THE $H^\infty$ ALGEBRAS OF HIGHER RANK GRAPHS

DAVID W. KRIBS AND STEPHEN C. POWER

Abstract. We begin the study of a new class of operator algebras that arise from higher rank graphs. Every higher rank graph generates a Fock space Hilbert space and creation operators which are partial isometries acting on the space. We call the weak operator topology closed algebra generated by these operators a higher rank semigroupoid algebra. A number of examples are discussed in detail, including the single vertex case and higher rank cycle graphs. In particular the cycle graph algebras are identified as matricial multivariable function algebras. We obtain reflexivity for a wide class of graphs and characterize semisimplicity in terms of the underlying graph.

In [22] Kumjian and Pask introduced $k$-graphs as an abstraction of the combinatorial structure underlying the higher rank graph C*-algebras of Robertson and Steger [31, 32]. A $k$-graph generalizes the set of finite paths of a countable directed graph when viewed as a partly defined multiplicative semigroup with vertices considered as degenerate paths. The C*-algebras associated with $k$-graphs include $k$-fold tensor products of graph C*-algebras, and much more [2, 21, 26, 27, 30]. On the other hand, as a generalization of the nonselfadjoint free semigroup algebras $L_n$ [3, 5, 6, 7, 20, 28, 29], the authors [17, 18] have recently studied free semigroupoid algebras $L_G$ associated with directed countable graphs $G$. In particular it was shown that these algebras are reflexive. (See also [12, 13, 14, 15, 16, 23, 24, 25, 34] for related recent work.) As it turns out, these algebras arise from the left regular representation of the 1-graph of the directed graph $G$. In the present paper we consider the higher rank versions of these algebras, the $k$-graph algebras $L_{(\Lambda, d)}$ associated with the $k$-graph $(\Lambda, d)$, as well as their norm closed subalgebras. To our knowledge such nonselfadjoint higher rank graph algebras have not been considered previously. However, from the perspective of contemporary operator algebra theory they evidently form a natural class and one which may play an

Key words and phrases. higher rank graph, Fock space, semigroupoid algebra, reflexivity, hyper-reflexivity, semisimple algebra.

1
important role in more general higher rank operator algebra considerations.

The algebras \( L_n \) are also referred to as the noncommutative analytic Toeplitz algebras and in the case \( n = 1 \) one obtains the usual algebra \( H^\infty \) acting on the Hardy space of the circle \([10, 11, 33]\). In the present paper we examine eigenvalues, reflexivity, hyper-reflexivity and semisimplicity for the algebras \( L(\Lambda, d) \) which can be viewed as the \( H^\infty \) algebras of higher rank graphs.

In \( \S 1 \) we outline the nomenclature associated with higher rank graphs \((\Lambda, d)\). In \( \S 2 \) we introduce higher rank semigroupoid algebras \( L(\Lambda, d) \) and derive some basic properties. We follow this in \( \S 3 \) by presenting a diverse collection of examples and in \( \S 4 \) we consider the single vertex algebras. In particular we determine the eigenvalues for the adjoint algebras and the Gelfand space of the norm closed subalgebras \( A(\Lambda, d) \). In the next section (\( \S 5 \)) we prove the algebras \( L(\Lambda, d) \) are reflexive or hyper-reflexive for various diverse graphs. In the final section (\( \S 6 \)) we find a graph condition which characterizes when \( L(\Lambda, d) \) is semisimple and give an explicit description of the Jacobson radical in the finite vertex case.

### 1. Higher Rank Graphs

Let \( G = (V, E) \) be a countable directed graph and let \( \Lambda_G \) denote the set of all directed paths \( \lambda = e_re_{r-1} \cdots e_1 \) where \( e_1 \) is an edge \((v_2, v_1)\) directed from \( v_1 \) to \( v_2 \) and where \( e_k \) is an edge \((v_{k+1}, v_k)\), for \( 1 \leq k \leq r \), where \( v_1, v_2, \ldots, v_r \) are the vertices of the path, in their directed order, possibly with repetitions. Let \( d : \Lambda_G \to \mathbb{N} \) be the length function. Then the pair \((\Lambda_G, d)\) is an example of a 1-graph in the sense of the definition below.

The set \( \Lambda_G \) has a natural partially defined multiplication which together with vertices as degenerate paths makes \( \Lambda_G \cup V \) into a (discrete) semigroupoid with vertices as units. (This is the terminology of \([17, 18]\).) However, \( \Lambda_G \) can be viewed as a set of morphisms between elements of \( V \), and as such \( \Lambda_G \) forms a small category with \( V \) as the set of objects. (‘Small’ since the objects form a set.) It is this viewpoint which is extended in the definition below.

