations induced by indomethacin. Direct visualization by transmission electron microscopy (TEM) revealed that architecture of mitochondrial cristae was significantly compromised in indomethacin-exposed injured tissues as evident from an overall loss of stacked structures (Fig. 5B). Because DRP1 is the ultimate mito-fragmenting mediator, its status during gastric mucosal injury was immediately analyzed along with other fission/fusion mediators. *In situ* analysis by confocal fluorescent immunohistochemistry further indicated that

---

*NSAID induces excess mitochondrial fission*
DRP1 expression was moderately higher in the injured gastric mucosa (indicated by white asterix) obtained from indomethacin treated rats. Notably, the colocalization of signals corresponding to DRP1 and TOM 20 (mitochondria) implied that indomethacin treatment resulted in elevated mitochondrial translocation of DRP1 compared to control (Fig. 5C). Immunohistochemical data were also supported by immunoblot analysis of DRP1 (Fig. 6A-B) and its predominant adapter MFF (Fig. 6B). Interestingly in corroboration with the observations in AGS cells, immunoblot analysis in rat gastric mucosa also revealed DRP1 activation by indomethacin, as evident from enhanced DRP1-Ser 616 phosphorylation (Fig. 6B). This DRP1 activation was found to be associated with phosphorylation of both PKC ζ and p38 MAPK (Fig. 6C). Moreover, depleted expression of mitochondrial fusion mediators namely MFN1, MFN2 and OPA1 was also documented upon indomethacin treatment relative to control (Fig. 6D).

Furthermore, western blot analysis also revealed increased level of Parkin and elevated ubiquitination of mitochondrial proteome in the indomethacin-treated gastric mucosal mitochondrial fractions (Fig. 6E) indicating onset of mitophagy in order to dispose damaged mitochondria. To study the consequence of these events on mitochondrial physiology and metabolism in vivo, a series of metabolic assays were performed (Table 3). Data indicated that indomethacin-induced elevated mitochondrial fission and clearance was concurrent with retarded ETC complex-I activity and complex-I driven mitochondrial respiration which was followed by analyzing the respiratory control ratio, RCR (measured as a ratio of state 3 and state 4 respirations). Data clearly indicated mitochondrial respiratory defect (Table 3). Because fatty acid oxidation and mitochondrial dehydrogenase activity majorly contributes to the supply of reducing equivalents for the ETC, we next checked these two parameters and found that indomethacin treatment resulted in significant reduction of dehydrogenase activity, fatty acid oxidation (Table 3). These detrimental changes to the mitochondrial metabolism were further concurrent with indomethacin-induced loss of mitochondrial integrity, as evident from the collapse of ΔΨm and associated bioenergetic deficit, as evident from ATP depletion (Table 3). Further, ultra-structural analysis of the tissue at this time point by TEM revealed that indomethacin caused significant damage to the gastric mucosal tissue architecture with prominent nuclear chromatin condensation and loss of structural integrity of plasma membrane (Fig.7). Induction of mitochondrial oxidative stress and mitochondrial disintegration upon indomethacin treatment, as evident from elevated level of macromolecular oxidation end product and reduced cardiolipin content (Table 4), significantly potentiated the damage. These detrimental reactions initiated by indomethacin finally led to the activation of caspase 9 and caspase 3 (Table 4) for triggering intrinsic pathway of apoptosis.

Mitochondrial division inhibitor-1 (Mdivi-1) prevents indomethacin-induced mitochondrial fission and metabolic crisis

So far the data clearly indicated that enhanced mitochondrial fission was associated with indomethacin-induced gastric injury. Therefore, we next asked, what would be the effect of blocking enhanced mitochondrial fission. With this aim we checked whether Mdivi-1 (a small molecule with several positive effects on mitochondrial metabolism (38) and fission reducing action (39-40) could offer mitochondrial protection in vivo. Data indicated that pre-treatment with Mdivi-1 at 2 mg/kg b.w. resulted in significant rectification of indomethacin-induced decrease in 14C palmitate oxidation, mitochondrial dehydrogenase activity, ETC complex-I activity, RCR and ΔΨm collapse (Table 3). The protective effects of Mdivi-1 were further positively associated with rectification of indomethacin-induced DRP1-serine 616 phosphorylation (Fig. 8A) as well as increased mitochondrial proteome ubiquitination (Fig. 8B). Notably, Mdivi-1 did not significantly affect basal mitochondrial metabolic parameters (Table 3). Thus, the data suggested that Mdivi-1 salvaged gastric mucosal mitochondria from NSAID-induced acute metabolic dysfunction.

Mdivi-1 also attenuates indomethacin-induced mitochondrial oxidative stress (MOS), apoptosis and mucosal inflammation to prevent gastropathy

Because indomethacin-induced excess fission and MOS were positively associated, we next checked the effect of Mdivi-1 on mitochondrial macromolecular integrity. Data indicated that Mdivi-1 significantly reduced indomethacin-induced mitochondrial oxidative damage as evident from reduced macromolecular oxidation...
as well as preservation of cardiolipin content in gastric mucosa of Mdivi-1-treated rats (Table 4). Notably, Mdivi-1 also prevented apoptotic tissue damage as evident from rectification of indomethacin-induced caspase activation (Table 4). Alteration in redox homeostasis activates NF-κB signaling which is found to be associated with proinflammatory tissue damage (41). Therefore, we subsequently checked the impact of Mdivi-1 on gastric inflammation. Data indicated that Mdivi-1 significantly inhibited indomethacin-induced nuclear translocation of NF-κB (Fig. 8C). Subsequently, gene expression analysis of some common proinflammatory biomarkers indicated that Mdivi-1 significantly corrected indomethacin-induced up-regulation of cytokines, IL1β, IL1α, IL17A, chemokines, CXCL2 and CXCL3, tissue remodeling matrix metalloproteases including MMP3 and MMP13 and FFlt, a classical marker of MOS (Table 5). Finally, morphological examination followed by the scoring of injury index and histological evaluation strongly indicated that Mdivi-1 offered significant gastroprotection by reducing indomethacin-induced epithelial denudation due to mucosal cell shedding (Fig. 8D).

Discussion

In the present study we report that indomethacin, a typical NSAID, shifts mitochondrial dynamics towards enhanced fission to induce bio-energetic crisis and subsequently triggers apoptosis in human gastric cancer cells in vitro and rat gastric mucosal cells in vivo. We further provide evidences that blocking excess mitochondrial fragmentation prevents NSAID-induced cellular damage. Indomethacin, used here as a representative NSAID, is an indoleacetic acid derivative with pKa of 4.5 (42) that elicits non-selective inhibitory effect on COX and helps in extending life span of cancer patients with diagnosed metastasis. Moreover, the anti-nociceptive action of NSAIDs makes their usage mandatory in spite of the negative effects of PG depletion on various systems (43-48). About 54.4 million adults are affected with arthritis in the USA (49) wherein NSAIDs are rampanty used for therapeutic intervention (50-51). Apart from arthritis, NSAIDs are extensively used to manage musculoskeletal pain, sprains, fractures, abdominal pains associated with menstrual cramps and bone pains in certain forms of cancer (52-54). The emerging role of NSAIDs as potential candidates of combinatorial chemotherapy has drawn sufficient attention leading to repurposing the use of these drugs (55-58). Apart from aspirin, various other NSAIDs including indomethacin are documented with potential anti-cancer effects. In addition, diclofenac potentiates the anti-neoplastic efficacy of chemotherapy and radiotherapy upon combinatorial usage against various cancers (10,57). In spite of their multiple beneficial attributes, NSAIDs are infamous for their PG-dependent and independent effects that account to the toxic actions on various cells and organs (6,11-12). The gastro-intestinal system is most severely harmed and stomach injury by chronic NSAID-consumption is characterized by mucosal perforation, bleeding, tissue wasting and abdominal pain (10,17,59).

