Abstract
We consider point-to-point last-passage times to every vertex in a neighbourhood of size $\delta N^{2/3}$ at distance $N$ from the starting point. The increments of the last-passage times in this neighbourhood are shown to be jointly equal to their stationary versions with high probability that depends only on $\delta$. Through this result we show that (1) the Airy$_2$ process is locally close to a Brownian motion in total variation; (2) the tree of point-to-point geodesics from every vertex in a box of side length $\delta N^{2/3}$ going to a point at distance $N$ agrees inside the box with the tree of semi-infinite geodesics going in the same direction; (3) two point-to-point geodesics started at distance $N^{2/3}$ from each other, to a point at distance $N$, will not coalesce close to either endpoint on the scale $N$. Our main results rely on probabilistic methods only.

1 Introduction

Planar last-passage percolation (LPP) belongs to the KPZ universality class where models of random surface growth exhibit height and transversal fluctuation exponents of order $1/3$ and $2/3$, respectively. The different models in the KPZ universality class are believed to have the same limiting behaviour under this scaling. The LPP with exponential weights belongs to the set of models in the KPZ universality class that are exactly solvable, or integrable. For models in this group, one can obtain closed form expressions for their prelimiting statistics. Coupling this with techniques from combinatorics, representation theory and random matrix theory, one can take the limits of the prelimiting expressions to obtain the statistics of the limiting object. By the KPZ universality conjecture, these statistics should be valid for all models in the KPZ universality class.

One of the interesting questions about the model involves its prelimiting local fluctuations. To make this more concrete, let $G_x$ be the last-passage time between the points $(0,0)$ and $x$. Define

$$L_{(x,y)}^N = G_{(N,N)+y} - G_{(N,N)+x}. \quad (1.1)$$
If $|x|, |y| = O(1)$, then $L^N$ is close to a stationary cocycle called the Busemann function [17]. In fact, these stationary cocycles are defined as, roughly speaking, the limits when $N$ is taken to infinity in (1.1). Busemann functions extend the stationary LPP process to the whole lattice $\mathbb{Z}^2$ and play a major role in the study of infinite geodesics.

The main contribution of this paper is the total variation convergence of $L^N$ to the Busemann function when $|x|, |y| \leq \delta N^{\frac{2}{3}}$, first $N \to \infty$ and then $\delta \to 0$. Moreover, the results are quantitative; we show that the decay of the error is polynomial in $\delta$. We stress that this cannot be obtained simply from the “crossing lemma” (Lemma B.2) which says that difference of geodesics along an edge is monotone in the starting point of the geodesics. Indeed, to compare the LPP increments to those of the stationary LPP one must tweak the intensity of the stationary LPP by order of $N^{-\frac{1}{3}}$ so that the error of the approximation along each edge is of the order of $N^{-\frac{1}{3}}$ as well. Therefore a simple union bound over $N^{\frac{2}{3}}$ edges gives $N^{\frac{2}{3}} N^{-\frac{1}{3}} = N^{\frac{1}{3}}$ and will not work. In a recent work, Fan and Seppäläinen [12] obtained a coupling of different Busemann functions using queueing mappings. We use new insights about this coupling to obtain a result we call local stationarity. Our other results are applications of local stationarity to questions about the Airy$_2$ process and geodesics.

LPP can be viewed as a $1+1$ dimensional growing surface, and also as a Markov process that takes values in the space of continuous functions. Using the 1:2:3 KPZ scaling, the conjectural limit of this Markov process is believed to be the KPZ-fixed point [26]. An extension of this limiting object was shown to exist recently in [9]. In [23] Johansson showed the convergence of the spatial fluctuations to the Airy$_2$ process minus a parabola and that the limit is continuous. As was mentioned previously, the fact that LPP has stationary counterparts whose spatial fluctuations are that of a simple random walk suggests that locally, the Airy$_2$ process should have a Brownian behaviour around a fixed point.

Known results on the Brownian behaviour of the Airy$_2$ process fall roughly into two types:

1. on a small interval $[0, \epsilon]$ the Airy$_2$ process should be close to the Brownian motion in some sense;
2. on the interval $[0, 1]$ the law of the Airy$_2$ process can be related to that of the Brownian motion.

Under point (1), Pimentel [29] showed, in the LPP setup, that locally the Airy$_2$ process converges weakly to a Brownian motion in the Skorohod topology. The proof relied on the comparison lemma, also called the crossing lemma (Lemma B.2). The idea is that the spatial increments of the last-passage time can be compared with high probability to stationary increments with a small drift. In [26, Theorem 4.14], Matetski, Quastel and Remenik showed that the Airy$_2$ process has Brownian regularity and its finite-dimensional distributions converges to those of two-sided Brownian motion. In [30] (that contains results under both points (1) and (2)) Pimentel extended the results in [29], though the convergence is still in the weak sense.

Under point (2), Corwin and Hammond [7] showed that the Airy line ensemble (the top line of which is the Airy$_2$ process) minus a parabola, conditioned on its
values at the boundaries, has the distribution of Brownian bridges conditioned not to meet. Building on these ideas, Calvert, Hammond and Hedge obtained through the Brownian LPP \[6,18\], among other things, control on the moment of the Radon-Nikodym derivative of the law of the Airy line ensemble with respect to the Brownian bridge and a modulus of continuity of the Airy\(_2\) process. In LPP on the lattice, control on the modulus of continuity of the prelimiting spatial fluctuations was obtained in \[1\] by Basu and Ganguly. In \[10\] Dauvergne and Virág, using better insight on the sampled Airy line ensemble, managed to show that the Airy line ensemble can be approximated, in total variation, by Brownian bridges, conditioned on not intersecting, without the conditioning on the lower boundary that appears in the Brownian Gibbs property.

Our work compares the Airy\(_2\) process with Brownian motion on a small interval. Our result on the Brownian regularity of Airy\(_2\) process belongs to point (1). In Theorem 2.2 we show that the Airy\(_2\) process is close in total variation to a rate 2 Brownian motion. This improves similar results under point (1). Our Corollary 2.3 shows that the regularity of the Airy\(_2\) process cannot be better than that of Brownian motion. This corollary can also be deduced from \[6, Theorem 1.1\].

Next we apply local stationarity to study two aspects of the behaviour of geodesics, their behaviour close to the endpoints which we refer to as stabilization, and the coalescence of point-to-point geodesics started from two points whose distance scales with \(N\). Let us start with the latter.

The first suite of methods for studying geodesics of growth models came from Newman and co-authors in planar first-passage percolation (FPP) \[20,21,25,28\]. FPP is another random growth model believed to be in the KPZ universality class. These methods were then used by Ferrari and Pimentel \[14\] and Coupier \[8\] to show that in exponential LPP, for a fixed direction, from any point on the lattice there exists a.s. a unique infinite geodesic and all these geodesics coalesce.

The first quantitative coalescence result in LPP came from Pimentel \[29\], who showed that two semi-infinite geodesics with the same direction, coming out of two points distance \(k\) apart, coalesce after about \(k^{3/2}\) steps. The tail of the decay was conjectured to be of exponent \(-2/3\). The proof used the distributional equality of the geodesic tree and its dual tree, and drew on existing bounds on the exit point of a geodesic in stationary LPP, derived with probabilistic proofs. The question of showing that the geodesics will not coalesce too far compared to \(k\) i.e. a matching upper bound, was left open. This question was then taken up by Basu, Sarkar and Sly \[3\] who proved the \(-2/3\) exponent for the lower bound and a matching upper bound. In that paper, the authors also proved a polynomial upper bound for point-to-point coalescence. In \[33\] Seppäläinen and Shen studied coalescence of semi-infinite geodesics. Without relying on integrable probability methods, they reproved the results of \[3\] up to a logarithmic error and obtained new upper and lower bounds of matching order on abnormally fast coalescence. In \[36\] Zhang proved the optimal bounds of \(-2/3\) for coalescence of two point-to-point geodesics from two points at distance \(k\). The proof relies on diffusive concentration of geodesic fluctuations coming from integrable probability.

The first coalescence question we consider is the following: if \(\pi^1\) and \(\pi^2\) are the geodesics from \((0, 0)\) and \((0, N^{2/3})\), respectively, that terminate at \((N, N)\), what is the typical distance of the coalescence point from the three endpoints? Results of that
flavour were proved in [19] and [2] for Brownian LPP, and in [13] for Poissonian LPP. We show in Theorem 2.8 and Theorem 2.9 that the coalescence point will not be too close, on the macroscopic scale $N$, to any of the end points. We emphasize that the methods used in [29] and [33] cannot be used here, as they rely on a well understood duality principle for stationary LPP geodesics [32].

We turn to stabilization. Let $\pi$ be the geodesic from $(0, 0)$ to $(N, N)$. Since the work of Johansson in [22] it is known that the fluctuations of $\pi$ around the diagonal at any macroscopic point should be of order $N^{2/3}$. If $1 \leq l \ll N$, as the geodesic is expected to have a self-similarity property, one would expect the fluctuation of $\pi$ in a square of size $l^2$ around the origin to be of order $l^{2/3}$. A proof of this was given in [3, Theorem 3] with diffusive concentration bounds. In [18] Hammond considered the regularity of the spatial fluctuation around the point $(l, l)$ for the Brownian LPP while for the lattice LPP with exponential weights this was proved in [1, Theorem 3] by Basu and Ganguly.

The behaviour of semi-infinite geodesics is somewhat better understood because they can be defined locally in terms of the Busemann functions, through the minimum gradient principle [16, 17, 32]. This implies that a link between point-to-point geodesics and infinite ones should provide better insight on the former. Consider a small square of side length $M$ around the origin. Denote by $T^{pp}$ the tree consisting of all the geodesics from points in the $M \times M$ square to the point $(N, N)$. Let $T^\infty$ be the tree of semi-infinite geodesics in direction $45^\circ$ started from the $M \times M$ square. Our stabilization result, Theorem 2.4, shows that on a square of side $M = \delta N^{2/3}$, the trees $T^{pp}$ and $T^\infty$ agree outside an event whose probability decays as a power of $\delta$.

We use this to show in (2.5), for example, that the fluctuations of the point-to-point geodesic in a small box of side $l$ around the origin are, with high probability, the same as those of a stationary geodesic for which the fluctuations are known to be of the order $l^{2/3}$.

Finally, we use stabilization to study coalescence of point-to-point geodesics to $(N, N)$ from two fixed starting points. For fixed $k > 0$ let $\pi^1$ and $\pi^2$ be the geodesics to $(N, N)$ started from $(0, 0)$ and $(0, k^{2/3})$, respectively. Let $p_c$ be the coalescence point of $\pi^1$ and $\pi^2$. Let $p_c^\infty$ be the coalescence point of the two semi-infinite geodesics in direction $(1, 1)$ started at the points $(0, 0)$ and $(0, k^{2/3})$. Theorem 2.6 shows that $p_c$ converges weakly to $p_c^\infty$. In this theorem we also show how our stabilization result gives an alternative route from the bounds on $p_c^\infty$ given in [3] to the tail decay of $|p_c|$ earlier derived in [36].

Evidence to the strength of the methods developed in this work can be seen in a recent work of one of the authors and Ferrari [5]. Precisely, in [5, Theorem 2.2] they obtain a lower bound on the probability of stabilization of the point to point profile increments to that of the stationary one in a neighbourhood of $o(N)$ in the time direction (as opposed to $o(N^{2/3})$ in this work) around the endpoint $(N, N)$. The main step towards such result is Theorem 2.4 in this paper. The idea is to show that geodesics terminating at $(N, N)$, with high probability, will cross a small spatial interval of size $o(N^{2/3})$ at time $N - o(N)$. Our Theorem 2.4 would then imply that these geodesics must have coalesced by that time. To execute this scheme, [5] employs a chaining argument from [4], that shows that geodesics fluctuations around their characteristic
along a time interval of size $O(N)$ is of order $O(N^{2/3})$. Moreover, [5, Theorem 2.6] gives an upper bound on the probability of stabilization in the setup of [5, Theorem 2.2]. This was done using the heavy traffic picture of the difference of Busemann functions developed in Sect. 5 and the Appendix of this work.

The correct exponent of stabilization of any geodesic leaving from a neighbourhood of $(0, 0)$ of size $O(N^{2/3})$ in space and $O(N)$ in time is 1/2, as was shown in [5]. It is not hard to verify that using concentration results from [24] one could improve the exponent in Theorem 2.4 from 3/8 to 1/2. However, the authors of this paper opt for simple probabilistic arguments for concentration bounds and therefore use suboptimal polynomial concentration bounds as in Lemma 5.5. Sharper concentration bounds using simple probabilistic arguments were developed in [11] and [5, Theorem 2.8].

The main body of our arguments only uses probabilistic methods. The only integrable-probability input used is the emergence of the Airy$_2$ process as the limit of the increments of the last-passage time.

**Some general notation and terminology**

$\mathbb{Z}_{\geq 0} = \{0, 1, 2, 3, \ldots\}$ and $\mathbb{Z}_{> 0} = \{1, 2, 3, \ldots\}$. For $n \in \mathbb{Z}_{> 0}$ we abbreviate $[n] = \{1, 2, \ldots, n\}$. A sequence of $n$ points is denoted by $x_{0,n} = (x_k)_{k=0}^n = \{x_0, x_1, \ldots, x_n\}$, and in case it is a path of length $n$ also by $x_\ast$. $a \lor b = \max\{a, b\}$, $a \land b = \min\{a, b\}$. $x^+ = x|_{x>0}$ and $x^- = |x|_{x<0}$. $C$ is a constant whose value can change from line to line.

The standard basis vectors of $\mathbb{R}^2$ are $e_1 = (1, 0)$ and $e_2 = (0, 1)$. For a point $x = (x_1, x_2) \in \mathbb{R}^2$ the $\ell^1$-norm is $|x| = |x_1| + |x_2|$. We call the $x$-axis occasionally the $e_1$-axis, and similarly the $y$-axis and the $e_2$-axis are the same thing. Inequalities on $\mathbb{R}^2$ are interpreted coordinatewise: for $x = (x_1, x_2) \in \mathbb{R}^2$ and $y = (y_1, y_2) \in \mathbb{R}^2$, $x \leq y$ means $x_1 \leq y_1$ and $x_2 \leq y_2$. Notation $[x, y]$ represents both the line segment $[x, y] = \{tx + (1-t)y : 0 \leq t \leq 1\}$ for $x, y \in \mathbb{R}$ and the rectangle $[x, y] = \{(z_i, z_2) \in \mathbb{R}^2 : x_i \leq z_i \leq y_i \text{ for } i = 1, 2\}$ for $x = (x_1, x_2), y = (y_1, y_2) \in \mathbb{R}^2$. The context will make clear which case is used. $0$ denotes the origin of both $\mathbb{R}$ and $\mathbb{R}^2$.

If $x < y$ we write $[x, y]$ for the set of integers $[x, y] \cap \mathbb{Z}$. If $x, y \in \mathbb{R}^2$ such that $x < y$ we denote by $[x, y] = \{x, y\} \cap \mathbb{Z}^2$. Nearest-neighbor edges $(x, x + e_i)$ are generically denoted by $e$. For $A \subset \mathbb{Z}^2$, $E(A)$ is the set of nearest-neighbor edges between points of $A$.

$X \sim \text{Exp}(\lambda)$ for $0 < \lambda < \infty$ means that random variable $X$ has exponential distribution with rate $\lambda$, in other words $\mathbb{P}(X > t) = e^{-\lambda t}$ for $t \geq 0$. The mean is $\mathbb{E}(X) = \lambda^{-1}$ and variance $\text{Var}(X) = \lambda^{-2}$. In general, $\overline{X} = X - \mathbb{E}(X)$ denotes a random variable $X$ centered at its mean.

To lighten on notation we generally ignore integer parts and treat for example $N\xi$ when $\xi \in \mathbb{R}^2$ as if it were a point on the lattice $\mathbb{Z}^2$ close to $N\xi$.

Let $\omega = \{\omega_x\}_{x \in \mathbb{Z}^2}$ be i.i.d. $\text{Exp}(1)$-distributed random weights on the vertices of $\mathbb{Z}^2$. For $o \in \mathbb{Z}^2$, define the last-passage percolation (LPP) process on $o + \mathbb{Z}^2_{\geq 0}$ by

$$G_{o,y} = \max_{x_\ast \in \Pi_{o,y}} \sum_{k=0}^{|y-o|} \omega_{x_k} \quad \text{for } y \in o + \mathbb{Z}^2_{\geq 0}. \tag{2.1}$$

$\Pi_{o,y}$ is the set of paths $x_\ast = (x_k)_{k=0}^n$ that start at $x_0 = o$, end at $x_n = y$ with $n = |y-o|$, and have increments $x_{k+1} - x_k \in \{e_1, e_2\}$. The a.s. unique path $\pi_{o,y}^o \in \Pi_{o,y}$ that attains the maximum in (2.1) is the geodesic from $o$ to $y$. A stationary LPP process $G_{o,y}^{\frac{1}{2}}$ associated with the direction $(1, 1)$ is defined similarly, but with altered weights on the boundary of the quadrant $o + \mathbb{Z}^2_{\geq 0}$ (precise definition follows below in (3.7)).

Let $\hat{R}^c = [N - cN^{\frac{2}{3}}, N]$ be the rectangle whose lower left corner is $(N - cN^{\frac{2}{3}}, N - cN^{\frac{2}{3}})$ and whose upper right corner is $(N, N)$. Let $\mathcal{E}(\hat{R}^c)$ be the set of directed edges in the subgraph of $\mathbb{Z}^2$ induced by the vertices in $\hat{R}^c$. Define the increment random variables indexed by the edges in $\mathcal{E}(\hat{R}^c)$ by

$$H_{(x,y)}^{N,c} = G_{o,y} - G_{o,x} \quad \text{and} \quad H_{(x,y)}^{\frac{1}{2},N,c} = G_{o,y}^{\frac{1}{2}} - G_{o,x}^{\frac{1}{2}},$$

and then the configurations of increment variables:

$$H^{N,c} = \{H_{(x,y)}^{N,c} : (x, y) \in \mathcal{E}(\hat{R}^c)\},$$

$$H^{\frac{1}{2},N,c} = \{H_{(x,y)}^{\frac{1}{2},N,c} : (x, y) \in \mathcal{E}(\hat{R}^c)\}.$$

Let $d_{TV}(\cdot, \cdot)$ denote the total variation distance between two probability distributions. If $X \sim \mu$ and $Y \sim \nu$, we also write $d_{TV}(X, Y) = d_{TV}(\mu, \nu)$. The following is the main result of the paper. It shows that on the scale of $N^{\frac{2}{3}}$, around the point $(N, N)$, local increments of $G$ jointly equal those of $G^{\frac{1}{2}}$ with high probability. The choice of direction $(1, 1)$ which determines the parameter $\frac{1}{2}$ in $G^{\frac{1}{2}}$, is made only to simplify exposition. The same result works for any direction vector $\xi$, with a different stationary process $G^0$ and constants that depend on $\xi$.