**Definition 1.1.** \([22]\) A \( k \)-graph \((\Lambda, d)\) consists of a countable small category \( \Lambda \), with range and source maps \( r \) and \( s \) respectively, together with a functor \( d : \Lambda \to \mathbb{Z}_+^k \) satisfying the factorization property: for every \( \lambda \in \Lambda \) and \( m, n \in \mathbb{Z}_+^k \) with \( d(\lambda) = m + n \), there are unique elements \( \mu, \nu \in \Lambda \) such that \( \lambda = \mu \nu \) and \( d(\mu) = m \) and \( d(\nu) = n \).
By the factorization property we may identify the objects Obj(Λ) of Λ with the subset Λ^0 = d^{-1}(0, \ldots, 0). We also write Λ^n for d^{-1}(n), n \in \mathbb{Z}^k_+. Observe that the factorization property implies that left and right cancellation hold in Λ. Let δ : Λ → Λ be the grading function defined by δ(λ) = |d(λ)| = n_1 + \ldots + n_k where d(λ) = (n_1, \ldots, n_k).

As indicated above the conventional definition of a directed graph, with its semigroupoid of paths, is captured in the special case of 1-graphs. The set Λ with its semigroupoid of paths, is captured in the special case of 1-graphs. In this way.

It is of immediate interest to see k-graphs which do not arise as direct products. For an elementary example let Λ be a 2-graph arising from the set Λ_{G_1 \times G_2} of paths in the direct product directed graph G_1 \times G_2, where G_1, G_2 are directed graphs, together with the natural map d : Λ_{G_1 \times G_2} → \mathbb{Z}^2_+. In this case, if e = (v_2, v_1) is an edge of G_1 and f = (w_2, w_1) is an edge of G_2, then e × f = ((v_2, w_2), (v_1, w_1)) is an edge of G_1 × G_2 and d(e × f) = (1, 1). Also, by definition G_1 × G_2 includes all edges ((v, w_2), (v, w_1)) and ((v_2, w), (v_1, w)), with d-degrees (0, 1) and (1, 0) respectively, for each vertex v of G_1 and w of G_2. More generally, a direct product G_1 × \ldots × G_k of k directed graphs generates a k-graph in this way.

It is of immediate interest to see k-graphs which do not arise as direct products. For an elementary example let Λ = \{v\}, Λ^{(1,0)} = \{a\}, Λ^{(0,1)} = \{b\} be singleton sets. Suppose moreover that composition of the morphisms a, b generate all morphisms of the category Λ. In view of the required factorization property and its uniqueness, it soon becomes clear that all the morphisms w = a^{n_1}b^{m_1}a^{n_2} \ldots b^{m_r} with degree defined by d(w) = (n, m), n = n_1 + \ldots + n_r, m = m_1 + \ldots + m_r must coincide. Thus set Λ^{(n,m)} = \{a^n b^m\} and in this way we obtain a 2-graph Λ = \bigcup_{n\in\mathbb{Z}^2_+} Λ^n.

Note that the 2-graph above is generated by the units and elements of total degree 1 subject to a simple commutation relation. We now give a similar such description of more general 2-graphs in which a commutation rule α × β = θ(α × β) is built in to ensure the factorization property.

Let A = Λ_{G_1, d_1} and B = Λ_{G_2, d_2} be 1-graphs such that A^0 = B^0, so that the underlying graphs G_1 and G_2 have the same number of vertices and the vertex sets are identified. Let v_1, v_2 be two vertices and consider the following sets of pairs of edges,

\[ E(v_2, v_1) = \left\{ \alpha \times \beta \in A^1 \times B^1 \mid s(\alpha) = r(\beta), s(\beta) = v_1, r(\alpha) = v_2 \right\} \]

\[ F(v_2, v_1) = \left\{ \beta \times \alpha \in B^1 \times A^1 \mid s(\beta) = r(\alpha), s(\alpha) = v_1, r(\beta) = v_2 \right\} \]
Suppose also that these sets have the same cardinality for all vertex pairs and that \( \theta \) is a bijection mapping each \( \alpha \times \beta \) in \( E(v_2, v_1) \) to an element \( \theta(\alpha \times \beta) \) in \( F(v_2, v_1) \), for all vertex pairs. To construct the 2-graph \( (\Lambda, d) = A \ast_\theta B \) define

\[
\Lambda^0 = V = V(G_1) = V(G_2),
\]

\[
\Lambda^{(1,0)} = \{ \alpha \times v \in A^1 \times V \mid s(\alpha) = v \},
\]

\[
\Lambda^{(0,1)} = \{ v \times \beta \in V \times B^1 \mid r(\beta) = v \},
\]

\[
\Lambda^{(1,1)} = \bigcup_{v,w \in V} E(v,w) = \bigcup_{v,w \in V} F(v,w),
\]

where the last equality arises from the identifications \( \alpha \times \beta = \theta(\alpha \times \beta) \). Plainly the factorization property holds for morphisms in \( \Lambda^{(1,1)} \). Finally define \( \Lambda^{(n,m)} \) as the set of morphisms obtained from arbitrary finite compositions of morphisms in \( \Lambda^{(1,0)} \) and \( \Lambda^{(0,1)} \) subject to the relations generated by the identifications \( (\alpha \times v)(v \times \beta) = (\beta_1 \times v)(v \times \alpha_1) \) if \( \alpha_1 \times \beta_1 = \theta(\alpha \times \beta) \). It is routine to check that \( \Lambda^{(n,m)} \) satisfies the factorization property with the natural map \( d : \Lambda \to \mathbb{Z}_2^+ \) (where \( \Lambda \) is the union of all the sets \( \Lambda^{(n,m)} \)), and thus the pair \( (\Lambda, d) \) is a 2-graph.