Although there are some evidences of different COX-independent cytotoxic actions of NSAIDs (7,9,60), it is yet unknown whether these drugs affect mitochondrial structural dynamics in the stomach to create the sub-cellular havoc. Diverse COX-independent molecular targets of NSAIDs and their metabolites have been found to mediate the effect of these drugs (7). The present study is an attempt to find a common COX-independent cytotoxic pathway that may be responsible for inducing apoptosis in cancer as well as normal gastric mucosal cells. A sub-lethal dose of indomethacin was selected based on the dose-response study in order to take into account the subtle effects on mitochondria, which would have otherwise got missed at a higher acute dose. Mitochondrial structural destabilization in gastric cancer cells initiated as early clumping and peri-nuclear clustering which progressed towards hyper fission and ultimately fragmentation. OPA-1 is associated with cristae remodeling, mitochondrial fusion and mitochondrial retention of cytochrome c against pro-apoptotic release (18,61-62). In this context, mitochondrial dynamics regulators reacted to indomethacin treatment in a way indicative of enhanced fission. DRP1 oligomerization on mitochondria is mandatory for the fragmentation of mitochondrial tubules (63-64). Various protein kinases and phosphatases control the phosphorylation of DRP1 on the serine residues 616 and 637 which in turn affects the function of the protein in opposing ways (65-71). Dysbalanced phosphorylation ratio at S616 and S637 is implicated in several pathologies (72). Therefore, we checked the status of DRP1 in the
NSAID-treated AGS cells. Up regulation of pDRP1Ser616 is evident in oxidative stress-associated pathologies (73–74). Since excess mitochondrial fission is reportedly detrimental to functional integrity and cellular health (75), the metabolic data in the present study were in close corroboration with reports of oxidative stress-induced mitochondrial damage during multiple pathologies (74,76–79). An obvious question is whether the effects pertaining to NSAID-induced metabolic failure are an attribute of cell death or it is indeed the faulty mitochondrial metabolism that increases the predisposition to cell death. To this end OCR analysis revealed that drastic deterioration of mitochondrial metabolic parameters was evident much earlier even when severe cell death has not set in, implying the contributing role of aberrant fission that initiates at the early hours of indomethacin treatment. In fact, alteration in mitochondrial dynamics via enhanced DRP1 activation along with loss of higher isoforms of OPA1 was found to start much earlier than cell death due to apoptosis. Next, it was mandatory to deduce the mechanistic basis of NSAID-induced DRP1 activation. Indomethacin is known to activate MAPK signaling in various experimental systems (80). Of the 3 MAPKs (ERK, JNK and p38), the latter two kinases were more attributed to the cytotoxic actions of the NSAIDs (81–82). Interestingly, in the present study a probable linear relation between NSAID treatment and mitochondrial fission was observed from the sequential phosphorylation-dependent activation of PKCζ followed by p38 and DRP1 along with notable rescue of ΔΨm collapse, mitochondrial hyper fission, DRP1 activation and cell death upon pre-treatment with specific p38 inhibitor, SB203580. It has been also established that indomethacin increases the permeability of gastric epithelial cells at the tight junctions by p38 MAPK activation (80) and that p38 MAPK activation is positively associated with PKCζ activation (83) under the influence of ROS (84). Thus it may be presumed that NSAIDs trigger PKCζ phosphorylation which plausibly activates p38 that finally acts as the probable DRP1-activating kinase. In fact, in the aforesaid context, PKCζ inhibitor, PKCζ-PSI offered significant protection against NSAID-induced mitochondrial depolarization, fragmentation and apoptosis comparable to p38 inhibitor. Moreover, blockade of p38 activation and DRP1 phosphorylation by PKCζ inhibition, in the present study, further indicated towards a probable regulatory action of PKCζ on p38-DRP1 signaling in response to indomethacin-induced oxidative stress in the AGS cells. It is worth mentioning that various PKC isoforms, including PKCζ, are associated with mitochondrial ROS production; however the signaling pathways triggered by ROS-induced activated PKCs are essentially isoform and cell type specific in addition to the differences based on intracellular sites of ROS generation (85). We also confirmed that mitochondrial fission was indeed a cause and not simply a consequence of NSAID-induced cancer cell death because DRP1-knocked down cells treated with indomethacin exhibited better metabolic integrity along with reduced fission.

Apart from cancer, the toxic effects of NSAIDs are observed as a side effect in various organs of which stomach is the most prominent target (10). However, it is yet unknown whether mitochondrial structural dynamics is affected by NSAIDs during the induction of gastric injury and if it happens at all, whether aberrant mitochondrial dynamics can be targeted for therapeutic management of NSAID-gastropathy. In the present study we show that as in the gastric cancer cells, indomethacin similarly affects mitochondrial dynamics to elicit the gastrodamaging effects. Fissogenic modification of DRP1 and its concerted association with PKCζ-p38 MAPK activation by NSAID may be justified because oxidative stress-induced p38 MAPK and JNK pathway activation is associated with stress responses including inflammation and apoptosis (86–87), while ERK-MAPK pathway is associated with cell survival, proliferation and mitotic division (88). Ultra structural micrographs of gastric mucosa after NSAID-induced damage to mitochondrial cristae logically explained cardiolipin depletion due to its location in the IMM. Clearance of metabolically unfit mitochondria commences with mitophagic activation and ubiquitination-induced degradation (89–90). However if the intensity of cytodamaging signal and extent of damage surpasses the limit of mitochondrial quality control machinery, the cells are sensitized to undergo apoptosis (89,91). ROS operates in a positive feedback cycle causing perpetual mitochondrial and tissue damage. In fact accumulation of damaged and fragmented mitochondria potentiates the intrinsic pathway of apoptosis (92). In this context it is worth mentioning that pharmacological blocking of altered mitochondrial dynamics by a well
established potent inhibitor of mitochondrial fission (93). Mdivi-1, offered significant protection against NSAID-induced mitopathology and gastropathy. Mdivi-1 has been extensively validated in several pre-clinical disease models of oxidative stress associated mitochondrial pathologies (31,94-96). It has been also shown that the dose of Mdivi-1 is very crucial since a higher dose may induce cytotoxicity instead of offering cytoprotection (97). Moreover, while Mdivi-1 offers protection against various oxidative stress-associated diseases (both in vitro and in vivo), it is toxic to cancer cells (98-99). Hence we used Mdivi-1 only in the in vivo study while DRP1 was knocked down in vitro by using siDRP1. The dose used in this study is in well accord with the diverse reports of the protective effect of Mdivi-1 in various diseases (39). Moreover, prevention of indomethacin-induced DRP1-activation and mitochondrial proteome ubiquitination confirmed the anti-fission action of Mdivi-1 in the present study which is also in accordance with reports of oxidative stress-associated brain tissue injury (72,100). Fragmented and depolarized mitochondria has been reported to aggravate ROS generation which further damages the organellar macromolecules in cardiovascular injury where mitochondrial fragmentation is positively correlated with elevated mitochondrial ROS generation (101). Thiobarbituric acid-reactive mitochondrial macromolecule oxidation end products are highly detrimental irreversible chemical changes induced by O$_2^-$ (102-105). Cardiolipin peroxidation (106) is associated with cytochrome C release (107) through the permeability transition pores (PTPs) formed during oxidative stress (108). In this work, we observed that in spite of not being a classical antioxidant, Mdivi-1 successfully prevented mitochondrial macromolecular oxidation and cardiolipin depletion which is most likely via stabilizing aberrant structural dynamics and preventing the onset of self-propagating oxidative damage. Furthermore, free heme released upon ROS-induced damage to mitochondrial heme-containing proteins, in concert with gastric acid-dependent erosion of microvasculature and consequent hemolysis, promotes localized pro-inflammatory cell recruitment (109-114). Activated phagocytes secrete more cytokines and chemokines to aggravate inflammation (115). NF-κB is a master regulator of inflammation (116) that controls the expression of several pro-inflammatory cytokines (117). Moreover cytokines like IL-1β and IL-17A regulate NF-κB activation (118-120). It is often observed that cytokine-induced activation of tissue remodeling matrix metalloproteases like MMP3 and MMP13 occurs via NF-κB in various chronic inflammatory diseases (121-122). Moreover IL-1β-induced CXCL2 and CXCL3 expression during vascular remodeling, leukocyte infiltration and inflammation is also regulated by NF-κB (123). Mitochondrial ferritin (FtMt), a classical marker of MOS gets upregulated upon intra-mitochondrial free iron accumulation during ROS-induced damage of mitochondrial iron-sulphur cluster containing proteins (124-125). A redox-active milieu with active inflammation thereby sets in to perpetuate tissue injury. In the current study, besides inhibiting caspase activation Mdivi-1 was also effective in preventing gastric mucosal inflammation and inflammation-associated detrimental tissue remodeling. It may be speculated that, ROS and mitochondrial fission proceeds in a self-perpetuating positive feedback loop in which defect in the mitochondrial ETC and subsequent ROS generation may trigger the initial activation of fissogenic signaling for segregation of damaged mitochondria. However excess fission becomes detrimental due to generation of more ROS in the subsequent stages. In addition, inflammation-associated ROS further amplifies the detrimental chain reactions (126). In this regard, Mdivi-1 is presumed to block excess fission thereby preventing the vicious feed-forward loop of ROS-fission chain reaction. It is worth mentioning that no significant change was found in the basal state of mitochondrial metabolic parameters when treated only with Mdivi-1. However, a slight increase in the ΔѰm in “Mdivi-1” sample might be due to the reduction of fission. Hence it may be considered that Mdivi-1 is potentially safe for use in murine experimental gastric injury models. Another notable fact is that a mitochondrially targeted antioxidant, mitoTEMPO, has been found to prevent pathological fission of mitochondria (127-128). Interestingly mitoTEMPO also offers gastroprotection from NSAIDs (129). Hence the contribution of ROS in initiating fissogenic activation of DRP1 is unequivocal. However, from the present study it may be concluded that aberrant mitochondrial fission is apparently one of the most significant events that underlie NSAID-induced gastric cell death,
predominantly due to the detrimental activation of DRP1 that participates both in triggering fission while contributing to apoptosis.