**Theorem 2.1** There exists $c_0 > 0$ and $C(c_0) > 0$ such that, for $c \in (0, c_0]$ and $N \geq 1$,

$$d_{TV}(H^{N,c}, H^{\frac{1}{2},N,c}) \leq Cc^{\frac{3}{5}}. \tag{2.2}$$

Let $A_2(x)$ denote the Airy$_2$ process and

$$L^N_x = 2^{-\frac{3}{4}}N^{-\frac{1}{2}}(G_{(0,0), (N+x(2N)^{\frac{2}{3}}, N-x(2N)^{\frac{2}{3}})} - 4N)$$
the process of LPP values on the antidiagonal at distance $2N$ from the origin. A continuous interpolation of $x \mapsto L^N_2$ converges in distribution to $A_2(x) - x^2$ as $N \to \infty$, in the uniform topology of continuous functions on compact sets. This was proved by Johansson [23] for LPP with geometric weights and in [15, Cor. 2.4] for the case of exponential weights we use here. Set

$$A'_2(x) = A_2(x) - A_2(0) - x^2.$$ 

Let $B$ be a two-sided Brownian motion of variance 2 on $\mathbb{R}$. As a consequence of Theorem 2.1, our next result shows that locally, the Airy$_2$ process looks like a Brownian motion in a strong sense. The proof is given at the end of Sect. 5.

**Theorem 2.2** There exists $c_0 > 0$ and $C(c_0) > 0$, such that for $c \leq c_0$

$$d_{TV}(A'_2|[-c,c], B|[-c,c]) \leq Cc^{\frac{3}{8}}.$$ 

By the transportation cost representation of the total variation distance [34, Thm. 1.27, p. 44], as a corollary we have the existence of a coupling between $A'_2|[-c,c]$ and $B|[-c,c]$ such that

$$P\{A'_2|[-c,c] = B|[-c,c]\} \geq 1 - Cc^{\frac{3}{8}}. \quad (2.3)$$

Precisely, $P$ is a probability measure on the product space $C([-c,c])^2$ of pairs of continuous functions on $[-c,c]$ and the marginals of $P$ are the distributions of $A'_2|[-c,c]$ and $B|[-c,c]$.

Let $I \subset \mathbb{R}$ be a compact interval containing the origin, and let

$$\omega_B(t) = 2\sqrt{t \log(t)^{-1}}$$

be the modulus of continuity of the Brownian motion. In [18, Theorem 1.11] Hammond showed that the regularity of the Airy process is not worse than that of a Brownian motion i.e.

$$\sup_{t \in I} \limsup_{h \downarrow 0} \frac{A_2(t + h) - A_2(t)}{\omega_B(h)} < \infty \quad \text{with probability 1.}$$

As a corollary of Theorem 2.2, we show that the regularity of the Airy$_2$ process is not better than that of a Brownian motion. As was mentioned earlier, this can also be deduced from [6, Theorem 1.1].

**Corollary 2.3**

$$\sup_{t \in I} \limsup_{h \downarrow 0} \frac{A_2(t + h) - A_2(t)}{\omega_B(h)} \geq 1 \quad \text{with probability 1.}$$

We turn to the stabilization results. The set of possible asymptotic velocities or direction vectors of semi-infinite up-right paths is $\mathcal{U} = \{(t, 1 - t) : 0 \leq t \leq 1\}$, with
Local stationarity in exponential last-passage percolation

The infinite geodesic \( \pi_{0, \infty}^{\xi} \) and the geodesic \( \pi_{0, N}^{\xi} \) agree in the box \( \mathcal{R}^{\xi, f} \). On the event \( S^{\xi, f} \) for any \( x \in \mathcal{R}^{\xi, f} \), the geodesics \( \pi_{x, \infty}^{\xi} \) and \( \pi_{x, N}^{\xi} \) have the same restriction on the small square \( \mathcal{R}^{\xi, f} \).

relative interior \( \text{ri} \mathcal{U} = \{(t, 1-t) : 0 < t < 1\} \). For \( \xi \in \text{ri} \mathcal{U} \), let \( \mathcal{R}^{\xi, M} = [0, M \xi] \) be the rectangle whose lower left corner is \((0, 0)\) and upper right corner is \( M \xi \). Let \( \pi \) be an up-right path whose origin is \((0, 0)\). Let \( I^\pi = \{i : \pi_i \in \mathcal{R}^{\xi, M}\} \) be the set of indices of \( \pi \) for which \( \pi \) is in \( \mathcal{R}^{\xi, M} \). We define \( \mathcal{P}^{\xi, M}(\pi) \) to be the restriction of the path \( \pi \) to the rectangle \( \mathcal{R}^{\xi, M} \), that is, \( \mathcal{P}^{\xi, M}(\pi) \) is a finite path defined by

\[
(\mathcal{P}^{\xi, M}(\pi))_i = \pi_i \quad \forall i \in I^\pi.
\]

Let \( \pi_{x, \infty}^{\xi} \) be the infinite geodesic started from \( x \) whose direction is \( \xi \) [32]. For \( M < N \), define the following event

\[
S^{\xi, M} = \{\mathcal{P}^{\xi, M}(\pi_{x, \infty}^{\xi}) = \mathcal{P}^{\xi, M}(\pi_{x, N}^{\xi}) \text{ for all } x \in \mathcal{R}^{\xi, M}\}.
\]

\( S^{\xi, M} \) is the event on which any geodesic leaving from any site \( x \in \mathcal{R}^{\xi, M} \) and terminating at \( \xi N \) agree with the infinite geodesic \( \pi_{x, \infty}^{\xi} \) on \( \mathcal{R}^{\xi, M} \) (see Fig. 1). Our first result gives a lower bound on the probability of stabilization on small enough rectangles.

**Theorem 2.4** For any \( \xi \in \text{ri} \mathcal{U} \) and \( c > 0 \) there exists a constant \( C = C(\xi, c) > 0 \), locally bounded in \( c \), such that the following holds: whenever \( 0 < M \leq c N^{-\frac{3}{8}} \),

\[
\mathbb{P}(S^{\xi, M}) \geq 1 - C N^{-\frac{1}{4}} M^{\frac{3}{8}}.
\]

As was mentioned earlier, stabilization can be used to study the behaviour of point-to-point geodesics close to their endpoints. The following result shows that around
the origin, on the scale of \( o(N) \) the geodesic has transversal fluctuations of exponent \( 2/3 \). A result of that flavour was obtained in [3, Theorem 3].

**Corollary 2.5** There exists \( C(\xi) > 0 \) such that for \( l \in \mathbb{Z}_{>0} \)

\[
\lim_{N \to \infty} \mathbb{P}(|\pi^{0,N\xi}_l - l\xi| > r l^{2/3}) \leq Cr^{-3}. \tag{2.7}
\]

**Proof** For fixed \( M \), on \( \mathcal{R}^{\xi,M} \) consider the stationary backward LPP \( \hat{\Pi}^{\rho}_{M\xi + e_1 + e_2,0} \) (precise definition below in (3.14)), starting from the point \( M\xi + e_1 + e_2 \) and terminating at the origin. Let us denote its geodesic by \( \hat{\pi}^\rho \). Let \( \pi^{0,N\xi} \) be the geodesic of LPP starting from the origin 0 and terminating at \( N\xi \). Theorem 2.4 and the fact that the distribution of an infinite geodesic going backwards is that of a stationary one (see the proof of Theorem 2.4) imply that

\[
\lim_{N \to \infty} d_{TV}(\mathbb{P}^{\xi,M}(\hat{\pi}^\rho), \mathbb{P}^{\xi,M}(\pi^{0,N\xi})) = 0. \tag{2.8}
\]

(2.7) follows from (2.8) and well known bounds on the fluctuations of stationary geodesics [31, Theorem 5.3]. \( \square \)

Stabilization relates results on semi-infinite geodesics with results on point-to-point geodesics. Consider the points \( q_1 = (0,0) \) and \( q_2 = k^{2/3}e_2 \) for some \( k \geq 1 \). Let \( \pi^{q_1,\infty\xi} \) and \( \pi^{q_2,\infty\xi} \) be the semi-infinite geodesics in direction \( \xi \) started from \( q_1 \) and \( q_2 \), respectively. Let \( p_c^\infty \) be the point in \( \pi^{q_1,\infty\xi} \cap \pi^{q_2,\infty\xi} \) that is closest to the origin. Similarly let \( p_c = (p_c(1), p_c(2)) \) be the closest point to the origin in \( \pi^{q_1,N\xi} \cap \pi^{q_2,N\xi} \). In [3] Basu, Sarkar and Sly showed that there exist universal constants \( C_1, C_2, R_0 \) such that for every \( k > 0 \) and \( R > R_0 \)

\[
C_1 R^{-2/3} \leq \mathbb{P}(|p_c^\infty| > Rk) \leq C_2 R^{-2/3}. \tag{2.9}
\]

Moreover, they showed that there exist \( C, R_0, c > 0 \) such that for every \( k > 0 \) and \( R > R_0 \)

\[
\limsup_{N \to \infty} \mathbb{P}(p_c(1) > Rk) \leq CR^{-c}. \tag{2.10}
\]

The exponent \( c \) in (2.10) was not identified but was conjectured to be \( 2/3 \). This was recently settled by Zhang in [36]. The theorem below shows how our stabilization result transfers the bounds (2.9) from \( p_c^\infty \) to \( p_c \).

**Theorem 2.6** The sequence \( |p_c| \) converges weakly to \( |p_c^\infty| \). Moreover, there exist universal constants \( C_1, C_2, R_0 > 0 \) such that for \( R > R_0 \), for any \( k \geq 1 \) and \( N > (Rk)^5 \)

\[
C_1 R^{-2/3} \leq \mathbb{P}(|p_c| > Rk) \leq C_2 R^{-2/3}. \tag{2.11}
\]
Proof If exactly one of the events \(|p^\infty_c| > Rk\), \(|p_c| > Rk\) occurs then paths must not have coalesced in \(\mathcal{R}^\xi, \frac{1}{2} Rk\) in other words, \(S^\xi, \frac{1}{2} Rk\) does not occur. Therefore, via the symmetric difference and using Theorem 2.4,

\[
\left| \mathbb{P}(|p^\infty_c| > Rk) - \mathbb{P}(|p_c| > Rk) \right| \leq \mathbb{P}(\{|p^\infty_c| > Rk\} \Delta \{|p_c| > Rk\}) \\
\leq \mathbb{P}(\{(S^\xi, \frac{1}{2} Rk)^c\}) \leq CN^{-\frac{1}{4}} (Rk)^{\frac{3}{8}},
\]

which shows that \(|p_c|\) converges weakly to \(|p^\infty_c|\). Taking \(N = (Rk)^5\) and using Theorem 2.4

\[
\mathbb{P}(|p^\infty_c| > Rk) - CR^{-\frac{7}{8}} \leq \mathbb{P}(|p_c| > Rk) \leq \mathbb{P}(|p^\infty_c| > Rk) + CR^{-\frac{7}{8}}.
\]

(2.11)

As \(7/8 > 2/3\), (2.11) and (2.9) imply the result. \(\Box\)

Remark 2.7 We note here that in terms of the conditions on \(N\), the results in [36, Theorem 1.1] are sharper. Indeed, in [36, Theorem 1.1] the requirement on \(N\) is \(N > RK\) while in Theorem 2.6 \(N > (Rk)^5\).

We turn to coalescence results where the distance between the starting point is of order \(N^{2/3}\). In \(\mathcal{R}^\xi, N = [0, N\xi]\), consider the points \(o = \xi N\), \(q^1 = (0, 0)\) and \(q^2 = aN^{\frac{2}{3}} e_2\) where \(a > 0\) and where we assume that \(N\) is large enough so that \(q^2 \in \mathcal{R}^\xi, N\). Let

\[
C^{a, \xi} = \pi q_1^{1, o} \cap \pi q_2^{2, o},
\]

(2.12)

be the points shared by the geodesics starting from \(q_i\) and terminating at \(o\) for \(i \in \{1, 2\}\). We define the coalescence point \(p_c\) to be the unique point such that

\[
p_c \in C^{a, \xi} \quad \text{and} \quad p_c \leq x \quad \forall x \in C^{a, \xi},
\]

(2.13)

as in Fig. 2. Our next result shows that the point \(p_c\) is not likely to be too close to the point \(o\) on a macroscopic scale.

Theorem 2.8 For every \(a > 0\) and \(\xi \in \mathbb{R}_+\), there exists a constant \(C(\xi, a) > 0\), locally bounded in \(a\), such that for every \(0 < \alpha < 1\) and \(N > N(\alpha)\)

\[
\mathbb{P}(|o - p_c| \leq \alpha N) \leq C\alpha^{\frac{3}{8}}.
\]

(2.14)

The following complementary result shows that the geodesics \(\pi q_1^{1, o}\) and \(\pi q_2^{2, o}\) do not coalesce too close to their origins on a macroscopic scale. Although the proof does not require local stationarity, we state it for completeness.

Theorem 2.9 For every \(a > 0\) and \(\xi \in \mathbb{R}_+\), there exists a constants \(C(\xi, a) > 0\) such that for every \(0 < \alpha < 1\) and \(N > N(\alpha)\)

\[
\mathbb{P}(|q_2^2 - p_c| \leq \alpha N) \leq Ca^2.
\]
3 Preliminaries

3.1 Ordering of paths

We construct a partial order on directed paths in $\mathbb{Z}^2$. For $x, y \in \mathbb{Z}^2$ we write $x \preceq y$ if $y$ is below and to the right of $x$, i.e.

$$x_1 \leq y_1 \quad \text{and} \quad x_2 \geq y_2.$$  \hfill (3.1)

We also write $x \prec y$ if

$$x \preceq y \quad \text{and} \quad x \neq y.$$  \hfill (3.2)

If $A, B \subset \mathbb{Z}^2$, we write $A \preceq B$ if

$$x \preceq y \quad \forall x \in A, y \in B.$$  \hfill (3.3)

A down-right path is a bi-infinite sequence $\gamma = (y_k)_{k \in \mathbb{Z}}$ in $\mathbb{Z}^2$ such that $y_k - y_{k-1} \in \{e_1, -e_2\}$ for all $k \in \mathbb{Z}$. Let $\mathcal{DR}$ be the set of infinite down-right paths in $\mathbb{Z}^2$. For two
up-right paths $\gamma_1, \gamma_2$ in $\mathbb{Z}^2$,

$$\gamma_1 \preceq \gamma_2 \quad \text{if} \quad \gamma_1 \cap \mathcal{Y} \preceq \gamma_2 \cap \mathcal{Y} \quad \forall \mathcal{Y} \in \mathcal{DR},$$

where we take the inequality to be vacuously true if one of the intersections in (3.4) is empty (see Fig. 3).

### 3.2 Stationary LPP

For a base point $o = (o_1, o_2) \in \mathbb{Z}^2$ and a parameter value $\rho \in (0, 1)$ we introduce the stationary last-passage percolation process $G^\rho_{o, \cdot}$ on $o + \mathbb{Z}^2_{\geq 0}$. This process has boundary conditions given by two independent sequences

$$\{I^\rho_{o+ie_1}\}_{i=1}^\infty \quad \text{and} \quad \{J^\rho_{o+je_2}\}_{j=1}^\infty$$

of i.i.d. random variables with marginal distributions $I^\rho_{o+e_1} \sim \text{Exp}(1-\rho)$ and $J^\rho_{o+e_2} \sim \text{Exp}(\rho)$. Put $G^\rho_{o, o} = 0$ and on the boundaries

$$G^\rho_{o, o+ke_1} = \sum_{i=1}^k I^\rho_{o+ie_1} \quad \text{and} \quad G^\rho_{o, o+le_2} = \sum_{j=1}^l J^\rho_{o+je_2}.$$

Then in the bulk for $x = (x_1, x_2) \in o + \mathbb{Z}^2_{\geq 0}$,

$$G^\rho_{o, x} = \max_{1 \leq k \leq x_1 - o_1} \left\{ \sum_{i=1}^k I^\rho_{o+ie_1} + G^\rho_{o+ke_1+e_2, x} \right\} \vee \max_{1 \leq \ell \leq x_2 - o_2} \left\{ \sum_{j=1}^\ell J^\rho_{o+je_2} + G^\rho_{o+\ell e_2+e_1, x} \right\}.$$
For a northeast endpoint \( p \in o + \mathbb{Z}^2_{\geq 0} \), let \( Z_{o,p}^\rho \) be the signed exit point of the geodesic \( \pi^{o,p} \) of \( G_{o,p}^\rho \) from the west and south boundaries of \( o + \mathbb{Z}^2_{\geq 0} \). More precisely,

\[
Z_{o,p}^\rho = \begin{cases} 
\arg \max_k \{ \sum_{i=1}^k L_{o+ie_1} + G_{o+k e_1 + e_2,x} \}, & \text{if } \pi_1^{o,p} = o + e_1, \\
-\arg \max_\ell \{ \sum_{j=1}^\ell J_{o+j e_2} + G_{o+\ell e_2 + e_1,x} \}, & \text{if } \pi_1^{o,p} = o + e_2.
\end{cases}
\tag{3.8}
\]

The value \( G_{o,x}^\rho \) can be determined by (3.6) and the recursion

\[
G_{o,x}^\rho = \omega_x + G_{o,x-e_1}^\rho \lor G_{o,x-e_2}^\rho.
\tag{3.9}
\]

Relation (3.9) implies that one can backtrack the geodesic \( \pi^{o,p} \) in the box \([o + e_1 + e_2, p]\) in the following way; for each (directed) edge \((x, y)\) in \([o + e_1 + e_2, p]\) assign the weight \(w_{x,y} = G_{o,y}^\rho - G_{o,x}^\rho\). Let \( m = |p - o|\), and \( p_i = \pi_i^{o,p} \). Then

\[
p_m = p, \\
p_i = \begin{cases} 
 p_{i+1} - e_1 & \text{if } w_{p_{i+1}-e_1, p_{i+1}} < w_{p_{i+1}-e_2, p_{i+1}}, \\
 p_{i+1} - e_2 & \text{if } w_{p_{i+1}-e_1, p_{i+1}} > w_{p_{i+1}-e_2, p_{i+1}}
\end{cases}
\tag{3.10}
\]

In other words, we trace the geodesic \( \pi^{o,p} \) backwards up to the exit point from the boundaries, by following the edges of minimal \( G_{o,p}^\rho \) increments.

