Gradient flows in the normal and Kähler metrics and triple bracket generated metriplectic systems

Anthony M. Bloch, Philip J. Morrison, and Tudor S. Ratiu

Abstract The dynamics of gradient and Hamiltonian flows with particular application to flows on adjoint orbits of a Lie group and the extension of this setting to flows on a loop group are discussed. Different types of gradient flows that arise from different metrics including the so-called normal metric on adjoint orbits of a Lie group and the Kähler metric are compared. It is discussed how a Kähler metric can arise from a complex structure induced by the Hilbert transform. Hybrid and metriplectic flows that arise when one has both Hamiltonian and gradient components are examined. A class of metriplectic systems that is generated by completely antisymmetric triple brackets is described and for finite-dimensional systems given a Lie algebraic interpretation. A variety of explicit examples of the several types of flows are given.

Keywords: loop groups, adjoint orbits, Hamiltonian systems, integrable systems, gradient flows, metriplectic systems, thermodynamics

1 Introduction

Dynamical systems, finite or infinite, that describe physical phenomena typically have parts that are in some sense Hamiltonian and parts that can be recognized as dissipative, with the Hamiltonian part being generated by a Poisson bracket and the dissipative part being some kind of gradient flow. The description of Hamiltonian systems has received much attention over nearly two centuries and, although some forms of dissipation have received general attention, the understanding and classification of dissipative dynamics is a much broader topic and consequently less well developed. Early modern treatments of geometric Hamiltonian mechanics include those of Souriau [1970] and Abraham and Marsden [1978], and the literature on this topic is now immense. A special type of gradient flow that preserves invariants, the double bracket formalism described in Brockett [1991] (see, e.g., Bloch [1990, 2003]), is a formalism that occurs in a variety of contexts (see Bloch, Krishnaprasad, Marsden, and Ratiu 1994, 1996) and is well-adapted to practical numerical computations (see Vallis, Carnevale, and Young 1989). Examples of infinite-dimensional gradient flows include the Cahn-Hilliard systems (see Otto [2001]) and the celebrated Ricci flows (see Hamilton 1982; Chow 2004), which are nonlinear diffusion-like equations. A general form for combined Hamiltonian and gradient flows was described in Morrison [1986], where such flows were termed metriplectic flows (see also Oettinger 2006; Morrison 2009; Liero and Mielke 2012). Thus, it is evident that there are a variety Hamiltonian and dissipative flows, and the purpose of this paper is to explore the form and geometric structure of such flows in both the ode and pde contexts.

Specifically, in this paper we discuss the dynamics of gradient and Hamiltonian flows, with particular application to flows on adjoint orbits of a Lie group and the extension of this setting to flows on a loop group. We compare the different types of gradient flows that arise from different metrics, in particular, the so-called normal metric on adjoint orbits of a Lie group and the Kähler metric. We discuss how a Kähler metric can arise from the complex structure induced from the Hilbert transform. We also consider flows that arise when one has both Hamiltonian and gradient structures present. In particular, we discuss metriplectic flows, flows that produce entropy while conserving energy. We consider such flows in both the finite and infinite settings, and discuss a general class of metriplectic flows that arise from completely antisymmetric triple brackets. For finite systems, we show how the triple bracket has a natural Lie algebraic formulation, and for infinite systems we give a procedure for constructing a quite general class of metriplectic pdes. We also consider, hybrid flows, of Hamiltonian and gradient form, that dissipate energy. Several examples of hybrid and metriplectic flows are given, including finite systems such as the Toda lattice on $\mathbb{R}$ and metriplectic $\mathfrak{so}(3)$ brackets. Various infinite-dimensional examples including a $1+1$ dissipative systems that conserves energy, and hybrid systems such as the KdV with dissipation, the Ott and Sudan [1969] equation that describes Landau damping, and others.

The paper is organized as follows. In section 2 we review material need for latter development. In particular, we discuss metrics on adjoint orbits, Toda flows and the double bracket formulation. Sections 3 and 4 contain the main new results of the paper as described above. In section 3 we discuss metrics on loop groups and related gradient flows, while in section 4 we discuss our results on metriplectic systems, in both finite- and infinite-dimensions, and give examples.

2 Metrics on adjoint orbits of compact Lie groups and associated dynamical systems

2.1 Double bracket systems

Let $\mathfrak{g}_u$ be the compact real form of a complex semisimple Lie algebra $\mathfrak{g}$, $G_u$ a compact connected real Lie group with Lie algebra $\mathfrak{g}_u$, and $\kappa$ the Killing form (on $\mathfrak{g}$ or $\mathfrak{g}_u$, depending on the context).

The “normal” metric on the adjoint orbit $\mathcal{O}$ of $G_u$ through $L_0 \in \mathfrak{g}_u$ (see Atiyah [1982], Bessis [2008, Chapter 8]) is given as follows. Decompose orthogonally $\mathfrak{g}_u = \mathfrak{g}_u^L \oplus \mathfrak{g}_u^L$, relative to the invariant inner product $(\cdot, \cdot) := -\kappa(\cdot, \cdot)$, where $\mathfrak{g}_u^L := \ker \text{ad} L$ is the centralizer of $L$ and $\mathfrak{g}_u^L = \text{range} \text{ad} L$; as usual, $\text{ad} L := [L, \cdot]$.

For $X \in \mathfrak{g}_u$, denote by $X^L \in \mathfrak{g}_u^L$ and $X_L \in \mathfrak{g}_u^L$ the orthogonal projections of $X$ on $\mathfrak{g}_u^L$ and $\mathfrak{g}_u^L$, respectively. Recall that a general vector tangent at $L$ to the adjoint orbit $\mathcal{O}$ is necessarily of the form $[L, X]$ for some $X \in \mathfrak{g}_u$. The normal metric on $\mathcal{O}$ is the $G_u$-invariant Riemannian metric given by

$$
\langle [L, X], [L, Y] \rangle_{\text{normal}} := \langle X^L, Y^L \rangle
$$

for any $X, Y \in \mathfrak{g}_u$.

Fix $N \in \mathfrak{g}_u$ and consider the flow on the adjoint orbit $\mathcal{O}$ of $G_u$ through $L_0 \in \mathfrak{g}_u$ given by

$$
\frac{d}{dt} L(t) = [L(t), [L(t), N]], \quad L(0) = L_0 \in \mathfrak{g}_u.
$$

We recall the following well-known result (Brockett [1991], Brockett [1994], Bloch, Brockett, and Ratiu [1990], Bloch, Iserles [2005]).

Proposition 1. The vector field given by the ordinary differential equation (2) is the gradient of the function $H(L) = \kappa(L, N)$ relative to the normal metric on $\mathcal{O}$.

Proof. By the definition of the gradient $\text{grad} H(L) \in T_L \mathcal{O} \subset \mathfrak{g}_u$ relative to the normal metric, we have for any $L \in \mathcal{O}$ and $\delta L \in \mathfrak{g}_u$,

$$
dH(L) \cdot [L, \delta L] = \langle \text{grad} H(L), [L, \delta L] \rangle_{\text{normal}}
$$

where $\cdot$ denotes the natural pairing between 1-forms and tangent vectors and $[L, \delta L]$ is an arbitrary tangent vector at $L$ to $\mathcal{O}$. Set $\text{grad} H(L) = [L, X] = [L, X^L]$. Then (3) becomes

$$
-\langle [L, \delta L], N \rangle = \langle [L, X], [L, \delta L] \rangle_{\text{normal}}
$$
or, equivalently,
Gradient flows and metriplectic systems

\[ \langle [L,N], \delta L \rangle = \langle X^L, \delta L^L \rangle = \langle X^L, \delta L \rangle. \]

Since \([L,N] \in \mathfrak{g}_u^L\), this implies that \(X^L = [L,N]\), and hence \(\text{grad} \, H(L) = [L,[L,N]]\), as stated.

The same computation, for a general function \(H \in C^\infty(\mathfrak{g}_u)\), yields

\[ \text{grad} \, H(L) = -[L,[L,\nabla H(L)]] \quad (4) \]

where \(\nabla H(L)\) denotes the gradient of the function \(H\) relative to the invariant inner product \(\langle \ , \ \rangle := -k(\ , \ , )\), i.e.,

\[ dH(L) \cdot X = \langle \nabla H(L), X \rangle \text{ for any } X \in \mathfrak{g}_u. \]

### 2.2 The finite Toda system

The double bracket equation (2) is intimately related to the finite non-compact Toda lattice system. This is a Hamiltonian system modeling \(n\) particles moving freely on the \(x\)-axis and interacting under an exponential potential. Denoting the position of the \(k\)th particle by \(x_k\), the Hamiltonian is given by

\[ H(x,y) = \frac{1}{2} \sum_{k=1}^{n} y_k^2 + \sum_{k=1}^{n-1} e^{x_k-x_{k+1}} \]

and hence the associated Hamiltonian equations are

\[ \dot{x}_k = \frac{\partial H}{\partial y_k} = y_k, \quad \dot{y}_k = -\frac{\partial H}{\partial x_k} = e^{x_{k-1}-x_k} - e^{x_k-x_{k+1}}, \quad (5) \]

where we use the conventions \(e^{x_0-x_1} = e^{x_n-x_{n+1}} = 0\), which corresponds to formally setting \(x_0 = -\infty\) and \(x_{n+1} = +\infty\).

This system of equations has an extraordinarily rich structure. Part of this is revealed by Flaschka’s change of variables \([\text{Flaschka} \, [1974]]\) given by

\[ a_k = \frac{1}{2} e^{(x_k-x_{k+1})/2} \quad \text{and} \quad b_k = -\frac{1}{2} y_k. \quad (6) \]

which transform (5) to

\[ \begin{aligned}
&\dot{a}_k = a_k(b_{k+1} - b_k), \quad k = 1, \ldots, n - 1, \\
&\dot{b}_k = 2(a_k^2 - a_{k-1}^2), \quad k = 1, \ldots, n,
\end{aligned} \]

with the boundary conditions \(a_0 = a_n = 0\). This system is equivalent to the Lax equation

\[ \frac{d}{dt} L = [B,L] = BL - LB, \quad (7) \]

where

\[ L = \begin{pmatrix} b_1 & a_1 & 0 & \cdots & 0 \\ a_1 & b_2 & a_2 & \cdots & 0 \\ \vdots & \ddots & \ddots & \ddots & \vdots \\ 0 & \cdots & b_{n-1} & a_{n-1} & 0 \\ 0 & \cdots & a_{n-1} & b_n & 0 \end{pmatrix}, \quad B = \begin{pmatrix} 0 & a_1 & 0 & \cdots & 0 \\ -a_1 & 0 & a_2 & \cdots & 0 \\ \vdots & \ddots & \ddots & \ddots & \vdots \\ 0 & \cdots & 0 & a_{n-1} & 0 \\ 0 & \cdots & -a_{n-1} & 0 & 0 \end{pmatrix}. \quad (8) \]

If \(O(t)\) is the orthogonal matrix solving the equation

\[ \frac{d}{dt} O = BO, \quad O(0) = \text{Identity}, \]

then from (7) we have

\[ \frac{d}{dt}(O^{-1}LO) = 0. \]
Thus, $O^{-1}L_0 = L(0)$, i.e., $L(t)$ is related to $L(0)$ by conjugation with an orthogonal matrix and thus the eigenvalues of $L$, which are real and distinct, are preserved along the flow. This is enough to show that this system is explicitly solvable or integrable. Equivalently, after fixing the center of mass, i.e., setting $b_1 + \cdots + b_n = 0$, the $n - 1$ integrals in involution whose differentials are linearly independent on an open dense set of phase space \([(a_1,\ldots,a_{n-1},b_1,\ldots,b_n) \mid b_1 + \cdots + b_n = 0]\) are $\text{Tr}L^2,\ldots,\text{Tr}L^n$.

2.3 Lie algebra integrability of the Toda system

Let us quickly recall the well-known Lie algebraic approach to integrability of the Toda lattice. Let $\mathfrak{g}$ be a Lie algebra with an invariant non-degenerate bilinear symmetric form $\langle , \rangle$, i.e., $\langle [\mathfrak{x}, \mathfrak{y}], \mathfrak{z} \rangle = \langle \mathfrak{x}, [\mathfrak{y}, \mathfrak{z}] \rangle$ for all $\mathfrak{x}, \mathfrak{y}, \mathfrak{z} \in \mathfrak{g}$ and $\langle \mathfrak{x}, \mathfrak{x} \rangle = 0$ implies $\mathfrak{x} = 0$. Suppose that $\mathfrak{t}, \mathfrak{s} \subset \mathfrak{g}$ are Lie subalgebras and that, as vector spaces, $\mathfrak{g} = \mathfrak{t} \oplus \mathfrak{s}$. Let $\pi_\mathfrak{s} : \mathfrak{g} \rightarrow \mathfrak{t}$, $\pi_\mathfrak{t} : \mathfrak{g} \rightarrow \mathfrak{s}$ be the two projections induced by this vector space direct sum decomposition. Since $\mathfrak{g} \ni \mathfrak{x} \mapsto \langle \mathfrak{x}, \cdot \rangle \in \mathfrak{g}^*$ is a vector space isomorphism, it naturally induces the isomorphisms $\mathfrak{t}^\perp \cong \mathfrak{s}^* \cong \mathfrak{t}^*$. By non-degeneracy of $\langle , \rangle$, we have $\mathfrak{g} = \mathfrak{t}^\perp \oplus \mathfrak{t}^\perp$; denote by $\pi_{\mathfrak{t}^\perp} : \mathfrak{g} \rightarrow \mathfrak{t}^\perp$, $\pi_{\mathfrak{t}^\perp} : \mathfrak{g} \rightarrow \mathfrak{s}^*$ the two projections induced by this vector space direct sum decomposition. In particular, $\mathfrak{g}$, $\mathfrak{s}^*$, $\mathfrak{t}^\perp$ all carry natural Lie-Poisson structures. The (-) Lie-Poisson bracket of $\mathfrak{s}^* \cong \mathfrak{t}^\perp$ is given by

$$ \{ \varphi, \psi \}(\mathfrak{x}) = -\langle \mathfrak{x}, [\pi_{\mathfrak{t}^\perp} \nabla \varphi(\mathfrak{x}) , \pi_{\mathfrak{t}^\perp} \nabla \psi(\mathfrak{x})] \rangle , \quad \mathfrak{x} \in \mathfrak{t}^\perp, \tag{9} $$

where $\varphi, \psi : \mathfrak{t}^\perp \rightarrow \mathbb{R}$ are any smooth functions, extended arbitrarily to smooth functions, also denoted by $\varphi$ and $\psi$, on $\mathfrak{g}$ and $\nabla \varphi, \nabla \psi$ are the gradients of these arbitrary extensions relative to $\langle , \rangle$. This formula follows from the fact that the gradient on $\mathfrak{t}^\perp$ of $\varphi_{\mathfrak{t}^\perp}$, which is an element of $\mathfrak{s}$ due to the isomorphism $\mathfrak{t}^\perp \cong \mathfrak{s}^*$, equals $\pi_{\mathfrak{t}^\perp} \nabla \varphi$. Thus, the Hamiltonian vector field of $\psi \in C^\infty(\mathfrak{t}^\perp)$, given by $\varphi = \{ \varphi, \psi \}$ for any $\varphi \in C^\infty(\mathfrak{t}^\perp)$, has the expression

$$ X_{\psi}(\mathfrak{x}) = -\pi_{\mathfrak{t}^\perp} [\pi_{\mathfrak{t}^\perp} \nabla \psi(\mathfrak{x})), \mathfrak{x}] , \quad \mathfrak{x} \in \mathfrak{t}^\perp, \tag{10} $$

with the same conventions as above.