Therefore, the present study for the first time demonstrates that NSAIDs induce mitochondrial hyper fission to induce apoptosis in both gastric cancer as well as normal gastric mucosal cells wherein targeting aberrant mitochondrial dynamics and contextual modulation of hyper fission can certainly help in increasing the therapeutic utility of NSAIDs.

**Experimental procedures**

**Materials**

Indomethacin, thiobarbituric acid, 5, 5'-dithiobis (nitrobenzoic acid), reduced glutathione (GSH), DMSO, paraformaldehyde and mitoTEMPO were obtained from Sigma. Fetal bovine serum was purchased from Gibco, Invitrogen. Mitotracker Red CMX-ROS, Nonyl acridine orange (NAO) and Hoechst 33342 were purchased from Invitrogen. 5,5',6,6'-tetra-chloro-1,1',3,3'-tetracyethylbenzimidazol carbocyanine iodide (JC-1) was procured from Molecular Probes (Eugene, OR). The mitochondria isolation kit was purchased from the Biochain Institute (Hayward, CA). Alexa Fluor 647 and Alexa Fluor 488 tagged antibodies were purchased from Invitrogen. MFN-1, OPA-1, DRP1, MFF, TOM-20 and NF-κB (p65) antibodies were procured from Abcam. Actin antibody was obtained from Biovision. pDRP-ser616 and pPKC ζ antibodies were obtained from Cell Signaling Technology. MFN2, TOM20, p38, phospho-p38 and ubiquitin antibodies as well as siRNAs, SB203580 and PKCζ pseudo substrate inhibitor peptide (PKCζ-PSI) were obtained from Santa Cruz Biotechnology. Mdivi-1 and Sodium Fluoride were purchased from Merck. 14C labeled palmitate was procured from BRIIT (Mumbai, India). F-12 Ham Kaighn’s Modification media was procured from HiMedia Laboratories. All other reagents were of analytical grade purity.

**Human gastric epithelial cell culture**

AGS cells (human gastric epithelial cells) (ATCC-CRL-1739) were procured from American Type Culture Collection (Manassas, USA). These cells were cultured in nutrient mixture F-12 Ham, Kaighn’s modification with 10% FBS, 100 units/mL penicillin, and 100 μg/mL streptomycin, at 37°C in 5% CO2 incubator. The cells were split by 1X trypsin-EDTA solution once every 3 days. All the experiments were done with the cells within 5 to 8 passages. The cells were plated at a density of 1X10^6 in 60 mm culture plates for most of the experiments and allowed to grow over-night after which experiments were performed in fresh media. For p38 MAPK inhibition, cells were treated with SB203580 (10 µM) initially for a period of 1.5 hr following which the cells were treated with 0.5 mM indomethacin. For PKCζ inhibition, cells were pre-treated with PKCζ-PSI (20 µM) initially for a period of 1.5 hr following which the cells were treated with 0.5 mM indomethacin. For immunofluorescence studies cells were grown on poly lysine coated glass cover-slips or glass bottom culture dishes.

**[3H]-Thymidine incorporation to follow cell proliferation**

DNA synthesis during cell proliferation was monitored by labeling the cells using [3H]-thymidine. Briefly, AGS cells (1X10^6 cells/ mL) were seeded in triplicates for each set of treatment in 96 well plates and allowed to grow overnight. Next day the media was changed and cells were treated with indomethacin at indicated concentrations for 24 hr. Next, an aqueous solution of [3H]-thymidine (1 mCi) (PerkinElmer, USA) diluted with media (final concentration 5 µCi/ well) was added to each well. After 24 hr of incubation, cells were harvested and transferred to scintillation liquid. The level of incorporated [3H]-thymidine was assessed using the PerkinElmer (Tricarb 2810TR) liquid scintillation counter. Radioactivity of the experimental samples was expressed as disintegrations/min, which was proportional to the amount of [3H]-thymidine incorporated into the DNA during synthesis.

**Isolation of mitochondria**

Mitochondria were isolated from both control and experimental sets of rat stomachs using a commercially available kit from Biochain. Briefly, gastric mucosal scrapings were isolated from the rats, after which they were weighed and equal amount of tissue (200mg) from various experimental sets were finely minced in mitochondria isolation buffer. The contents were finally homogenized in a Dounce homogenizer. In order to get the mitochondrial fraction, the nuclei and the unbroken cells were first eliminated from the homogenate by centrifuging at 600 X g for 10 min and the supernatant was further centrifuged at 12000 X g for 15 min.
After this the entire process was repeated and the mitochondrial pellet was washed thrice times by centrifugation. For future use the pellet which was formed as a result of the above step was resuspended in mitochondrial storage buffer. Mitochondria from cells were isolated using a commercially available kit from Qiagen following the manufacturer’s instructions. Percoll density gradient centrifugation was done to further purify the mitochondrial pellet for mitochondrial respiration assay (130).