The following result will be used repeatedly in this paper.

**Lemma 3.1** [31, Corollary 5.10] Fix \( 0 < \rho < 1 \) and let \((m, n) = (N(1 - \rho)^2, N\rho^2)\). There exists \( C(\rho) > 0 \) such that for \( N > 0 \) such that \( m \land n \geq 1 \) and \( r > 0 \)

\[
\mathbb{P}\left( Z_{(0,0),(m,n+rN^{2/3})}^\rho \geq 1 \right) \leq \frac{C}{r^3}, \\
\mathbb{P}\left( Z_{(0,0),(m,n-rN^{2/3})}^\rho \leq -1 \right) \leq \frac{C}{r^3}.
\]

The constant \( C \) is locally bounded in its parameter. Similar results hold for the exit point of the stationary geodesic going from the origin to the points \((m + rN^{2/3}, n)\) and \((m - rN^{2/3}, n)\).

### 3.3 Backward LPP

Next we consider LPP maximizing down-left paths. For \( y \leq o \), define

\[
\hat{G}_{o,y} = G_{y,o}.
\tag{3.11}
\]

For each \( o \in \mathbb{Z}^2 \) and a parameter value \( \rho \in (0, 1) \) define a stationary last-passage percolation processes \( \hat{G}^\rho \) on \( o + \mathbb{Z}^2_{\leq 0} \), with boundary variables on the north and east.
in the following way. Let

\[ \{ I^p_{o-i e_1} \}_{i=1}^\infty \quad \text{and} \quad \{ J^p_{o-j e_2} \}_{j=1}^\infty \]  

be mutually independent sequences of i.i.d. random variables with marginal distributions \( I^p_{o-i e_1} \sim \text{Exp}(1 - \rho) \) and \( J^p_{o-j e_2} \sim \text{Exp}(\rho) \). The boundary variables in (3.5) and those in (3.12) are taken independent of each other. Put \( \hat{G}^p_{o, o} = 0 \) and on the boundaries

\[ \hat{G}^p_{o, o-ke_1} = \sum_{i=1}^k I_{o-i e_1} \quad \text{and} \quad \hat{G}^p_{o, o-le_2} = \sum_{j=1}^l J_{o-j e_2}. \]  

Then in the bulk for \( x = (x_1, x_2) \in o + \mathbb{Z}^2_{\leq 0} \),

\[ \hat{G}^p_{o, x} = \max_{1 \leq k \leq o_1 - x_1} \left\{ \sum_{i=1}^k I_{o-i e_1} + \hat{G}^p_{o-ke_1-e_2, x} \right\} \vee \max_{1 \leq \ell \leq o_2 - x_2} \left\{ \sum_{j=1}^\ell J_{o-j e_2} + \hat{G}^p_{o-le_2-e_1, x} \right\}. \]  

For a southwest endpoint \( p \in o + \mathbb{Z}^2_{\leq 0} \), let \( \hat{Z}^p_{o, p} \) be the signed exit point of the geodesic \( \pi^{o, p}_{\cdot} \) of \( \hat{G}^p_{o, p} \) from the north and east boundaries of \( o + \mathbb{Z}^2_{\leq 0} \). Precisely,

\[ \hat{Z}^p_{o, x} = \begin{cases} \arg \max_k \left\{ \sum_{i=1}^k I_{o-i e_1} + \hat{G}^p_{o-ke_1-e_2, x} \right\}, & \text{if } \pi^{o, x}_1 = o - e_1, \\ -\arg \max_\ell \left\{ \sum_{j=1}^\ell J_{o-j e_2} + \hat{G}^p_{o-le_2-e_1, x} \right\}, & \text{if } \pi^{o, x}_1 = o - e_2. \end{cases} \]  

Similar to (3.10), one can backtrack the geodesic \( \pi^{o, p}_{\cdot} \) in the box \( [p, o - e_1 - e_2] \) in the following way; for each edge \((x, y)\) (where \( y \leq x \)) in \([p, o - e_1 - e_2]\) assign the weight

\[ \hat{w}_{y, x} = \hat{G}^p_{o, y} - \hat{G}^p_{o, x}. \]  

Letting \( p_i = \pi^{o, p}_{i, \cdot} \), we have

\[ p_m = p, \]

\[ p_i = \begin{cases} p_i + e_1 & \text{if } \hat{w}_{p_i+1, p_i+1+e_1} < \hat{w}_{p_i+1, p_i+1+e_2} \quad \text{for } |\hat{Z}^p_{o, p}| \leq i \leq m - 1, \\ p_i + e_2 & \text{if } \hat{w}_{p_i+1, p_i+1+e_1} > \hat{w}_{p_i+1, p_i+1+e_2}. \end{cases} \]

Since

\[ \omega_x = (\hat{G}^p_{o, x} - \hat{G}^p_{o, x+e_1}) \land (\hat{G}^p_{o, x} - \hat{G}^p_{o, x+e_2}) \]  

we see that (3.17) can be written as

\[ \pi^{o, p}_{m, \cdot} = p \]

\[ \omega_{\pi^{o, p}_{i, \cdot}} = \omega_{\pi^{o, p}_{i, \cdot}, \pi^{o, p}_{i-1, \cdot}}. \]
Illustration of Lemma 3.2. Path $u-x-y$ is a geodesic of $G_{u,y}$ and path $v-x-y$ is a geodesic of $G_{v,y}^{[u]}$.

### 3.4 Nested LPP processes

The following is a construction we shall refer to often. For general weights $\{Y_x\}_{x \in \mathbb{Z}^2}$ on the lattice and a point $u \in \mathbb{Z}^2$, let $G_{u,x}$ be the LPP defined by

$$G_{u,x} = \max_{x_* \in \Pi_{u,x}} \sum_{k=0}^{x-u} Y_{x_k} \quad \text{for } x \in u + \mathbb{Z}^2_{\geq 0}. \quad (3.19)$$

Now let $v \in \mathbb{Z}^2$ be such that $u \leq v$. One can construct a new LPP on $\mathbb{Z}^2_{>0}$ as follows. Define the south-west boundary weights

$$I_{v+ke_1}^{[u]} = G_{u,v+ke_1} - G_{u,v+(k-1)e_1} \quad \text{for } 1 \leq k \leq \infty,$$

$$J_{v+ke_2}^{[u]} = G_{u,v+ke_2} - G_{u,v+(k-1)e_2} \quad \text{for } 1 \leq k \leq \infty. \quad (3.20)$$

Let $\{G_{v,x}^{[u]}\}_{x \in \mathbb{Z}_{>0}}$ be the LPP defined through relations (3.6)–(3.7) using the base point $o = v$, the boundary conditions (3.20) and the bulk weights $\{Y_x\}_{x \in \mathbb{Z}_{>0}}$. We call $G^{[u]}$ the induced LPP at $v$ by $G_{u,x}$. The superscript $[u]$ indicates that $G^{[u]}$ uses boundary weights determined by the process $G_{u,\bullet}$ with base point $u$. Figure 4 illustrates the next lemma. The proof of the lemma is elementary.

**Lemma 3.2** Let $u \leq v \leq y$ in $\mathbb{Z}^2$. Then $G_{u,y} = G_{u,v} + G_{v,y}^{[u]}$. The restriction of any geodesic of $G_{u,y}$ to $v + \mathbb{Z}^2_{\geq 0}$ is part of a geodesic of $G_{v,y}^{[u]}$. The edges with one endpoint in $v + \mathbb{Z}^2_{>0}$ that belong to a geodesic of $G_{v,y}^{[u]}$ extend to a geodesic of $G_{u,y}$.

In case the process inherited is associated to a stationary process $G^\rho$ we shall use the notation $G^{\rho, [u]}$ to indicate the density $\rho$ as well. Similarly, if $\widehat{G}_{u,x}$ is a LLP on $\mathbb{Z}_{<u}$ for some $u \in \mathbb{Z}^2$, if $v < u$, we can construct the induced process $\widehat{G}_{v,x}^{[u]}$ on $\mathbb{Z}_{<v}$. A result similar to Lemma 3.2 holds for $\widehat{G}_{u,x}$ and $\widehat{G}_{v,x}^{[u]}$. 

\(\blacksquare\) Springer
4 Busemann functions

4.1 Existence and properties of Busemann functions

Let $(\Omega, \mathcal{F}, \mathbb{P})$ be a probability space and let $\{\tau_z\}_{z \in \mathbb{Z}^2}$ be a group of translations on $\Omega$.

**Definition 4.1** A measurable function $B : \Omega \times \mathbb{Z}^2 \times \mathbb{Z}^2 \to \mathbb{R}$ is a covariant cocycle if it satisfies these two conditions for $\mathbb{P}$-a.e. $\omega$ and all $x, y, z \in \mathbb{Z}^2$:

\begin{align}
B(\omega, x + z, y + z) &= B(\tau_z \omega, x, y) \quad (4.1) \\
B(\omega, x, y) + B(\omega, y, z) &= B(\omega, x, z). \quad (4.2)
\end{align}

Given a down-right path $\mathcal{Y} \in \mathcal{DR}$, the lattice decomposes into a disjoint union $\mathbb{Z}^2 = \mathcal{G}_- \cup \mathcal{Y} \cup \mathcal{G}_+$ where the two regions are

$$
\mathcal{G}_- = \{ x \in \mathbb{Z}^2 : \exists j \in \mathbb{Z}_{>0} \text{ such that } x + j(e_1 + e_2) \in \mathcal{Y} \}$$

and

$$
\mathcal{G}_+ = \{ x \in \mathbb{Z}^2 : \exists j \in \mathbb{Z}_{>0} \text{ such that } x - j(e_1 + e_2) \in \mathcal{Y} \}.
$$

**Definition 4.2** Let $0 < \alpha < 1$. Let us say that a process

$$
\{ \eta_x, I_x, J_x, \tilde{\eta}_x : x \in \mathbb{Z}^2 \} \quad (4.3)
$$

is an exponential-$\alpha$ last-passage percolation system if the following properties (a)–(b) hold.

(a) The process is stationary with marginal distributions

$$
\eta_x, \tilde{\eta}_x \sim \text{Exp}(1), \quad I_x \sim \text{Exp}(1 - \alpha), \quad \text{and} \quad J_x \sim \text{Exp}(\alpha). \quad (4.4)
$$

For any down-right path $\mathcal{Y} = (y_k)_{k \in \mathbb{Z}}$ in $\mathbb{Z}^2$, the random variables

$$
\{ \tilde{\eta}_z : z \in \mathcal{G}_- \}, \quad \{ t([y_{k-1}, y_k]) : k \in \mathbb{Z} \}, \quad \text{and} \quad \{ \eta_x : x \in \mathcal{G}_+ \} \quad (4.5)
$$

are all mutually independent, where the undirected edge variables $t(e)$ are defined as

$$
t(e) = \begin{cases} 
I_x & \text{if } e = \{x - e_1, x\} \\
J_x & \text{if } e = \{x - e_2, x\}. 
\end{cases} \quad (4.6)
$$

(b) The following equations are in force at all $x \in \mathbb{Z}^2$:

$$
\tilde{\eta}_{x-e_1-e_2} = I_{x-e_2} \land J_{x-e_1} \quad (4.7)
$$
\[ I_x = \eta_x + (I_{x-e_2} - J_{x-e_1})^+ \quad (4.8) \]
\[ J_x = \eta_x + (I_{x-e_2} - J_{x-e_1})^- . \quad (4.9) \]

The following theorem can be found in the lecture notes [31]. The Busemann limit (4.14) below uses the characteristic direction associated with the parameter \( \rho \in (0, 1) \), defined by

\[ \xi(\rho) = \left( \frac{(1-\rho)^2}{(1-\rho)^2 + \rho^2}, \frac{\rho^2}{(1-\rho)^2 + \rho^2} \right) \quad (4.10) \]

When \( \xi \in \mathbb{R}^2 \) is given, \( \rho(\xi) \) denotes the unique parameter value \( \rho \) that satisfies (4.10).

**Theorem 4.3** For each \( 0 < \alpha < 1 \) there exist a stationary cocycle \( B^\alpha \) and a family of random weights \( \{X^\alpha_x\}_{x \in \mathbb{Z}^2} \) on \((\Omega, \mathcal{F}, \mathbb{P})\) with the following properties.

(i) For each \( 0 < \alpha < 1 \), process

\[ \{X^\alpha_x, B^\alpha_{x-e_1,x}, B^\alpha_{x-e_2,x}, \omega_x : x \in \mathbb{Z}^2\} \quad (4.11) \]

is an exponential-\( \alpha \) last-passage system as described in Definition 4.2.

(ii) There exists a single event \( \Omega_2(\alpha) \) of full probability such that for all \( \omega \in \Omega_2 \), all \( x \in \mathbb{Z}^2 \) and all \( \lambda < \rho \) in \((0, 1)\) we have the inequalities

\[ B^\lambda_{x,x+e_1}(\omega) \leq B^\rho_{x,x+e_1}(\omega) \quad \text{and} \quad B^\lambda_{x,x+e_2}(\omega) \geq B^\rho_{x,x+e_2}(\omega). \quad (4.12) \]

Furthermore, for all \( \omega \in \Omega_2 \) and \( x, y \in \mathbb{Z}^2 \), the function \( \lambda \mapsto B^\lambda_{x,y}(\omega) \) is right-continuous with left limits.

(iii) For each fixed \( 0 < \alpha < 1 \) there exists an event \( \Omega_2^{(\alpha)} \) of full probability such that the following holds: for each \( \omega \in \Omega_2^{(\alpha)} \) and any sequence \( v_n \in \mathbb{Z}^2 \) such that \( |v_n| \to \infty \) and

\[ \lim_{n \to \infty} \frac{v_n}{|v_n|} = \xi(\alpha) \quad (4.13) \]

we have the limits

\[ B^\alpha_{x,y}(\omega) = \lim_{n \to \infty} [G_{x,v_n}(\omega) - G_{y,v_n}(\omega)] \quad \forall x, y \in \mathbb{Z}^2. \quad (4.14) \]

The LPP process \( G_{x,y} \) is now defined by (2.1). Furthermore, for all \( \omega \in \Omega_2^{(\alpha)} \) and \( x, y \in \mathbb{Z}^2 \),

\[ \lim_{\lambda \to \alpha} B^\lambda_{x,y}(\omega) = B^\alpha_{x,y}(\omega). \quad (4.15) \]

### 4.2 Busemann functions and infinite geodesics

Fix \( x \in \mathbb{Z}^2 \). An infinite up-right path \( \pi_{x,\infty} \) originating at \( x \) is called a geodesic if for all \( m, n \in \mathbb{Z}_{>0} \) such that \( m < n \), the path \( \{\pi_{l,\infty}^{x,\infty}\}_{l \in [m,n]} \) is a geodesic. We say a
Local stationarity in exponential last-passage percolation 131

geodesic has direction $\xi \in \text{ri } \mathcal{U}$ if

$$\lim_{n \to \infty} \frac{\pi_n^{x,\infty}}{\pi_n^{x,\infty}(1)} = \frac{\xi_2}{\xi_1}. \quad (4.16)$$

It is known that for a given $\xi \in \text{ri } \mathcal{U}$, with probability one, from every point $x \in \mathbb{Z}^2$ there is a unique semi-infinite geodesic $\pi^{x,\infty}_{x,\infty}$ in direction $\xi$. Busemann functions can be used to construct these semi-infinite geodesics. Consider the family of random variables

$$\{B^\alpha_{x-e_1,x}, B^\alpha_{x-e_2,x}, \omega_x : x \in \mathbb{Z}^2\}\quad (4.17)$$

defined in (4.11). Let $\xi := \xi(\alpha)$ be the characteristic direction associated with $\alpha$. One can trace the infinite geodesic $\pi^{x,\infty}_{x,\infty}$ by following the gradient of the Busemann function $B^\alpha$. (This is developed for example in [16].) Let $\{p_i\}_{i \in \mathbb{Z}_{\geq 0}}$ be an enumeration of the vertices in $\pi^{x,\infty}_{x,\infty}$, i.e.

$$p_0 = x, \quad p_i = \pi^{x,\infty}_{x,\infty} i \in \mathbb{Z}_{\geq 0},$$

where $p_0 = x$. Then the vertices $\{p_i\}_{i \in \mathbb{Z}_{\geq 0}}$ are given recursively through

$$p_i = \begin{cases} p_{i-1} + e_1 & \text{if } B^\alpha_{p_{i-1},p_{i-1}+e_1} < B^\alpha_{p_{i-1},p_{i-1}+e_2} \\ p_{i-1} + e_2 & \text{if } B^\alpha_{p_{i-1},p_{i-1}+e_1} > B^\alpha_{p_{i-1},p_{i-1}+e_2} \end{cases} \quad (4.18)$$

(Equality happens with probability zero on the right, due to the independence of $B^\alpha_{x,x+e_1}$ and $B^\alpha_{x,x+e_2}$.) Note that in (4.18) $p_i$ is attained by taking an up \ right step from the point $p_{i-1}$ in the direction of the minimal increment of the Busemann function. Since $\omega_x = B^\alpha_{x,x+e_1} \wedge B^\alpha_{x,x+e_2}$, $\pi^{x,\infty}_{x,\infty}$ is the unique path that satisfies

$$\pi^{x,\infty}_0 = x \quad \omega_{p_i} = B^\alpha_{p_i^{x,\infty},p_{i+1}^{x,\infty}}. \quad (4.19)$$

The monotonicity (4.12) of Busemann functions implies a spatial ordering of geodesics:

**Lemma 4.4** Let $x \in \mathbb{Z}^2$ and $\xi_1, \xi_2 \in \text{ri } \mathcal{U}$ such that $\xi_1 \preceq \xi_2$. For $i \in \{1, 2\}$ let $\pi^{x,\xi_i}_{x,\infty}$ be the infinite geodesic starting from $x$ in direction $\xi_i$. Then

$$\pi^{x,\xi_1}_{x,\infty} \preceq \pi^{x,\xi_2}_{x,\infty}. \quad (4.20)$$

**4.3 Coupling Busemann functions**

In [12, Theorem 3.2] a coupling between Busemann functions of different densities was developed, expressed in terms of queueing mappings.
Lemma 4.5 Let $0 < \rho < \bar{\rho} < 1$. The coupling of $B^\rho$ and $B^{\bar{\rho}}$ in Theorem 4.3 has the following properties.