**Remark 1.2.** We shall find it convenient to view a 2-graph as being specified through a directed graph in which edges are of two types, perhaps red or blue, according to their degree, \((1, 0)\) or \((0, 1)\), together with a set of relations that define the factorization property. For instance, if \( \lambda = e_3 e_2 e_1 \) is a path with \( d(\lambda) = (2, 1), \delta(\lambda) = 3 \) and \( e_1, e_2, e_3 \) coloured red, red, blue respectively, then there must be red edges \( f_1, f_3, g_2, g_3 \) and blue edges \( f_2, g_1 \) such that \( \lambda = f_3 f_2 f_1 = g_3 g_2 g_1 \). The initial (respectively final) vertices of \( e_1, f_1, g_1 \) (respectively \( e_3, f_3, g_3 \)) must coincide but \( e_2, f_2, g_2 \) may have distinct initial and final vertices.

It is thus understood that a given path in the chromatic graph represents an equivalence class of paths under the commutation relations which are either specified explicitly, or implied by the factorization property. Of course, the same remarks apply to a \( k \)-graph, which corresponds to a \( k \)-coloured graph \( \Lambda^{(e_1)} \cup \ldots \cup \Lambda^{(e_k)} \) together with commutation relations distinct colours.

**Remark 1.3.** Let us clarify our use of the terminology “semigroupoid” and “freeness”. To each directed graph \( G \) one can associate the (universal) graph \( C^* \)-algebra, and under mild hypotheses this is isomorphic to a (topological) groupoid \( C^* \)-algebra \( C^*(G) \) associated with the topological path groupoid \( \mathcal{G} \) of \( G \). We have no cause in this paper to consider this groupoid but we do find it convenient to use terminology which derives from the (discrete) groupoid of an undirected graph \( G \). This
consists of paths in the edges $e$ of $G$ and their formal inverses $e^{-1}$, together with the vertices viewed as degenerate edges forming units. With the understanding that the only identification of paths is through the relations $ee^{-1} = r(e)$ and $e^{-1}e = s(e)$, it is natural to refer to this groupoid as the free groupoid $\mathbb{F}(G)$ of $G$. Indeed, in the case of a single vertex graph this groupoid is the free group on $n$-generators where $n$ is the number of edges of $G$. Moreover, if $\mathcal{E}$ is a discrete groupoid generated by elements $e_1, e_2, \ldots$ together with units $x_1, x_2, \ldots$, then this set of generators determines a graph, $G$ say. If $\alpha : \mathcal{E} \to \mathcal{F}$ is a discrete groupoid homomorphism then there is a lifting $\beta : \mathcal{F}(G) \to \mathcal{F}$ such that $\beta = \pi \circ \alpha$ where $\pi : \mathcal{F}(G) \to \mathcal{E}$ is the natural map. Thus, $\mathcal{F}(G)$ is the free object in the category of discrete groupoids with generators labelled by the graph $G$.

Similarly, if we omit the formal inverses $e^{-1}$ of the edges of a graph $G$ then we identify a unital semigroupoid in $\mathcal{F}(G)$ which we denote as $\mathcal{F}^+(G)$ and refer to as the (discrete) free semigroupoid of $G$. Thus, a 1-graph coincides with the pair $(\mathcal{F}^+(G), d)$ where $d$ is the length function and $G$ is the graph arising from elements of total degree 1.

2. **Higher Rank Semigroupoid Algebras**

Let $(\Lambda, d)$ be a $k$-graph. Let $\mathcal{H}_\Lambda$ be the Fock space of $\Lambda$ which we define to be the Hilbert space with orthonormal basis $\{\xi_\lambda : \lambda \in \Lambda\}$. For $\lambda \in \Lambda$ define the operator $L_\lambda$ on $\mathcal{H}_\Lambda$ such that

$$L_\lambda \xi_\mu = \begin{cases} 
\xi_\mu & \text{if } s(\lambda) = r(\mu) \\
0 & \text{if } s(\lambda) \neq r(\mu)
\end{cases}.$$

It follows from the factorization property that each $L_\lambda$ is a partial isometry. Moreover, $L_v, v \in \Lambda^0$, is the projection onto the subspace $\text{span}\{\xi_\lambda : r(\lambda) = v\}$.