**Cellular dehydrogenase assay**

Cellular dehydrogenase activity was evaluated by measuring 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide (MTT) reduction. The principle of the assay was that cellular dehydrogenases are capable of reducing MTT into purple colored formazan dye which upon dissolution in DMSO can be estimated spectrophotometrically at 570 nm. AGS cells were plated in 48 well tissue culture plates and allowed to grow to 60-70% confluency after which they were treated with indomethacin at indicated concentrations for 24 hr. After treatment, the cells were incubated with 1% MTT in PBS and incubated for 3.5 hr under 37°C/5% CO₂ condition. The MTT solution was subsequently aspirated out and the formazan precipitates were solubilized in DMSO and spectrophotometrically measured at 570 nm. For measuring mitochondrial dehydrogenase activity of rat gastric mucosa, isolated mitochondria from control and treated gastric tissues were measured by Lowry method and equal amount of mitochondrial protein was incubated with MTT (dissolved in PBS) for 3.5 hrs at 37°C/ 5% CO₂. After incubation was over, samples were centrifuged and the formazan precipitate was dissolved in equal amount of DMSO and measured at 570 nm.

**Confocal microscopy for mitochondrial fragmentation in live cells; phase contrast, confocal and STED-based super resolution microscopy for immunocytochemistry and immunohistochemistry**

Sample preparation for live cell imaging was done as mentioned earlier with minor modifications (131). Live cell phase contrast microscopy was done by treating AGS cells with indomethacin in a 35 mm culture plate followed by washing and viewing under inverted phase contrast microscope (Leica Microsystems). Representative images of control and indomethacin-treated cells have been provided. For live cell imaging to document mitochondrial fragmentation, the cells were washed with pre-warmed PBS and loaded with Mitotracker red CMX ROS (100 nM) for 20 min at 37°C. Nucleus was counterstained by Hoechst 33342. The cells were next washed with PBS and viewed under the microscope on thermo-regulated stage at 5% CO₂ environment at the indicated time points. Samples were viewed under 63X oil immersion lens and digital zooming was performed. Image cropping and global adjustments to brightness and contrast were done in Adobe Photoshop CS6. The data presented are a typical representation of individually repeated experiments with similar results. Approximately 100 cells were screened per experimental set. The image acquisition times were kept as low as possible (not exceeding 30 sec) and laser intensities were kept < 2% to avoid any possible laser-induced toxicity. Immunofluorescent staining of DRP1, MFF or p-Drp1S616 was performed as mentioned previously (132). Briefly, AGS cells were plated on poly lysine coated cover-slips. After the treatment the cells were washed with pre-warmed PBS and subsequently fixed in 2% buffered paraformaldehyde for 10 min and next blocked in a buffer containing 2% BSA in PBS-Tween 20 for 1 hr. Immunostaining was done using antibodies against TOM20 (sc-136211, 1:250) developed in mice and DRP1 (ab54038, 1:100) or MFF (ab81127, 1:250) or p-Drp1S616 (4494S, 1:400) developed in rabbit. Goat antimouse Alexa Fluor 488 conjugated secondary antibody (A-11034, 1:500; Invitrogen) was used for staining DRP1 or MFF while goat antirabbit Alexa Fluor 647 conjugated secondary antibody (A-21245, 1:1000; Invitrogen) was used for staining TOM 20 to visualize mitochondria. For STED super resolution microscopy the samples were imaged by excitation with 592 nm depletion laser under 100X oil immersion objective lens. Precise location of DRP1 on mitochondrial filaments was visualized as discrete dotted fluorescent signals. Colocalization of the red (mitochondria) with the green (DRP1) signals were quantified using the LAS-X software taking into account the Pearson’s correlation coefficient and images provided were a representative of 3 independent experiments performed. About 100 cells were scanned and representative images of different fields were provided. For immunohistochemical analysis of DRP1 and NF-kB p65 translocation

---

NSAID induces excess mitochondrial fission
in gastric mucosal tissues, formalin-fixed and paraffin-embedded tissue sections were deparaffinized and finally heated in sodium citrate buffer for antigen retrieval. 10% goat serum and 1% BSA, prepared in Tris-buffered saline was used as a blocking solution to block the tissue sections for 2 hrs. For DRP1 immunohistochemistry, mitochondria were stained by TOM 20 primary antibody (sc-136211, 1:250) and DRP1 by anti-DRP1 primary antibody (ab54038, 1:100). For nuclear translocation of NF-κB, the fixed, permeabilized tissues were stained with antibody against NF-κB p65 (ab7970, 1:400), while nuclei were stained with DAPI. All experiments were performed thrice and confocal micrographs presented were representatives of randomly chosen cells or portion of the gastric mucosal sections. Digital zooming of the obtained micrographs was performed as and when required. Images were cropped and processed globally for enhancement of brightness and contrast using Adobe Photoshop CS6. Images were assembled in Corel DRAW X7 software to prepare the figure.

**Immunoblot analysis**

Gastric cancer cells were extracted by trypsinization after treatment with indomethacin and total protein or mitochondrial extract were prepared. Cellular mitochondria were isolated using Mitochondria Isolation kit (Qiagen) following the manufacturer’s instructions. While tissue mitochondria were isolated as mentioned previously (133) using a commercially available kit from Biochain. Isolated mitochondrial fractions were lysed in the lysis buffer supplemented with the protease inhibitor cocktail that was provided along with the kit. Protein quantification was done by Lowry method and equal amount of protein was loaded in each well of the 10% SDS PAGE gels. The electrophoresis was performed and subsequently immunoblotting was done at a constant voltage of 100 V. Pre-stained molecular weight markers were used as a reference. Proteins were transferred in nitrocellulose membrane in a transfer buffer (190 mM glycine, 20 mM Tris base buffer, pH 8.3, containing 20% methanol). The membranes were blocked in 5% BSA or non-fat milk in TBS (Tris-buffered saline) solution. The membranes were incubated in respective primary antibody solutions overnight followed by washing in TBS containing 0.1% Tween-20. Next the blots were incubated in secondary anti-body solution for 2 hr at room temperature. The membranes were again washed and blots were developed by staining with either 3,3′-diaminobenzidine (DAB) solution containing H2O2 or developed in Bio-Rad ChemiDoc MP imaging system. The documentation of DAB-based developed bands was done by scanning at high resolution (300 dpi) in scanner. For total protein, cells were lysed in mammalian cell lysis buffer and used for western immunoblotting. For phospho-protein immunoblotting, cell lysates were also supplemented with phosphatase inhibitor cocktail form Sigma immediately after cell harvesting. TOM 20 and actin were used as the internal controls for mitochondrial extract and total cell lysates respectively. Densitometric analyses of the developed bands were done by ImageJ software (134) and a representative immunoblot image of one of the several independently performed experiments have been provided in the image with calculation of fold change relative to control after normalization with actin or mitochondria as required for total lysates or mitochondria respectively. Further, densitometric analyses of the immunoblot data are provided as bar graphs adjacent to the respective blots. The antibodies from Abcam were as follows: Drp1, ab54038, 1:1000; Mfn1, ab104274, 1:1000; Mfn2, ab56889, 1:1000; OPA1, ab42364, 1:1000 and MFF, ab81127, 1:1000. The antibodies from Cell Signaling Technology were as follows: p-Drp1S616, 4494S, 1:1000; phospho-p38, 9211S, 1:1000; PKC ζ, 9368S, 1:1000 and pPKC ζ, 9378S, 1:1000. The antibodies from Santa Cruz Biotechnology were as follows: Ubiquitin, sc-8017, 1:500; p38, sc7972, 1:1000; TOM20, sc-11415, 1:1000; Actin, 3598R, 1:2000; Parkin, P6248, 1:1000; Anti-rabbit, IgG, A0545, 1:4000 and Anti-mouse IgG, A9044, 1:25000.