(i) For every $x \in \mathbb{Z}^2$

$$B^\rho_{x,x+e_2} \geq B^{\bar{\rho}}_{x,x+e_2}$$

$$B^{\bar{\rho}}_{x,x+e_1} \geq B^\rho_{x,x+e_1},$$

(ii) For every $x \in \mathbb{Z}^2$ we have the joint distributions

$$\left(B^\rho_{x+i_1 e_1 + (i+1) e_1}, B^\rho_{x+i_2 e_2 + (i+1) e_2}\right)_{i \in \mathbb{Z}} \sim \nu^{1-\bar{\rho},1-\rho},$$

$$\left(B^{\bar{\rho}}_{x+i_1 e_1 + (i+1) e_1}, B^{\bar{\rho}}_{x+i_2 e_2 + (i+1) e_2}\right)_{i \in \mathbb{Z}} \sim \nu^{\rho,\bar{\rho}},$$

where $\nu^{\lambda,\rho}$ is the distribution defined in (A.4).

5 Stabilization

In this section we prove Theorems 2.1 and 2.4. Recall (3.11) and define the event

$$H^{\xi,M} = \{\hat{G}_{N\xi,y} - \hat{G}_{N\xi,x} = B^\rho_{x,y} \text{ for all } (x,y) \in \mathcal{E}(R^{\xi,M})\}. (5.1)$$

$H^{\xi,M}$ is the event where the increments of $\hat{G}$ along the edges in $\mathcal{E}(R^{\xi,M})$ coincide with those of the Busemann function associated with the direction $\xi$.

5.1 Bounds on $\mathbb{P}(S^{\xi,M})$ and $\mathbb{P}(H^{\xi,M})$

Recall definition (4.10) that connects directions and parameter values. Fix a direction vector $\xi \in \text{ri}\mathcal{U}$ with its parameter $\rho(\xi)$. For $r > 0$ define perturbed parameters

$$\rho = \rho(\xi) = \rho(\xi) - rN^{-\frac{1}{3}}$$

$$\bar{\rho} = \bar{\rho}(\xi) = \rho(\xi) + rN^{-\frac{1}{3}},$$

with characteristic directions

$$\bar{\xi} = \xi(\bar{\rho}) \quad \text{and} \quad \xi = \xi(\rho). (5.2)$$

Set a northeast base vertex at $\tilde{\theta}_N = \xi N + e_1 + e_2$. Assign weights on the edges of the north and east outer boundaries of $R^{\xi,N}$ by

$$I^\rho_i = B^\rho_{\tilde{\theta}_N - (i+1)e_1,\tilde{\theta}_N - ie_1} \quad 0 \leq i \leq N\xi_1$$

$$J^\rho_i = B^\rho_{\tilde{\theta}_N - (i+1)e_2,\tilde{\theta}_N - ie_2} \quad 0 \leq i \leq N\xi_2. (5.3)$$

Use the boundary weights $\{I^\rho_i\}_{0 \leq i \leq N\xi_1}$, $\{J^\rho_i\}_{0 \leq i \leq N\xi_2}$ and the bulk weights $\{\omega_x\}_{x \in R^{\xi,N}}$ to construct the stationary LPP $\hat{G}^\rho$ as in (3.13)–(3.14). Similarly we construct $\hat{G}^\bar{\rho}$ as
in (3.15) we let \( \hat{Z}^\rho_{\partial N,x} \) (resp. \( \hat{Z}^\rho_{\partial N,x} \)) denote the exit point of the geodesic \( \pi^{\rho,\partial N,x} \) of \( \hat{G}^\rho \) (resp. geodesic \( \pi^{\rho,\partial N,x} \) of \( \hat{G}^\rho \)). For \( 0 < M < N \) let
\[
\bar{\hat{A}}^{x,M}_\xi = \left\{ \sup_{x \in \mathcal{R}^x_M} \hat{Z}^\rho_{\partial N,x}(\xi) < 0 \right\} \bigcap \left\{ \inf_{x \in \mathcal{R}^x_M} \hat{Z}^\rho(\xi) > 0 \right\}.
\] (5.4)
\( \bar{\hat{A}}^{x,M}_\xi \) is the event that for each \( x \in \mathcal{R}^x_M \), the geodesic \( \pi^{\rho,\partial N,x} \) of \( \hat{G}^\rho_{\partial N,x} \) (and geodesic \( \pi^{\rho,\partial N,x} \) of \( \hat{G}^\rho_{\partial N,x} \)) crosses the boundary of \( \mathcal{R}^{x,N}_\xi \) (not to be confused with \( \mathcal{R}^{x,M}_\xi \)) from the north (from the east).

**Lemma 5.1** Let \( \xi \in \text{ri} \mathcal{U} \) and \( N > M > 0 \). On the event \( \bar{\hat{A}}^{x,M}_\xi \) the following ordering of geodesics holds in the rectangle \( \mathcal{R}^{x,N}_\xi \):
\[
\pi^{x,\infty}_x \leq \pi^{x,N}_x \leq \pi^{x,\infty}_x \quad \forall \text{ starting points } x \in \mathcal{R}^{x,M}_\xi.
\] (5.5)

**Proof** We show the first inequality in (5.5), the second one being analogous. Because the boundary conditions (5.3) come from the Busemann functions, the geodesic \( \pi^{\rho,\partial N,x} \) of the stationary LPP process \( \hat{G}^\rho_{\partial N,x} \) follows the semi-infinite geodesic \( \pi^{x,\infty}_x \) from \( x \) until they hit together the north/east boundary of the rectangle \([x, \hat{G}]\). (This is a version of Lemma 3.2 where Fig. 4 is rotated 180 degrees and then the base point \( u \) is taken to infinity in direction \( \xi \).) Event \( \bar{\hat{A}}^{x,M}_\xi \) constrains this hit to happen on the north boundary, that is, to the left of the point \( N\xi \). Uniqueness of point-to-point geodesics then forces \( \pi^{x,N}_x \) to stay to the right of \( \pi^{x,\infty}_x \).

Let \( \partial_M = M\xi + e_1 + e_2 \) be the outer upper right corner of \( \mathcal{R}^{x,M}_\xi \). Assign weights on the edges of the north-east outer boundary of \( \mathcal{R}^{x,M}_\xi \) from the Busemann function:
\[
I^\rho_i = B^\rho_{\partial_M-(i+1)e_1,\partial_M-ie_1} \quad 0 \leq i \leq M\xi_1 \quad (5.6)
\]
\[
J^\rho_j = B^\rho_{\partial_M-(i+1)e_2,\partial_M-je_2} \quad 0 \leq j \leq M\xi_2.
\]
Define the event where the increment variables for \( \hat{\rho} \) and \( \rho \) agree on the north and east boundaries of the rectangle \([0, \partial_M]\):
\[
C^{x,M}_\xi = \left\{ I^\rho_i = I^\rho_i \quad \forall i \in \mathbb{I} \right\} \bigcap \left\{ J^\rho_j = J^\rho_j \quad \forall j \in \mathbb{I} \right\}.
\] (5.7)

**Lemma 5.2** On the event \( C^{x,M}_\xi \),
\[
B^\rho_e = B^\rho_e(\xi) \quad \forall e \in \mathcal{E}(\mathcal{R}^{x,M}_\xi) \quad (5.8)
\]
and
\[
\mathcal{P}^{x,M}(\pi^{x,\infty}_x) = \mathcal{P}^{x,M}(\pi^{x,\infty}_x). \quad (5.9)
\]

**Proof** The values \( \{ B^\rho_e : e \in \mathcal{E}(\mathcal{R}^{x,M}_\xi) \} \) are determined by the bulk weights \( \{ \omega \}_{x \in \mathcal{R}^{x,M}_\xi} \) and the boundary weights in (5.6) through the recursion (4.8)–(4.9):
\[
B^\rho_{x,x+e_1} = \omega_x + (B^\rho_{x+e_2,x+e_1+e_2} - B^\rho_{x+e_1,x+e_1+e_2})^+.
\]
\[ B_{x,x+e_2}^\rho = \omega_x + (B_{x+e_2,x+e_1+e_2}^\rho - B_{x+e_1,x+e_1+e_2}^\rho) - \]

As both \( \{B_{e}^\rho\}_{e \in \mathcal{E}(\mathcal{R}^{\xi,M})} \) and \( \{B_{e}^\rho\}_{e \in \mathcal{E}(\mathcal{R}^{\xi,M})} \) use the same bulk weights and the event \( C^{\xi,M} \) forces their boundary conditions to agree, \( B_{e}^\rho = B_{e}^\rho \ \forall e \in \mathcal{E}(\mathcal{R}^{\xi,M}) \). Equality (5.8) follows from the monotonicity (4.12) of Busemann functions. (5.9) follows from (5.8) because the geodesics \( \mathcal{P}^{\xi,M}(\pi^{x,\infty_\xi}) \) and \( \mathcal{P}^{\xi,M}(\pi^{x,\infty_\xi}) \) are determined by the Busemann function increments through (4.18).

**Corollary 5.3** On the event \( C^{\xi,M} \cap \hat{A}^{\xi,M} \),

\[
\hat{G}_{N^{\xi},y} - \hat{G}_{N^{\xi},x} = B_{x,y}^\rho(x,y) \in \mathcal{E}(\mathcal{R}^{\xi,M}) \text{ and }

\mathcal{P}^{\xi,M}(\pi^{x,\infty_\xi}) = \mathcal{P}^{\xi,M}(\pi^{x,\infty_\xi}) = \mathcal{P}^{\xi,M}(\pi^{x,\infty_\xi}) \forall x \in \mathcal{R}^{\xi,M}.
\]

**Proof** By Lemma B.2, on the event \( \hat{A}^{\xi,M} \)

\[
B_{x,x+e_2}^\rho \leq \hat{G}_{N^{\xi},x+e_2} - \hat{G}_{N^{\xi},x} \leq B_{x+e_2,x+e_1+e_2}^\rho \ \forall (x,x+e_2) \in \mathcal{E}(\mathcal{R}^{\xi,M})
\]

and

\[
B_{x,x+e_1}^\rho \leq \hat{G}_{N^{\xi},x+e_1} - \hat{G}_{N^{\xi},x} \leq B_{x+e_1,x+e_1+e_2}^\rho \ \forall (x,x+e_1) \in \mathcal{E}(\mathcal{R}^{\xi,M}),
\]

which implies (5.10), using (5.8). By Lemma 4.4 we see that

\[
\pi^{x,\infty_\xi} \leq \pi^{x,\infty_\xi} \leq \pi^{x,\infty_\xi} \quad x \in \mathbb{Z}^2.
\]

By Lemma 5.1, on \( \hat{A}^{\xi,M} \)

\[
\pi^{x,\infty_\xi} \leq \pi^{x,N^{\xi}} \leq \pi^{x,\infty_\xi} \quad x \in \mathcal{R}^{\xi,M}.
\]

Lemma 5.2 along with (5.12) and (5.13) imply the result.

For \( M > 0 \), recall the event \( S^{\xi,M} \) in (2.5). Using Corollary 5.3 we have the following.

**Corollary 5.4**

\[
\mathbb{P}(S^{\xi,M}) \geq \mathbb{P}(H^{\xi,M}) \geq \mathbb{P}(C^{\xi,M} \cap \hat{A}^{\xi,M}) \geq 1 - \mathbb{P}((C^{\xi,M})^c) - \mathbb{P}((\hat{A}^{\xi,M})^c).
\]

**Proof** The first inequality comes from

\[
H^{\xi,M} \subseteq S^{\xi,M},
\]

which is true because last-passage and Busemann increments determine the geodesics. The second inequality comes from Corollary 5.3.
5.2 Upper bound on $\mathbb{P}(\hat{A}^{x,M})$

**Lemma 5.5** For $\xi \in \mathfrak{ri} \mathcal{U}$ and $c > 0$ there exist finite constants $C = C(c, \xi)$ and $N_0 = N_0(\xi, c)$, locally bounded in $c$, such that the following hold: whenever $N \geq N_0$, $0 < M \leq c N^{2/3}$ and $1 \leq r \leq N^{2/3} (\log(N))^{-1}$,

$$\mathbb{P}\left( \sup_{x \in \mathbb{R}^d} \hat{Z}_{\bar{o}_N,x}^\rho(\xi) > 0 \right) \leq \frac{C}{r^3}, \quad (5.15)$$

and

$$\mathbb{P}\left( \inf_{x \in \mathbb{R}^d} \hat{Z}_{\bar{o}_N,x}^{\hat{\rho}(\xi)} < 0 \right) \leq \frac{C}{r^3}, \quad (5.16)$$

where $\bar{o}_N = N \xi + e_1 + e_2$, $\rho(\xi) = \rho(\xi) - r N^{-1/3}$ and $\hat{\rho}(\xi) = \rho(\xi) + r N^{-1/3}$.

**Proof** We only prove (5.16) as (5.15) is similar. Given $\xi \in \mathfrak{ri} \mathcal{U}$, abbreviate $\rho = \rho(\xi)$ and $\hat{\rho} = \hat{\rho}(\xi)$. Let $x^0 = (M \xi_1, 0)$ be the lower-right corner of $\mathcal{R}^{x,M}$. By the order on geodesics we have

$$\left\{ \inf_{x \in \mathbb{R}^d} \hat{Z}_{\bar{o}_N,x}^{\hat{\rho}} < 0 \right\} \subset \left\{ \hat{Z}_{\bar{o}_N,x^0}^\rho < 0 \right\},$$

which implies

$$\mathbb{P}\left( \inf_{x \in \mathbb{R}^d} \hat{Z}_{\bar{o}_N,x}^{\hat{\rho}} < 0 \right) \leq \mathbb{P}\left( \hat{Z}_{\bar{o}_N,x^0}^\rho < 0 \right). \quad (5.17)$$

In order to upper bound (5.17) we must show that the characteristic line of direction $-\xi(\hat{\rho})$ that leaves from $\bar{o}_N$ goes, on the scale of $N^{2/3}$, well below the point $x^0 = (x^0(1), x^0(2)) = (M \xi_1, 0)$. We have, via (4.10),

$$x^0(2) - N \xi_2 - \frac{(N \xi_1 - M \xi_1) \hat{\rho}^2}{(1 - \hat{\rho})^2} = \frac{N \xi_2 (1 - \hat{\rho})^2 - (N \xi_1 - M \xi_1) \hat{\rho}^2}{(1 - \hat{\rho})^2}, \quad (5.18)$$

$$= \frac{\xi_2 [2(1 - \rho) r N^{2/3} + r^2 N^{4/3}] - \xi_1 [2 \rho r N^{2/3} + r^2 N^{4/3}] + \xi_1 M \hat{\rho}^2}{(1 - \hat{\rho})^2}$$

$$\leq -r N^{2/3} \left[ \frac{\xi_2 [2(1 - \rho) + \xi_1 2 \rho]}{(1 - \hat{\rho})^2} + \frac{M \xi_1 \hat{\rho}^2}{(1 - \hat{\rho})^2} \right] + \frac{(\xi_2 - \xi_1) r N^{4/3}}{(1 - \hat{\rho})^2}$$

$$\leq -r N^{2/3} \left[ \frac{\xi_2 [2(1 - \rho) + \xi_1 2 \rho]}{(1 - \hat{\rho})^2} + \frac{c N^{2/3} \xi_1 \hat{\rho}^2}{(1 - \hat{\rho})^2} \right] + \frac{(\xi_2 - \xi_1) r N^{4/3}}{(1 - \hat{\rho})^2}$$

$$\leq -r N^{2/3} \left[ \frac{\xi_2 [2(1 - \rho) + \xi_1 2 \rho - r^{-1} c \xi_1 (\rho^2 - 2 \rho r N^{-1/3} + r^2 N^{-2} - r N^{-4/3})]}{(1 - \hat{\rho})^2} \right]. \quad (5.19)$$

where in the first inequality we used that $M \leq c N^{2/3}$ and in the second inequality the definition of $\hat{\rho}$. For large enough $N$ and $r \leq N^{2/3} (\log(N))^{-1}$ plug into (5.19) to obtain
such that for $N$ large enough

\[
N\xi_2 - \frac{(N\xi_1 - M\xi_1)\bar{\rho}^2}{(1 - \bar{\rho})^2} \leq -rN^\frac{2}{3} \left[ \xi_2(1 - \rho) + \xi_1\bar{\rho}^2 + c\xi_1(2\rho N^{-\frac{1}{3}} + N^{-\frac{1}{3}}(\log(N))^{-1} - (\log(N))^{-1}) \right]
\]

For

\[
r > \frac{c\xi_1\rho^2}{[\xi_2(1 - \rho) + \xi_1\bar{\rho}^2 - (1 - \rho)^2]} \lor 1,
\]

the right hand side of (5.20) is smaller than $-N^\frac{2}{3}$. This in turn implies that there exists a constant $C'(\xi, c) > 0$ (locally bounded in $c$) such that

\[
N\xi_2 - \frac{(N\xi_1 - M\xi_1)\bar{\rho}^2}{(1 - \bar{\rho})^2} \leq -C'(\xi, c)rN^\frac{2}{3},
\]

It then follows by Lemma 3.1 that there exists a constant $C_1(\xi, c) > 0$

\[
\mathbb{P}\left(\hat{\mathcal{A}}_{\bar{\rho}, x_0} < 0\right) \leq C_1 r^{-3},
\]

which proves the result. \qed

**Corollary 5.6** Fix $\xi \in (0, 1)$ and $c > 0$. There exists $C(c, \xi) > 0$, locally bounded in $c$, such that for every $0 < M \leq cN^\frac{2}{3}$ and $1 \leq r \leq N^\frac{1}{3}(\log(N))^{-1}$

\[
\mathbb{P}\left((\hat{\mathcal{A}}_{\bar{\rho}, M})^c \right) \leq \frac{C}{r^3}.
\]

**Proof** By the definition of $\hat{\mathcal{A}}_{\bar{\rho}, M}$ we see that

\[
(\hat{\mathcal{A}}_{\bar{\rho}, M})^c \subseteq \left\{ \sup_{x \in R_{\bar{\rho}, M}} \hat{\mathcal{Z}}_{0, x}^{(\xi)} > 0 \right\} \cup \left\{ \inf_{x \in R_{\bar{\rho}, M}} \hat{\mathcal{Z}}_{0, x}^{(\xi)} < 0 \right\}
\]

Taking probability on both sides of (5.22) and using (5.15) and (5.16) we obtain the result. \qed
5.3 Upper bound on $\mathbb{P}((\mathcal{C}^{\xi,M})^c)$

Express $\mathcal{C}^{\xi,M}$ from (5.7) as

$$\mathcal{C}^{\xi,M} = \mathcal{C}^{\xi,M}_1 \cap \mathcal{C}^{\xi,M}_2. \quad (5.23)$$

where

$$\mathcal{C}^{\xi,M}_1 = \{ B_{\rho_{M-k\epsilon_1,\rho_M-(k-1)\epsilon_1}^\circ \rho_{M-k\epsilon_1,\rho_M-(k-1)\epsilon_1} \} \text{ for } 1 \leq k \leq \xi_1 M \}$$

$$\mathcal{C}^{\xi,M}_2 = \{ B_{\rho_{M-k\epsilon_2,\rho_M-(k-1)\epsilon_2}^\circ \rho_{M-k\epsilon_2,\rho_M-(k-1)\epsilon_2} \} \text{ for } 1 \leq k \leq \xi_2 M \}.$$ 

This subsection proves the following.