If $\psi \in C^\infty(\mathfrak{g})$ is invariant, i.e., $[\nabla \psi(\mathfrak{x}), \mathfrak{x}] = 0$ for all $\mathfrak{x} \in \mathfrak{g}$, then (10) simplifies to

$$ X_{\psi}(\mathfrak{x}) = -\pi_{\mathfrak{t}^\perp} [\pi_{\mathfrak{t}^\perp} \nabla \psi(\mathfrak{x})), \mathfrak{x}] = -\pi_{\mathfrak{t}^\perp} \nabla \psi(\mathfrak{x})), \mathfrak{x}] , \quad \mathfrak{x} \in \mathfrak{t}^\perp. \tag{11} $$

The Adler-Kostant-Symes Theorem (see [Adler 1979], [Kostant 1979], [Symes 1980a,b], and [Ratiu 1980] for many theorems of the same type) states that if $\varphi$ and $\psi$ are both invariant functions on $\mathfrak{g}$, then $\{ \varphi, \psi \} = 0$ on $\mathfrak{t}^\perp$ which is equivalent to the commutation of the flows of the Hamiltonian vector fields $\{ \varphi, \psi \}$.

Suppose that $G = KS$, where $G$ is a Lie group with Lie algebra $\mathfrak{g}$ and $K, S \subset G$ are closed subgroups with Lie algebras $\mathfrak{t}$ and $\mathfrak{s}$, respectively. The writing $G = KS$ means that each element $g \in G$ can be uniquely decomposed as $g = ks$, where $k \in K$ and $s \in S$ and that this decomposition defines a smooth diffeomorphism $K \times S \rightarrow G$. The coadjoint action of $S$ on $\mathfrak{s}^*$ has the following expression, if $\mathfrak{s}^*$ is identified with $\mathfrak{t}^\perp$ via $\langle , \rangle$: if $s \in S$, $\mathfrak{x} \in \mathfrak{t}^\perp$, then $s \cdot \mathfrak{x} = \pi_{\mathfrak{t}^\perp} \mathbf{Ad}_s \mathfrak{x}$, where $\mathbf{Ad}_s \mathfrak{x}$ is the adjoint action in $G$ of the element $s \in S \subset G$ on $\mathfrak{x} \in \mathfrak{t}^\perp \subset \mathfrak{g}$.

For the Toda lattice, this general setup applies in the following way. Let $G = GL(n, \mathbb{R})$, $K = SO(n)$, $S = \{\text{invertible lower triangular matrices}\}$, $G = KS$ is the Gram-Schmidt orthonormalization process, $\mathfrak{g} = gl(n, \mathbb{R})$, $\mathfrak{t} = so(n)$, $\mathfrak{s} = \{\text{lower triangular matrices}\}$, $\langle \xi, \eta \rangle := \text{Tr}(\xi \eta)$ for all $\xi, \eta \in gl(n, \mathbb{R})$, $\mathfrak{t}^\perp = \text{sym}(n)$ the vector space of symmetric matrices, and $\mathfrak{s}^* = \mathbb{R}$, the nilpotent Lie algebra of strictly lower triangular matrices. The set of matrices $L$ in $L$ is a union of $S$-coadjoint orbits parametrized by the value of the trace; for example, the set of trace zero matrices $L$ of the form $[\mathfrak{B}]$ equals the $S$-coadjoint orbit through the symmetric matrix that has everywhere zero entries with the exception of the upper and lower first diagonals where all entries are equal to one. Thus, the Toda lattice is a Poisson system whose restriction to a symplectic leaf is a classical Hamiltonian system with $n - 1$ degrees of freedom. The Hamiltonian of the Toda lattice is $\frac{1}{2} \text{Tr}L^2$ and the $f_k(L) := \frac{1}{2} \text{Tr}L^k$, $k = 1,\ldots,n-1$ are the $n-1$ integrals in involution (by the Adler-Kostant-Symes Theorem) and are generically independent.
2.4 The Toda system as a double bracket equation

If $N$ is the matrix $\text{diag}(1, 2, \ldots, n)$, the Toda equations (7) may be written in the double bracket form (2) for $B := [N, L]$. This was shown in [Bloch, 1990]; the consequences of this fact were further analyzed for general compact Lie algebras in [Bloch, Brockett, and Ratiu, 1999], [Bloch, Brockett, and Ratiu, 1992], and [Bloch, Flaschka, and Ratiu, 1990]. As shown in Proposition [1] the double bracket equation, with $L$ replaced by $iL$ and $N$ by $iN$, restricted to a level set of the integrals described above, i.e., restricted to a generic adjoint orbit of $SU(n)$, is the gradient flow of the function $\text{Tr}LN$ with respect to the normal metric; see [Bloch, Flaschka, and Ratiu, 1990] for this approach.

This observation easily implies that the flow tends asymptotically to a diagonal matrix with the eigenvalues of $L(0)$ on the diagonal and ordered according to magnitude, recovering the result of [Moser, 1975], [Symes, 1982], and [Deift, Nanda, and Tomei, 1983].

2.5 Riemannian metrics on $\mathcal{O}$

Now, we recall that, in addition to the normal metric on an adjoint orbit, there are other natural $G_u$-invariant metrics: the induced and the group invariant Kähler metrics (as discussed in [Atiyah, 1982, §4], [Atiyah and Pressley, 1983], and [Besse, 2008, Chapter 8]).

Firstly, there is the induced metric $b$ on $\mathcal{O}$, defined by $b := t^* (\langle \cdot , \cdot \rangle)$, where $t : \mathcal{O} \hookrightarrow g_u$ is the inclusion and $\langle \cdot , \cdot \rangle := -\langle \cdot , \cdot \rangle$ is thought of as a constant Riemannian metric on $g_u$. Therefore,

$$b(L)([L, X], [L, Y]) := \langle [L, X], [L, Y] \rangle$$

for any $L \in \mathcal{O}, X, Y \in g_u$. The induced metric on $\mathcal{O}$ is also $G_u$-invariant.

Secondly, there are the $G_u$-invariant Kähler metrics on $\mathcal{O}$ compatible with the natural complex structure (of course, induced by the complex structure of $G$). These are in bijective correspondence (by the transgression homomorphism) with the set of $G_u$-invariant sections of the trivial vector bundle over $\mathcal{O}$ whose fiber at $L \in \mathcal{O}$ is the center of $\ker (\text{ad}_L)$ and whose scalar product with all positive roots is positive ([Besse, 2008, Proposition 8.83]). Among these, there is the $G_u$-invariant Kähler metric $b_2$ which is compatible with both the natural complex structure on $\mathcal{O}$ and has as imaginary part the orbit symplectic structure; $b_2$ is called the standard Kähler metric on $\mathcal{O}$.

The $G_u$-invariant Riemannian metrics on a maximal dimensional orbit $\mathcal{O}$ are completely determined by $T$-invariant inner products on the direct sum of the two dimensional root spaces of $g_u$, which is the tangent space to $\mathcal{O}$ at the point $L_0 \in t$ in the interior of the positive Weyl chamber; recall that $\mathcal{O}$ intersects the positive Weyl chamber in a unique point. The negative of the Killing form induces on each such 2-dimensional space an inner product. This inner product, left translated at all points of $\mathcal{O}$ by elements of $G_u$, yields the normal metric on $\mathcal{O}$. Any other $G_u$-invariant inner product on $\mathcal{O}$ is obtained by left translating at all points of $\mathcal{O}$ the inner product on this direct sum of 2-dimensional root spaces obtained by multiplying in each 2-dimensional summand the inner product with a positive real constant.

Since $L_0$ lies in the interior of the positive Weyl chamber (because $\mathcal{O}$ is maximal dimensional), $\alpha(L_0) > 0$ for all positive roots $\alpha$ of $g_u$. Then the constant by which the natural inner product on the 2-dimensional root space needs to be multiplied in order to get the standard Kähler metric is $\alpha(L_0)$, whereas to get the induced metric, it is $\alpha(L_0)^2$ ([Atiyah, 1982, Remark 2 in §4]). We can formulate this differently, as in [Bloch, Flaschka, and Ratiu, 1990]. Since, by (12) and (11),

$$b(L)([L, X], [L, Y]) = \langle [L, X], [L, Y] \rangle = \langle [L, X^L], [L, Y^L] \rangle = \langle -[L, [L, X^L]], Y^L \rangle = \langle -[L, [L, X^L]]^*, Y^L \rangle$$

we have

$$b(L)([L, X], [L, Y]) = b_1(L)(\mathcal{A}(L)^2[L, X], [L, Y]),$$

where we denote now by $b_1$ the normal metric and $\mathcal{A}(L) := \sqrt{(i\text{ad}_L)^2}$ is the positive square root of $(i\text{ad}_L)^2 = -\text{ad}_L^2 = \mathcal{A}(L)^2$. The standard Kähler metric on $\mathcal{O}$ is then given by

$$b_2(L)[L, X], [L, Y]) = b_1(\mathcal{A}(L)[L, X], [L, Y]).$$
Note that, as opposed to the normal and induced metrics which have explicit expressions, the standard Kähler metric on \( O \) requires the spectral decomposition of \( \mathcal{A}(L) \) at any point \( L \in O \). Or, as explained above, one expresses it at the point \( L_0 \) in the positive Weyl chamber in terms of the positive roots and then left translates the resulting inner product at any point of \( O \). The normal metric does not depend on the operators \( \mathcal{A}(L) \), whereas the standard Kähler and induced metrics do.

3 Gradient flows on the loop group of the circle

In this section we introduce three weak Riemannian metrics on the subgroup of average zero functions of the connected component of the loop group \( \tilde{L}\left(S^1\right) \) of the circle, analogous to the normal, standard Kähler, and induced metrics on adjoint orbits of compact semisimple Lie groups. Of course, we shall not work on adjoint orbits of this group because they degenerate to points, \( \tilde{L}\left(S^1\right) \) being a commutative group. Then we shall compute the gradient flows for these three metrics.

3.1 The loop group of \( S^1 \)

Recall (e.g., Pressley and Segal [1986]) that the loop group \( \tilde{L}\left(S^1\right) \) of the circle \( S^1 \) consists of smooth maps of \( S^1 \) to \( S^1 \). With pointwise multiplication, \( L(S^1) \) is a commutative group. Often, elements of \( \tilde{L}(S^1) \) are written as \( e^{i\theta} \), where \( f \in \tilde{L}(\mathbb{R}) := \{ g : [-\pi, \pi] \to \mathbb{R} \mid g \text{ is } C^\infty, g(\pi) = g(-\pi) + 2n\pi, \text{ for some } n \in \mathbb{Z}\} \); \( n \) is the winding number of the closed curve \([-\pi, \pi] \ni t \mapsto e^{i\theta(t)} \in S^1 \) about the origin. More precisely, there is an exact sequence of groups

\[
0 \to \mathbb{R} \to \tilde{L}(\mathbb{R}) \xrightarrow{\exp} \tilde{L}(S^1) \to \mathbb{Z} \to 0
\]

which shows that \( \ker \exp = \mathbb{Z} \) and \( \operatorname{coker} \exp = \{0\} \). Thus the connected components of \( \tilde{L}(S^1) \) are indexed by the winding number. The connected component of the identity \( \tilde{L}(S^1)_0 \) consists of loops with winding number zero about the origin.

If one insists on working with smooth loops, then one can consider \( \tilde{L}(S^1) \) and \( \tilde{L}(S^1)_0 \) as Fréchet Lie groups either in the convenient calculus of [Kriegl and Michor 1997] or in the tame category of [Hamilton 1982].

Alternatively, one can work with loops \( e^{i\theta} \) for \( f : [-\pi, \pi] \to \mathbb{R} \) of Sobolev class \( H^s \), where \( s \geq 1 \) (or appropriate \( W^{s,p} \) or Hölder spaces). By standard theory (see, e.g., Palais [1968] or Adams and Fournier [2003]), it is checked that \( \tilde{L}(S^1) \) is a Hilbert Lie group (see, e.g., [Bourbaki 1973] or [Neeb 2004]). We shall not add the index \( s \) on \( \tilde{L}(\mathbb{R}) \) and \( \tilde{L}(S^1) \); from now on we work exclusively in this category of \( H^s \) Sobolev class maps and loops. A simple proof of the fact that \( \tilde{L}(\mathbb{R}) \) is a Hilbert Lie group was given to us by K.-H. Neeb. First, note that \( \tilde{L}(\mathbb{R}) \) is a closed additive subgroup of the Hilbert space \( H^s(\mathbb{R}) := \{ h : \mathbb{R} \to \mathbb{R} \mid h \text{ of class } H^s \} \). Second, \( \tilde{L}(\mathbb{R}) = \tilde{L}(\mathbb{R})_0 \times \mathbb{Z} \) as topological groups, where \( \tilde{L}(\mathbb{R})_0 := \{ g \in \tilde{L}(\mathbb{R}) \mid g(\pi) = g(-\pi) \} \) is the closed vector subspace of \( H^s(\mathbb{R}) \) consisting of periodic functions; hence it is an additive Hilbert Lie group. Therefore, there is a unique Hilbert Lie group structure on \( \tilde{L}(\mathbb{R})_0 \) for which \( \tilde{L}(\mathbb{R})_0 \) is the connected component of the identity. For general criteria that characterize Lie subgroups in infinite dimensions, see [Neeb 2004, Theorem IV.3.3] (even for certain classes of Lie groups modeled on locally convex spaces). Third, since \( \exp : \tilde{L}(\mathbb{R}) \to \tilde{L}(S^1) \) maps bijectively each connected component of \( \tilde{L}(\mathbb{R}) \) to a connected component of \( \tilde{L}(S^1) \), it induces a Hilbert Lie group structure on \( \tilde{L}(S^1) \).

The commutative Hilbert Lie algebra of \( \tilde{L}(S^1) \) is clearly \( H^s(S^1, \mathbb{R}) := \{ u : S^1 \to \mathbb{R} \mid u \text{ of class } H^s \} \), the space of periodic \( H^s \) maps, and the exponential map \( \exp : H^s(S^1, \mathbb{R}) \to \tilde{L}(S^1) \) is given by \( \exp(u)(\theta) = e^{iu(\theta)} \), where \( \theta \in \mathbb{R}/2\pi\mathbb{Z} = S^1 \).