**Oxygen consumption ratio (OCR) by extracellular flux analyzer**

Oxygen consumption ratio was measured as mentioned previously (135-136) with minor modifications. AGS cells were counted in a TC-10 cell counter (Bio-Rad, Hercules, CA, USA), plated at a density of 30,000/well in a XF24 plate (Seahorse Biosciences, North Billerica, MA, USA) and allowed to grow for 24 hr in 5% CO2-37 °C. Next day the media was changed and cells were treated with 0.5 mM indomethacin for 6 hours in presence/absence of SB203580. In siDRP1 treated cells, transfection
was done 48 hrs before indomethacin treatment. After the treatment the cells were washed and incubated for 1 hr in 500 µl of sodium bicarbonate free XF Assay media (143 mM NaCl, 5.4 mM KCl, 0.91 mM NaHPO₄, 20 mM glucose, 2 mg/ml BSA, 1 mM sodium pyruvate, 0.8 mM MgSO₄ and 1 mM glutamine) at pH 7.4 for 1 h. Subsequently oligomycin (2 mM), FCCP [carbonyl cyanide -4 - (trifluoromethoxy) phenyllhydrazone] (1 mM), and rotenone + antimycin A (1 mM each) were injected over a span of 100 min (via loading in the injection ports A, B and C respectively) to measure the different stages of mitochondrial respiration at 37 °C. The analysis was performed with XFe 2.0.0 software (Seahorse Biosciences). Oxygen consumption ratio for each sample was normalized with the respective protein concentrations. The formulae for calculations were as follows:

**Basal Respiration** = (Measurement prior to oligomycin addition) - Non mitochondrial respiration

**Proton leak** = (First measurement after oligomycin injection through measurement before FCCP) - non-mitochondrial respiration.

**ATP production** = Basal respiration - proton leak

**Maximal respiration** = (First measurement after oligomycin addition through measurement prior to rotenone + antimycin A injection) - Non mitochondrial respiration.

**Spare/reserve respiratory capacity** = Maximal respiration - Basal respiration

**Analysis of mitochondrial trans-membrane potential (ΔΨm)**

After treatment the cells were rinsed in pre-warmed media (37°C) and incubated in the JC-1 (5µg/mL) diluted in cell culture media for 15 min at 37°C/5% CO₂ in darkness. After incubation, the cells were dissociated and diluted in PBS to a density of 1X10⁶ cells/mL and analyzed by fluorescence-activated cell sorter (FACS) LSR Fortessa, BD, using FACS DIVA software under standard parameters. Experiments were repeated thrice and representative images of the FACS scatter plots corresponding to each set were presented in the image. For analysis of ΔΨm in vivo, mitochondria were isolated from control and treated stomachs. Mitochondrial protein was estimated and equal amount of mitochondria from different experimental sets were incubated in darkness for 15 min in 500 µL of JC-1 assay buffer containing 300 nM of JC-1. For measuring fluorescence an F-7000 Fluorescence Spectrophotometer (Hitachi High-Technologies Corporation) was used with single excitation-dual emission format. ΔΨm was expressed as fluorescence ratio of 590 nm/530 nm.

**FITC-Annexin V staining for cell death determination**

Annexin V staining was done to measure the apoptosis in AGS cell after DCF treatment. Briefly, in complete medium 1X10⁶ cells were plated in 6 cm culture plates and grown overnight. Next day cells were treated with different concentration of indomethacin for 24 hours by replacing the existing media with fresh media. After the treatment, the media was removed and the cells were harvested by trypsinization. Cells were then counted and 1X10⁶ cells were taken in 2 ml of micro centrifuge tubes. Cells were then stained with FITC-Annexin V in Annexin V binding buffer as instructed in the manufacturer’s protocol (Abcam, Cambridge, MA, US). The cells were next counter stained with propidium iodide (PI) and finally analyzed in FACS as mentioned above. Experiments were repeated thrice and representative images of the FACs scatter plots corresponding to each set were presented in the image.

**Transient transfection for DRP1 silencing**

Reverse transfection protocol was followed. The lyophilized siRNA duplex was re-suspended to make a 10 µM solution in the re-suspension buffer (10 µM Tris-HCl, 20 mM NaCl, 1 mM EDTA pH 8.0). Cells were plated and allowed to grow till 50-60% confluence following which they were transfected. For each transfection, Lipofectamine RNAiMAX was diluted in OptiMEM media. siRNA was also diluted individually to 80 pmol in Opti-MEM media. Both the incubations were of 5 min each and mixed by gentle tapping. The diluted siRNA was added drop wise to the lipofectamine solution and gently mixed by tapping following which the mixture was incubated at room temperature for 30 min. In the mean while the cells were also acclimatized in Opti-MEM media for 30 minutes. Finally, the siRNA-lipofectamine mix was added to the cells and incubated for 16-18 hr after which the transfection media was replaced by complete growth media. After 48 hr from the initiation of transfection process, the...
cells were treated with indomethacin for 24 hr and finally analyzed for dehydrogenase activity. The sequence of DRP1 siRNA was as follows:

Sense: 5′-AACGCAGAGCAGCGGAAAGAgit-3′

Antisense: 5′-CUUUCGCUGUCUGCUUt-3′

**Animals and NSAID-induced gastric mucosal injury**

All *in vivo* studies were performed following the protocol approved by the animal ethics committee of CSIR-Indian Institute of Chemical Biology, Kolkata registered with the Committee for the Purpose of Control and Supervision of Experiments on Animals (CPCSEA), India (Permit Number: 147/1999/CPCSEA). Maximum care was laid while handling the animals for minimizing their suffering. Sprague-Dawley rats weighing 180-220g were used. For proper maintenance the animals were kept in the institutional animal house at a temperature of 24 ± 2°C with a 12 hr light and dark cycle and provided with standard rat chow. To avoid unnecessary food induced acid secretion and its adverse aggravating effects on gastric injury, animals were fasted for 24 hr (with ad libitum access to water) prior to the experiments. All the animals were divided into following experimental groups (with n = 6-8 in each group); “control”, “indomethacin-treated” and “Mdivi-1 + indomethacin treated”. The vehicle controls were treated separately each time. Indomethacin was administered orally to the rats at a dose of 48 mg/kg b.w. Mdivi-1 (2mg/ kg b.w.) was administered 1h prior to NSAID treatment by intra-venous injection. The stock solution of Mdivi-1 (dissolved in DMSO) was diluted in sterile saline during injection so as to keep the final concentration of DMSO at 0.1%. At this concentration DMSO did not impose any effect on gastric injury caused by the NSAIDs (data not shown). A separate set of rats were treated only with Mdivi-1 and mitochondrial metabolic parameters were measured to follow the effect of Mdivi-1 on basal mitochondrial metabolism. After 4 hr of NSAID administration the rats were sacrificed upon proper euthanasia. The stomachs of the rats were dissected out after washing and gathered. An individual ignorant of the treatment was called for scoring the ulceration which was indicated as injury index (II). This is calculated as a percentage of injured area in the gut of the rats formed by bleeding lesions and clots. Mean II was calculated as the sum of the total scores in each group of rats divided by the number of individuals in that group.