**Proposition 5.7** For $\xi \in \text{ri} \mathcal{U}$ and $c > 0$ there exists a constant $C(\xi, c) > 0$, locally bounded in $c$, such that for $0 < M \leq cN^{\frac{2}{3}}$, there exists $r(\xi, M, N) > 0$ for which the following holds

$$\mathbb{P}((\mathcal{C}^{\xi,M})^c) \leq C N^{-\frac{1}{4}} M^{\frac{3}{8}}. \quad (5.24)$$

Before we prove Proposition 5.7 we obtain some auxiliary results. As was noted in Lemma 4.5[ii], for $\xi \preceq \xi$ (and therefore $\rho \leq \tilde{\rho}$)

$$\mathbb{P}(B_{\rho_{M-k\epsilon_1,\rho_M-(k-1)\epsilon_1}^\circ \rho_{M-k\epsilon_1,\rho_M-(k-1)\epsilon_1} \} \text{ for } 1 \leq k \leq \xi_1 M \} = \nu^{1-\tilde{\rho},1-\tilde{\rho}} \begin{pmatrix} d_i = s_i \text{ for } 1 \leq i \leq \xi_1 M \end{pmatrix},$$

where $d = D(a, s)$ from “Appendix A”, and $a = (a_j)_{j \in \mathbb{Z}}$ and $s = (s_j)_{j \in \mathbb{Z}}$ are two independent i.i.d sequences of exponential random variables of intensity $1 - \tilde{\rho}$ and $1 - \rho$ respectively, such that $0 < \rho < \tilde{\rho} < 1$. Using (A.9)

$$\nu^{1-\tilde{\rho},1-\tilde{\rho}} \begin{pmatrix} d_i = s_i \text{ for } 1 \leq i \leq \xi_1 M \end{pmatrix} = \nu^{1-\tilde{\rho},1-\tilde{\rho}} \begin{pmatrix} e_i = 0 \text{ for } 1 \leq i \leq \xi_1 M \end{pmatrix}$$

It follows that

$$\mathbb{P}(C^{\xi,M}_1) = \nu^{1-\tilde{\rho},1-\tilde{\rho}} \begin{pmatrix} e_i = 0 \text{ for } 1 \leq i \leq \xi_1 M \end{pmatrix}, \quad (5.25)$$

and similarly

$$\mathbb{P}(C^{\xi,M}_2) = \nu^{2,\tilde{\rho}} \begin{pmatrix} e_i = 0 \text{ for } 1 \leq i \leq \xi_1 M \end{pmatrix}. \quad (5.26)$$
Altogether, plugging (5.25) and (5.26) into (5.23) we obtain

$$
\mathbb{P}((C_{\xi,M})^c) \leq v^{1-\tilde{\rho},1-\rho} \left( \sum_{i=1}^{\xi_1 M} e_i > 0 \right) + v^{\tilde{\rho}} \left( \sum_{i=1}^{\xi_1 M} e_i > 0 \right).
$$

(5.27)

Let us now try to explain the idea behind the proof. Let $x_j = s_{j-1} - a_j$, from (A.6) we see that

$$
w_j = (w_{j-1} + x_j)^+.
$$

Define the stopping time

$$
T = \sup \{ k : k > 0, w_{k-1} + x_k \geq 0 \}
$$

so that

$$
w_j = w_{j-1} + x_j \quad 1 \leq j \leq T.
$$

Using this recursion and (A.10)

$$
w_j = w_0 + S_{1,j} \quad 1 \leq j \leq T
$$

and $w_j \geq 0 \quad 1 \leq j \leq T$. (5.28)

The dynamics behind (5.28) is as follows. The waiting time $w_j$ increases when the service times are longer than usual and the interarrival times are shorter i.e. when the random walk $S_{0,j}$ goes up. Similarly, the $w_j$ decreases when the service times are fast compared to the arrival of customers i.e. $S_{0,j}$ goes down. This dynamics hold until the random walk goes below $-w_0$ where the waiting time at the queue vanishes. The r.v. $\sum_{i=1}^{\xi_1 M} e_i$ can be thought of as the local time of the queue at zero, i.e. the accumulated time of the queue being empty. The main idea behind the proof of Proposition 5.7 is the observation that when $\tilde{\rho} - \rho \sim N^{-1/3}$, that is when the queue is in the so-called heavy traffic regime, at stationarity, the waiting time $w_0$ of customer 0, is of order $N^{1/3}$.

As the difference between the average service time rate and the average inter-arrival time rate is of order $\tilde{\rho} - \rho \sim N^{-1/3}$, the simple random walk $S_{0,j}$ has drift $-N^{-1/3}$. (5.28) implies that the queue’s waiting time vanishes by time of order $N^{2/3}$. Over time $t = o(N^{2/3})$ the random walk $S_t$ will not change the waiting time at the queue by much so that with high probability $w_t$ will be of order $N^{1/3}$ and the r.v. $\sum_{i=1}^t e_i$ will be zero (see Fig. 5). The proof of the following result is deferred to the appendix.

**Lemma 5.8** Let $\xi \in rilU$ and let $M > 0$. For $0 < \beta < \alpha < 1$

$$
v^{\beta,\alpha} \left( \sum_{i=1}^{\xi_1 M} e_i > 0 \right) \leq 1 - \frac{\beta}{\alpha} + \int \frac{\alpha}{(\alpha + \theta)} \frac{\beta}{(\beta - \theta)} \cdot \frac{\gamma^{\xi_1 M}}{\alpha} e^{-\theta w} (\alpha - \beta)^\beta e^{-(\alpha - \beta)} w \, dw.
$$

(5.29)
Local stationarity in exponential last-passage percolation

Fig. 5 The two cases of a queue at stationarity. $S_t$ is the random walk whose incremental step is $x_t = s_{t-1} - a_t$. As the rate of service at the queue is higher than the rate of interarrival $E(x_t) < 0$ and so $S_t$ is a simple random walk with a negative drift. The waiting time at the queue decreases by $S_t$ until it vanishes.

Lemma 5.9 Let $\xi \in \text{ri} U$ and let $M > 0$. For $\tilde{\rho}(\xi) = \rho(\xi) - rN^{-\frac{1}{3}}$, $\tilde{\rho}(\xi) = \rho(\xi) + rN^{-\frac{1}{3}}$ and $0 < \theta < \tilde{\rho}$,

$$
\forall \tilde{\rho} \left( \sum_{i=1}^{\xi_1 M} e_i > 0 \right) \leq \frac{2rN^{-\frac{1}{3}} + \rho - rN^{-\frac{1}{3}}}{\rho + rN^{-\frac{1}{3}}} \left[ 1 + \frac{2r\theta N^{-\frac{1}{3}} + \theta^2}{\rho^2 - (r^2 N^{-\frac{2}{3}} + 2 r N^{-\frac{1}{3}} \theta + \theta^2)} \right]^{\xi_1 M} (1 + 2\theta^{-1}N^{\frac{1}{3}})^{-1}. \tag{5.30}
$$

Proof Set $\beta = \rho$ and $\alpha = \tilde{\rho}$ so that

$$
\left[ \frac{\alpha}{(\alpha + \theta)} \frac{\beta}{(\beta - \theta)} \right]^{\xi_1 M} e^{-\theta w} \leq \left[ \frac{\rho + rN^{-\frac{1}{3}}}{(\rho + rN^{-\frac{1}{3}} + \theta)} \frac{\rho - rN^{-\frac{1}{3}}}{(\rho - rN^{-\frac{1}{3}} - \theta)} \right]^{\xi_1 M} e^{-\theta w} = \left[ \frac{\rho^2 - r^2 N^{-\frac{2}{3}}}{\rho^2 - (r^2 N^{-\frac{2}{3}} + 2 r N^{-\frac{1}{3}} \theta + \theta^2)} \right]^{\xi_1 M} e^{-\theta w}
$$

and that

$$
\frac{(\alpha - \beta)\beta}{\alpha} e^{-(\alpha - \beta) w} 1_{(0, \infty)} = \frac{(2rN^{-\frac{1}{3}})(\rho - rN^{-\frac{1}{3}})}{\rho + rN^{-\frac{1}{3}}} e^{-2rN^{-\frac{1}{3}} w} 1_{(0, \infty)}. \tag{5.32}
$$
Using (5.31) and (5.32) in (5.29) and the change of variable $2 r N^{-\frac{1}{3}} w \mapsto w$

\[
\nu^\rho, \tilde{\rho} \left( \sum_{i=1}^{\xi_1 M} e_i > 0 \right) = \frac{2 r N^{-\frac{1}{3}}}{\rho + r N^{-\frac{1}{3}}} + \frac{\rho - r N^{-\frac{1}{3}}}{\rho + r N^{-\frac{1}{3}}} \int_0^\infty \left[ 1 + \frac{2 r \theta N^{-\frac{1}{3}} + \theta^2}{\rho^2 - (r^2 N^{-\frac{2}{3}} + 2 r N^{-\frac{1}{3}} \theta + \theta^2)} \right] \xi_1 M e^{-\theta \frac{1}{3} N^{-\frac{1}{3}} w} e^{-w} dw
\]

\[
= \frac{2 r N^{-\frac{1}{3}}}{\rho + r N^{-\frac{1}{3}}} + \frac{\rho - r N^{-\frac{1}{3}}}{\rho + r N^{-\frac{1}{3}}} \left[ 1 + \frac{2 r \theta N^{-\frac{1}{3}} + \theta^2}{\rho^2 - (r^2 N^{-\frac{2}{3}} + 2 r N^{-\frac{1}{3}} \theta + \theta^2)} \right] \xi_1 M \left( 1 + \theta 2 r^{-1} N^{-\frac{1}{3}} \right)^{-1}
\]

\[\square\]

**Lemma 5.10** Let $\xi \in \mathcal{U}$ and let $M > 0$ such that $M \leq c N^{\frac{7}{4}}$. There exists $C(\xi, c) > 0$ such that

\[\mathbb{P}\left( \left( c_2^{\xi, M} \right)^c \right) \leq C N^{-\frac{1}{4}} (\xi_1 M)^{\frac{3}{8}}. \tag{5.33}\]

**Proof** Let $r = (\xi_1 M)^{-\frac{1}{3}} N^{\frac{1}{12}}$ and $\theta = (\xi_1 M)^{-\frac{1}{2}}$ in (5.30) to obtain

\[
\nu^\rho, \tilde{\rho} \left( \sum_{i=1}^{\xi_1 M} e_i > 0 \right) \leq A + B, \tag{5.34}
\]

where

\[
A = \frac{2 N^{-\frac{1}{4}} (\xi_1 M)^{-\frac{1}{8}}}{\rho + N^{-\frac{1}{4}} (\xi_1 M)^{-\frac{1}{8}}}
\]

and

\[
B = B_1 \times B_2 \times B_3 \tag{5.35}
\]

where

\[
B_1 = \frac{\rho - N^{-\frac{1}{4}} (\xi_1 M)^{-\frac{1}{8}}}{\rho + N^{-\frac{1}{4}} (\xi_1 M)^{-\frac{1}{8}}} = 1 - \frac{2 N^{-\frac{1}{4}} (\xi_1 M)^{-\frac{1}{8}}}{\rho + N^{-\frac{1}{4}} (\xi_1 M)^{-\frac{1}{8}}} \tag{5.36}
\]

\[
B_2 = \left[ 1 + \frac{2 N^{-\frac{1}{4}} (\xi_1 M)^{-\frac{5}{8}} + (\xi_1 M)^{-1}}{\rho^2 - (N^{-\frac{1}{2}} (\xi_1 M)^{-\frac{1}{4}} + 2 N^{-\frac{1}{4}} (\xi_1 M)^{-\frac{5}{8}} + (\xi_1 M)^{-1})} \right] \xi_1 M \tag{5.37}
\]

\[
B_3 = \left( 1 + 2 (\xi_1 M)^{-\frac{5}{8}} N^{\frac{1}{12}} \right)^{-1} \leq N^{-\frac{1}{4}} (\xi_1 M)^{\frac{3}{8}}. \tag{5.38}
\]
There exists $C_A(\rho) > 0$ such that
\[ A \leq C_A N^{-\frac{1}{4}} (\xi_1 M)^{-\frac{1}{8}} \quad \text{for } N \geq 1. \] (5.39)

Note that by our assumption on $M$ the numerator in (5.37) is dominated by $2cN^{\frac{2}{3}} \vee (\xi_1 M)^{-1}$ and
\[ B_2 \to C(c) \quad \text{as } N \to \infty, \]
where $C(c) > 0$ is locally bounded in $c$. In particular, there exists $C_{B_2}(\rho) > 0$ such that
\[ B_2 \leq C_{B_2} \quad \text{for } N \geq 1. \] (5.40)

Plugging (5.36), (5.40) and (5.38) into (5.35) we see that there exists $C_B(\rho) > 0$ such that
\[ B \leq N^{-\frac{1}{4}} (\xi_1 M)^{\frac{3}{8}}. \] (5.41)

Plugging now (5.39) and (5.41) into (5.34) and using (5.25) we obtain the result.

**Proof of Proposition 5.7** Similar to Lemma 5.10 one can show that for $\xi \in ri\mathcal{U}$ and $M > 0$ such that $M \leq cN^{\frac{2}{3}}$, there exists $C(\xi, c) > 0$ such that
\[ \mathbb{P}\left( \left( C_{1, M}^\xi \right)^c \right) \leq C \left( N^{-\frac{1}{4}} (\xi_2 M)^{\frac{3}{8}} \right). \] (5.42)

(5.33) and (5.42) imply the result.