3.2 The based loop group of \( S^1 \)

The inner product on the Hilbert space \( L^2(S^1) \) of \( L^2 \) real valued functions on \( S^1 \) is defined by
\[ \langle f, g \rangle := \frac{1}{2\pi} \int_{-\pi}^{\pi} d\theta f(\theta)g(\theta), \quad f, g \in L^2(S^1). \]

Following Pressley [1982] and Atiyah and Pressley [1983], we introduce the closed Hilbert subgroup \( L(S^1) := \{ \varphi \in L(S^1) \mid \varphi(1) = 1 \} \) of \( L(S^1) \) whose closed commutative Hilbert Lie algebra is \( L(\mathbb{R}) := \{ u \in H^1(\mathbb{R}) \mid u(1) = 0 \} \). The exponential map \( \exp : L(\mathbb{R}) \ni u \mapsto e^{iu} \in L(S^1) \) is a Lie group isomorphism (with \( L(\mathbb{R}) \) thought of as a commutative group relative to addition), a fact that will play a very important role later (see also Pressley and Segal [1986, page 151, §8.9]).

There is a natural 2-cocycle \( \omega \) on \( L(\mathbb{R}) \), namely

\[ \omega(u, v) := \frac{1}{2\pi} \int_{-\pi}^{\pi} d\theta u' v(\theta) = \langle u', v \rangle, \quad (15) \]

where \( u' := du/d\theta \). Therefore, there is a central extension of Lie algebras

\[ 0 \rightarrow \mathbb{R} \rightarrow \widehat{L(\mathbb{R})} \rightarrow L(\mathbb{R}) \rightarrow 0 \]

which, as shown in Segal [1981], integrates to a central extension of Lie groups

\[ 1 \rightarrow S^1 \rightarrow \widehat{L(S^1)} \rightarrow L(\mathbb{R}) \rightarrow 1. \]

The “geometric duals” of \( L(\mathbb{R}) \) and \( \widehat{L(\mathbb{R})} = \mathbb{R} \oplus L(\mathbb{R}) \) are themselves, relative to the weak \( L^2 \)-pairing. It turns out that the coadjoint action of \( \widehat{L(S^1)} \) on \( \widehat{L(\mathbb{R})} \) preserves \( \{ 1 \} \oplus L(\mathbb{R}) \) so that, as usual, the coadjoint action of \( \widehat{L(S^1)} \) on \( L(\mathbb{R}) \) is an affine action which, in this case, because the group is commutative, equals

\[ \text{Ad}_{e^i} \mu = \left( \frac{f'}{f} \right), \quad e^i \in L(S^1), \quad \mu \in L(\mathbb{R}). \]

Thus, the orbit of the constant function 0 is \( \widehat{L(S^1)}/S^1 \) (where the denominator is thought of as constant loops), i.e., it equals \( L(S^1) \). Therefore, every element \( u \in L(\mathbb{R}) \) of its Lie algebra has, in Fourier representation, vanishing zero order Fourier coefficient, i.e., \( \hat{u}(0) = 0 \).

Thus, the based loop group is a coadjoint orbit of its natural central extension and, according to [42] has three distinguished weak Riemannian metrics. These were computed explicitly in Pressley [1982], Atiyah and Pressley [1983], Pressley and Segal [1986]; we recall them below.

### 3.3 \( L(S^1) \) as a weak Kähler manifold

Note that on \( L(\mathbb{R}) \), the cocycle \( (15) \) is weakly non-degenerate. Therefore, left (or right) translating it at every point of the group \( L(S^1) \) yields a weakly non-degenerate closed two-form, i.e., a symplectic form. Thus, as expected, since it is a coadjoint orbit, the Hilbert Lie group \( L(S^1) \) carries an invariant symplectic form whose value at the identity element 1 (the constant loop equal to 1) is given by \( (15) \).

Now we introduce the Hilbert transform on the circle

\[ \mathcal{H}u(\theta) := \frac{1}{2\pi} \int_{-\pi}^{\pi} ds u(s) \cot \left( \frac{\theta - s}{2} \right) = \frac{1}{2\pi} \int_{-\pi}^{\pi} ds u(\theta - s) \cot \left( \frac{s}{2} \right) := \lim_{\varepsilon \rightarrow 0^+} \frac{1}{\pi} \int_{\varepsilon \leq |s| \leq \pi} ds u(\theta - s) \cot \left( \frac{s}{2} \right) \quad (16) \]

for any \( u \in L^2(S^1) \), where \( f \) denotes the Cauchy principal value. We adopt here the sign conventions in [King, 2009, Formulas (3.202) and (6.38), Vol. 1]. If \( u \in L^2(S^1) \), then \( \mathcal{H}u \in L^2(S^1) \) and it is defined for almost every \( \theta \in [-\pi, \pi] \) (Lusin’s Theorem, [King, 2009, §6.19, Vol. 1]). The Hilbert transform has the following remarkable properties that will be used later on:

- If \( u(\theta) = \sum_{n=-\infty}^{\infty} \tilde{u}(n)e^{in\theta} \in L^2(S^1) \), where \( \tilde{u}(n) := \frac{1}{2\pi} \int_{-\pi}^{\pi} d\theta u(\theta)e^{-in\theta} \), so \( \tilde{u}(n) = \tilde{u}(-n) \) since \( u \) is real valued, then
\[ \mathcal{H}u(\theta) = -i \sum_{n = -\infty}^{\infty} \tilde{u}(n) \text{sign}(n) e^{in\theta} \in L^2(S^1) \]  

(17)

which follows from the identity \( \tilde{\mathcal{H}}f(n) = -i \hat{f}(n) \text{sign}(n) \) \cite[(6.100), (6.124), Vol. 1]{King}. Here, \( \text{sign}(n) = 1 \) if \( n \in \mathbb{N} \), \( \text{sign}(n) = -1 \) if \( n \in -\mathbb{N} \), and \( \text{sign}(0) = 0 \). Note that \( \mathcal{H}u \) is also real valued since \( \tilde{u}(n) \text{sign}(n) = -\tilde{u}(-n) \text{sign}(-n) \). The formula above implies that \( \int_{-\pi}^{\pi} ds \mathcal{H}u(s) = 0 \).

• For every \( u \in L^2(S^1) \), we have the orthogonality property \( \langle u, \mathcal{H}u \rangle = 0 \).

• Take the orthonormal Hilbert basis \( \{ \varphi_n(\theta) := e^{in\theta} \mid n \in \mathbb{Z} \} \) of \( L^2(S^1) \). Then \( \mathcal{H} \varphi_n(\theta) = -i \text{sign}(n) \varphi_n(\theta) \), for all \( n \in \mathbb{Z} \).

So, the eigenvalues of \( \mathcal{H} \) are: \(-i\) for all \( n > 0 \), \( i \) for all \( n < 0 \), and \( 0 \) if \( n = 0 \).

• If \( u, v \in L^2(S^1) \) then \( \langle u, v \rangle = \frac{1}{4\pi^2} \left( \int_{-\pi}^{\pi} ds u(s) \right) \left( \int_{-\pi}^{\pi} ds v(s) \right) + \langle \mathcal{H}u, \mathcal{H}v \rangle \)

and hence \( \|u\|_{L^2(S^1)}^2 = \left( \frac{1}{2\pi} \int_{-\pi}^{\pi} ds u(s) \right)^2 + \|\mathcal{H}u\|_{L^2(S^1)}^2 \)

for any \( u \in L^2(S^1) \). This shows that \( \|\mathcal{H}u\|_{L^2(S^1)}^2 \leq \|u\|_{L^2(S^1)}^2 \) and the constant 1 is the best possible \cite[(6.167), and (6.168), Vol. 1]{King}. In particular, if the average of \( u \) is zero, then \( \mathcal{H} \) is an isometry of \( L^2(S^1) \).

• The Hilbert transform is skew-adjoint relative to the \( L^2(S^1) \)-inner product, i.e., \( \mathcal{H}^* = -\mathcal{H} \) \cite[(6.98) or (6.106), Vol. 1]{King}.

• For any \( u \in L^2(S^1) \) we have \( \mathcal{H}^2 u(\theta) = -u(\theta) + \frac{1}{2\pi} \int_{-\pi}^{\pi} ds u(s) = -u(\theta) + \tilde{u}(0) \).

• For any \( u \in H^s(S^1) \) with \( s \geq 0 \) we have \( \mathcal{H}u \in H^s(S^1) \); this is an immediate consequence of (17). If \( s \geq 1 \), then \( \mathcal{H} u' = (\mathcal{H}u)' \), i.e., \( \mathcal{H} \circ \frac{d}{d\theta} = \frac{d}{d\theta} \circ \mathcal{H} \) on \( H^s(S^1) \) with \( s \geq 1 \).

Using these properties, if \( u(\theta) = \sum_{n = -\infty}^{\infty} \tilde{u}(n)e^{in\theta} \in H^1(S^1) \), then \( u'(\theta) = \sum_{n = -\infty}^{\infty} n|n|\tilde{u}(n)e^{in\theta} \in L^2(S^1) \) and hence

\[ (\mathcal{H}u')(\theta) = (\mathcal{H}u)'(\theta) = \left( -i \sum_{n = -\infty}^{\infty} \tilde{u}(n) \text{sign}(n) e^{in\theta} \right)' = \sum_{n = -\infty}^{\infty} |n|\tilde{u}(n)e^{in\theta} . \]

(18)

On the other hand, if \( v \in H^2(S^1) \), then

\[ -\frac{d^2}{d\theta^2} v(\theta) = \sum_{n = -\infty}^{\infty} n^2\tilde{v}(n)e^{in\theta} \]

(19)

and hence if \( u \in H^1(S^1) \),

\[ \left( -\frac{d^2}{d\theta^2} \right)^{\frac{1}{2}} u(\theta) = \sum_{n = -\infty}^{\infty} |n|\tilde{u}(n)e^{in\theta} = \langle \mathcal{H}u', \theta \rangle = \left( \left( \mathcal{H} \circ \frac{d}{d\theta} \right) u \right)(\theta) \]

(20)
by \(\langle 13 \rangle\). By the previous properties we have \((\mathcal{H} \circ d/d\theta)^2 = -d^2/d\theta^2\), as expected; note that the extra term, which is the zero order Fourier coefficient, does not appear in this case, because the derivative eliminates it.

Now, if \(\varphi = e^{it} \in L(S^1)\), i.e., \(\varphi(1) = 1\) and \(f : [-\pi, \pi] \to \mathbb{R}\) is a periodic function, then \(\hat{f}(0) = f(0) = 0\). Similarly, if \(u \in L(\mathbb{R})\), i.e., \(u(1) = 0\) and we think of \(u\) as a periodic function \(u : [-\pi, \pi] \to \mathbb{R}\), then \(\hat{u}(0) = u(0) = 0\). This, and the properties of the Hilbert transform on the circle, imply: \(\mathcal{H} (L(\mathbb{R})) \subseteq L(\mathbb{R})\), \(\mathcal{H}\) is unitary on \(L(\mathbb{R})\) (relative to the \(H^s\)-inner product), \(\mathcal{H} \circ \mathcal{H} = -I\) on \(L(\mathbb{R})\). Concretely, the Hilbert transform on \(L(\mathbb{R})\) has the form:

\[
\hat{u}(\theta) = \sum_{n \in \mathbb{Z}\setminus\{0\}} \hat{u}(n)e^{in\theta} \in L(\mathbb{R}) \implies \mathcal{H} u(\theta) = -i \sum_{n \in \mathbb{Z}\setminus\{0\}} \hat{u}(n) \text{sign}(n) e^{in\theta} \in L(\mathbb{R}).
\]

Thus, \(\mathcal{H}\) defines the structure of a complex Hilbert space on \(L(\mathbb{R})\), relative to the \(H^s\) inner product, \(s \geq 1\). Hence, translating \(\mathcal{H}\) to any tangent space of \(L(S^1)\), we obtain an invariant almost complex structure on the Hilbert Lie group \(L(S^1)\) which is, in fact, a complex structure. For general criteria how to obtain complex structures on real Banach manifolds, see [Beliţa \(\langle 2005 \rangle\)]; the argument above is a very special case of these general methods.

Finally, \(L(S^1)\) is a Kähler manifold, as proved in [Atiyah and Pressley \(\langle 1983 \rangle\)]. This is immediately seen by noting that

\[
g(1)(u, v) := \omega(\mathcal{H} u, v) = \sum_{n = -\infty}^{\infty} |n| \hat{u}(n) \hat{v}(n) \tag{21}
\]

is symmetric and positive definite and so, by translations, defines a weak Riemannian metric on \(L(S^1)\). Note that this metric is not the \(H^s\) metric for any \(s \geq 1\). In fact, the metric \(g\) is incomplete, whereas the \(H^s\) metric is complete.

Concluding, \((L(S^1), \omega, g, \mathcal{H})\) is a weak Kähler manifold and all structures are group invariant (see [Pressley \(\langle 1982 \rangle\], [Atiyah and Pressley \(\langle 1983 \rangle\], [Pressley and Segal \(\langle 1986 \rangle\)].

### 3.4 Weak Riemannian metrics on \(L(S^1)\)

The three metrics discussed in \(\langle 2 \rangle\) for \(L(S^1)\), viewed as a coadjoint orbit of its central extension, have been computed by [Pressley \(\langle 1982 \rangle\)]. We recall here relevant formulas.

The **induced metric** is defined by the natural inner product on \(L(\mathbb{R})\), which is the usual \(L^2\)-inner product. Hence, the induced metric is obtained by left (equivalently, right) translation of the inner product

\[
b(1)(u, v) := \langle u, v \rangle = \frac{1}{2\pi} \int_{-\pi}^{\pi} dt\, u(t)v(t) \tag{22}
\]

for any two functions \(u, v \in L(\mathbb{R})\).

Define the following inner products on \(L(\mathbb{R})\):

\[
b_2(1)(u, v) := b(1)(u, \mathcal{H} v') = \langle u, \mathcal{H} v' \rangle, \quad \text{if} \quad u, v \in H^1(S^1), \quad s \geq 1 \tag{23}
\]

\[
b_1(1)(u, v) := b(1)(u', v') = \langle u', v' \rangle, \quad \text{if} \quad u, v \in H^1(S^1), \quad s \geq 1. \tag{24}
\]

Bilinearity and symmetry of \(b_1(1)\) and \(b_2(1)\) are obvious. If \(u \in L(S^1)\), writing \(u(\theta) = \sum_{n = -\infty}^{\infty} \hat{u}(n)e^{in\theta}\) with \(\hat{u}(0) = 0\), we have \(u'(\theta) = i \sum_{n = -\infty}^{\infty} n\hat{u}(n)e^{in\theta}\). Since \(\{e^{in\theta} \mid n \in \mathbb{Z}\}\) is an orthonormal Hilbert basis of \(L^2(S^1)\), we get

\[
b_1(1)(u, u) = \sum_{n = -\infty}^{\infty} n^2 |\hat{u}(n)|^2 \geq 0.
\]

In addition, \(b_1(1)(u, u) = 0\) if and only if \(\hat{u}(n) = 0\) for all \(n \neq 0\), i.e., \(u(\theta) = \hat{u}(0) = 0\). This shows that \(b_1(1)\) is indeed an inner product on \(L(\mathbb{R})\) which coincides with the \(H^1\) inner product. Hence, if \(L(\mathbb{R})\) is endowed with the \(H^1\) topology for \(s \geq 1\), this inner product is strong if \(s = 1\) and weak if \(s > 1\). Left translating this inner product to any tangent space of \(L(S^1)\) (endowed with the \(H^s\) topology for \(s \geq 1\)), yields a Riemannian metric on \(L(S^1)\) that is strong for \(s = 1\) and weak for \(s > 1\). This Riemannian metric is the **normal metric** on \(L(S^1)\).