**Transmission electron microscopy (TEM)**

Sample preparation for TEM analysis was done as mentioned previously (133). Control and indomethacin-treated gastric mucosal tissues were cut into small pieces (1 mm³) and fixed with 4% paraformaldehyde and 2% glutaraldehyde in 0.1 M sodium phosphate buffer, pH 7.4, for 4 hr at room temperature. The tissues were then washed in 0.1M sodium phosphate buffer and subsequently incubated in 2% osmium tetroxide for 2 hr. The post-fixed tissues were then dehydrated in ascending grades of ethanol and embedded in Epon 812 by polymerization at 60 °C for 24 h. Ultracut ultramicrotome (Leica Microsystems GmbH, Wetzlar, Germany) was used for tissue sectioning (50–70 nm). The sections were then picked up onto 200 mesh copper grids and double stained with uranyl acetate and lead citrate followed by visualization under FEI Tecnai-12 Twin Transmission Electron Microscope at 80 kV (FEI Company, Hillsboro, OR).

**Measurement of mitochondrial oxidative stress (MOS)**

Mitochondrial oxidative stress was evaluated by measuring thiobarbituric acid reactive macromolecule oxidation products including malondialdehyde, which is one of the major aldehyde-adducts formed during oxidative modification of cellular as well as organellar macromolecules like proteins, lipids and nucleic acids. Therefore, *in vivo* MOS was measured by analyzing the extent of accumulated oxidized mitochondrial macromolecules in the rat gastric mucosa. For this, equal amount of mitochondrial fraction (100 µg) were taken from both the control and treated groups, homogenized them in ice-cold 0.9 % saline. Next 0.5ml of the homogenate was taken and mixed with 1 ml of a thiobarbituric acid-trichloroacetic acid mixture (0.375% w/v, 15% w/v, respectively) in 0.25 N HCl. Then the mixture was boiled for 15 min. The solutions were then cooled to room temperature and spun at high speed for 10 min. The clear supernatant was collected and measured at 535 nm with tetra-ethoxypropano considered as standard.

**Measurement of fatty acid oxidation**
Oxidation of $^{14}$C labeled palmitate to $^{14}$CO$_2$ was measured via the assay which was described previously (73) with minor change. In brief, equal amount of gastric mucosal tissue was taken to perform the assay. Assay mixture contained 1µCi of [1-$^{14}$C] which was pre-incubated in 5% BSA. $^{14}$CO$_2$ was trapped in Whatman chromatography paper which was soaked in 3M NaOH. The papers were allowed to dry overnight and finally the $^{14}$C levels were measured in a scintillation counter (Perkin-Elmer, U.S.A). The assay was performed in triplicate and normalized by tissue weight.

**Mitochondrial respiration**

Estimation of oxygen consumption rate was performed to evaluate the mitochondrial respiration. Clark-type electrode was used in a liquid-phase oxygen measurement system (Oxytherm System, Hansatech Instruments Ltd. United Kingdom). Respiratory control ratio (RCR) was derived from the ratio of State 3 and State 4 respiration which was measured in terms of nanomoles of O$_2$ consumed. Briefly, malate (5 mM) and glutamate (5 mM) were added to the respiratory medium (5 mM KH$_2$PO$_4$,250 mM sucrose, 0.1 mM EDTA,5 mM MgCl$_2$, and 0.1% BSA in 20 mM HEPES, pH 7.2). After adding 1 mM of ADP state 3 respiration was measured while state 4 respiration was recorded in presence of 15 μM oligomycin (acts as an ATP synthase blocker). Mitochondrial respiration was normalized by protein content of the respective mitochondrial fractions in control and different experimental sets.

**Mitochondrial ETC complex-I assay**

Mitochondrial complex-I activity was measured spectrophotometrically as described (137–138). Equal amount of isolated mitochondria (15 μg) isolated from control as well as treated rat stomachs were exposed to 2 rounds of freeze thaw cycles in hypotonic buffer. Complex I activity was assayed based on change in OD$_{340}$ nm caused by oxidation of NADH along with ubiquinone as the substrate. In a separate reaction rotenone was used for control as well as each treatment sets comprising of all the reagents. Decrease in absorbance was recorded in a Shimadzu UV-VIS Spectrometer for a period of 2 min (Shimadzu Corporation, Japan). Complex 1 activity was estimated by measuring rotenone sensitive NADH–ubiquinone oxidoreductase activity.

**Assays of caspase-9 and caspase-3 activities**

Caspase-9 and caspase-3 activities in gastric tissue homogenate were measured by commercially available kit from Calbiochem (Merck, Germany) following the protocol of the manufacturer. For both the assays 30 mg of gastric mucosa was homogenized in the lysis buffer provided with the respective kit. The homogenate was spun at 16,000 X g for 15 min. The supernatant was collected and the protein quantity was measured by Lowry’s method. Finally, the samples containing the equal amount of proteins from both the control and the treated groups were used to perform the assay. The respective substrates provided in the kit were added in the reaction mixture and incubated in darkness at 37°C for 2 hours. The assay was kinetically monitored; although the end point reading was considered to depict the respective caspase activities in the tissue samples from control as well as the treated rats.

**Measurement of cardiolipin content**

Nonyl acridine orange (NAO) was used to measure the content of mitochondrial cardiolipin (CL) as mentioned previously (133) with minor modifications. In brief, mitochondria were isolated from the gastric tissue of control and treated rats and equal amount of mitochondria (25 μg) were used to perform the assay. After the incubation with NAO the fluorescence of each sample was measured in a spectrofluorimeter micro plate reader (BioTek Instruments, Inc., BioTek India, Mumbai) (excitation 495 nm; emission 519 nm, gain 50%). Mean fluorescence was calculated per mg of mitochondrial protein and presented as fold decrease relative to control for both control and treated gastric mitochondrial fractions.

**Measurement of tissue ATP content**

ATP Determination Kit (Invitrogen Corp., Carlsbad, CA, USA) was used to measure the ATP. Briefly, 50 mg of gastric mucosal tissue from both the control and NSAID-treated rat was minced and lysed in 5% sulfosalicylic acid. Next the lysate was centrifuged. The supernatant was collected and used for the measurement of ATP in a Varioskan Flash luminometer (Thermo Fisher Scientific Inc., NYSE: TMO). The ATP content was represented as relative luciferase unit (RLU) after the blank is subtracted from the samples.

**RNA isolation and qPCR**

RNA isolation and qPCR
Total RNA were isolated from control and treated tissues using TRIzol reagent (Invitrogen, Carlsbad, CA) following the manufacturer’s protocol. DNA contamination was eliminated by applying rDNase (DNA-free kit, Invitrogen, Carlsbad, CA) to 10 µg of RNA. Now cDNA was synthesized from the total RNA (2 µg) by using oligo dT18 primer with the help of RevertAid First Strand cDNA synthesis kit (Thermo Fisher Scientific Inc.). Now the synthesized cDNA was qPCR amplified by using gene specific primers (Integrated DNA Technologies Inc. San Diego, California, USA) listed in Table 1 to study the gene expression profile using Power SYBR green (Applied Biosystems), in a ABI 7500 Real-Time PCR System (Applied Biosystems). The reaction conditions were maintained as follows; 1 cycle of 95°C for 10 min and then 40 cycles of 15 s at 95°C and 60°C for 1 min. Gapdh was chosen as an internal control. 2−ΔΔCT method (134) was opted for the analysis of data which were normalized to the Gapdh levels and expressed as fold change compared to control. The primer sequences are provided in Table 8

**Histological study of gastric mucosal tissue sections and Soret spectroscopy to detect mucosal bleeding**

Gastric mucosal tissues were collected each from control as well as drug treated rats and were fixed in 10% buffered formalin (pH 7.4) for 12 hr followed by passage through graded ethanol and finally embedded in paraffin wax. Next, semi thin sections (5 µM) were made and collected on poly-L-lysine coated glass slides. The tissue sections were ultimately double stained using eosin-hematoxylin and visualized under microscope (Leica DM-2500, Germany). Soret spectroscopy was used to check gastric mucosal bleeding by following hemoglobin release. Briefly, the stomachs from control and treated rats were washed in PBS (pH 7.4). The clarified PBS (mucosal washing) was analyzed for hemoglobin content by wavelength scanning (360-600 nm) in UV-VIS spectrophotometer (Shimadzu, UV-1700 PharmaSpec).