**Definition 2.1.** The semigroupoid algebra $\mathcal{L}_{(\Lambda, d)}$ of the $k$-graph $(\Lambda, d)$ is the weak operator topology closed linear span of $\{L_\lambda : \lambda \in \Lambda\}$.

Recalling the definition of the grading function $\delta$, it is evident that $\mathcal{H}_\Lambda$ is naturally graded as $\mathcal{H}_\Lambda = \mathcal{H}_0 \oplus \mathcal{H}_1 \oplus \mathcal{H}_2 \oplus \ldots$, where $\mathcal{H}_n$ is the closed span of the $\xi_\lambda$ with $\delta(\lambda) = n$.

By arguing exactly as in the case of free semigroupoid algebras [17] one can obtain the following proposition. For brevity we write $\mathcal{L}_\Lambda$ for $\mathcal{L}_{(\Lambda, d)}$ and $\mathcal{R}_\Lambda$ for the analogue of $\mathcal{L}_\Lambda$ for right actions.
Proposition 2.2. If $A \in \mathfrak{L}_\Lambda$ then $A$ is the sot-limit of the Cesaro sums
\[
\sum_{\delta(\lambda) \leq n} \left(1 - \frac{\delta(\lambda)}{n}\right) a_\lambda L_\lambda,
\]
where $a_\lambda \in \mathbb{C}$ is the coefficient of $\xi_\lambda$ in $A \xi_v = \sum_{s(\lambda) = v} a_\lambda \xi_\lambda$, for $v \in \Lambda^0$.

Thus elements of $\mathfrak{L}_\Lambda$ have Fourier expansions $A \sim \sum_{\lambda \in \Lambda} a_\lambda L_\lambda$. In particular, this leads to the following description of the commutant.

Proposition 2.3. The commutant of $\mathfrak{R}_\Lambda$ is $\mathfrak{L}_\Lambda$.

Proof. As in the directed graph case we can consider the Cesaro operators associated with the partition $I = E_0 + E_1 + \ldots$ where $E_n$ is the projection onto $\mathcal{H}_n$. These operators are given by
\[
\Sigma_n(A) = \sum_{\delta(\lambda) = m < n} \left(1 - \frac{\delta(\lambda)}{n}\right) \Phi_m(A),
\]
where the operators $\Phi_m(A) = \sum_{n \geq \text{max} \{0, -m\}} E_n A E_{n+m}$ are the diagonals of $A$ with respect to the block matrix decomposition associated with the partition. The operators $\Sigma_n(A)$ converges to $A$ in the strong operator topology for all $A \in \mathcal{B}(\mathcal{H}_\Lambda)$.

It is clear that $\mathfrak{L}_\Lambda$ is contained in $\mathfrak{R}_\Lambda^\prime$, thus for the converse we fix $A \in \mathfrak{L}_\Lambda^\prime$. We will show that $A_v \equiv AL_v$ belongs to $\mathfrak{L}_\Lambda$ for all $v \in \Lambda^0$. This will finish the proof since $A = \sum_{v \in \Lambda^0} AL_v$, the sum converging sot when $\Lambda^0$ is infinite. Let $A \xi_v = R_v A v \xi_v = \sum_{s(\lambda) = v} a_\lambda \xi_\lambda$. Define operators in $\mathfrak{L}_\Lambda$ by
\[
p_n(A_v) = \sum_{\delta(\lambda) < n; s(\lambda) = v} \left(1 - \frac{\delta(\lambda)}{n}\right) a_\lambda L_\lambda.
\]
We will prove that $A_v = \text{sot-} \lim_{n \to \infty} p_n(A_v)$ by showing that $p_n(A_v) = \Sigma_n(A_v)$. First note that $\Phi_m(A_v)$ belongs to $\mathfrak{R}_\Lambda^\prime$ for all $m$ since $A_v$ belongs to $\mathfrak{R}_\Lambda^\prime$ and $E_{n+1} R_\lambda = R_\lambda E_n$ for all $n$ and $\lambda \in \Lambda^1$, while $\Phi_m(A_v)$ commutes with each projection $R_w$ since $R_w E_n = E_n R_w$ is the projection onto $\text{span}\{\xi_\lambda : \delta(\lambda) = n, s(\lambda) = w\}$ for all $n$. It follows that $\Sigma_n(A_v)$ belongs to $\mathfrak{R}_\Lambda^\prime$ for $n \geq 1$.