The inner product \(b_2(1)\) is identical to \(g(1)\) by \(\langle 21 \rangle\), \(\langle 23 \rangle\), and \(\langle 15 \rangle\). Thus, translating this inner product to the tangent space at every point of the Hilbert Lie group \(L(S^1)\), yields the **standard Kähler metric** \(b_2 = g\) on \(L(S^1)\), endowed with
the $H^s$ topology for $s \geq 1$. Note that if $u \in L(S^1)$, then
\[ b_2(1)(u,u) = \sum_{n=-\infty}^{\infty} |n|\tilde{u}(n)|^2 \]
which shows that the Kähler metric $b_2$ coincides with the $H^{1/2}$ metric and is, therefore, a weak metric on $L(S^1)$.

There are relations similar to (13) and (14), namely
\[ b(1)(u,v) = b_1(1)(\mathcal{A}^2 u,v), \quad b_2(1)(u,v) = b_1(1)(\mathcal{A} u,v), \]
where
\[ (\mathcal{A}^2 u)(\theta) = \sum_{n=-\infty}^{\infty} n^2\tilde{u}(n)e^{in\theta}, \quad (\mathcal{A} u)(\theta) = \sum_{n=-\infty}^{\infty} |n|\tilde{u}(n)e^{in\theta} \]
if $u(\theta) = \sum_{n=-\infty}^{\infty} \tilde{u}(n)e^{in\theta}$. However, note that the relation involving $\mathcal{A}^2$ requires that $u \in H^1(S^1)$ with $s \geq 2$.

### 3.5 Vector fields on $L(S^1)$ and $L(\mathbb{R})$

Recall that the exponential map $\exp : L(\mathbb{R}) \ni u \mapsto e^{iu} \in L(S^1)$ is a Lie group isomorphism ([Pressley and Segal, 1986, page 151, §8.9]). Here, we identified the Lie algebra of $S^1$ with $\mathbb{R}$, even though, naturally, it is the imaginary axis, the tangent space at $1 \in S^1$ to $S^1$. This means that care must be taken when carrying out standard Lie group operations with the exponential map, interpreted as the exponential of a purely imaginary number. Since such computations affect our next results, we clarify these statements below.

The tangent space at the identity $1$ to $S^1$ is the imaginary axis. This is the natural Lie algebra of the Lie group $S^1$ and the exponential map is given by $\exp : i\mathbb{R} \ni (ix) \mapsto e^{ix} \in S^1$. Of course, traditionally, one identifies $i\mathbb{R}$ with $\mathbb{R}$ by dividing by $i$ and thinks of the exponential map as $\exp : \mathbb{R} \ni x \mapsto e^{ix} \in S^1$. Unfortunately, this induces some problems. For example, since (left) translation is given by $L_{e^{iy}} y := e^{iy}e^{ix}$, it follows that
\[ T_1L_{e^{iy}}(y) := \frac{d}{d\epsilon} \bigg|_{\epsilon=0} L_{e^{iy}} e^{ix} = \frac{d}{d\epsilon} \bigg|_{\epsilon=0} e^{ix}e^{iy} = iye^{ix}, \quad (25) \]
so the identification of the Lie algebra with $\mathbb{R}$ poses no problems and we have, dividing both sides by $i$,
\[ T_1L_{e^{iy}}(y) = ye^{ix}. \quad (26) \]

However, the definition of the exponential map for any Lie group $G$ with Lie algebra $\mathfrak{g}$, yields
\[ \frac{d}{dt} \exp(tx) = T_t L_{\exp(t\xi)} \xi, \quad \text{for all} \quad \xi \in \mathfrak{g}. \quad (27) \]

This formula works perfectly well if the Lie algebra of $S^1$ is $i\mathbb{R}$. Indeed
\[ \frac{d}{dt} e^{ix} = ixe^{ix} \]
which coincides with (27) in view of (25). On the other hand, if the Lie algebra is thought of as $\mathbb{R}$, i.e., the right hand side needs to be divided by $i$, then with the definition of $\exp(tx) = e^{ix}$ the identity above is no longer valid. What we should get is
\[ \frac{d}{dt} \exp(tx) = x\exp(tx) = T_t L_{\exp(t\xi)} x = xe^{ix} \]
by (26) if $\exp(tx) = e^{ix}$, but the right hand side gives $ixe^{ix}$, as we saw above. In other words, if the Lie algebra of $S^1$ is thought of as $\mathbb{R}$, as is traditionally done, then we need a formula for the derivative of the Lie group exponential map in terms of the exponential map of purely imaginary numbers. In view of the previous discussion, this formula is
\[
\frac{d}{dt} \exp(tx) := \frac{1}{i} \frac{d}{dt} e^{itx} = xe^{itx}.
\] (28)

With these remarks in mind, we shall now compute the push-forward of a vector field on \(L(\mathbb{R})\) to \(L(S^1)\).

**Proposition 2.** Let \(X \in \mathfrak{X}(L(\mathbb{R}))\) be an arbitrary vector field. Then its push-forward to \(L(S^1)\) has the expression

\[
(\exp_s X)(e^{iu}) = X(u)e^{iu}
\]

for any \(u \in L(\mathbb{R})\).

**Proof.** By the definition of push forward of vector fields by a diffeomorphism, we have

\[
(\exp_s X)(e^{iu}) = (T \exp \circ X \circ \exp^{-1})(e^{iu}) = T_u \exp(X(u)) = \left. \frac{d}{d\varepsilon} \right|_{\varepsilon=0} \exp(u + \varepsilon X(u)) = \frac{d}{d\varepsilon} \left|_{\varepsilon=0} \exp(u + \varepsilon X(u)) \right) \exp(u) = \left. \frac{d}{d\varepsilon} \right|_{\varepsilon=0} \exp \left( \frac{1}{2} \varepsilon X(u) \right) e^{iu}
\]

as stated. \(\square\)

### 3.6 The gradient vector fields in the three metrics of \(L(S^1)\)

We compute now the gradients of a specific function using the three metrics.

**Theorem 1.** The gradients of the smooth function \(H : L(S^1) \to \mathbb{R}\) given by

\[
H(e^{if}) = \frac{1}{4\pi} \int_{-\pi}^{\pi} d\theta f'(\theta)^2
\]

are

(i) \(\nabla^1 H(e^{if}) = f e^{if}\) for the normal metric \(b_1\);

(ii) \(\nabla H(e^{if}) = -f'' e^{if}\) with respect to the induced metric \(b\) for \(f \in H^s(S^1)\) with \(s \geq 2\);

(iii) \(\nabla^2 H(e^{if}) = (\mathcal{H} f') e^{if}\) with respect to the weak Kähler metric \(b_2\).

**Proof.** (i) Since \(T_{1L(u)} u = ue^{if}\) for any \(u \in L(\mathbb{R})\) and \(e^{if} \in L(S^1)\), invariance of \(b_1\) yields

\[
b_1(1) \left( e^{-if} \nabla^1 H(e^{if}) , u \right) = b_1 \left( e^{if} \left( \nabla^1 H(e^{if}) \right) , ue^{if} \right) = \Delta H(e^{if}) \left( ue^{if} \right)
\]

\[
= \frac{d}{dt} \bigg|_{t=0} H(e^{i(f+t)u}) = \frac{d}{dt} \bigg|_{t=0} \frac{1}{4\pi} \int_{-\pi}^{\pi} d\theta \left( f'(\theta) + tu'(\theta) \right)^2
\]

\[
= \frac{1}{2\pi} \int_{-\pi}^{\pi} d\theta f'(\theta)u'(\theta) = \langle f', u' \rangle = b_1(1)(f, u)
\]

which shows that \(\nabla^1 H(e^{if}) = f e^{if}\).

(ii) Proceeding as above, using the same notations, and assuming that \(f \in H^s(S^1)\) with \(s \geq 2\), we have

\[
b(1) \left( e^{-if} \nabla H(e^{if}) , u \right) = b \left( e^{if} \left( \nabla H(e^{if}) \right) , ue^{if} \right) = \Delta H(e^{if}) \left( ue^{if} \right)
\]

\[
= \frac{1}{2\pi} \int_{-\pi}^{\pi} d\theta f'(\theta)u'(\theta) = -\frac{1}{2\pi} \int_{-\pi}^{\pi} d\theta f''(\theta)u(\theta)
\]

\[
= \langle -f'', u \rangle = b(1)(-f'', u)
\]

which shows that \(\nabla H(e^{if}) = -f'' e^{if}\).
(iii) This computation uses the isometry property of $\mathcal{H}$ relative to the $L^2$ inner product. We have,

$$b_2(1) \left( e^{-i\theta} \nabla^2 H \left( e^{i\theta} \right), u \right) = b_2 \left( e^{i\theta} \left( \nabla^2 H \left( e^{i\theta} \right) \right), u e^{i\theta} \right) = \mathbf{d} H \left( e^{i\theta} \right) \left( u e^{i\theta} \right)$$

which shows that $\nabla^2 H \left( e^{i\theta} \right) = \langle \mathcal{H} f', \mathcal{H} u \rangle$. $\blacksquare$

Since

$$\omega \left( e^{i\theta} \right) \left( \mathcal{H} \nabla^2 H \left( e^{i\theta} \right), u e^{i\theta} \right) = b_2 \left( e^{i\theta} \left( \nabla^2 H \left( e^{i\theta} \right) \right), u e^{i\theta} \right) = \mathbf{d} H \left( e^{i\theta} \right) \left( u e^{i\theta} \right)$$

it follows that the Hamiltonian vector field on $(L(S^1), \omega)$ for the function $H$ is $X_H = \mathcal{H} \nabla^2 H$. Since $\mathcal{H}$ commutes with the tangent lift to group translations, Theorem (iii) implies that

$$X_H \left( e^{i\theta} \right) = \left( \mathcal{H} \nabla^2 H \right) \left( e^{i\theta} \right) = \mathcal{H} \left( \nabla^2 H \left( e^{i\theta} \right) \right) = \mathcal{H} \left( \mathcal{H} f' \left( e^{i\theta} \right) \right) = -f' e^{i\theta}.$$

This proves the first part of the following statement.

**Corollary 1.** The Hamiltonian vector field of $H$ relative to the translation invariant symplectic form $\omega$ on $L(S^1)$ whose value at the identity element is given by (15) has the expression $X_H \left( e^{i\theta} \right) = -f' e^{i\theta}$. Its flow is the rotation

$$\left( F_t \left( e^{i\theta} \right) \right) \left( \theta \right) = e^{-i(f(t+\theta)-f(t))}.$$

**Proof.** Since $L(\mathbb{R}) \ni u \rightarrow e^{iu} \in L(S^1)$ is the exponential map and we think of $\mathbb{R}$ as the Lie algebra of $S^1$ (and not the imaginary axis), we write $de^{iu}/dt = u e^{iu}$ without the factor of $i$ in front (see (28)). The verification that $F_t$ is indeed the flow of $X_H$ is straightforward:

$$\frac{d}{dt} \left( F_t \left( e^{i\theta} \right) \right) \left( \theta \right) = \frac{d}{dt} e^{-i(f(t+\theta)-f(t))} = -\left( f'(t+\theta) - f'(t) \right) e^{-i(f(t+\theta)-f(t))}$$

as required. $\blacksquare$

We recover thus [Pressley, 1982, Proposition 3.1] (up to a sign which is due to different conventions calibrating $\omega$, $\mathcal{H}$, and $b_2$).

Applying Proposition 4 to Theorem 1 we get the following result:

**Corollary 2.** The three gradient vector fields for the smooth function $H_1 : L(\mathbb{R}) \rightarrow \mathbb{R}$ given by

$$H_1(u) = \frac{1}{4\pi} \int_{-\pi}^{\pi} d\theta \left( u' \right)^2$$

are

(i) $\nabla^1 H_1(u) = u$ for the weak inner product $b_1(1)$ defining the normal metric;
(ii) $\nabla^2 H_1(u) = -u'$ for the weak inner product $b(1)$ defining the induced metric, where for $u \in H^s(\mathbb{R})$ with $s \geq 2$;
(iii) $\nabla^3 H_1(u) = \mathcal{H} u'$ for the weak inner product $b_2(1)$ defining the Kähler metric.

Since the exponential map is a Lie group isomorphism and the three metrics coincide with the respective inner products at the identity, their left invariance guarantees that the three inner products on $L(\mathbb{R})$ correspond to the three invariant metrics on $L(S^1)$.

Applying Proposition 4 to Corollary 1, we conclude:

**Corollary 3.** The Hamiltonian vector field of $H_1$ relative to the symplectic form $\omega$ given by (15) has the expression $X_H(u) = -u'$. Its flow is $(F_t(u)) \left( \theta \right) = u(\theta - t)$. 

The verification of the statement about the flow is immediate:

\[
\frac{d}{dt} (F_t(\theta))(\theta) = \frac{d}{dt} u(\theta - t) = -u'(\theta - t) = (X_H(F_t(\theta)))(\theta).
\]

If one is willing to put more stringent hypotheses on the functional, it is possible to obtain a general result.

**Theorem 2.** Let \( H : L(S^1) \rightarrow \mathbb{R} \) be a smooth function (with \( L(S^1) \) endowed, as usual, with the \( H^s \) topology for \( s \geq 1 \)) and assume that the functional derivative \( \delta H/\delta u \in L(S^1) \) exists. Then the gradient vector fields are

(i) \( \nabla H(u) = \frac{\delta H}{\delta u} \) with respect to the weak inner product \( b(1) \) defining the induced metric;

(ii) \( \langle \nabla^1 H(u) \rangle(\theta) = -\int_0^\theta d\phi \left( \int_0^\phi d\psi \frac{\delta H}{\delta u} (\psi) \right) \) with respect to the (weak) inner product \( b_1(1) \) defining the normal metric, provided both \( \int_0^\theta d\phi \frac{\delta H}{\delta u} (\phi) \) and \( \int_0^\theta d\phi \left( \int_0^\phi d\psi \frac{\delta H}{\delta u} (\psi) \right) \) are periodic;

(iii) \( \langle \nabla^2 H(u) \rangle(\theta) = -\mathcal{H} \int_0^\theta d\phi \frac{\delta H}{\delta u} (\phi) \) with respect to the weak inner product \( b_2(1) \) defining the Kähler metric, provided \( \int_0^\theta d\phi \frac{\delta H}{\delta u} (\phi) \) is periodic.