**Statistical analysis**

All animal experiments were done in triplicates with at least six to eight animals in each group (n = 6–8). All in vitro experiments were done in triplicates and repeated. Data obtained from all experiments were expressed as mean ± SD. Unpaired ‘t test’ was used to calculate the levels of significance while comparing ‘control’ and ‘indomethacin’ groups while using one-way ANOVA followed by Bonferroni post-hoc test was used for comparing multiple groups. P value less than 0.05 (P < 0.05) was considered as statistically significant. Statistical analysis of the data was performed with the help of GraphPad Prism 6 and Microsoft Office Excel 2007 software.

Table 2
Indomethacin-induced alteration in viability and respiration of AGS cells as well as effect of p38 MAPK inhibition or DRP1 silencing in the pathology.

AGS cells were pre-treated with p38 inhibitor (SB203580) or siDRP1 followed by treatment with indomethacin at the IC₅₀ dose (0.5 mM). Cells were subsequently analyzed for viability by measuring MTT reduction and metabolic integrity in by measuring oxygen consumption ratio (OCR) in extracellular flux analyzer as described under “Experimental Procedures.” All experiments were done in triplicate. Data are presented as means ± SD.

**Figure Legends**

**Figure 1: Indomethacin enhances mitochondrial fragmentation in human gastric cancer cells.**

(A) Phase contrast micrographs of AGS cells treated with indomethacin (0.5 mM) for 6 hrs, 12 hrs and 24 hrs; size bar indicates 100 µm. Red arrows indicate blebbings and pinching off of cellular structures. (B) High resolution confocal micrographs to demonstrate time-dependent effect of indomethacin on AGS cells; white scale bars correspond to 10 µm; 80-100 cells were randomly screened and a single cell was randomly selected for demonstration of mitochondrial fission at the single-cell level; enlarged images of the region of interest (ROI) were prepared by digital zooming of the selected region for clear visualization of mitochondrial filaments. Green arrows indicate clumped and peri-nucleary clustered mitochondria and white arrows indicate fragmented and punctate mitochondrial particles. (C) Immunoblot analysis of DRP1 in the mitochondrial extract and phosphorylation level of DRP1 at Serine 616 along with expression of MFF in the whole cell lysates from control and indomethacin-treated AGS cells. Actin and TOM 20 were used as the loading control for cell lysates and mitochondrial fractions respectively. Numerical values at the side of the blots indicate the positions of corresponding molecular weight markers. Bar graphs adjacent to the blots represent the densitometric analyses of the immunoblot data after normalization with respective loading controls. (D) Super resolution (STED) microscopy to precisely follow mitochondrial translocation of DRP1; scale bars correspond to 10 µm; 80-100 cells were randomly screened and a single cell was randomly selected for precise demonstration of mitochondrial localization of DRP1 at the single-cell level. Mitochondria were immunostained by anti-TOM 20 antibody. A representative image of one of the several experiments performed has been presented. Corresponding values in the inset represent Pearson’s correlation coefficient (r) of the red and green signals corresponding to TOM 20 and DRP1 respectively. (E) Confocal microscopy to follow expression and localization of MFF; Corresponding values in the inset represent Pearson’s correlation coefficient (r) of the red and green signals corresponding to TOM 20 and MFF respectively. (F) Immunoblot analysis of MFN1 and OPA1. Actin was used as the loading control. Numerical values at the side of the blots indicate the positions of corresponding molecular weight markers. Bar graphs adjacent to the blots represent the densitometric analyses of the immunoblot data after normalization with the respective loading controls. All experiments were done in triplicate. A detail of each method is described under “Experimental procedures”. *P < 0.05 versus control calculated by unpaired Student’s t test.

**Figure 2: Indomethacin induces mitochondrial depolarization, fragmentation and gastric cancer cell apoptosis through PKCζ-p38-MAPK pathway.** (A) Flow cytometric analysis to follow mitochondrial transmembrane potential (ΔΨm) in control and indomethacin-treated AGS cells at 6 hrs and 24 hrs of incubation; 10,000 events were screened per experimental set. Experiments were performed in triplicates and a representative image has been presented. Red signal in the scatter plot indicated JC-1 aggregates fluorescing at 590 nm while green signal indicated JC-1 monomers...
NSAID induces excess mitochondrial fission

(corresponding to depolarized mitochondria) fluorescing at 530 nm; % values in the P3 and P4 quadrants correspond to number of cells with polarized and depolarized mitochondria respectively. (B) FACS analysis to show apoptosis in control and indomethacin treated cells at 6hrs and 24 hrs. Values in the Q4 and Q2 quadrants represent percentage of cells showing apoptotic and late apoptotic-necrotic cell death respectively; dot plot representations of FACS analysis are representative of one of the three independent experiments repeated under similar experimental conditions. (C) Immunoblot analysis of pDRP1Ser616, DRP1, and OPA1. Actin was used as the loading control. (D) Immunoblot analysis for phospho PKCζ, PKCζ, phospho p38 and p38 in the total cell lysates of control and indomethacin-treated AGS cells. Actin was used as the loading control. (E) Immunoblot analysis for phospho PKCζ and PKCζ in control and PKCζ-PSI (PKCζ pseudo substrate inhibitor)-treated cells to show the basal effect of PKCζ-PSI on PKCζ activation. Actin was used as the loading control. (F) Immunoblot analysis for phospho p38 and p38 in control and SB203580 (p38 inhibitor)-treated cells to show the basal effect of SB203580 on p38 activation. Actin was used as the loading control. (G) Immunoblot analysis to document the efficiency of DRP1 silencing in the siDRP1-treated AGS cells compared to control siRNA treatment for 72 hrs. Actin was used as the loading control. Numerical at the side of the blots indicate the positions of corresponding molecular weight markers. Bar graphs adjacent to the blots represent the densitometric analyses of the immunoblot data after normalization with actin. A detail of each method is described under “Experimental procedures”. *P < 0.05, **P < 0.001 versus control calculated by unpaired Student’s t test; ns = non significant

Figure 3: Blocking PKCζ or p38 or silencing DRP1 reduces indomethacin-induced mitochondrial membrane depolarization, fragmentation and apoptosis. (A) Flow cytometric analysis to follow mitochondrial transmembrane potential (ΔΨm) in AGS cells treated with indomethacin in presence and/or absence of PKCζ inhibitor, p38 inhibitor or siDRP1; 10,000 events were screened per experimental set. % values in the P2 and P3 quadrants correspond to number of cells with polarized ad depolarized mitochondria respectively. Experiments were performed in triplicates and a representative image has been presented. (B) High resolution confocal micrographs to demonstrate the effect of PKCζ blocking or p38 blocking or DRP1 silencing against indomethacin-induced mitochondrial fragmentation in AGS cells; white scale bars correspond to 10 μm; 80-100 cells were randomly screened and a single cell was randomly selected for demonstration of mitochondrial fission at the single-cell level; enlarged images of the region of interest (ROI) were prepared by digital zooming of the selected region for clear visualization of mitochondrial filaments. Experiments were performed in triplicates and a representative image has been presented. (C) Flow cytometric analysis to follow apoptosis in AGS cells treated with indomethacin in presence and/or absence of PKCζ inhibitor, p38 inhibitor or siDRP1; 10,000 events were screened per experimental set. Values in the Q4 and Q2 quadrants represent percentage of cells showing apoptotic and late apoptotic-necrotic cell death respectively; dot plot representations of FACS analysis are representative
NSAID induces excess mitochondrial fission

of one of the three independent experiments repeated under similar experimental conditions. A representative flow cytometry scatter plot of gated cell population was presented. All experiments were done in triplicates. A detail of each method is described under “Experimental procedures”.