Now it is enough to show that $\Sigma_n(A_v) \xi_v = p_n(A_v) \xi_v$. If this is the case, then for $\lambda \in \Lambda$ with $r(\lambda) = v$ we have
\[
\Sigma_n(A_v) \xi_\lambda = R_\lambda \Sigma_n(A_v) \xi_v = R_\lambda p_n(A_v) \xi_v = p_n(A_v) \xi_\lambda,
\]
whereas, if $r(\lambda) = w$ with $w \neq v$ then
\[
\Sigma_n(A_v) \xi_\lambda = \sum_{s(\lambda) = v} \xi_\lambda = 0 = p_n(A_v) L_v \xi_\lambda = p_n(A_v) \xi_\lambda,
\]
since $L_v$ commutes with each $E_n$. 
Observe that \( \Phi_0(A_v)\xi_v = E_0(A_v)E_0\xi_v = a_v\xi_v, \) and \( \Phi_m(A_v)\xi_v = 0 \) for \( m > 0. \) Further, for \( m < 0 \) we have \( \Phi_m(A_v)\xi_v = (E_{-m}A_v)\xi_v = E_{-m} \sum_{s(\lambda) = v} a_{\lambda}\xi_{\lambda} = \sum_{s(\lambda) = v; \delta(\lambda) = -m} a_{\lambda}\xi_{\lambda}. \)

Hence it follows that
\[
\Sigma_n(A_v)\xi_v = \sum_{\delta(\lambda) < n; s(\lambda) = v} \left(1 - \frac{\delta(\lambda)}{n}\right)a_{\lambda}\xi_{\lambda} = p_n(A_v)\xi_v,
\]
as required. Therefore each \( A_v = AL_v \) belongs to \( L_\Lambda \) and this completes the proof. \( \blacksquare \)

Given \( \Lambda, \) let \( \Lambda' \) be a category with the same functor \( d, \) with \( \text{Obj}(\Lambda') = \text{Obj}(\Lambda) \) and morphisms for each \( \lambda \in \Lambda \) denoted by \( \lambda' \) with \( s(\lambda') = r(\lambda) \) and \( r(\lambda') = s(\lambda). \) Then a simple argument shows that \( L_\Lambda \) and \( R_{\Lambda'} \) are unitarily equivalent via the unitary \( U : H_{\Lambda'} \to H_\Lambda \) defined by \( U\xi_{\lambda'} = \xi_\lambda. \)

**Corollary 2.4.** The commutant of \( L_\Lambda \) is \( R_\Lambda. \)

**Proof.** If \( U \) is the unitary above then \( R'_{\Lambda'} = (U^*L_\Lambda U)' = U^*L_\Lambda U. \) Hence by Proposition 2.3 we have \( R_\Lambda = U^*L_\Lambda U^* = U R_{\Lambda'} U^* = L'_{\Lambda'} \). \( \blacksquare \)

**Corollary 2.5.** \( L_\Lambda \) is its own second commutant, \( L_\Lambda = L''_\Lambda. \)

### 3. Examples

We now describe a number of examples of higher rank semigroupoid algebras starting with some elementary direct product \( k \)-graphs.

**Example 3.1.** Let \( C_1 \) be the directed graph with a single vertex \( v \) and loop edge \( e. \) Then the Fock space \( H_{AC_1} \) may be identified with the Hardy space \( H^2 \) and under this identification \( L_{AC_1} \) is unitarily equivalent to the analytic Toeplitz algebra \( H^\infty [10, 11, 33]. \) Consider, as in \( \S 4 \) the natural direct product \( \Lambda = \Lambda_{C_1} \times \Lambda_{C_1} \) and let \( \overline{v} = v \times v, \ a = e \times v \) and \( b = v \times e. \) Then \( \Lambda^0 = \{\overline{v}\}, \ \Lambda^{(1,0)} = \{a\}, \ \Lambda^{(0,1)} = \{b\} \) and it becomes clear that \( \Lambda \) is the simple \( 2 \)-graph discussed in \( \S 4 \) The standard basis for the Fock space \( H_\Lambda \cong H^2 \otimes H^2 \) may be identified with the vertices in the \( 2 \)-lattice of positive integers \( \mathbb{Z}_+^2 \) and \( L_\Lambda \) is unitarily equivalent to \( H^\infty \otimes H^\infty. \)

More generally, given directed graphs \( G_1, \ldots, G_k \) the standard basis for the Fock space \( H_{AC_{G_1} \times \ldots \times AC_{G_k}} \) may be identified with the standard basis for \( H_{G_1} \otimes \ldots \otimes H_{G_k} \) and this identification yields the unitary equivalence \( L_{AC_{G_1} \times \ldots \times AC_{G_k}} \cong L_{G_1} \otimes \ldots \otimes L_{G_k}. \) For example, if \( F_n \) is the directed graph with a single vertex and \( n \geq 2 \) distinct loop edges,
then \( \mathcal{L}_{F_n} = \mathcal{L}_n \) is the free semigroup algebra (the noncommutative analytic Toeplitz algebra) which acts on unrestricted \( n \)-variable Fock space \( \mathcal{H}_{F_n} \equiv \mathcal{H}_n \). The standard basis for \( \mathcal{H}_n \) is identified with the set of all words from an alphabet with \( n \) and \( L \) letters. Thus, given positive integers \( n_1, \ldots, n_k \) we have \( \mathcal{H}_{\Lambda n_1} \times \cdots \times \Lambda n_k \equiv \mathcal{H}_{n_1} \otimes \cdots \otimes \mathcal{H}_{n_k} \) and \( \mathcal{L}_{\Lambda n_1} \times \cdots \times \Lambda n_k \equiv \mathcal{L}_{n_1} \otimes \cdots \otimes \mathcal{L}_{n_k} \).