**Proof.**

(i) For the inner product \( b(1) \) on \( L(S^1) \) defining the induced metric, if \( u, v \in L(\mathbb{R}) \), we have by periodicity of \( u, v, \)

\[
b(1) (\nabla H(u), v) = DH(u) \cdot v = \left\langle \frac{\delta H}{\delta u} , v \right\rangle = \int_0^\theta d\phi \frac{\delta H}{\delta u} (\phi) v(\phi).
\]

This shows that \( \nabla H(u) = \frac{\delta H}{\delta u} \).

(ii) For the inner product \( b_1(1) \) on \( L(S^1) \) defining the normal metric, if \( u, v \in L(\mathbb{R}) \), we have by periodicity of \( \int_0^\theta d\phi \frac{\delta H}{\delta u} (\phi) \) and \( \int_0^\theta d\phi \left( \int_0^\phi d\psi \frac{\delta H}{\delta u} (\psi) \right) \),

\[
b_1(1) \langle \nabla^1 H(u) \rangle(\theta)\) = -\int_0^\theta d\phi \left( \int_0^\phi d\psi \frac{\delta H}{\delta u} (\psi) \right) \),
\]

which shows that \( \langle \nabla^1 H(u) \rangle(\theta) = -\int_0^\theta d\phi \frac{\delta H}{\delta u} (\phi) \).

(iii) For the inner product \( b_2(1) \) on \( L(S^1) \) defining the Kähler metric, if \( u, v \in L(\mathbb{R}) \), we have by periodicity of \( \int_0^\theta d\phi \frac{\delta H}{\delta u} (\phi) \) and the isometry property of \( \mathcal{H} \),

\[
b_2(1) \langle \nabla^2 H(u) \rangle(\theta)\) = -\mathcal{H} \int_0^\theta d\phi \frac{\delta H}{\delta u} (\phi) \),
\]

which shows that \( \langle \nabla^2 H(u) \rangle(\theta) = -\mathcal{H} \int_0^\theta d\phi \frac{\delta H}{\delta u} (\phi) \).

**Corollary 4.** Under the same hypothesis as in Theorem 2(iii), the Hamiltonian vector field of the smooth function \( H : L(S^1) \rightarrow \mathbb{R} \) relative to the symplectic form \( \omega \) on \( L(\mathbb{R}) \) given by \ref{15} has the expression \( X_H(u) = \int_0^\theta d\phi \frac{\delta H}{\delta u} (\phi) \).

**Proof.** We have \( X_H(u) = \mathcal{H} \nabla^2 H(u) = \int_0^\theta d\phi \frac{\delta H}{\delta u} (\phi) \).
Of course, using Proposition 2 there are immediate counterparts of Theorem 2 and Corollary 4 on the loop group $L(S^1)$, which we shall not spell out explicitly.

The hypotheses guaranteeing the existence of the functional derivative of $H$ relative to the weakly non-degenerate $L^2$ pairing are quite severe. For example, the theorem can be applied to the functional $H_1$ in Corollary 2 but one needs additional smoothness. Indeed, the first thing to check is if this functional has a functional derivative. In fact, it does not, unless we assume that $u \in H^s(S^1)$ for $s \geq 2$, in which case we have

$$DH_1(u) \cdot v = \frac{1}{2\pi} \int_{-\pi}^{\pi} ds u'(s)v'(s) = \frac{1}{2\pi} \int_{-\pi}^{\pi} ds u''(s)v(s) = \left. -\frac{1}{2\pi} \int_{-\pi}^{\pi} ds u''(s)v(s) = \langle -u'', v \rangle, \right.$$  

i.e., $\delta H/\delta u = -u''$. With this additional hypothesis, the gradient flow with respect to the weak inner product $b(1)$ defining the induced metric is given by $u_t = -u''$.

Therefore, to continue computing the other two gradients of $H_1$, we need to assume that $u \in H^s(S^1)$ for $s \geq 2$. Provided this holds, to find the gradient relative to the (weak) inner product $b_1(1)$ defining the normal metric, we have to check that both

$$\int_0^\theta d\theta \frac{\delta H}{\delta u}(\varphi) = -\int_0^\theta d\theta u''(\varphi) = -u'(\theta) + u'(0)$$

and

$$\int_0^\theta d\theta \left( \int_0^\theta d\theta \frac{\delta H}{\delta u}(\psi) \right) = -\int_0^\theta d\theta (u'(\varphi) - u'(0)) = -u(\theta) + u'(0)\theta$$

are periodic. While the first one is periodic, the second one is not unless we assume that $u'(0) = 0$. With this additional hypothesis, the gradient is given by $u_t = u$. However, we know from Corollary 2 that neither $s \geq 2$, nor $u'(0) = 0$ is needed. In addition, this can also be seen directly, as follows. For any $u, v \in L(\mathbb{R})$, we have

$$b_1(1)(\nabla^1 H(u), v) = DH(u) \cdot v = \frac{1}{2\pi} \int_{-\pi}^{\pi} ds u'(s)v'(s) = \langle u', v' \rangle \triangleq b_1(u, v)$$

which shows that $\nabla^1 H(u) = u$.

The same situation occurs in the computation of the third gradient. In the hypotheses of the theorem, we have

$$\left( \nabla^2 H(u) \right)(\theta) = -\mathcal{H} \int_0^\theta d\theta \frac{\delta H}{\delta u}(\varphi) = \mathcal{H}(u' - u'(0)) = \mathcal{H} u'$$

because the Hilbert transform of a constant is zero. Thus, the gradient flow is given in this case by

$$u_t = \mathcal{H} u \triangleq \left( -\frac{d^2}{d\theta^2} \right)^{\frac{1}{2}} u.$$  

As before, the same result can be obtained easier and without any additional hypotheses in the following way:

$$b_2(1)(\nabla^2 H(u), v) = DH(u) \cdot v = \langle u', v' \rangle = \langle \mathcal{H} u', \mathcal{H} v' \rangle \triangleq b_2(1)(\mathcal{H} u', v).$$

### 3.7 Symplectic structure on periodic functions

The form of the periodic Korteweg-de Vries (KdV) equation we shall use is

$$u_t - 6uu_\theta + u_{\theta\theta\theta} = 0,$$  

where $u(t, \theta)$ is a real valued function of $t \in \mathbb{R}$ and $\theta \in [-\pi, \pi]$, periodic in $\theta$, and $u_\theta := \partial u/\partial \theta$. The KdV equation is, of course, a famous integrable infinite dimensional Hamiltonian system. It is Hamiltonian on the Poisson manifold of all periodic functions relative to the [Gardner 1971] bracket.
\[ \{ F, G \} = \frac{1}{2\pi} \int_{-\pi}^{\pi} d\theta \frac{\delta F}{\delta u} \frac{d}{d\theta} \frac{\delta G}{\delta u}, \]

where

\[ F(u) = \int_{S^1} d\theta f(u, u_\theta, u_{\theta\theta}, \ldots) \]

and similarly for \( G \); the functional derivative \( \frac{\delta F}{\delta u} \) is the usual one relative to the \( L^2(S^1) \) inner product, i.e.,

\[ \frac{\delta F}{\delta u} = \frac{\partial f}{\partial u} - \frac{d}{d\theta} \left( \frac{\partial f}{\partial u_\theta} \right) + \frac{d^2}{d\theta^2} \left( \frac{\partial f}{\partial u_{\theta\theta}} \right) - \ldots. \]

The Hamiltonian vector field of \( H(u) = \frac{1}{2\pi} \int_{-\pi}^{\pi} d\theta h(u, u_\theta, u_{\theta\theta}, \ldots) \) has the expression

\[ X_H(u) = \frac{d}{d\theta} \left( \frac{\delta H}{\delta u} \right). \]

For the KdV equation one takes

\[ H(u) = \frac{1}{2\pi} \int_{-\pi}^{\pi} d\theta \left( u^3 + \frac{1}{2} u_\theta^2 \right). \]

The Casimir functions of the Gardner bracket are all smooth functionals \( C \) for which \( \delta C / \delta u = c \) is a constant function, i.e.,

\[ C(u) = \langle c, u \rangle = \frac{1}{2\pi} \int_{-\pi}^{\pi} d\theta cu(\theta) = cu(0). \]

Thus \( C^{-1}(0) \) is a candidate weak symplectic leaf in the phase space of all periodic functions. The situation in infinite dimensions is not as clear as in finite dimensions, where this would be a conclusion, because there is no general stratification theorem and one cannot expect, in general, more than a weak symplectic form. However, in our case, this actually holds, as shown in [Zaharov and Faddeev 1971]. Indeed,

\[ \sigma(u_1, u_2) = \frac{1}{4\pi} \int_{-\pi}^{\pi} d\theta \left( \int_0^\theta d\phi (u_1(\phi)u_2(\theta) - u_2(\phi)u_1(\theta)) \right) = \frac{1}{2\pi} \int_{-\pi}^{\pi} d\theta \left( \int_0^\theta d\phi u_1(\phi) \right) u_2(\theta) \]

\[ = \left( \int_0^\theta d\phi u_1(\phi), u_2 \right) \]

defines a weak symplectic form on \( L(\mathbb{R}) \) whose formal Poisson bracket is (30). This immediately shows that there is a tight relationship with the symplectic form \( \omega \) of the complex Hilbert space \( L(\mathbb{R}) \), the Lie algebra of the based loop groups, given by (15), namely

\[ \sigma \left( \frac{d^2}{d\theta^2} u, v \right) = \omega(u, v) \]

for all \( u, v \in L(\mathbb{R}) \) of class \( H^s, s \geq 2 \). Defining

\[ \left( \frac{d}{d\theta} \right)^{-1} u := \int_0^\theta d\phi u(\phi), \]

the KdV symplectic form \( \sigma \) has the suggestive expression (see (28))

\[ \sigma(u_1, u_2) = \left( \left( \frac{d}{d\theta} \right)^{-1} u_1, u_2 \right), \]

which is well defined on \( H^{-\frac{1}{2}}(S^1, \mathbb{R}) \).

On the other hand, the Poisson bracket given by the Kähler symplectic form (15) on \( L(\mathbb{R}) \) is

\[ \{ F, G \} = \frac{1}{2\pi} \int_{-\pi}^{\pi} d\theta \frac{\delta F}{\delta u} \left( \frac{d}{d\theta} \right)^{-1} \frac{\delta G}{\delta u}, \]

(33)
which is similarly well defined on $H^{-\frac{1}{2}}$, and the Hamiltonian vector field defined by this bracket is given by Corollary 4.1, i.e.,

$$
u_t = X_H(u) = \left(\frac{d}{d\theta}\right)^{-1} \delta H \frac{\delta u}{\delta \theta}.
$$

Now, the gradient vector field for the corresponding Kähler metric, as computed in Theorem 2(iii), is written as

$$
u_t = -\mathcal{H} \left(\frac{d}{d\theta}\right)^{-1} \delta H \frac{\delta u}{\delta \theta}.
$$

### 4 Metriplectic Systems

In this section we define metriplectic systems and show how to construct general classes of such systems in terms of triple brackets for both finite- and infinite-dimensional theories. We use some of the machinery developed above to address specific examples.

#### 4.1 Definition and consequences

A metriplectic system consists of a smooth manifold $P$, two smooth vector bundle maps $\pi, \kappa : T^*P \rightarrow TP$ covering the identity, and two functions $H, S \in C^\infty(P)$, the Hamiltonian or total energy and the entropy of the system, such that

1. $\{F, G\} := (dF, \pi(dG))$ is a Poisson bracket; in particular $\pi^* = -\pi$;
2. $\{F, G\} := (dF, \kappa(dG))$ is a positive semidefinite symmetric bracket, i.e., $(,) \in \mathbb{R}$-bilinear and symmetric, so $\kappa^* = \kappa$, and $(F, F) \geq 0$ for every $F \in C^\infty(P)$;
3. $\{S, F\} = 0$ and $(H, F) = 0$ for all $F \in C^\infty(P) \iff \pi(dS) = \kappa(dH) = 0$.

The metriplectic dynamics of the system is given in terms of the two brackets by

$$
\frac{d}{dt} F = \{F, H + S\} + \{F, H + S\} = \{F, H\} + \{F, S\}, \quad \text{for all} \quad F \in C^\infty(P),
$$

or, equivalently, as an ordinary differential equation, by

$$
\frac{d}{dt} c(t) = \pi(c(t)) dH(c(t)) + \kappa(c(t)) dS(c(t)).
$$

The Hamiltonian vector field $X_H := \pi(dH) \in \mathfrak{X}(P)$ represents the conservative or Hamiltonian part, whereas $Y_S := \kappa(dS) \in \mathfrak{X}(P)$ the dissipative part of the full metriplectic dynamics 36 or 37.

As far as we know, first attempts to introduce such a structure were given in adjacent papers by Kaufman [1984] and Morrison [1984]. (See also Kaufman and Morrison [1982].) Kaufman [1984] imposed, instead of (iii), the weaker degeneracy condition of (iii), were stated explicitly in Morrison [1984] and Morrison [1984], the former treated the same kinetic example as Kaufman [1984] along with additional formalism, while the latter presented the metriplectic formalism for the compressible Navier-Stokes equations with entropy production. All three axioms were restated in Morrison [1986], where the terminology metriplectic was introduced and a detailed physical motivation for the introduction of (iii) is presented along with other examples such as a dissipative free rigid body equation and the Vlasov-Poisson equation with a collision term that generalizes the Landau and Balescu-Lenard equations. In Grmela and Øttinger [1997], under the name GENERIC (General Equations for Non-Equilibrium Reversible Irreversible Coupling), the same geometric structure was used to analyze many other equations; due to this paper and subsequent work of these authors, the metriplectic formalism has been popularized. For a very interesting modern application of this structure see Mielle [2011] and for further discussion about avenues for generalization see Morrison [2009].
The definition of metriplectic systems has three immediate important consequences. Let $c(t)$ be an integral curve of the system (37).