**Proof of Theorem 2.1** Plugging (5.21) and (5.24) into (5.14) we see that there exists $c_0 > 0$ such that for every $c \leq c_0$
\[ \mathbb{P}\left( \left( \mathcal{H}^\xi, cN^{\frac{2}{3}} \right)^c \right) \leq C \left( N^{-\frac{1}{4}} (cN^{\frac{2}{3}})^{\frac{3}{8}} \right) \leq Cc^{\frac{3}{8}}. \] (5.43)

By the definition (5.1) of $\mathcal{H}^\xi, cN^{\frac{2}{3}}$, (5.43) shows that there exists a coupling between
\[ \tilde{H}^{N,c} = \{ \tilde{H}^{N,c}_{(x,y)} = \tilde{G}^{N,c}_{(x,y)} : (x, y) \in \mathcal{E}(R^\xi, cN^{2/3}) \}, \]
and $B^{\xi(\rho)}|_{\mathcal{E}(R^\xi, cN^{2/3})}$, the Busemann function $B^{\xi(\rho)}$ restricted to the edges in $\mathcal{E}(R^\xi, cN^{2/3})$, such that
\[ \mathbb{P}\left( \tilde{H}^{N,c} \neq B^{\xi(\rho)}|_{\mathcal{E}(R^\xi, cN^{2/3})} \right) \leq Cc^{\frac{3}{8}}. \] (5.44)
In general, the coupling inequality above bounds the total variation distance. Hence
\[
d_{TV}(\tilde{H}^{N,c}, B^{\xi(\rho)}_{E(R^{\xi,cN^{2/3}})}) \leq Cc^{\frac{3}{8}}.
\]  
(5.45)

As the distribution of \(B^{\xi(\rho)}_{E(R^{\xi,cN^{2/3}})}\) equals that of \(\tilde{H}^{\xi(\rho),N,c}\),
\[
(5.45) \text{also gives}
\[
d_{TV}(\tilde{H}^{N,c}, \tilde{H}^{\xi(\rho),N,c}) \leq Cc^{\frac{3}{8}}.
\]  
(5.46)

With \(\xi = \left(\frac{1}{2}, \frac{1}{2}\right)\) and \(\rho = \frac{1}{2}\), (5.46) is the same as (2.2) after rotating the LPP picture by 180 degrees. \(\Box\)

**Proof of Theorem 2.4** Plugging (5.21) and (5.24) into (5.14) we obtain the result. \(\Box\)

**Proof of Theorem 2.2** Define
\[
\Delta L_{N}^{N} = L_{N}^{N} - L_{0}^{N} = 2^{-\frac{4}{3}} N^{-\frac{1}{3}} \left( G_{(0,0),(N+x(2N)^{\frac{2}{3}},N-x(2N)^{\frac{2}{3}})} - G_{(0,0),(N,N)} \right).
\]

By Theorem 2.1 there exists \(c_{0} > 0\) and \(C(c_{0}) > 0\) such that for any \(|c| \leq c_{0}\), with probability at least \(1 - Cc^{\frac{3}{8}}\), simultaneously for all \(|x| \leq c\)
\[
C_{G} = \left( G_{(0,0),(N+x(2N)^{\frac{2}{3}},N-x(2N)^{\frac{2}{3}})} - G_{(0,0),(N,N)} \right).
\]

Defining
\[
\Delta L_{x}^{\frac{1}{2},N} = 2^{-\frac{4}{3}} N^{-\frac{1}{3}} \left( G_{(0,0),(N+x(2N)^{\frac{2}{3}},N-x(2N)^{\frac{2}{3}})}^{\frac{1}{2}} - G_{(0,0),(N,N)}^{\frac{1}{2}} \right),
\]
we conclude that with probability at least \(1 - Cc^{\frac{3}{8}}\), simultaneously for all \(|x| \leq c\)
\[
\Delta L_{x}^{N} = \Delta L_{x}^{\frac{1}{2},N}.
\]  
(5.47)

This coupling implies the bound
\[
d_{TV}(\Delta L_{N}^{N}|_{[-c,c]}, \Delta L_{x}^{\frac{1}{2},N}|_{[-c,c]}) \leq Cc^{\frac{3}{8}}.
\]  
(5.48)
The following limits are in distribution in the topology of continuous functions on $[-c, c]$.

$$\lim_{N \to \infty} \Delta L^N = A'_2 = A_2(x) - A_2(0) - x^2 \quad (5.49)$$

$$\lim_{N \to \infty} \Delta L^{\frac{1}{2} \cdot N} = B. \quad (5.50)$$

To see that (5.50) holds, note that by Theorem 4.3 and Definition 4.2, $\Delta L^{\frac{1}{2} \cdot N}$ is an unbiased random walk, Donsker’s invariance principal implies (5.50). Using Lemma C.2 with (5.49)–(5.50) and (5.48) implies that

$$d_{TV}(A'_2|[-c,c], B|[-c,c]) \leq 3Ce^{\frac{3}{8}},$$

which implies the result. □

Proof of Corollary 2.3 By the stationarity of the $A_2$, it is enough to verify the claim for $I = [0, a]$ for some $a > 0$. For every $\epsilon > 0$, let $\Omega^\epsilon = C[0, \epsilon]$ be the space of continuous functions on the interval $[0, \epsilon]$. Let $\mathcal{F}^\epsilon$ be the Borel sigma algebra associated with the supremum metric on $\Omega^\epsilon$. By Theorem 2.2, for every $\delta > 0$ there exists $0 < \epsilon \leq a$ and a probability space $(\Omega^\epsilon, \mathbb{P}^\epsilon)$ such that

$$\mathbb{P}^\epsilon(A'_2|0, \epsilon] = B|0, \epsilon]) > 1 - \delta. \quad (5.51)$$

For $\epsilon \in (0, a]$, (5.51) implies that with probability larger than $1 - \delta$

$$\sup_{t \in I} \limsup_{h \downarrow 0} \frac{A'_2(t + h) - A'_2(t)}{\omega_B(h)} \geq \sup_{t \in [0, \epsilon)} \limsup_{h \downarrow 0} \frac{A'_2(t + h) - A'_2(t)}{\omega_B(h)} = 1,$$  

where the last equality comes from Lévy’s modulus of continuity [27, Theorem 10.1] and the self-similarity of Brownian motion. Taking $\delta \to 0$

$$\sup_{t \in I} \limsup_{h \downarrow 0} \frac{A'_2(t + h) - A'_2(t)}{\omega_B(h)} \geq 1 \quad \text{with probability 1.}$$

Note that

$$\sup_{t \in I} \limsup_{h \downarrow 0} \frac{A'_2(t + h) - A'_2(t)}{\omega_B(h)} = \sup_{t \in I} \limsup_{h \downarrow 0} \frac{A_2(t + h) - A_2(t)}{\omega_B(h)} + \sup_{t \in I} \limsup_{h \downarrow 0} \frac{(t + h)^2 - t^2}{\omega_B(h)}$$

$$= \sup_{t \in I} \limsup_{h \downarrow 0} \frac{A_2(t + h) - A_2(t)}{\omega_B(h)} \quad (5.53)$$
Plugging (5.53) in (5.52) implies the result. □

6 Coalescence of point-to-point geodesics

In this section we prove Theorem 2.8 and Theorem 2.9. For technical reasons, namely the direction in which we send $v_n$ to infinity in (4.13), we prove the results for a setup that is a bit different, yet equivalent, to the one in Fig. 2 i.e. we set $q^1 = \xi N$, $q^2 = \xi N - aN^{2/3}e_2$ and $o = (0, 0)$ (see Fig. 6).

6.1 Upper bound on $\mathbb{P}(|o - p_c| \leq aN)$

Let $\hat{G}^{\tilde{\rho}}$ and $\hat{G}^{\bar{\rho}}$ be the stationary LPP with $\tilde{\rho} = \rho + rN^{-\frac{1}{2}}$ and $\bar{\rho} = \rho - rN^{-\frac{1}{2}}$ constructed through (3.13)–(3.14) with the boundary weights on the north-east boundaries of $\mathcal{R}^{\xi,N}$ as in (5.6) (with $M = N$) and the bulk weights $\{\omega_x\}_{x \in \mathcal{R}^{\xi,N}}$. Recall (3.15).

Similarly to (5.4) define

$$\hat{A}' = \left\{ \hat{Z}_{\tilde{\rho}(\xi)}^{p(\xi)}_{q^1,o} < -aN^{\frac{2}{3}} \right\} \cap \left\{ \hat{Z}_{\bar{\rho}(\xi)}^{p(\xi)}_{q^1,o} > 0 \right\}.$$ 

Similarly to Corollary 5.6 we have

**Lemma 6.1** Fix $\xi \in \mathfrak{r}i$ and $a > 0$. There exist $C(\xi, a) > 0$, locally bounded in $a$, and $N_0(\xi, r) > 0$ such that

$$\mathbb{P}((\hat{A}')^c) \leq Cr^{-3}.$$  

**Proof** By definition of $\hat{A}'$

$$\mathbb{P}((\hat{A}')^c) \leq \mathbb{P}\left( \hat{Z}_{q^1,o}^{\tilde{\rho}(\xi)} \geq -aN^{\frac{2}{3}} \right) + \mathbb{P}\left( \hat{Z}_{q^1,o}^{\bar{\rho}(\xi)} < 0 \right)$$  

The bound on $\mathbb{P}\left( \hat{Z}_{q^1,o}^{\tilde{\rho}(\xi)} < 0 \right)$ comes from (5.16), it remains to bound $\mathbb{P}\left( \hat{Z}_{q^1,o}^{\bar{\rho}(\xi)} \geq -aN^{\frac{2}{3}} \right)$. Let $u = (u_1, u_2) = (\xi N - aN^{2/3}e_2)$, and let $\hat{G}^{\rho, [q^1]}_{u,x}$ be the LPP induced by $\hat{G}^{\rho}_{q^1,x}$ at $u$. By Lemma 3.2 we see that

$$\mathbb{P}\left( \hat{Z}_{q^1,x}^{\rho} \geq -aN^{\frac{2}{3}} \right) = \mathbb{P}\left( \hat{Z}_{u,x}^{[q^1]} \geq 0 \right),$$  

where $\hat{Z}_{u,x}^{[q^1]}$ is the exit point of $\hat{G}^{\rho, [q^1]}_{u,x}$. Compute

$$(u_2 - \frac{\rho^2}{(1 - \rho)^2}u_1) - o_2 = \xi_2 N - \frac{\rho^2}{(1 - \rho)^2} \xi_1 N - aN^{\frac{2}{3}}$$
\[
\begin{align*}
\frac{\xi_2 N \left( 1 - 2(\rho - rN^{-\frac{1}{2}}) + (\rho - rN^{-\frac{1}{2}})^2 \right) - (\rho^2 - 2\rho r N^{-\frac{1}{2}} + r^2 N^{-\frac{3}{2}})\xi_1 N}{(1 - \rho)^2} &= N \left( \frac{\xi_2 (1 - \rho)^2 - \xi_1 \rho^2}{(1 - \rho)^2} + 2r N^\frac{3}{2} (\xi_1 \rho + \xi_2 (1 - \rho)) + N^\frac{1}{2} r^2 (\xi_2 - \xi_1) \right) - a N^\frac{3}{2} \xi_1 N \left( 1 - \rho \right)^2 - \xi_1 \rho^2 - A N^\frac{3}{2} - 2rN^2 \frac{1}{3} \left( \xi_1 \rho + \xi_2 (1 - \rho) \right) + N^{-\frac{1}{2}} r^2 (\xi_2 - \xi_1),
\end{align*}
\]

where

\[c' = \frac{(1 - \rho)^2}{2[\xi_1 \rho + \xi_2 (1 - \rho)]}.\]  

(6.4)

It follows that there exists \( N_0(\xi, \rho) \) such that for \( N > N_0 \)

\[\left( u_2 - \frac{\rho^2}{(1 - \rho)^2} u_1 \right) - o_2 > \frac{(r - ca) N^\frac{3}{2} (\xi_1 \rho + \xi_2 (1 - \rho))}{(1 - \rho)^2},\]

where

\[c = \frac{(1 - \rho)^2}{4[\xi_1 \rho + \xi_2 (1 - \rho)]}.\]  

(6.5)

It then follows by Lemma 3.1 that there exists a constant \( C(\xi) > 0 \) such that

\[P(\hat{Z}_{\alpha, \xi} > 0) \leq C_1 (r - ca)^{-3}.\]

the proof is now complete. Taking \( C > 0 \) large enough implies (6.1) \( \square \)

Let \( 0 < \alpha < 1 \) and \( o_\alpha = o + \alpha \xi N = \alpha \xi N \). We define \( \mathcal{R}_\alpha = [o, o_\alpha] \) to be the rectangle whose left bottom corner is \( o \) and whose upper right corner is \( o_\alpha \). We shall need the following result.

**Lemma 6.2** Fix \( \xi \in \text{ri} \mathcal{U}, \) \( 0 < \alpha < 1 \) and \( r > 0 \). There exists \( C(\xi) > 0 \) such that for \( t > \alpha r \) and \( N > N_0(\xi, \rho) \)

\[P\left( |\hat{Z}_{o_\alpha, o}| \geq t N^\frac{3}{2} \right) \leq C^2 t^{-3}, \]

(6.6)

\[P\left( |\hat{Z}_{o_\alpha, o}| \geq t N^\frac{3}{2} \right) \leq C^2 t^{-3}. \]

(6.7)

**Proof** We prove (6.6) as (6.7) is similar. In fact we only prove here the upper bound for \( P(\hat{Z}_{o_\alpha, o} > t N^\frac{3}{2}) \) as the bound on \( P(\hat{Z}_{o_\alpha, o} < t N^\frac{3}{2}) \) is similar. Let \( \hat{G}_{u, x}^{\rho, [\alpha]} \) be the LPP induced by \( \hat{G}_{o_\alpha, x}^{\rho} \) at \( u \) where \( u = \alpha \xi N - A_1 t N^\frac{3}{2} e_1 \), and

\[A_1 = \frac{4(\xi_1 \rho + \xi_2 (1 - \rho))}{\rho^2}. \]

(6.8)
By Lemma 3.2 we see that

$$\mathbb{P}(\hat{Z}_{u,x}^{[\alpha]} > 0) = \mathbb{P}(\hat{Z}_{\bar{\rho},x}^{\rho} > A_1tN^{\frac{3}{2}}). \quad (6.9)$$

where \(\hat{Z}_{u,x}^{[\alpha]}\) and \(\hat{Z}_{\bar{\rho},x}^{\rho}\) are the exit points of \(\hat{G}_{\bar{\rho},x}^{[\alpha]}\) and \(\hat{G}_{\rho,x}^{\rho}\) respectively. We would like to show that the characteristic \(\xi(\bar{\rho})\) emanating from the point \(u = (u_1, u_2)\) goes well above the point \(o\) on the scale of \(N^{\frac{3}{2}}\). Compute

$$\left( u_2 - \frac{\bar{\rho}^2}{(1 - \bar{\rho})^2}u_1 \right) - o_2 = \alpha\xi_2N - \frac{\bar{\rho}^2}{(1 - \bar{\rho})^2}(\alpha\xi_1N - A_1tN^{\frac{3}{2}})$$

$$= \frac{\alpha\xi_2N(1 - 2(\rho + rN^{-\frac{1}{2}}) + (\rho + rN^{-\frac{1}{2}})^2) - (\rho^2 + 2\rho rN^{-\frac{1}{2}} + r^2N^{-\frac{3}{2}})\alpha\xi_1N}{(1 - \bar{\rho})^2}$$

$$+ \frac{\bar{\rho}^2}{(1 - \bar{\rho})^2}A_1tN^{\frac{3}{2}}$$

$$= \frac{\alpha N(\xi_2(1 - \rho)^2 - \xi_1\rho^2) - 2\rho rN^{\frac{3}{2}}(\xi_1\rho + \xi_2(1 - \rho)) + \alpha N^{\frac{1}{2}}r^2(\xi_2 - \xi_1)}{(1 - \bar{\rho})^2}$$

$$+ \frac{\bar{\rho}^2}{(1 - \bar{\rho})^2}A_1tN^{\frac{3}{2}}$$

$$tN^{\frac{3}{2}}\left( \rho^2A_1 - \frac{2\rho r}{t}(\xi_1\rho + \xi_2(1 - \rho)) + \frac{\alpha r^2}{t}N^{-\frac{1}{2}}(\xi_2 - \xi_1) \right) \geq \frac{\alpha N^{\frac{1}{2}}r^2(\xi_2 - \xi_1)}{(1 - \rho)^2}.$$
Applying the change of variables $A_1 t \mapsto t$, there exists $C_1(\xi) > 0$ such that

$$\mathbb{P}(\hat{Z}_{0_\alpha,x}^\rho > tN^{3/2}) \leq C_1 \alpha^2 t^{-3}. \quad (6.11)$$

Similarly we show that there exists $C_2(\xi)$ such that

$$\mathbb{P}(\hat{Z}_{0_\alpha,x}^\rho < -tN^{3/2}) \leq C_2 \alpha^2 t^{-3}.$$

Setting $C = C_1 \lor C_2$ implies the result. \hfill \Box

Define the sets

$$\partial^\alpha = \{\alpha \xi e_1 \}_{0 \leq i \leq \alpha N} \cup \{\alpha \xi e_2 \}_{0 \leq i \leq \alpha N}$$

$$\partial^{\alpha,t}_c = \{\alpha \xi e_1 \}_{0 \leq i \leq tN^{2/3}} \cup \{\alpha \xi e_2 \}_{0 \leq i \leq tN^{2/3}}$$

$$\partial^{\alpha,t}_f = \partial^\alpha \setminus \partial^{\alpha,t}_c.$$

In words, $\partial^\alpha$ is the north-east boundary of $\mathcal{R}_\alpha$, $\partial^{\alpha,t}_c$ are all the points in $\partial^\alpha$ whose $l_1$ distance from $o_\alpha$ is less or equal to $tN^{2/3}$ while $\partial^{\alpha,t}_f$ are the set of points in $\partial^\alpha$ whose $l_1$ distance from $o_\alpha$ is larger or equal to $tN^{2/3}$. Let $\bar{\pi}^q_{1,o}$ and $\pi^q_{1,o}$ be the stationary geodesics that start from $q^1$ and terminate at $o$, associated to $\hat{G}_{\bar{\rho}}$ and $\hat{G}_{\rho}$ respectively. Define

$$B^{r,\alpha,t} = \{\bar{\pi}^q_{1,o} \cap \partial^{\alpha,t} \neq \emptyset\} \cap \{\pi^q_{1,o} \cap \partial^{\alpha,t} \neq \emptyset\} \quad (6.12)$$

The superscript $r$ in $B^{r,\alpha,t}$ appears implicitly in $\bar{\rho}, \rho$. The following result shows that with high probability the geodesics $\bar{\pi}^q_{1,o}$ and $\pi^q_{1,o}$ will not wonder too far from the point $o_\alpha$.

**Corollary 6.3** Fix $\xi \in \text{ri} \mathcal{U}$, $0 < \alpha < 1$ and $r > 0$. There exists $C(\xi) > 0$ such that for $t > \alpha r$ and $N > N_0(\xi, r)$

$$\mathbb{P}((B^{r,\alpha,t})^c) \leq C \alpha^2 t^{-3}. \quad (6.13)$$

**Proof** Note that it is possible to couple $\hat{Z}_{0_\alpha,o}^\bar{\rho}, \hat{Z}_{0_\alpha,o}^\rho, \bar{\pi}^q_{1,o}$ and $\pi^q_{1,o}$ so that

$$\{\bar{\pi}^q_{1,o} \cap \partial^{\alpha,t}_f \neq \emptyset\} = \{|\hat{Z}_{0_\alpha,o}^\bar{\rho}| \geq tN^{3/2}\} \quad (6.14)$$

$$\{\pi^q_{1,o} \cap \partial^{\alpha,t}_f \neq \emptyset\} = \{|\hat{Z}_{0_\alpha,o}^\rho| \geq tN^{3/2}\}. \quad (6.15)$$

Taking probabilities on both sides of (6.14) and (6.15), using Lemma 6.2 and union bound we obtain (6.13). \hfill \Box
Define the sets
\[\mathcal{D}_{1}^{r,\alpha,t} = \{ B_{\bar{o}_{\alpha} - ke_{1},o_{\alpha} - (k-1)e_{1}} \} \quad \text{for } 1 \leq k \leq tN^{\frac{2}{3}}\]
\[\mathcal{D}_{2}^{r,\alpha,t} = \{ B_{\bar{o}_{\alpha} - ke_{2},o_{\alpha} - (k-1)e_{2}} \} \quad \text{for } 1 \leq k \leq tN^{\frac{2}{3}}\]
\[\mathcal{D}_{r}^{r,\alpha,t} = \mathcal{D}_{1}^{r,\alpha,t} \cap \mathcal{D}_{2}^{r,\alpha,t},\]
where the superscript \(r\) is implicit in \(\bar{\rho}, \rho\) ((5.2)).