**Example 3.2.** Let \( G \) be the connected directed graph with two edges \( a_1 = (x_2, x_1) \), \( a_2 = (x_3, x_2) \). Then the free semigroupoid algebra \( \mathcal{L}_G \) is unitarily equivalent to the operator algebra of matrices

\[
\begin{bmatrix}
\alpha & 0 & 0 \\
\delta & \beta & 0 \\
\kappa & \epsilon & \gamma
\end{bmatrix}
\oplus \begin{bmatrix}
\beta & 0 \\
\epsilon & \gamma
\end{bmatrix},
\]

where \( \alpha, \beta, \gamma, \delta, \epsilon, \kappa \in \mathbb{C} \), acting on the Fock space

\( \mathcal{H}_G = (\mathbb{C} \xi_{x_1} + \mathbb{C} \xi_{a_1} + \mathbb{C} \xi_{a_2 a_1}) \oplus (\mathbb{C} \xi_{x_2} + \mathbb{C} \xi_{a_2}) \oplus \mathbb{C} \xi_{x_3} \).

We can construct the finite 2-graph \( \Lambda = \Lambda_G \ast \vartheta \Lambda_G \) described in § 4 as follows:

\[
\Lambda^0 = \{x_1, x_2, x_3\},
\]
\[
\Lambda^{(1,0)} = \{a_1, a_2\}, \quad \Lambda^{(0,1)} = \{b_1, b_2\},
\]
\[
\Lambda^{(1,1)} = \{b_2 a_1\} = \{a_2 b_1\},
\]

with range and source maps such that \( x_1 = s(a_1) = s(b_1), r(a_1) = x_2 = s(a_2), r(b_1) = x_2 = s(b_2), x_3 = r(a_2) = r(b_2) \). The rest of \( \Lambda \) consists of \( \Lambda^{(2,0)} = \{a_2 a_1\} \) and \( \Lambda^{(0,2)} = \{b_2 b_1\} \). Thus \( \Lambda^1 = \Lambda^{(1,0)} \cup \Lambda^{(0,1)} \) includes two ‘red’ and two ‘blue’ edges and the relation \( b_2 a_1 = a_2 b_1 \) specifies all possible commutation relations within \( \Lambda \).

The Fock space \( \mathcal{H}_\Lambda \) is naturally identified with the vertices of three disjoint downward directed graphs, with vertices for the basis vectors \( \{\xi_{x_1}, \xi_{x_2}, \xi_{x_3}\} \) at level one, for \( \{\xi_{a_1}, \xi_{b_1}, \xi_{a_2}, \xi_{b_2}\} \) at level two and for \( \{\xi_{a_2 a_1}, \xi_{b_2 a_1} = \xi_{a_2 b_1}, \xi_{b_2 b_1}\} \) at level three. The action of \( L_\Lambda, \lambda \in \Lambda \), is given as the appropriate downward (partial) shift. In particular, \( \mathcal{L}_\Lambda \) can be identified as a matrix algebra on a ten dimensional Hilbert space.

**Example 3.3.** *(Higher rank cycle algebras)* Let \( C_n \) be the directed cycle graph with \( n \) edges \( e_i = (x_{i+1}, x_i), 1 \leq i \leq n \ (i + 1 \mod n) \). We define \( k \)-graphs \( C_n^{(k)} \) which are the higher rank variants of these graphs and identify their operator algebras as matrix function algebras. Assume first that \( k = 2 \). Define \( C_n^{(2)} \) to be the 2-graph \( \Lambda \) such that

\[
\Lambda^{(0)} = \{x_1, \ldots, x_n\},
\]
\[
\Lambda^{(1,0)} = \{e_1, \ldots, e_n\} \quad \text{and} \quad \Lambda^{(0,1)} = \{f_1, \ldots, f_n\},
\]
where $f_i$ and $e_i$ have the same sources and same ranges, and where

$$f_{i+1}e_i = e_{i+1}f_i \quad \text{for} \quad 1 \leq i \leq n.$$  

In fact $\Lambda$ is the unique 2-graph arising from the $*_\theta$ construction with $A = B = C_2$. The Fock space $\mathcal{H}_\Lambda$ has a basis $\{\xi_\lambda\}$ which is in natural correspondence with the vertices of $n$ disjoint graphs, each of which is a downward directed rectangular lattice. The generators $L_{e_i}, L_{f_i}$ can be realized as downward partial shifts, with leftward and rightward actions, respectively. Each vertex carries a label of the form $\xi_\lambda$ where

$$\lambda = f_{p+q} \cdots f_{p+1}e_p \cdots e_{i+1}e_i.$$  

Thus we may identify $\mathcal{H}_\Lambda$ with $n$ copies of $H^2 \otimes H^2 = H^2(z,w)$, the Hardy space for the torus $\mathbb{T}^2 = \{(z,w) : |z| = |w| = 1\}$, with its basis $\{z^p w^q : p, q \in \mathbb{Z}_+\}$.