1. **Energy conservation:**
   $$\frac{d}{dt} H(c(t)) = \{H, H\}(c(t)) + (H, S)(c(t)) = 0.$$  \hspace{1cm} (38)

2. **Entropy production:**
   $$\frac{d}{dt} S(c(t)) = \{S, H\}(c(t)) + (S, S)(c(t)) \geq 0.$$  \hspace{1cm} (39)

3. **Maximum entropy principle yields equilibria:** Suppose that there are $n$ functions $C_1, \ldots, C_n \in C^\omega(P)$ such that $\{F, C_i\} = (F, C_i) = 0$ for all $F \in C^\omega(P)$, i.e., these functions are simultaneously conserved by the conservative and dissipative part of the metriplectic dynamics. Let $p_0 \in P$ be a maximum of the entropy $S$ subject to the constraints $H^{-1}(h) \cap C_1^{-1}(c_1) \cap \ldots \cap C_n^{-1}(c_n)$, for given regular values $h, c_1, \ldots, c_n \in \mathbb{R}$ of $H, C_1, \ldots, C_n$, respectively. By the Lagrange Multiplier Theorem, there exist $\alpha, \beta_1, \ldots, \beta_n \in \mathbb{R}$ such that
   
   $$dS(p_0) = \alpha dH(p_0) + \beta_1 dc_1(p_0) + \cdots + \beta_n dc_n(p_0).$$

   But then, assuming that $\alpha \neq 0$, for every $F \in C^\omega(P)$, we have
   
   $$\{F, H\}(p_0) + (F, S)(p_0) = \langle dF(p_0), \pi(p_0) (dH(p_0)) \rangle + \langle dF(p_0), \kappa(p_0) (dS(p_0)) \rangle$$
   
   $$= \left(\langle dF(p_0), \frac{1}{\alpha} \pi(p_0) (dS(p_0) - \beta_1 dc_1(p_0) - \cdots - \beta_n dc_n(p_0)) \rangle + \langle dF(p_0), \kappa(p_0) (\alpha dH(p_0) + \beta_1 dc_1(p_0) + \cdots + \beta_n dc_n(p_0)) \rangle \right)$$
   
   $$= \frac{1}{\alpha} \{F, S\}(p_0) - \frac{\beta_1}{\alpha} \{F, C_1\}(p_0) - \cdots - \frac{\beta_n}{\alpha} \{F, C_n\}(p_0)$$
   
   $$+ \alpha (F, H)(p_0) + \beta_1 (F, C_1)(p_0) + \cdots + \beta_n (F, C_n)(p_0) = 0$$

   which means that $p_0$ is an equilibrium of the metriplectic dynamics (36) or (37). This is akin to the free energy extremization of thermodynamics, as noted by Morrison [1984b] and Morrison [1986] where it was suggested that one can build in degeneracies associated with Hamiltonian “dynamical constraints.” (See also Mielke [2011].)

   Suppose that $K \in C^\omega(P)$ is a conserved quantity for the Hamiltonian part of the metriplectic dynamics, i.e., $\{K, H\} = 0$. Then, if $c(t)$ is an integral curve of the metriplectic dynamics, we have
   
   $$\frac{d}{dt} K(c(t)) = dK(c(t)) (c(t)) = (dF(c(t)), \pi(c(t)) (dH(c(t)))) + (dF(c(t)), \kappa(c(t)) (dS(c(t))))$$
   
   $$= \{K, H\}(c(t)) + (K, S)(c(t)) = (K, S)(c(t)).$$

   As pointed out in Morrison [1986], this immediately implies that a function that is simultaneously conserved for the full metriplectic dynamics and its Hamiltonian part, is necessarily conserved for the dissipative part. Physically, it is advantageous for general metriplectic systems to conserve dynamical constraints, i.e., conserved quantities of its Hamiltonian part and the examples given in Kaufman [1984], Morrison [1984a], Morrison [1984b], and Morrison [1986] satisfy this condition.

### 4.2 Metriplectic systems based on Lie algebra triple brackets

Associated with any quadratic Lie algebra (i.e., a Lie algebra admitting a bilinear symmetric invariant form) is a natural completely antisymmetric triple bracket. This is used to construct Lie algebra based metriplectic systems. The algebra $\mathfrak{so}(3)$ is worked out explicitly and examples are given.
4.2.1 General theory

A quadratic Lie algebra is, by definition, a Lie algebra admitting a bilinear symmetric non-degenerate invariant form \( \kappa : g \times g \rightarrow \mathbb{R} \) (the letter \( \kappa \) is meant to remind one of the Killing form in a semisimple Lie algebra). Recall that invariance means that \( \kappa([\xi, \eta], \zeta) = \kappa(\xi, [\eta, \zeta]) \) for all \( \xi, \eta, \zeta \in g \) or, equivalently, that the adjoint operators \( \text{ad}_\eta \) for all \( \eta \in g \) are antisymmetric relative to \( \kappa \). Non-degeneracy (strong) means that the map \( g \ni \xi \mapsto \kappa(\xi, \cdot) \in g^* \) is an isomorphism. Finite dimensional quadratic Lie algebras have been completely classified in [Medina and Revoy, 1985]. For finite dimensional Lie algebras, non-degeneracy is equivalent to the following statement: \( \kappa(\xi, \eta) = 0 \) for all \( \eta \in g \) if and only if \( \xi = 0 \). In infinite dimensions this condition is called weak non-degeneracy and it is implied by non-degeneracy but the converse is, in general, false.

For example, let \( g \) be an arbitrary finite dimensional Lie algebra. Recall that the Killing form is defined by \( \kappa(\xi, \eta) := \text{Trace}(\text{ad}_\xi \circ \text{ad}_\eta) \). If \( \{e_i\}, i = 1, \ldots \dim g \), is an arbitrary basis of \( g \) and \( c^p_{ij} \) are the structure constants of \( g \), i.e., \( [e_i, e_j] = c^p_{ij}e_p \), then

\[
\kappa\big(\xi, \eta\big) = \xi^i c^p_{iq} \eta^j c^q_{jp}
\]

and hence the components of \( \kappa \) in the basis \( \{e_i\}, i = 1, \ldots \dim g \), are given by

\[
\kappa_{ij} = \kappa\big(e_i, e_j\big) = c^p_{iq} c^q_{jp}.
\]

The Killing form is bilinear symmetric and invariant; it is non-degenerate if and only if \( g \) is semisimple. Moreover, \( -\kappa \) is a positive definite inner product if and only if the Lie algebra \( g \) is compact (i.e., it is the Lie algebra of a compact Lie group).

In general, let \( \kappa \) be a bilinear symmetric non-degenerate invariant form and define the completely antisymmetric covariant 3-tensor

\[
c(\xi, \eta, \zeta) := \kappa(\xi, [\eta, \zeta]) = -c(\xi, \zeta, \eta) = -c(\eta, \xi, \zeta) = -c(\zeta, \eta, \xi).
\]

In the coordinates given by the basis \( \{e_i\}, i = 1, \ldots \dim g \), the components of \( c \) are

\[
c_{ijk} := \kappa_{im} c^m_{jk} = -c_{ikj} = -c_{kji}.
\]

This construction immediately leads to the triple bracket introduced by [Bialynicki-Birula and Morrison, 1991] (see also [Morrison, 1998]), \( \{\cdot, \cdot, \cdot\} : C^\omega(\mathfrak{g}) \times C^\omega(\mathfrak{g}) \times C^\omega(\mathfrak{g}) \rightarrow C^\omega(\mathfrak{g}) \) defined by

\[
\{f, g, h\}(\xi) := c(\nabla f(\xi), \nabla g(\xi), \nabla h(\xi)) := \kappa(\nabla f(\xi), [\nabla g(\xi), \nabla h(\xi)]), \tag{40}
\]

where the gradient is taken relative to the non-degenerate bilinear form \( \kappa \), i.e., for any \( \xi \in g \) we have

\[
\kappa(\nabla f(\xi), \cdot) := df(\xi)
\]

or, in coordinates

\[
\nabla^i f(\xi) = \kappa_{ij} \frac{\partial f}{\partial \xi^j}
\]

where \([\kappa^{ij}] = [\kappa_{ij}]^{-1}\), i.e., \( \kappa^{ij}\kappa_{jk} = \delta_i^j \). This triple bracket is trilinear over \( \mathbb{R} \), completely antisymmetric, and satisfies the Leibniz rule in any of its variables. In coordinates it is given by

\[
\{f, g, h\} = c_{ijk} \nabla^i f \nabla^j g \nabla^k h = \kappa_{im} c^m_{jk} \frac{\partial f}{\partial \xi^p} \kappa^{pq}_{kl} \frac{\partial g}{\partial \xi^q} \kappa_{kr} \frac{\partial h}{\partial \xi^r} = c^p_{ik} \kappa^{qr}_{jk} \frac{\partial f}{\partial \xi^p} \frac{\partial g}{\partial \xi^q} \frac{\partial h}{\partial \xi^r}
\]

where \( c^{pqr} \) are the components of the contravariant completely antisymmetric 3-tensor \( \tilde{c} \) associated to \( c \) by raising its indices with the non-degenerate symmetric bilinear form \( \kappa \), i.e., for any \( \xi, \eta, \zeta \in g \), we have

\[
\tilde{c}(\kappa(\xi, \cdot), \kappa(\eta, \cdot), \kappa(\zeta, \cdot)) := c(\xi, \eta, \zeta).
\]
This construction extends the bracket due to [Nambu 1973] to a Lie algebra setting. Nambu considered ordinary vectors in $\mathbb{R}^3$ and defined
\[
\{f, g, h\}_{\text{Nambu}}(\Pi) = \nabla f(\Pi) \cdot (\nabla g(\Pi) \times \nabla h(\Pi)),
\]
where `·` and `×` are the ordinary dot and cross products. Thus, the Nambu bracket is a special case of the triple bracket in the case of $\mathfrak{g} = \mathfrak{so}(3)$, whose the structure constants are the completely antisymmetric Levi-Civita symbol $\varepsilon_{ijk}$.

Such 'modified rigid body brackets' were also described in Bloch and Marsden [1990], Holm and Marsden [1991], and Marsden and Ratiu [1999].

If $\mathfrak{g}$ is an arbitrary quadratic Lie algebra with bilinear symmetric non-degenerate invariant form $\kappa$, the quadratic function
\[
C_2(\xi) := \frac{1}{2} \kappa(\xi, \xi)
\]
is a Casimir function for the Lie-Poisson bracket on $\mathfrak{g}$, identified with $\mathfrak{g}^*$ via $\kappa$, i.e.,
\[
\{f, g\}_\pm(\xi) = \pm \kappa(\xi, [\nabla f(\xi), \nabla g(\xi)]),
\]
as an easy verification shows since $\nabla C_2(\xi) = \xi$. In view of (43), the following identity is obvious
\[
\{f, g\}_+ = \{C_2, f, g\}
\]
(this was first pointed out in Bialynicki-Birula and Morrison [1991]). For example, if $\mathfrak{g} = \mathfrak{so}(3)$, the (-)Lie-Poisson bracket
\[
\{f, g\}_{-\mathfrak{so}(3)}(\Pi) = -\{C_2, f, g\}_{\text{Nambu}}(\Pi) = -\Pi \cdot (\nabla f(\Pi) \times \nabla g(\Pi))
\]
is the rigid body bracket, i.e., if $h(\Pi) = \frac{1}{2} \Pi \cdot \Omega$, where $\Pi_i = I_i \Omega_i$, $I_i > 0$, $i = 1, 2, 3$, and $I_i$ are the principal moments of inertia of the body, then Hamilton’s equations $\frac{d}{dt} F(\Pi) = \{f, h\}_{-\mathfrak{so}(3)}(\Pi)$ are equivalent to Euler’s equations $\dot{\Pi} = \Pi \times \Omega$.

Note that given any two functions, $f, g \in C^\infty(\mathfrak{g})$, because the triple bracket satisfies the Leibniz identity in every factor, the map $C^\infty(\mathfrak{g}) \ni h \mapsto \{h, f, g\} \in C^\infty(\mathfrak{g})$ is a derivation and hence defines a vector field on $\mathfrak{g}$, denoted by $X_{f, g} : \mathfrak{g} \to \mathfrak{g}$, i.e.,
\[
\langle dh(\xi), X_{f, g}(\xi) \rangle = \kappa(\nabla h(\xi), X_{f, g}(\xi)) = \{h, f, g\}(\xi)
\]
for all $h \in C^\infty(\mathfrak{g})$.

Note that $X_{f, f} = 0$. Thus, for triple brackets, two functions define a vector field, analogous to the Hamiltonian vector field defined by a single function associated to a standard Poisson bracket.

From (40) we have the following result.

**Proposition 3.** The vector field $X_{f, g}$ on $\mathfrak{g}$ corresponding to the pair of functions $f, g$ is given by
\[
X_{f, g}(\xi) = [\nabla f(\xi), \nabla g(\xi)].
\]

Triple brackets of the form (40) can be used to construct metriplectic systems on a quadratic Lie algebra $\mathfrak{g}$ in the following manner. Let $\kappa$ be the bilinear symmetric non-degenerate form on $\mathfrak{g}$ defining the quadratic structure and fix some $h \in C^\infty(\mathfrak{g})$. Define the symmetric bracket
\[
(f, g)_h^\kappa(\xi) := -\kappa(X_{h, f}(\xi), X_{h, g}(\xi)).
\]
Assume that $-\kappa$ is a positive definite inner product. Then $(f, f) \geq 0$. Thus we have the manifold $\mathfrak{g}$ endowed with the Lie-Poisson bracket (43), the symmetric bracket (47), the Hamiltonian $h$, and for the entropy $S$ we take any Casimir function of the Lie-Poisson bracket. Then the conditions (i)–(iii) of (41) are all satisfied, because $(h, g)_h^\kappa = -\kappa(X_{h, h}, X_{h, g}) = -\kappa(0, X_{h, g}) = 0$ for any $g \in C^\infty(\mathfrak{g})$. The equations of motion (36) are in this case given by
\[
\frac{d}{dt} f(\xi) = \kappa \left( \nabla f(\xi), \frac{d}{dt} \xi \right) = \{f, h\}_{\pm}(\xi) + \{f, S\}(\xi) = \pm \kappa(\xi, [\nabla f(\xi), \nabla h(\xi)]) - \kappa(X_{h, f}(\xi), X_{h, g}(\xi)) = \mp \kappa(\nabla f(\xi), [\xi, \nabla h(\xi)]) - \kappa([\nabla h(\xi), \nabla f(\xi)], [\nabla h(\xi), \nabla S(\xi)])
\]
for any $f \in C^\infty(\mathfrak{g})$. 

This gives the equations of motion
\[ \dot{\xi} = \pm [\xi, \nabla h(\xi)] + [\nabla h(\xi), [\nabla h(\xi), \nabla S(\xi)]] . \tag{48} \]

Note that the flow corresponding to $S$ is a generalized double bracket flow. Observe also that this flow reduces to a double bracket flow and is tangent to an orbit of the group if $\nabla h(\xi) = \xi$. Indeed if $h = \frac{1}{2} \kappa(\xi, \xi)$ the symmetric bracket \[ \{u, v\} \] reduces to the symmetric bracket induced from the normal metric.