**Lemma 6.4** For every \(\xi \in \operatorname{ri} \mathcal{U}\) and \(0 < \alpha < 1\), there exists \(C(\xi) > 0\) so that for every \(r \geq 1\) and \(t \leq r^{-2}\) there exists \(N_{0}(r) > 0\) such that for \(N \geq N_{0}\)
\[
P\left((\mathcal{D}_{r}^{r,\alpha,t})^{c}\right) \leq Ct^{\frac{1}{2}}r. \quad (6.16)\]

**Proof** We show (6.16) for \(\mathcal{D}_{2}^{r,\alpha,t}\) the result then follows by union bound. As in (5.26) we have
\[
P\left((\mathcal{D}_{2}^{r,\alpha,t})^{c}\right) = v_{\bar{\rho}, \rho}^{r} \hat{\rho} \left(\sum_{i=1}^{N^{\frac{2}{3}}} e_{i} > 0\right). \quad (6.17)\]
Using (5.30) with \(\theta = t^{-\frac{1}{2}}N^{-\frac{1}{3}}\)
\[
v_{\bar{\rho}, \rho}^{r} \hat{\rho} \left(\sum_{i=1}^{N^{\frac{2}{3}}} e_{i} > 0\right) \leq \frac{2rN^{-\frac{1}{3}}}{\rho + rN^{-\frac{1}{3}}}
+ \frac{\rho - rN^{-\frac{1}{3}}}{\rho + rN^{-\frac{1}{3}}} \left[1 + \frac{(2rt^{\frac{1}{2}} + 1)t^{-1}N^{-\frac{2}{3}}}{\rho^{2} - (r^{2}N^{-\frac{2}{3}} + 2rt^{-\frac{1}{2}}N^{-\frac{2}{3}} + t^{-1}N^{-\frac{2}{3}})}\right]tN^{\frac{2}{3}} \left(1 + 2t^{-\frac{1}{2}}r^{-1}\right)^{-1}. \quad (6.18)\]
Sending \(N\) to \(\infty\), the right hand site of (6.18) converges to
\[
e^{\rho^{-2}(2rt^{\frac{1}{2}} + 1)} \left(1 + 2t^{-\frac{1}{2}}r^{-1}\right)^{-1} \leq e^{\rho^{-2}(2rt^{\frac{1}{2}} + 1)} \frac{1}{2} t^{\frac{1}{2}} r. \quad (6.19)\]
Plugging (6.19) in (6.17), by our assumption on \(t, rt^{\frac{1}{2}} \leq 1\), and so we see that there exists \(C_{2}(\xi) > 0\) such that for every \(r \geq 1\), there exists \(N_{0}(r) > 0\) such that for \(N \geq N_{0}\)
\[
P\left((\mathcal{D}_{2}^{r,\alpha,t})^{c}\right) \leq C_{2}t^{\frac{1}{2}}r.\]
Similar bound can be obtained for \(\mathcal{D}_{1}^{r,\alpha,t}\) the result then follows by union bound. \(\square\)
Local stationarity in exponential last-passage percolation

Fig. 6 With high probability the geodesics $\pi_{q_1,o}$ and $\pi_{q_1,o}$ sandwich the geodesics $\pi_{q_1,o}$ and $\pi_{q_2,o}$. The stationary geodesics (in red) use the same weights on edges in $E(\partial_\alpha,t)$. The proof of Theorem 2.8

**Proof of Theorem 2.8** We first claim that on the event $\hat{A}_r \cap B_r,\alpha,t \cap D_r,\alpha,t$ the geodesics $\pi_{q_1,o}$ and $\pi_{q_1,o}$ must coalesce outside $\mathcal{R}_\alpha$ (see Fig. 6). On the event $\hat{A}_r$

$$\pi_{q_1,o} \preceq \pi_{q_1,o} \preceq \pi_{q_1,o}.$$  \hspace{1cm} (6.20)

This means that coalescence of the geodesics $\pi_{q_1,o}$ and $\pi_{q_1,o}$ outside $\mathcal{R}_\alpha$ implies the coalescence of the geodesics $\pi_{q_1,o}$ and $\pi_{q_2,o}$ outside $\mathcal{R}_\alpha$. It is therefore enough to show that on the set $B_r,\alpha,t \cap D_r,\alpha,t$

$$\mathcal{P}^{\xi,\alpha N}(\pi_{q_1,o}) = \mathcal{P}^{\xi,\alpha N}(\pi_{q_1,o}).$$  \hspace{1cm} (6.21)

On the event $B_r,\alpha,t$ the geodesics $\pi_{q_1,o}$ and $\pi_{q_1,o}$ do not cross $\partial_\alpha^{t}$ and therefore use only the weights $B_\alpha^t, B_\alpha^t$ where $e \in \mathcal{E}(\partial_\alpha^{t})$ and the bulk weights $\{\omega_\alpha\}_{x \in \mathcal{R}_\alpha}$. It follows that on $B_r,\alpha,t \cap D_r,\alpha,t$ (6.21) holds. Set $r = \alpha^{-\frac{2}{7}}, t = \alpha^{\frac{16}{27}}$ so that $t = \alpha^{\frac{16}{27}} \geq \alpha^{\frac{25}{27}} = \alpha r$ holds (since $0 < \alpha < 1$). Note that under this choice of parameters $t^{1/2} < 1$. Use (6.1), (6.13) and (6.16) to see that there exists $C'(\xi, a) > 0$ such that

$$\mathbb{P}(|o - p_c| \leq (\xi_1 \wedge \xi_2)\alpha N) \leq \mathbb{P}(p_c \in \mathcal{R}_\alpha)$$

$$\leq \mathbb{P}\left(\left(\mathcal{A}^{\alpha^{-\frac{2}{7}}}\right)^c\right) + \mathbb{P}\left(\left(\mathcal{B}^{\alpha^{-\frac{2}{7}},\alpha,\alpha^{\frac{16}{27}}}\right)^c\right) + \mathbb{P}\left(\left(\mathcal{D}^{\alpha^{-\frac{2}{7}},\alpha,\alpha^{\frac{16}{27}}}\right)^c\right).$$
\[
\leq C' \left( \alpha \frac{\hat{\sigma}}{N} + \alpha \frac{\hat{\sigma}}{N} + \alpha \frac{\hat{\sigma}}{N} \right).
\]

The result now follows. \(\square\)

### 6.2 Upper bound on \(\mathbb{P}(|q^2 - pc| \leq \alpha N)\)

For every \(\xi \in riU\) and \(m \in \mathbb{Z}\), define the set
\[
C_{m,t}^\xi = \{m\} \times \{y \in \mathbb{Z} : m\xi_2/\xi_1 - y \leq tN^{\frac{2}{3}}\}
\]
\[
C_{m,t}^{-\xi} = \{m\} \times \{y \in \mathbb{Z} : m\xi_2/\xi_1 - y \geq -tN^{\frac{2}{3}}\}.
\]

Let \(\xi^1 = \xi\) and \(\xi^2 = \xi - (0, aN^{-\frac{1}{3}})\) be two vectors whose direction is that of the characteristics emanating from \(o\) associated with the point \(q^1\) and \(q^2\) respectively. Let \(\bar{\rho} = \rho(\xi) + r N^{-\frac{1}{3}}, \tilde{\rho} = \rho(\xi) - r N^{-\frac{1}{3}}\) and consider \(G_{0,x}^{\bar{\rho}}\) and \(G_{0,x}^{\rho}\) on \(\mathcal{R}^{\mathcal{N}_d}\) as in (3.7).

For \(x \in o + \mathbb{Z}_2 > 0\), let \(\bar{\pi}^{\rho,x}\) and \(\pi^{\rho,x}\) be the geodesics associated with the last-passage time \(G_{o,x}^{\rho}\) and \(G_{o,x}^{\rho}\) respectively. We shall need the following auxiliary result.

**Lemma 6.5** Let \(0 < \alpha < 1\) and \(r \geq 1\). There exists \(N_0(\xi, r), C(\xi), A(\xi) > 0\) such that for \(N > N_0\) and \(t \geq A\alpha r\) \((\text{see Fig. 7})\)

\[
\mathbb{P}\left(\bar{\pi}^{\rho,0} \in \left(C_{(1-\alpha)\xi_1 N,t}^{\xi^1}\right)^c\right) \leq C(\alpha^2 t^{-3} + r^{-3}) \tag{6.22}
\]
\[
\mathbb{P}\left(\pi^{\rho,0} \in \left(C_{(1-\alpha)\xi_1 N,t}^{\xi^2}\right)^c\right) \leq C(\alpha^2 t^{-3} + r^{-3}). \tag{6.23}
\]

**Proof** We prove only (6.22) as the proof of (6.23) is similar. We would first like to show that there exist \(N_0(\xi, r), C_1(\xi), A(\xi) > 0\) such that for \(N > N_0\) and \(t \geq A\alpha r\) (see Fig. 7)

\[
\mathbb{P}\left(\bar{\pi}^{\rho,0} \in \left(C_{(1-\alpha)\xi_1 N,t}^{\xi^1}\right)^c\right) \leq C_1\alpha^2 t^{-3}. \tag{6.24}
\]

To see that (6.24) holds, let \(u = \left((1 - \alpha)\xi_1 N, (1 - \alpha)\xi_2 N - tN^{\frac{2}{3}}\right)\) and consider \(G_{u,x}^{\bar{\rho},[\alpha]}\). Note that

\[
\left\{\bar{\pi}^{\rho,0} \in \left(C_{(1-\alpha)\xi_1 N,t}^{\xi^1}\right)^c\right\} = \left\{Z_{u,q^1}^{[\alpha]} > 0\right\}. \tag{6.25}
\]

We compute
\[
\xi_2 N - \left[(1 - \alpha)\xi_2 N - tN^{\frac{2}{3}} + \frac{\bar{\rho}^2}{(1 - \bar{\rho})^2} \alpha \xi_1 N\right]
\]
\[
= \alpha \xi_2 N + \frac{\bar{\rho}^2}{(1 - \bar{\rho})^2} \alpha \xi_1 N + tN^{\frac{2}{3}}
\]
Fig. 7 With high probability the geodesic $\bar{\pi}^{o,q^1}$ exits from the south boundary of $\mathcal{R}^{\xi,N}$ and crosses the set $C^{\xi^1+}_{(1-\alpha)\xi_1N,t}$.

\[
\mathcal{R}^{\xi,N}
\]

\[
\begin{align*}
\mathcal{C}^{\xi^1+}_{(1-\alpha)\xi_1N,t} & = \frac{\alpha \xi_2 N (1 - 2(\rho + rN^{-\frac{1}{2}}) + (\rho + rN^{-\frac{1}{2}})^2) - \left(\rho^2 + 2\rho N^{-\frac{1}{2}} + r^2 N^{-\frac{3}{2}}\right) \alpha \xi_1 N}{(1 - \bar{\rho})^2} + tN^{\frac{3}{2}} \\
& = \frac{\alpha N(\xi_2(1-\rho)^2 - \xi_1\rho^2) - 2\alpha N^\frac{3}{2}((\xi_1\rho + \xi_2(1-\rho)) + \alpha N^\frac{3}{2}r^2(\xi_2 - \xi_1))}{(1 - \bar{\rho})^2} + tN^{\frac{3}{2}} \\
& = \frac{tN^\frac{3}{2}((1-\bar{\rho})^2 - (1-\rho)^2 + (1-\rho)^2 - 2\alpha \xi_2 \xi_1 (\xi_1\rho + \xi_2(1-\rho)) + \alpha N^\frac{3}{2}r^2(\xi_2 - \xi_1))}{(1 - \bar{\rho})^2}.
\end{align*}
\]

If

\[
I \geq \frac{5\alpha r (\xi_1\rho + \xi_2(1-\rho))}{(1-\rho)^2},
\]

then there for $C'(\xi) > 0$

\[
\begin{align*}
\alpha \xi_2 N - \frac{\bar{\rho}^2}{(1 - \bar{\rho})^2} \alpha \xi_1 N + tN^\frac{3}{2} \\
& \geq \frac{tN^\frac{3}{2}((1-\bar{\rho})^2 - (1-\rho)^2 + \frac{3}{5}(1-\rho)^2 + C'rN^{-\frac{1}{2}}(\xi_2 - \xi_1))}{(1 - \bar{\rho})^2},
\end{align*}
\]

(6.26)
Fig. 8 With high probability the geodesic $\pi^{o,q_1}$ crosses the vertical line at $(1 - \alpha)\xi_1 N$ no too far below the characteristic $\xi^1$ while $\pi^{o,q_2}$ crosses no too far above the characteristic $\xi^2$ so that there exists $N_0(\xi, r)$ such that for $N > N_0$ the left hand side of (6.26) is greater of equal to

$$\frac{tN^{\frac{3}{2}}(\frac{1}{2}(1 - \rho)^2)}{(1 - \rho)^2} = \frac{1}{2} \alpha^{-\frac{3}{2}} t(\alpha N)^{\frac{3}{2}}.$$  

It then follows by Lemma 3.1 that there exists a constant $C_1(\xi) > 0$ such that for $N > N_0$

$$\mathbb{P}(Z^{[\alpha]}_{\rho,q_1} > 0) \leq C_1 \alpha^2 t^{-3}.$$  

(6.27)

(6.24) now follows from (6.27) using (6.25). Next we use (6.24) to obtain (6.22). To see that, we first note that (similar to (5.16)) there exists $C_2(\xi) > 0$ such that

$$\mathbb{P}(Z^{[\rho]}_{\alpha,q_1} > 0) \geq 1 - C_2 r^{-3}$$

which implies that

$$\mathbb{P}(\pi^{q_1,o} \leq \tilde{\pi}^{\alpha,q_1}) \geq 1 - C_2 r^{-3}.$$  

(6.28)
Note that
\[
\{\pi^{o,q_1} \in (\sigma_{(1-a)\xi_1 N,t})^c \cap \{\pi^{q_1,o} \leq \tilde{\pi}^{o,q_1} \} \subset \{\tilde{\pi}^{o,q_1} \in (\sigma_{(1-a)\xi_1 N,t})^c \}. \tag{6.29}
\]
Taking probability in (6.29) and using (6.24) and (6.28) we arrive at (6.22).

Proof of Theorem 2.9 Fix 0 < \alpha < 1. Note that
\[
(N\xi_2 - N\xi_1 - aN^{\alpha \frac{2}{3}})N(1-\alpha)\xi_1 N = a(1-\alpha)N^{\frac{2}{3}}
\]
Let \( t = \frac{a}{3}(1-\alpha) + r = \frac{2}{3}\alpha^{-\frac{2}{3}} \) where A is the constant from Lemma 6.5, so that \( t \geq Aar = ta^{\frac{1}{3}} \). By Lemma 6.5, there exists \( C(\xi, a) > 0 \)
\[
\mathbb{P}(\pi^{q_1,o} \in (\sigma_{(1-a)\xi_1 N,t})^c) \leq Ca^2
\]
\[
\mathbb{P}(\pi^{q_2,o} \in (\sigma_{(1-a)\xi_1 N,t})^c) \leq Ca^2. \tag{6.30}
\]
Let \( p_1 = \inf\{y : ((1-\alpha)\xi_1 N, y) \in \pi^{q_1,o}\} \) and \( p_2 = \sup\{y : ((1-\alpha)\xi_1 N, y) \in \pi^{q_2,o}\} \) be the lowest and highest intersection points of the vertical line at \((1-\alpha)\xi_1 N\) with \( \pi^{q_1,o} \) and \( \pi^{q_2,o} \) respectively (Fig. 8). (6.30) implies that
\[
\mathbb{P}(p_1 - p_2 < \frac{a}{3}(1-\alpha)N^{\frac{2}{3}}) \leq 2Ca^2.
\]
It follows that
\[
\mathbb{P}(p_c \in [(1-\alpha)\xi_1 N, 0], \xi N)] \leq 2Ca^2. \tag{6.31}
\]
(6.31) implies the result.

Appendix A. Queues

We formulate last-passage percolation over a bi-infinite strip as a queueing operator. The inputs are two bi-infinite sequences: the inter-arrival process \( a = (a_j)_{j \in \mathbb{Z}} \) and
the service process \( \mathbf{s} = (s_j)_{j \in \mathbb{Z}} \). The queueing interpretation is that \( a_j \) is the time between the arrivals of customers \( j - 1 \) and \( j \) and \( s_j \) is the service time of customer \( j \).

The operations below are well-defined as long as \( \lim_{m \to -\infty} \sum_{i=m}^{0} (s_i - a_{i+1}) = -\infty \).

From inputs \( (a, s) \) three output sequences \( \mathbf{d} = D(a, s), \quad \mathbf{t} = S(a, s), \quad \mathbf{\tilde{s}} = R(a, s) \) (A.1)

are constructed through explicit mappings: the inter-departure process \( \mathbf{d} = (d_j)_{j \in \mathbb{Z}}, \)

the sojourn process \( \mathbf{t} = (t_j)_{j \in \mathbb{Z}}, \)

and the dual service times \( \mathbf{\tilde{s}} = (\tilde{s}_j)_{j \in \mathbb{Z}}. \)

The formulas are as follows. Choose a sequence \( G = (G_j)_{j \in \mathbb{Z}} \) that satisfies \( a_j = G_j - G_{j-1}. \)

Define the sequence \( \tilde{G} = (\tilde{G}_j)_{j \in \mathbb{Z}} \) by

\[
\tilde{G}_j = \sup_{k : k \leq j} \left\{ G_k + \sum_{i=k}^{j} s_i \right\}. \tag{A.2}
\]

The supremum above is taken at some finite \( k. \) Then set

\[
d_j = \tilde{G}_j - \tilde{G}_{j-1}, \quad t_j = \tilde{G}_j - G_j, \quad \text{and} \quad \tilde{s}_j = a_j \wedge t_{j-1}. \tag{A.3}
\]

The outputs (A.3) are independent of the choice of \( G. \) Note that to compute \( \{d_j, t_j, \tilde{s}_j : j \leq m\}, \) only inputs \( \{a_j, s_j : j \leq m\} \) are needed. Let \( \mathbf{a} = (a_j)_{j \in \mathbb{Z}} \) and \( \mathbf{s} = (s_j)_{j \in \mathbb{Z}} \) be two independent sequences of i.i.d. exponential r.v. of intensity \( \lambda \) and \( \rho \) respectively, where \( 0 < \lambda < \rho < 1. \) We denote by \( \nu^{\lambda, \rho} \) the distribution of \( (D(a, s), s) \) on \( \mathbb{R}_+^\mathbb{Z} \times \mathbb{R}_+^\mathbb{Z}, \)

i.e.

\[
\nu^{\lambda, \rho} \sim (D(a, s), s). \tag{A.4}
\]

By Burke's Theorem \( D(a, s) \) is sequences of i.i.d. Exponential r.v. of intensity \( \lambda, \) consequently, the measure \( \nu^{\lambda, \rho} \) is referred to as a stationary measure of the queue.