However, there is a more useful related $n$-fold decomposition of $\mathcal{H}_\Lambda$. We first illustrate this in the case $n = 3$. In this case the identification above is $\mathcal{H}_\Lambda \cong \mathbb{C}^3 \otimes H^2(z,w)$ with orthonormal basis

$$\{g_i \otimes z^p w^q : 1 \leq i \leq 3, p, q \in \mathbb{Z}_+\}$$

where $\{g_1, g_2, g_3\}$ is an orthonormal basis for $\mathbb{C}^3$. Consider now the decomposition $\mathcal{H}_\Lambda = \mathcal{H}_1 \oplus \mathcal{H}_2 \oplus \mathcal{H}_3$ where

$$\mathcal{H}_1 = \text{span} \{g_i \otimes z^p w^q : p_1 + q_1 \equiv 0, p_2 + q_2 \equiv 2, p_3 + q_3 \equiv 1\}$$

$$\mathcal{H}_2 = \text{span} \{g_i \otimes z^p w^q : p_2 + q_2 \equiv 0, p_3 + q_3 \equiv 2, p_1 + q_1 \equiv 1\}$$

$$\mathcal{H}_3 = \text{span} \{g_i \otimes z^p w^q : p_3 + q_3 \equiv 0, p_1 + q_1 \equiv 2, p_2 + q_2 \equiv 1\},$$

where each of these subspaces is closed and the prescribed addition is modulo 3. Let us dispense with the $\mathbb{C}^3 \otimes H^2(z,w)$ identification above and identify $\mathcal{H}_1, \mathcal{H}_2, \mathcal{H}_3$ afresh with $H^2(\mathbb{T}^2)$ in the natural way. Now $\mathcal{H}_\Lambda = H^2(\mathbb{T}^2) \oplus H^2(\mathbb{T}^2) \oplus H^2(\mathbb{T}^2)$ and we see that the operators $L_{e_1}, L_{e_2}, L_{e_3}, L_{f_1}, L_{f_2}, L_{f_3}$ are represented by the operator matrices

$$\begin{bmatrix} 0 & 0 & 0 \\ T_z & 0 & 0 \\ 0 & T_z & 0 \end{bmatrix}, \quad \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & T_z \end{bmatrix}, \quad \begin{bmatrix} 0 & 0 & T_z \\ 0 & 0 & 0 \\ T_z & 0 & 0 \end{bmatrix},$$

$$\begin{bmatrix} 0 & 0 & 0 \\ T_w & 0 & 0 \\ 0 & T_w & 0 \end{bmatrix}, \quad \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & T_w \end{bmatrix}, \quad \begin{bmatrix} 0 & 0 & 0 \\ 0 & T_w & 0 \\ T_w & 0 & 0 \end{bmatrix},$$

while $\alpha L_{x_1} + \beta L_{x_2} + \gamma L_{x_3}$ is represented by

$$\begin{bmatrix} \alpha I & 0 & 0 \\ 0 & \beta I & 0 \\ 0 & 0 & \gamma I \end{bmatrix}.$$
It follows readily now that $\mathcal{L}_\Lambda$ is unitarily equivalent to the matrix function algebra

$$
\begin{bmatrix}
H_{3,0}^\infty(z, w) & H_{3,2}^\infty(z, w) & H_{3,1}^\infty(z, w) \\
H_{3,1}^\infty(z, w) & H_{3,0}^\infty(z, w) & H_{3,2}^\infty(z, w) \\
H_{3,2}^\infty(z, w) & H_{3,1}^\infty(z, w) & H_{3,0}^\infty(z, w)
\end{bmatrix}
$$

where $H_{3,i}^\infty(z, w)$ is the closed span of the basis elements $\{z^p w^q : p+q \equiv i \mod 3\}$, for $i = 1, 2$.