### 4.2.2 Special case of $\mathfrak{so}(3)$

If the quadratic Lie algebra is $\mathfrak{so}(3)$, we identify it with $\mathbb{R}^3$ with the cross product as Lie bracket via the Lie algebra isomorphism \( \hat{\cdot} : \mathbb{R}^3 \to \mathfrak{so}(3) \) given by \( \hat{uv} := u \times v \) for all \( u, v \in \mathbb{R}^3 \). Since \( \text{Ad}_A \hat{u} = \hat{Au} \), for any \( A \in SO(3) \) and \( u \in \mathbb{R}^3 \), we conclude that the usual inner product on $\mathbb{R}^3$ is an invariant inner product. In terms of elements of $\mathfrak{so}(3)$ we have \( u \cdot v = -\frac{1}{2} \text{Trace}(\hat{uv}) \). We shall show below that the metriplectic structure on $\mathbb{R}^3$ is precisely the one given in Morrison [1986].

Recall that the Nambu bracket is given for $\mathfrak{so}(3)$ by \[ \{f, g, h\} = \xi^m \frac{\partial f}{\partial \Pi^m} \delta_{ij} \xi^n \frac{\partial g}{\partial \Pi^n} - \xi^n \frac{\partial f}{\partial \Pi^n} \delta_{ij} \xi^m \frac{\partial h}{\partial \Pi^m} \] and hence the symmetric bracket \[ \{u, v\} \] has the form

\[ \kappa(\{\Pi, h, f\}, \{\Pi, h, g\}) = \epsilon^{imn} \frac{\partial h}{\partial \Pi^m} \frac{\partial f}{\partial \Pi^n} \delta_{ij} \epsilon^{mnt} \frac{\partial h}{\partial \Pi^t} \frac{\partial g}{\partial \Pi^m} \]

\[ = \epsilon^{imn} \epsilon_{ij} \frac{\partial h}{\partial \Pi^m} \frac{\partial f}{\partial \Pi^n} \frac{\partial h}{\partial \Pi^n} \frac{\partial g}{\partial \Pi^m} \]

\[ = \|\nabla h\|^2 \hat{\nabla} g \cdot \hat{\nabla} f - (\hat{\nabla} f \cdot \hat{\nabla} h)(\hat{\nabla} g \cdot \hat{\nabla} h) \] \quad \tag{49}

where in the third equality we have used the identity \( \epsilon^{imn} \epsilon_{ij} = \delta^{ms} \delta^{nt} - \delta^{mt} \delta^{ns} \). This coincides with Morrison [1986, equation (31)].

With the choice \( S(\Pi) = \|\Pi\|^2/2 \) and the usual rigid body Hamiltonian, the equations of motion \[ \{H, \Pi\} \] are those for the relaxing rigid body given in Morrison [1986].

**Comments.**

- In three dimensions any Poisson bracket can be written as
  \[ \{f, g\} = J^{ij} \frac{\partial f}{\partial \Pi^i} \frac{\partial g}{\partial \Pi^j} = \epsilon^{ij} \epsilon^{kl} (\Pi) \frac{\partial f}{\partial \Pi^l} \frac{\partial g}{\partial \Pi^k} \] \quad \tag{50}

where \( i, j, k = 1, 2, 3 \), and \( V \in \mathbb{R}^3 \). The last equality follows from the identification of \( 3 \times 3 \) antisymmetric matrices with vectors (the hat map discussed above). Using the well know fact (which is easy to show directly) that brackets of the form of \[ \{F, G\} \] satisfy the Jacobi identity if

\[ V \cdot \nabla \times V = 0, \] \quad \tag{51}

we conclude that

\[ \{F, G\}_f = \{f, F, G\}_{\text{Nambu}} \] \quad \tag{52}

satisfies the Jacobi identity for any smooth function \( f \); i.e., unlike the general case where the theorem of Bialynicki-Birula and Morrison [1991] requires \( f \) to be the quadratic Casimir, one obtains a good Poisson bracket for any \( f \). Thus, for the special case of three dimensions, one can interchange the roles of Hamiltonian and entropy in the metriplectic formalism.

- Thinking in terms of $\mathfrak{so}(3)^*$, the setting arising from reduction (see e.g. Marsden and Ratiu [1999]), this construction leads to a natural geometric interpretation of a metriplectic system on the manifold $P = \mathbb{R}^3$. With the Poisson bracket on $\mathbb{R}^3$ of \[ \{\}, \Pi\] the bundle map $\pi : T^*\mathbb{R}^3 \to T\mathbb{R}^3$ has the expression

\[ \pi_f(x, \Pi) = \left( x, \nabla f(\Pi) \times (\cdot)^\top \right) \]
Gradient flows and metriplectic systems

since \( dH(\Pi)^\top = \nabla H(\Pi) \) (\( dH(\Pi) \) is a row vector and \( \nabla H(\Pi) \) is its transpose, a column vector). Now the triple bracket associated to the equation \(48\) can be used to generate a symmetric bracket given in Bloch, Krishnaprasad, Marsden, and Ratiu [1994] as follows:

\[
(F,G)_{BKMR}(\Pi) = (F,G)_C = \kappa(\{\Pi,C,F\}, \{\Pi,C,G\}) \\
= (\Pi \times \nabla F(\Pi)) \cdot (\Pi \times \nabla G(\Pi)). \tag{53}
\]

where now \( C = ||\Pi||^2/2 \). Hence the bundle map \( \kappa : T^*\mathbb{R}^3 \to T\mathbb{R}^3 \) has the expression

\[
\kappa(x,\Pi) = -\Pi \times (\Pi \times (\cdot)^\top). 
\]

Thus, with the freedom to choose any quantity \( S = f \) as an entropy, with the assurance that \((51)\) will be satisfied because \( \nabla \times V = \nabla \times \nabla f = 0 \), we can take \( H = C \) and have \( \{F,S\}_f = 0 \) and \( (F,H) = 0 \) for all \( F \in C^\infty(\mathbb{R}^3) \). The equations of motion for this metriplectic system are

\[
\dot{\Pi} = -\Pi \times \nabla f(\Pi) - \Pi \times (\Pi \times \nabla f(\Pi)). \tag{54}
\]

The symmetric bracket is the inner product of the two Hamiltonian vector fields on each concentric sphere. As discussed in Bloch, Krishnaprasad, Marsden, and Ratiu [1994], this symmetric bracket can be defined on any compact Lie algebra by taking the normal metric on each coadjoint orbit.

The following set of equations were given in Fish [2005]:

\[
\Pi = \nabla S(\Pi) \times \nabla H(\Pi) - \nabla H(\Pi) \times (\nabla H(\Pi) \times \nabla S(\Pi)). \tag{55}
\]

Yet, this metriplectic system is identical to that obtained from \((48)\), using \((49)\), viz.

\[
\Pi = \{\Pi,S,H\} + \kappa(\{\Pi,H,\Pi\}, \{\Pi,H,S\}), \tag{56}
\]

Replacing \( H \) by \( g \) in \((49)\) gives

\[
(F,G)_g(\Pi) = \kappa(\{\Pi,G,F\}, \{\Pi,G,G\}) = (\nabla g(\Pi) \times \nabla F(\Pi)) \cdot (\nabla g(\Pi) \times \nabla G(\Pi)). \tag{57}
\]

Thus, the bundle map \( \kappa : T^*\mathbb{R}^3 \to T\mathbb{R}^3 \) has the expression

\[
\kappa_g(x,\Pi) = -\nabla g(\Pi) \times (\nabla \Pi \times (\cdot)^\top). 
\]

**Examples:** Two special cases of the equation \((55)\) are of interest.

(i) If we take \( H = \frac{1}{2}||\Pi||^2 \) and \( S = c \cdot \Pi, \) \( c \) a constant vector, we obtain

\[
\dot{\Pi} = c \times \Pi - \Pi \times (\Pi \times c). \tag{58}
\]

(ii) If we take \( S = \frac{1}{2}||\Pi||^2 \) and \( H = c \cdot \Pi, \) \( c \) a constant, we obtain

\[
\dot{\Pi} = \Pi \times c - c \times (c \times \Pi). \tag{59}
\]

The equations of motion \((58)\) is an instance of double bracket damping, where the damping is due to the normal metric, whereas \((59)\) gives linear damping of the sort arising in quantum systems.
4.3 The Toda system revisited

4.3.1 The Toda lattice equation revisited

We note that the Toda lattice equation fits into the metriplectic picture in a degenerate but interesting fashion since it has a dual Hamiltonian and gradient character which may be seen by writing it in the double bracket form (2).

It may be viewed either as the Hamiltonian part or the dissipative part of a metriplectic system with Hamiltonian

\[ H = \frac{1}{2} \text{Tr} L^2 \]

or entropy function \( S = \text{Tr} LN \) respectively with the Toda lattice equations in the corresponding form (7) or (2), as discussed in Section 2. This observation may be extended to the Toda lattice flow on the normal form of any complex semisimple Lie algebra as can be seen in Bloch, Brockett, and Ratiu [1992].

4.3.2 Full Toda with dissipation

It is possible to construct an interesting metriplectic system which incorporates the full Toda dynamics.

We consider the again the flow on the vector space of symmetric matrices \( k = \text{sym}(n) \) but now consider the flow on a generic orbit as discussed in Deift et al. [1992] where it was shown that the flow is integrable. The Hamiltonian is again \( \frac{1}{2} \text{Tr} L^2 \) and the flow on full symmetric matrices is given by

\[ \dot{L} = [\pi_s L, L] \]

with \( \pi_s \) being the projection onto the skew symmetric matrices in the lower triangular skew decomposition of a matrix.

In this setting there are nontrivial Casimir functions of the bracket (9). These are given as follows. For \( L \) an \( n \times n \) symmetric matrix set for \( 0 \leq k \leq \lfloor \frac{n}{2} \rfloor \)

\[ \det(L - \lambda_k) = \sum_{r=0}^{n-2k} E_{r k}(L) \lambda^{n-2k-r} \]

where the subscript \( k \) denotes the matrix obtained by deleting the first \( k \) rows and the last \( k \) columns. Then \( I_{1k}(L) = E_{1k}(L)/E_{0k}(L) \) are Casimir functions of the generic orbit in \( \text{sym}(n) \) as shown in Deift et al. [1992].

Thus we obtain the metriplectic systems

\[ L = [\pi_s L, L] + [L, [L, \nabla I_{1k}]] \]

where the metric is the normal metric on orbits of \( \text{su}(n) \) restricted to the symmetric matrices (identified with \( i \) times the symmetric matrices) as in Bloch, Brockett, and Ratiu [1992]. Here \( H = \frac{1}{2} \text{Tr} L^2 \) and \( S = I_{1k} \).

4.4 Metriplectic systems for pdes: metriplectic brackets and examples

First we construct a class of metriplectic brackets based on triple brackets for infinite systems, then we consider in detail an example based on Gardner’s bracket on \( S^1 \). Lastly, we mention various generalizations.

4.4.1 Symmetric brackets for pdes based on triple brackets

Similar to §4.2 we can construct metriplectic flows for infinite-dimensional systems from completely antisymmetric triple brackets of the form

\[ \{E, F, G\} = \int_{S^1} d\theta_1 \int_{S^1} d\theta_2 \int_{S^1} d\theta_3 \left( C_{ijk}(\theta_1, \theta_2, \theta_3) (P^i E_u)(\theta_1) (P^j F_u)(\theta_2) (P^k G_u)(\theta_3) \right) \]

where \( E, F, \) and \( G \) are smooth functions on \( S^1 \), \( C_{ijk} \) is a smooth function on \( S^1 \times S^1 \times S^1 \) which is completely antisymmetric in its arguments, so as to assure complete antisymmetry of \( \{E, F, G\} \). In addition, we denote \( E_u := \partial E / \partial u, \)
etc. Let \( \mathcal{P}^i, i = 1, 2, 3 \), be pseudo-differential operators. Evidently, the triple bracket of (63) is trilinear and completely antisymmetric in \( E, F, G \).

From (63) and a Hamiltonian \( H \), we construct a symmetric bracket as follows:

\[
(F, G)_H = \int_{S^1} d\theta' \int_{S^1} d\theta'' \left\{ U(\theta'), H, F \right\} \mathcal{G}(\theta', \theta'') \left\{ U(\theta''), H, G \right\},
\]

(64)

where \( U(\theta) \) in (64) denotes the functional

\[
U(\theta) : u \mapsto \int_{S^1} d\theta' u(\theta') \delta(\theta - \theta').
\]

(65)

We shall use this notation in subsequent expressions below. The ‘metric’ \( \mathcal{G} \) is assumed to be symmetric and positive semidefinite, i.e., the smooth function \( \mathcal{G} : S^1 \times S^1 \to \mathbb{R} \) satisfies \( \mathcal{G}(\theta', \theta'') = \mathcal{G}(\theta'', \theta') \) and

\[
\int_{S^1} d\theta' \int_{S^1} d\theta'' \mathcal{G}(\theta', \theta'') f(\theta') f(\theta'') \geq 0
\]

(66)

for all functions \( f \in C^\infty(S^1) \). Therefore, by construction, it is clear that (64) satisfies the following:

(i) \( (F, G)_H = (G, F)_H \) for all \( F, G \),

(ii) \( (F, H)_H = 0 \) for all \( F \), and

(iii) \( (F, F)_H \geq 0 \) for all \( F \).

As a special case suppose \( \mathcal{P}^i = \mathcal{P} \) for all \( i = 1, 2, 3 \); then (63) becomes

\[
\{ E, F, G \} = \int_{S^1} d\theta_1 \int_{S^1} d\theta_2 \int_{S^1} d\theta_3 \mathcal{C}(\theta_1, \theta_2, \theta_3) \mathcal{P}(\theta_1) E_u \mathcal{P}(\theta_2) F_u \mathcal{P}(\theta_3) G_u.
\]

(67)

As a further specialization, suppose \( \mathcal{C}(\theta_1, \theta_2, \theta_3) \) is given by

\[
\mathcal{C}(\theta_1, \theta_2, \theta_3) = A(\theta_1, \theta_2) + A(\theta_2, \theta_3) + A(\theta_3, \theta_1)
\]

(68)

where \( A \) is any antisymmetric function, i.e.,

\[
A(\theta_1, \theta_2) = -A(\theta_2, \theta_1).
\]

(69)

The form (68), assuming (69), assures complete antisymmetry of \( \mathcal{C} \).

Finally, a particularly interesting, self-contained, case would be to suppose the \( A \)’s come from some Poisson bracket, according to

\[
A(\theta_1, \theta_2) = \{ U(\theta_1), U(\theta_2) \}.
\]

(70)

It would be quite natural to choose the entropy, \( S \), to be a Casimir function of this bracket and to choose this bracket as the Hamiltonian part of the metriplectic system with symmetric bracket given by (64). We give an example of this construction in Sec. 4.4.2.