The waiting time of the \( j \)th customer is given by

\[
w_j = \sup_{i \leq j} \left( \sum_{k=i}^{j} s_{k-1} - a_k \right)^+. \tag{A.5}
\]

The random variables \( \{w_j\}_{j \in \mathbb{Z}} \) satisfy

\[
w_j = \left( w_{j-1} + s_{j-1} - a_j \right)^+. \tag{A.6}
\]

The distribution of \( w_0 \) (and by stationarity the distribution of any \( w_j \) for \( j \in \mathbb{Z} \)) is given by

\[
f_w(dw) = \mathbb{P}(w_0 \in dw) = \left(1 - \frac{\lambda}{\rho}\right)\delta_0(dw) + \frac{(\rho - \lambda)\lambda}{\rho} e^{-(\rho - \lambda)w} dw. \tag{A.7}
\]
One can write

\[ d_j = e_j + s_j, \tag{A.8} \]

where \( e_j \) is called the \( j \)'th idle time and is given by

\[ e_j = (w_{j-1} + s_{j-1} - a_j)^-. \tag{A.9} \]

e\(_j\) is the time between the departure of customer \( j - 1 \) and the arrival of customer \( j \) in which the sever is idle. Define

\[ x_j = s_{j-1} - a_j, \]

and the summation operator

\[ S_{k,l} = \sum_{i=k}^l x_i \tag{A.10} \]

Summing \( e_j \) we obtain the cumulative idle time \([35][Chapter 9.2, Eq. 2.7]\) as in the following lemma.

**Lemma A.1** For any \( k \leq l \)

\[ \sum_{i=k}^l e_i = \left( \inf_{k \leq i \leq l} w_{k-1} + S_{i,i}^k \right)^-. \tag{A.11} \]

**Proof** For simpler exposition we set \( k = 1 \). By (A.5)

\[
\begin{align*}
    w_l &= \left( \sup_{1 \leq i \leq l} S_{i,i}^l \right)^+ \lor \left( \sup_{-\infty < i \leq 0} S_{i,0}^l + S_{1,l}^1 \right)^+ \\
    &= \left( \sup_{1 \leq i \leq l} S_{i,i}^l \right)^+ \lor \left( \sup_{-\infty < i \leq 0} S_{i,0}^l \right)^+ + S_{1,l}^1.
\end{align*}
\]

To see that the last equality holds, note that

\[
\begin{array}{ll}
    w_l = \left( \sup_{1 \leq i \leq l} S_{i,i}^l \right)^+ & \text{sup}_{-\infty < i \leq 0} S_{i,0}^l < 0 \\
    \lor \left( \sup_{1 \leq i \leq l} S_{i,i}^l \right)^+ & \text{sup}_{-\infty < i \leq 0} S_{i,0}^l \geq 0.
\end{array}
\]

It follows that

\[ w_l = \left( \sup_{1 \leq i \leq l} S_{i,i}^l \right)^+ \lor \left( S_{1,l}^1 + w_0 \right)^+ \]
\[
\begin{align*}
&= \left( \sup_{2 \leq i \leq l} \left[ S^{1,i} - S^{1,i-1} \right] \right)^+ \lor (S^{1,l} + w_0)^+ \\
&= \left( S^{1,l} - \inf_{1 \leq i \leq l-1} S^{1,i} \right)^+ \lor (S^{1,l} + w_0)^+ \\
&= \left( S^{1,l} + w_0 - \inf_{0 \leq i \leq l-1} \left[ w_0 + \hat{S}^{1,i} \right] \right)^+ \tag{A.12}
\end{align*}
\]

where

\[
\hat{S}^{1,i} = \begin{cases} 
S^{1,i} & i > 0 \\
-w_0 & i = 0
\end{cases},
\]

where the last equality in (A.12) follows since

\[
\left( S^{1,l} + w_0 - \left[ w_0 + \hat{S}^{1,0} \right] \right)^+ = (S^{1,l} + w_0)^+.
\]

It follows that

\[
w_l = S^{1,l} + w_0 - \inf_{0 \leq i \leq l} \left[ w_0 + \hat{S}^{1,i} \right]. \tag{A.13}
\]

where we dropped the positive part because

\[
w_j \geq S^{1,l} + w_0 - \left[ w_0 + \hat{S}^{1,l} \right] = 0.
\]

By (A.6) and (A.9) we see that

\[
-e_j + w_j = w_{j-1} + s_{j-1} - a_j
\implies e_j = w_j - w_{j-1} - x_j. \tag{A.14}
\]

Summing on both sides of (A.14) and using (A.13)

\[
\sum_{i=1}^{l} e_i = w_l - w_0 - S^{1,l}
\]

where

\[
= - \inf_{0 \leq i \leq l} w_0 + \hat{S}^{1,i}
\]

\[
= \left( \inf_{1 \leq i \leq l} w_0 + S^{1,i} \right)^-. \tag{A.15}
\]

Proof of Lemma 5.8 By (A.11)

\[
\sum_{i=1}^{\xi_1 M} e_i = \left( \inf_{1 \leq i \leq \xi_1 M} w_0 + S^{1,i}_x \right)^-. \tag{A.15}
\]

Springer
where

\[ S_{x}^{1,i} = \sum_{j=1}^{i} s_{j-1} - a_{j}. \]

Next we bound from above the probability that the infimum of the path of \( \{S_{x}^{1,i}\}_{1 \leq i \leq \xi_{1} M} \) drops too low. Let \( C > 0 \), then

\[ \mathbb{P}\left( \inf_{1 \leq i \leq \xi_{1} M} S_{x}^{1,i} \leq -C \right) = \mathbb{P}\left( \sup_{1 \leq i \leq \xi_{1} M} -S_{x}^{1,i} \geq C \right). \]

As \( -S_{x}^{1,i} \) is a submartingale and \( \phi_{\theta}(x) = e^{\theta x} \) is a strictly increasing convex function for \( \theta > 0 \), \( \phi_{\theta}(-S_{x}^{1,i}) \) is again a submartingale. By Doob’s inequality

\[ \mathbb{P}\left( \sup_{1 \leq i \leq \xi_{1} M} e^{\theta(-S_{x}^{1,i})} \geq e^{\theta C} \right) \leq \frac{\mathbb{E}(e^{\theta(-S_{x}^{1,i})})}{e^{\theta C}} \]

(A.16)

Note that by the independence of \( a = (a_{j})_{j \in \mathbb{Z}} \) and \( s = (s_{j})_{j \in \mathbb{Z}} \), for \( 0 < \theta < \beta \)

\[ \mathbb{E}(e^{\theta(-S_{x}^{1,i})}) = \left[ \mathbb{E}(e^{-\theta s_{1}}) \mathbb{E}(e^{\theta a_{1}}) \right]^{\xi_{1} M} = \left[ \frac{\alpha}{(\alpha + \theta)} \frac{\beta}{(\beta - \theta)} \right]^{\xi_{1} M}. \]

(A.17)

Plugging (A.17) in (A.16)

\[ \mathbb{P}\left( \sup_{1 \leq i \leq \xi_{1} M} -S_{x}^{1,i} \geq C \right) \leq \left[ \frac{\alpha}{(\alpha + \theta)} \frac{\beta}{(\beta - \theta)} \right]^{\xi_{1} M} e^{-\theta C} \]

(A.18)

By (A.15)

\[ \sum_{i=1}^{\xi_{1} M} e_{i} > 0 \iff w_{0} + \inf_{1 \leq i \leq \xi_{1} M} S_{x}^{1,i} < 0, \]

and so

\[ \mathbb{P}\left( \sum_{i=1}^{\xi_{1} M} e_{i} > 0 \right) = \mathbb{P}\left( w_{0} + \inf_{1 \leq i \leq \xi_{1} M} S_{x}^{1,i} < 0 \right) \]

(A.19)

Note that by the definition of \( w_{0} \) ((A.5)), \( w_{0} \) is independent of \( \{S_{x}^{1,i}\}_{i \in \mathbb{Z} > 0} \) and so

\[ \mathbb{P}\left( w_{0} + \inf_{1 \leq i \leq \xi_{1} M} S_{x}^{1,i} < 0 \right) = \mathbb{P}\left( \sup_{1 \leq i \leq \xi_{1} M} -S_{x}^{1,i} > w_{0} \right) = \int \mathbb{P}\left( \sup_{1 \leq i \leq \xi_{1} M} -S_{x}^{1,i} > w \mid w_{0} = w \right) \mathbb{P}(w_{0} \in dw) \]
In this section passage values are defined.

(Crossing Lemma) The inequalities below are valid whenever the last-passage values defined by (2.1). No probability is involved.

\[ f_w(dw) = \left(1 - \frac{\beta}{\alpha}\right)\delta_0(dw) + \frac{(\alpha - \beta)\beta}{\alpha}e^{-(\alpha-\beta)w}dw, \]  

(A.21)

so that

\[ \mathbb{P}\left(w_0 + \inf_{1 \leq i \leq \xi_1M} S_{x,i}^{1,1} < 0\right) \leq 1 - \frac{\beta}{\alpha} + \int \mathbb{P}\left(\sup_{1 \leq i \leq \xi_1M} -S_{x,i}^{1,1} > w\right)\frac{(\alpha - \beta)\beta}{\alpha}e^{-(\alpha-\beta)w}dw. \]  

(A.22)

Plugging (A.18) in (A.22) we obtain the result. \( \square \)

Appendix B. Coupling and monotonicity in last-passage percolation

In this section \( \omega = (\omega_x)_{x \in \mathbb{Z}^2} \) is a fixed assignment of real weights. \( G_{x,y} \) is the last-passage value defined by (2.1). No probability is involved.

Lemma B.1 Suppose weights \( \omega \) and \( \tilde{\omega} \) satisfy \( \omega_{o+ie_1} \geq \tilde{\omega}_{o+ie_1}, \omega_{o+je_2} \leq \tilde{\omega}_{o+je_2}, \) and \( \omega_x = \tilde{\omega}_x \) for \( i, j \geq 1 \) and \( x \in o + \mathbb{Z}^2_{\geq 0}. \) As in (2.1) define LPP processes

\[ G_{o,y} = \max_{x, y \in \Pi_{o,y}} \sum_{k=0}^{\lfloor y-o \rfloor} \omega_{x_k} \quad \text{and} \quad \tilde{G}_{o,y} = \max_{x, y \in \Pi_{o,y}} \sum_{k=0}^{\lfloor y-x \rfloor} \tilde{\omega}_{x_k} \quad \text{for} \quad y \in o + \mathbb{Z}^2_{\geq 0}. \]

Then for all \( y \in o + \mathbb{Z}^2_{\geq 0}, \) the increments over nearest-neighbor edges satisfy

\[ G_{o,y+e_1} - G_{o,y} \geq \tilde{G}_{o,y+e_1} - \tilde{G}_{o,y} \quad \text{and} \quad G_{o,y+e_2} - G_{o,y} \leq \tilde{G}_{o,y+e_2} - \tilde{G}_{o,y}. \]

Proof The statements are true by construction for edges \( (y, y + e_i) \) that lie on the axes \( o + \mathbb{Z}_{\geq 0}e_i. \) Proceed by induction: assuming the inequalities hold for the edges \( (y, y + e_2) \) and \( (y, y + e_1), \) deduce them for the edges \( (y + e_2, y + e_1 + e_2) \) and \( (y + e_1, y + e_1 + e_2). \) \( \square \)

Lemma B.2 (Crossing Lemma) The inequalities below are valid whenever the last-passage values are defined.

\[ G_{o+e_1, x+e_2} - G_{o+e_1, x} \leq G_{o, x+e_2} - G_{o, x} \leq G_{o+e_2, x+e_2} - G_{o+e_2, x} \]  

(B.1)

\[ G_{o+e_2, x+e_1} - G_{o+e_2, x} \leq G_{o, x+e_1} - G_{o, x} \leq G_{o+e_1, x+e_1} - G_{o+e_1, x}. \]  

(B.2)
The proofs of all parts are similar. We prove the second inequality in (B.1), that is,

\[ G_{o,x+e} - G_{o,x} \leq G_{o+e_2,x+e} - G_{o+e_2,x}. \]  

(B.3)

The geodesics \( \pi_{o,x+e} \) and \( \pi_{o+e_2,x} \) must cross. Let \( u \) be the first point where they meet. Note that 

\[ G_{o,u} + G_{u,x} \leq G_{o,x} \quad \text{and} \quad G_{o+e_2,u} + G_{u,x+e} \leq G_{o+e_2,x+e}. \]  

(B.4)

Add the two inequalities in (B.4) and rearrange to obtain (B.3).

\[ \square \]

Appendix C. Convergence of distributions

Let \((X, \rho)\) be a complete, separable metric space and let \(M_1(X)\) be the space of Borel probability distributions on \(X\). For \(\mu, \nu \in M_1(X)\) and \(\epsilon \geq 0\) we define

\[ d_{TV}(\mu, \nu) = \inf \{ \mathbb{P}(\rho(X, Y) > \epsilon) : (X, Y) \text{ is a r.v. s.t. } X \sim \mu, Y \sim \nu \}. \]

For \(\epsilon = 0\) we obtain exactly the definition of total variation distance of distributions.

Lemma C.1 Let \(\mu_1, \mu_2, \mu_3 \in M_1(X)\). Suppose that for some \(\delta > 0\)

\[ d_{TV}(\mu_1, \mu_2) \leq \delta \quad \text{and} \quad d_{TV}(\mu_1, \mu_3) \leq \delta. \]  

(C.1)

Then

\[ d_{TV_2}(\mu_2, \mu_3) \leq 2\delta. \]

Proof Let \(X_1, X_2\) and \(X_3\) be three copies of \(X\) and let \(\Omega = X_1 \times X_2 \times X_3\). By (C.1), there exist \(f_{\mu_1,\mu_2}, f_{\mu_1,\mu_3} \in M_1(X^2)\) s.t.

\[ \int_{X^2} 1_{\rho(x,y) > \epsilon} df_{\mu_1,\mu_i}(x, y) \leq \delta \quad \text{for } i \in \{2, 3\}. \]

For \(i \in \{2, 3\}\) let \(df_{\mu_i|\mu_1}\) be the conditional distribution of \(\mu_i\) given \(\mu_1\) w.r.t. \(f_{\mu_1,\mu_i}\). Define the distribution \(F\) on \(\Omega\) by

\[ dF = d\mu_1(x_1)df_{\mu_2|\mu_1}(x_2)df_{\mu_3|\mu_1}(x_3). \]

Note that the marginals of \(F\) are \(\mu_1, \mu_2\) and \(\mu_3\). Let \(P_{2,3} : \Omega \to X^2\) be the projection map of the last two coordinates in \(\Omega\) and let \(F'\) be the pushforward measure of \(F\) with
respect to $\mathcal{P}_{2,3}$. Then $F'$ is a coupling of $\mu_2$ and $\mu_3$ and

\[
\int_{\mathcal{X}^2} 1_{\rho(x,y) > 2\epsilon} \, dF'(x, y) = \int_{\Omega} 1_{\rho(x_2, x_3) > 2\epsilon} \, dF(x_1, x_2, x_3) \\
\leq \int_{\Omega} 1_{\rho(x_1, x_3) > \epsilon} \, dF(x_1, x_2, x_3) + \int_{\Omega} 1_{\rho(x_2, x_1) > \epsilon} \, dF(x_1, x_2, x_3) \\
\leq 2\delta.
\]  
(C.2)

(C.2) implies the result. □

Lemma C.2 Let $\{\mu_n\}_{n \in \mathbb{N}}$ and $\{\nu_n\}_{n \in \mathbb{N}}$ be two sequences of distributions on $\mathcal{X}$. Suppose that

\[\mu_n \to \mu \text{ and } \nu_n \to \nu \text{ weakly.} \]  
(C.3)

Assume that for every $n \in \mathbb{N}$

\[d_{TV}(\mu_n, \nu_n) \leq \delta. \]  
(C.4)

Then

\[d_{TV}(\mu, \nu) \leq 3\delta. \]

Proof Fix $k \in \mathbb{N}$. The convergences in (C.3) can be realized a.s. and so, there exists $N(k)$ such that for $n > N(k)$

\[d_{TV_{k-1}}(\mu_n, \mu) \leq \delta \]
\[d_{TV_{k-1}}(\nu_n, \nu) \leq \delta. \]

Using Lemma C.1 twice with (C.4) implies that for $n > N(k)$

\[d_{TV_{k-1}}(\mu, \nu) \leq 3\delta, \]

and so there must be a coupling $F^k$ of $\mu$ and $\nu$ such that

\[\int 1_{\rho(x,y) > k^{-1}} \, dF^k \leq 3\delta. \]

The sequence $\{F^k\}_{k \in \mathbb{N}}$ is tight with respect to the product metric as the marginals of $F^k$ are independent of $k$. It follows that there must be a weakly convergent subsequence $F^{k_m}$ such that

\[F^{k_m} \to F, \]
where $F$ is a coupling of $\mu$ and $\nu$ and that for every $k \in \mathbb{N}$

$$\int 1_{\rho(x,y) > k-1} \, dF \leq 3\delta.$$ 

Sending $k$ to infinity implies the result. □