Figure 4: Blocking p38 activation or PKCζ activation affects indomethacin-induced PKCζ-p38 MAPK signaling and prevents fissogenic DRP1 activation. (A) Immunoblot analysis of OPA1, phospho PKCζ, phospho p38 and p38 in the whole cell lysates from control and SB203580 treated AGS cells. Actin was used as the loading control for cell lysates. Bar graphs adjacent to the blots represent the densitometric analyses of the immunoblot data after normalization with actin. (B) Immunoblot analysis of OPA1, phospho p38 and p38 in the whole cell lysates from control and PKCζ-PSI pre-treated, indomethacin treated AGS cells. Actin was used as the loading control for cell lysates. Numerical values at the side of the blots indicate the positions of corresponding molecular weight markers. Bar graphs adjacent to the blots represent the densitometric analyses of the immunoblot data after normalization with actin. (C) Confocal microscopy to follow the level of Ser616 phosphorylation of DRP1 in control, indomethacin-treated, PKCζ-PSI-treated, PKCζ-PSI-pre-treated indomethacin-treated, SB203580-treated, and SB203580-pre-treated indomethacin treated AGS cells. Scale bars correspond to 10 µm; 80-100 cells were randomly screened and a single cell was randomly selected for precise demonstration of mitochondrial localization of pDRP1Ser616 (green) at the single-cell level. Mitochondria (red) were immunostained by anti-TOM 20 antibody. A representative image of one of the several experiments performed has been presented. Mean intensity values corresponding to pDRP1Ser616 were indicated in each image. (D) Immunoblot analysis of OPA1, phospho PKCζ, phospho p38 and p38 in the whole cell lysates from control and siDRP1 treated AGS cells. Actin was used as the loading control for cell lysates. Numerical values at the side of the blots indicate the positions of corresponding molecular weight markers. Bar graphs adjacent to the blots represent the densitometric analyses of the immunoblot data after normalization with actin. All experiments were done in triplicates. \( *P < 0.05 \) versus control and \( ^{#}P < 0.05 \) versus indomethacin calculated by ANOVA followed by Bonferroni’s post hoc test. ns = not significant. A detail of each method is described under “Experimental procedures”.

Figure 5: Indomethacin induces mitochondrial clumping and fission in vivo in rat gastric mucosa. (A) High resolution confocal micrographs of gastric mucosal primary cells isolated from control and indomethacin-treated rats after 4 hrs; white scale bars correspond to 10 µm; white arrows indicate clumped, punctuated and peri-nuclearly clustered mitochondria. 80-100 cells were screened and experiments have been replicated thrice; a representative image has been presented. Size bar corresponds to 10 µm. (B) Ultra structural analysis of gastric mucosa by transmission electron microscopy (TEM) to visualize mitochondrial cristae upon indomethacin treatment. Magnified
regions of interest (ROI) have been presented as “ROI enlarged” adjacent to the “broad view” to clearly demonstrate loss of stacked structures (mitochondrial cristae) after indomethacin treatment. A representative image of one of the several micrographs captured during independent experiments performed has been presented. (C) Immunohistochemical analysis of mitochondrial translocation of DRP1 upon indomethacin treatment; white asterix shows the region of mucosal surface erosion/injury and white arrows indicate shredded gastric mucosal cells. Numerical values presented in green fonts as insets correspond to respective mean intensity values of DRP1. Size bars represent 50 μm. Experiments have been repeated thrice and a representative image for each experimental set is provided. Corresponding values adjacent to the micrographs represent Pearson’s correlation coefficient (r) of the red and green signals corresponding to TOM 20 and DRP1 respectively. All experiments were done in triplicate. A detail of each method is described under “Experimental procedures”.

**Figure 6:** Indomethacin-induced mitochondrial fission *in vivo* is associated with activation of PKCζ-p38-DRP1 pathway, depletion of fusogenic mediators and elevation of mitochondrial ubiquitination. (A) Immunoblot analysis of DRP1 in the mitochondrial extracts isolated from control and indomethacin-treated rat gastric mucosa. TOM 20 was used as the loading control. (B) Immunoblot analysis of pDRP1Ser 616 and MFF in the total tissue lysates from control and indomethacin-treated rat gastric mucosa. Actin was used as the loading control. (C) Immunoblot analysis of phospho PKCζ, PKCζ, phospho p38 and p38 in control and indomethacin-treated rat gastric mucosal extracts; Actin was used as the loading control. (D) Immunoblot analysis of fusogenic mediators MFN1, MFN2 and OPA1 in control and indomethacin-treated rat gastric mucosal extracts; Actin was used as the loading control. (E) Immunoblot analysis of Parkin and protein ubiquitination in the mitochondrial extracts from control and indomethacin-treated rat gastric mucosa; TOM 20 was used as the loading control. Numerical values at the side of the blots indicate the positions of corresponding molecular weight markers. Bar graphs adjacent to the blots represent the densitometric analyses of the immunoblot data after normalization with the respective loading controls. A representative image of one of the several experiments performed has been presented. *P < 0.05, **P < 0.001 versus control calculated by unpaired Student’s t test; ns = non significant. A detail of each method is described under “Experimental procedures”.

**Figure 7:** Indomethacin damages the gastric mucosal ultra structure. Transmission electron microscopic (TEM) analysis of the gastric mucosal sections from control and indomethacin-treated rats to visualize cyto-architectural damage. Yellow arrow indicates nuclear chromatin condensation. A representative image of one of the several micrographs captured during independent experiments performed has been presented. All experiments were replicated. A detail of each method is described under “Experimental procedures”.

**Figure 8: Mdivi-1 prevents indomethacin-induced mitochondrial damage, inflammation and gastric injury.** Immunoblot analyses for DRP-Ser 616 phosphorylation (A) and mitochondrial proteome ubiquitination (B) in control, indomethacin-treated and Mdivi-1 + indomethacin-treated rat gastric mucosa. Actin and TOM 20 were used as the loading control for total cell lysates and mitochondrial fractions respectively. Numerical values at the side of the blots indicate the positions of corresponding molecular weight markers. Bar graphs adjacent to the blots represent the densitometric analyses of the immunoblot data after normalization with the respective loading controls. (C) Immunohistochemical analysis of nuclear translocation of NF-κB upon indomethacin treatment or Mdivi-1 + indomethacin treatment; white arrows indicate mucosal epithelial cells with higher degree of nuclear NF-κB. NF-κB (green) was immunostained by anti-NF-κB (p65) primary and Alexa fluor 488 tagged anti rabbit secondary antibodies. Nucleus (blue) was stained by DAPI. Scale bars correspond to 50 µm. Corresponding values in the inset represent Pearson’s correlation coefficient (r) of the blue and green signals corresponding to nucleus and NF-κB respectively. Random tissue sections were screened and a representative image of one of the several experiments has been presented. (D) Gastric mucosal morphology and histology by hematoxylin-eosin staining. Black arrows indicate injured mucosal surface. For all animal experiments n = 6-8 and experiments were performed thrice. **P < 0.01 versus control and ##P < 0.01 versus indomethacin as calculated by ANOVA followed by Bonferroni’s post hoc test. A detail of each method is described under “Experimental procedures”.