It is evident that one can construct a wide variety of symmetric brackets based on triple brackets. For example, one can choose the pseudo-differential operators from the list \( \{ \mathcal{I}_d, d/d\theta, (d/d\theta)^{-1}, \mathcal{H} \} \), where \( \mathcal{I}_d \) is the identity operator, and the Hamiltonian, \( H \), and entropy (Casimir) \( C \) could be one of the following functionals:

\[
H_0 = \int_{S^1} d\theta u
\]

(71)

\[
H_2 = \int_{S^1} d\theta u^2/2
\]

(72)

\[
H_1 = \int_{S^1} d\theta u^2/2
\]

(73)

\[
H_{KdV} = \int_{S^1} d\theta \left( u^3 + u^2/2 \right).
\]

(74)
4.4.2 Metriplectic systems based on the Gardner bracket

For simplicity we choose \( \mathcal{P}_i = \mathcal{J}_d \) for all \( i \), and as mentioned above, we suppose \( A(\theta_1, \theta_2) \) is generated from the Gardner bracket \( (30) \), i.e.,

\[
A(\theta_1, \theta_2) := \{U(\theta_1), U(\theta_2)\} = \int_{S^1} d\theta \delta(\theta - \theta_1) \frac{d}{d\theta} \delta(\theta - \theta_2) = \delta'(\theta_1 - \theta_2),
\]

where prime denotes differentiation with respect to argument and \( \delta'(\theta_1 - \theta_2) \) is defined by

\[
\int_{S^1} d\theta_1 \int_{S^1} d\theta_2 \delta'(\theta_1 - \theta_2) f(\theta_1)g(\theta_2) = -\int_{S^1} d\theta \int_{S^1} ds \delta'(s) f(\theta_1)g(\theta_1-s) = \int_{S^1} d\theta_1 f(\theta_1)g'(\theta_1)
\]

\[
= -\int_{S^1} d\theta_1 \int_{S^1} d\theta_2 \delta'(\theta_2 - \theta_1) f(\theta_1)g(\theta_2)
\]

for any \( f, g \in C^\infty(S^1) \), which shows that \( \delta'(\theta_2 - \theta_1) = -\delta'(\theta_1 - \theta_2) \). With this choice for \( A \) we obtain

\[
\mathcal{C}(\theta_1, \theta_2, \theta_3) = \delta'(\theta_1 - \theta_2) + \delta'(\theta_2 - \theta_3) + \delta'(\theta_3 - \theta_1),
\]

and Eq. (67) becomes

\[
\{E,F,G\} = \int_{S^1} d\theta_1 \int_{S^1} d\theta_2 \int_{S^1} d\theta_3 \left[ \delta'(\theta_1 - \theta_2) + \delta'(\theta_2 - \theta_3) + \delta'(\theta_3 - \theta_1) \right] E_a(\theta_1) F_u(\theta_2) G_a(\theta_3)
\]

\[
= \left( \int_{S^1} d\bar{\theta} G_a(\bar{\theta}) \right) \int_{S^1} d\theta F_u(\theta) E'_a(\theta) + \left( \int_{S^1} d\bar{\theta} E_a(\bar{\theta}) \right) \int_{S^1} d\theta G_a(\theta) F'_u(\theta)
\]

\[
+ \left( \int_{S^1} d\bar{\theta} F_u(\bar{\theta}) \right) \int_{S^1} d\theta E_u(\theta) G'_a(\theta). \tag{76}
\]

We shall construct a metriplectic system of the form

\[
\dot{F} = \{H,F,G\} + \int_{S^1} d\theta' \int_{S^1} d\theta'' \left\{ U(\theta'), S, F \right\} \mathcal{G}(\theta', \theta'') \left\{ U(\theta''), S, G \right\},
\]

using the Gardner bracket \( (71) \).

Observe if we now set \( F = H_0 \), the Casimir for the Gardner bracket \( (71) \), then, since \( \delta H_0/\delta u = 1 \), we obtain

\[
\{F,H_0,G\} = \int_{S^1} d\theta F_u G'_a \tag{77}
\]

which is precisely the Gardner bracket. To see this, let us compute, for example, the integral in the third term of \( (76) \). Changing variables \( s = \theta_3 - \theta_1 \) we get

\[
\int_{S^1} d\theta_1 \int_{S^1} d\theta_2 \int_{S^1} d\theta_3 \delta'(\theta_1 - \theta_2) E_u(\theta_1) G_a(\theta_3) = -\int_{S^1} ds \int_{S^1} d\theta_3 \delta'(s) E_a(\theta_3-s) G_u(\theta_3) = \int_{S^1} d\theta_3 E'_a(\theta_3) G_u(\theta_3).
\]

A similar computation shows that the first and second terms vanish.

In order to construct the symmetric bracket in \( (64) \), we need the following, computed using \( (76) \):

\[
\left\{ U(\theta), H, G \right\} = -\int_{S^1} d\bar{\theta} G_a(\bar{\theta}) H'_a(\bar{\theta}) + \int_{S^1} d\bar{\theta} G_u(\bar{\theta}) H'_u(\bar{\theta}) + \int_{S^1} d\bar{\theta} H_u(\bar{\theta}) G'_a(\bar{\theta}). \tag{78}
\]

Now with the counterpart of \( (78) \) for the functional \( F \) with \( U(\theta') \), a choice for \( H \), and a choice for \( \mathcal{G} \), we can construct \( (F,G)_H \). We make the following choices:
Fourier series. After such a solution is constructed, one must enforce the fact that the global quantities are given by the usual method of constructing a temporal Green’s function out of the heat kernel and expanding in a Fourier series with a source and with the inclusion of a linear advection term. One can proceed to solve this problem by constructing the symmetric bracket (64), which gives
\[ \{U(\theta), H_2, G\} = \left(\int_{S^1} d\bar{\theta} G_u(\bar{\theta}) \right) u'(\theta) + \int_{S^1} d\bar{\theta} G_u(\bar{\theta}) u'(\bar{\theta}) + SG_u'(\bar{\theta}) \]  
and to construct the symmetric bracket (64), we need
\[ \{U(\theta''), H_2, S\} = -u'(\theta'') \]  
Thus, the equations of motion are
\[ \frac{d}{dt} F = \{F, H_0, H_2\} + (F, S)_{H_2} \]
where
\[ (F, S)_{H_2} = \int_{S^1} d\theta' \int_{S^1} d\theta'' \{U(\theta'), H_2, F\} \mathcal{G}(\theta', \theta'') \{U(\theta''), H_2, S\} \].
This yields
\[ u_i - u_{i\theta} = S u_{i\theta\theta} + Q \quad \text{with} \quad Q := \int_{S^1} d\theta' |u_{\theta'}|^2. \]  
Equation (84) has several interesting features. For fixed given constant $S$ and $Q$, it is a linear equation composed of the heat equation with a source and with the inclusion of a linear advection term. One can proceed to solve this equation by the usual method of constructing a temporal Green’s function out of the heat kernel and expanding in a Fourier series. After such a solution is constructed, one must enforce the fact that the global quantities $S$ and $Q$ are both time dependent and, importantly, dependent on the solution so constructed. Only after these constraints are enforced would one actually have a solution. Pursuing this construction, although interesting, is outside the scope of the present paper and will be treated elsewhere.

We observe that the equation (84) is metriplectic. Indeed, by construction, we have a Poisson bracket (77) (the Gardner bracket) and a symmetric bracket (83). Since these were constructed out of triple brackets, property (iii) of Definition in Section 4.1 holds. Positive semidefiniteness of the symmetric bracket follows from (81).

The nature of the dissipation of (84) is of particular interest in that it involves the global quantities $S$ and $Q$. This is reminiscent of collision operators, such as that due to Boltzmann and generalized nonlinear Fokker-Planck operators such as those due to Landau, Lenard-Balescu, and others (see, e.g., Morrison [1986]). The usual dissipation in $1 + 1$ systems is local in nature (see Sec. 4.5) and dissipates energy. Thus the metriplectic construction of this section has pointed to a quite natural type of dynamical system that has dynamical versions of both the first and second laws of thermodynamics. The pathway for constructing other systems with nonlinear and dispersive Hamiltonian components, other kinds of dissipation, etc. is now cleared, and some will be considered in future publications.

4.4.3 Some metriplectic generalizations

It is evident that many generalizations are possible. We mention a few.

- Without destroying the symmetries or formal metriplectic bracket properties we could allow one or both of the functions $C$ and $\mathcal{G}$ to depend on the field variable $u$ or even contain pseudodifferential operations. In fact, such ideas were used in similar brackets in Flierl and Morrison [2011] to facilitate numerical computation.
- It is clear how to generalize (64) to preserve more constraints, say $l_1, l_2, \ldots$, in addition to $H$. One simply first constructs the completely antisymmetric multilinear brackets $\{E, F, G, H, \ldots\}$ paralleling (64), and then, analogous to (64), constructs
\[ (F, G)_{H, l_1, l_2, \ldots} = \int_{S^1} d\theta' \int_{S^1} d\theta'' \{U(\theta'), H, l_1, l_2, \ldots, F\} \mathcal{G}(\theta', \theta'') \{U(\theta''), H, l_1, l_2, \ldots, G\}. \]  
The bracket $(F, G)_{H, l_1, l_2, \ldots}$ is guaranteed to be symmetric, conserve the invariants, and be positive semidefinite.
• It is of general interest to have metriplectic systems of the form
\[
\dot{F} = \{H, F, G\} + \int_{S^1} d\theta' \int_{S^1} d\theta'' \left\{ \partial(\theta'), S, F \right\} \partial(\theta', \theta'') \left\{ \partial(\theta''), S, G \right\}
\]
(such as our example of Sec. 4.4.2) for a suitably chosen function \(G\); here \(H\) is the Hamiltonian and \(S\) is the entropy. Exploring the mathematics of when this is possible is an area to pursue.

The construction here is easily extendable to higher spatial dimensions. For example consider the following triple bracket given in Bialynicki-Birula and Morrison [1991]:
\[
\{E, F, G\} = \int_{D} d^6z E f \left[ f, G \right],
\]
where \(z = (q, p)\) is a canonical six-dimensional phase space variable, \(f(z, t)\) is a phase space density, as in Vlasov theory, the ‘inner’ Poisson bracket is defined by
\[
[f, g] = f_q g_p - f_p g_q.
\]
We assume that the domain \(D\) with boundary conditions enables us to set all surface terms obtained by integrations by parts to zero, thereby assuring complete antisymmetry. Inserting the quadratic Casimir \(C_2 = \int_{D} d^6z f^2/2\) into (86) gives
\[
\{F, G\}_{VP} = \{C_2, F, G\} = \int_{D} d^6z f \left[ f, G \right],
\]
the Lie-Poisson bracket for the Vlasov-Poisson system, as given in Morrison [1980]. Thus, this bracket with the quadratic Casimir is formally akin to the construction given in Sec. 4.2.1 (although we note it reduces to a good bracket for any Casimir and in this way is like the case of \(so(3)\) of Sec 4.2.2). The triple bracket of (86) can be used in a generalization of the bracket of (64) to obtain a variety of energy conserving collision operators, with a wide choice of Casimirs as entropies.

4.5 Hybrid dissipative structures

Even if a system is not metriplectic, it is of interest to see if it can be obtained from an equation which consists of a Hamiltonian part and a gradient part with respect to a suitable Poisson bracket and metric, respectively.

For KdV-like equations, energy (the Hamiltonian) is generally not conserved when dissipation is added to the system. This is common for physical systems, but a more complete model would conserve energy while accounting for heat loss, i.e., entropy production. In the terminology of Morrison [2009], models that lose energy, such as those treated here and those described by the double bracket formalism of [2.1] are incomplete, while those that do represent dynamical models of the laws of thermodynamics, such as metriplectic systems, are termed complete. Although incomplete systems do not conserve energy, they may conserve other invariants, and building this in, represents an advantage of various bracket formulations. Thus, we construct incomplete hybrid Hamiltonian and dissipative dynamics by combining a Hamiltonian and a gradient vector field according to the prescription
\[
\dot{u} = \{u, H\} + (u, S)
\]
where \(u \rightarrow \{u, H\}\) is a Hamiltonian vector field generated by \(H\) and \(u \rightarrow (u, S)\) is a gradient vector field generated by \(S\) (which could be \(H\)). Thus, (, ) is, up to a sign, an inner product on the space of functions \(u\).

Consider the following examples:

• With the usual KdV Hamiltonian of (31) and the Gardner bracket of (30) describing the Hamiltonian vector field, together with the choice
\[
S(u) = H_1(u) = \frac{1}{4\pi} \int_{-\pi}^{\pi} d\theta (u_\theta)^2
\]
we obtain for the gradients of Corollary 2.
Gradient flows and metriplectic systems

\begin{align*}
(\text{i}) \quad u_t &= \{u,H\} - \nabla^1 H_1 = -u_{\theta \theta} + 6uu_{\theta} - u \\
(\text{ii}) \quad u_t &= \{u,H\} - \nabla H_1 = -u_{\theta \theta} + 6uu_{\theta} + u_{\theta} \\
(\text{iii}) \quad u_t &= \{u,H\} - \nabla^2 H_1 = -u_{\theta \theta \theta} + 6uu_{\theta} - \mathcal{H}(u_{\theta})
\end{align*}

which is the KdV equation of (29) with the inclusion of a new term that describes dissipation. Case (i) corresponds to simple linear damping, case (ii) to ‘viscous’ diffusion, and case (iii) to the equation of [Ott and Sudan [1969]] which adds a term to the KdV equation that describes Landau damping. For these systems the KdV invariant $\int u^2 \theta$ serves as a Lyapunov function.

• Choosing $H = S = H_1$, the Kähler Hamiltonian flow of (34) together with the dissipative flow generated by (21), yields

\[ u_t = \{u,H_1\} - \nabla^2 H_1 = -u_{\theta \theta} - \mathcal{H}(u_{\theta}) \]

which describes simple advection with Landau damping. This equation possesses the damped traveling wave solution.

• We note that we can derive the heat equation from a symmetric bracket of the form (64), again with $\mathcal{G}(\theta', \theta'') = \delta(\theta' - \theta'')$. Using this $\mathcal{G}$ and noting $\{U(\theta), H_0, F\} = G'_u(\theta)$, we obtain

\[ \langle F, G \rangle_{H_0} = \int_{S^1} d\theta \ F_u' G_u'. \tag{89} \]

Let us compute, for example, $F(u) = (F, -H_2)_{H_0}$ (see (72)). Since $\delta H_2 / \delta u = -u$, we obtain

\[ \int_{S^1} d\theta F_u \dot{u} = \frac{d}{dt} F(u) = (F, H_2)_{H_0} = -\int_{S^1} d\theta F_u' u' = \int_{S^1} d\theta F_u u'' . \]

This yields

\[ u_t = u_{xx} \]

which is the heat equation.

From these examples it is clear how a variety of hybrid Hamiltonian and dissipative flows can be constructed from the machinery we have developed. For example, if we replace the KdV Hamiltonian by $H(u) = \int_{S^1} d\theta \left( \frac{1}{2} u \mathcal{H}(u_{\theta}) + \frac{1}{2} u^3 \right)$ we obtain the Benjamin-Ono equation with the various dissipative terms. Related ideas apply to fluid dynamics may be found in [Gay-Balmaz and Holm [2012]].