For the general case, $\Lambda = C_n^{(k)}$ (with $n \neq 3, k \neq 2$) we have $k$ sets of morphisms/edges of total $\delta$-degree 1, say

$$
\Lambda^{(1,0,\ldots,0)} = \{e_1^1, \ldots, e_n^1\}, \ldots, \Lambda^{(0,\ldots,0,1)} = \{e_1^k, \ldots, e_n^k\}
$$

and all other morphisms arise from compositions, subject only to identifications through the relations

$$
e_{i+1}^r e_i^s = e_{i+1}^r e_i^s
$$

for all $i (i+1 \mod n)$, and all $1 \leq r \neq s \leq k$. We identify the subspace of $H_\Lambda$ which is spanned by $\{\lambda : r(\lambda) = x_i\}$ with $H^2(\mathbb{T}^k)$. Then $H_\Lambda$ is isomorphic to $H^2(\mathbb{T}^k) \oplus \cdots \oplus H^2(\mathbb{T}^k)$ and we identify, as before, $\mathcal{L}_\Lambda$ with the matrix function algebra

$$
\begin{bmatrix}
H_{n,0}^\infty(\mathbb{T}^k) & H_{n,n-1}^\infty(\mathbb{T}^k) & \cdots & H_{n,1}^\infty(\mathbb{T}^k) \\
H_{n,1}^\infty(\mathbb{T}^k) & H_{n,0}^\infty(\mathbb{T}^k) & \cdots & \vdots \\
\vdots & \vdots & \ddots & \ddots \\
H_{n,n-1}^\infty(\mathbb{T}^k) & \cdots & H_{n,0}^\infty(\mathbb{T}^k)
\end{bmatrix},
$$

where $H_{n,i}^\infty(\mathbb{T}^k)$ is the weak-* closed subspace of $H^\infty(\mathbb{T}^k)$ spanned by the monomials $z_1^{i_1} \cdots z_k^{i_k}$ with $i_1 + \cdots + i_k \equiv i \mod n$.

In view of the matrix function identifications in Alainia and Peters [1], it is now possible to see that for the higher rank cycle graph $C_n^{(k)}$ its higher rank semigroupoid algebra is equal to the higher rank $\sigma$-weakly closed semicrossed product $C_n \rtimes^\sigma_{\alpha} \mathbb{Z}_+^k$ where the action $\alpha : \mathbb{Z}_+^k \to \text{Aut}(\mathbb{C}^n)$ is given by $\alpha(m_1, \ldots, m_k) = \sigma^{m_1+\cdots+m_k}$ where $\sigma$ is the cyclic shift.

4. The Algebras $\mathcal{A}_{\mathbb{T},\theta}$ and $\mathcal{L}_{\mathbb{T},\theta}$

We now consider single vertex $k$-graphs and their nonselfadjoint operator algebras $\mathcal{A}_{\mathbb{T},\theta}$ (norm closed) and $\mathcal{L}_{\mathbb{T},\theta}$ (wot-closed). First we determine the codimension one invariant subspaces of $\mathcal{L}_{\mathbb{T},\theta}$ and identify the natural connection with the Gelfand space of the quotient of the
algebra $\mathcal{A}_{\underline{n},\theta}$ by its norm-closed commutator ideal. As we shall see this Gelfand space is biholomorphically equivalent to a subspace of the direct product $\mathbb{B}_{n_1} \times \ldots \times \mathbb{B}_{n_k}$ determined by a complex algebraic variety associated with the relations latent in the $k$-graph.

Let us now specify a general single vertex $k$-graph explicitly in terms of edge generators and commutation relations. We write $\Lambda_{\underline{n},\theta}$ for such a $k$-graph, where $\underline{n} = (n_1, \ldots, n_k)$, where $n_i$ is the number of edges $e$ of degree $d(e) = \delta_i = (0, \ldots, 0, 1, 0, \ldots, 0)$, and where $\theta$ denotes a set $\{\theta_{i,j} : 1 \leq i < j \leq k\}$ of permutations which determine the relations

$$e^{(i)} e^{(j)} = \left(\theta_{i,j}(e^{(i)} e^{(j)})\right)^{\text{op}},$$

where $d(e^{(i)}) = \delta_i$, and where $(ef)^{\text{op}}$ denotes the opposite product $fe$. Thus $\theta_{i,j}$ is a permutation of the $n_i n_j$ products $e^{(i)} e^{(j)}$, which, when necessary, we enumerate in the natural order

$$e^{(i)}_1 e^{(j)}_1, e^{(i)}_1 e^{(j)}_2, \ldots, e^{(i)}_1 e^{(j)}_{n_j}, e^{(i)}_2 e^{(j)}_1, \ldots, e^{(i)}_{n_i} e^{(j)}_1.$$

Here we have labelled the edges of degree $\delta_i$ as $e^{(i)}_1, e^{(i)}_2, \ldots, e^{(i)}_{n_i}$.

Consider now a path $\lambda$ in $\Lambda = \Lambda_{\underline{n},\theta}$ with unique factorization $\lambda = \lambda_1 \lambda_2 \cdots \lambda_k$ where each $\lambda_j$ is a free word in the loop edges of degree $\delta_j$. For a point $\alpha^{(j)} \in \mathbb{C}^{n_j}$ define the corresponding word $\lambda_j(\alpha^{(j)})$, corresponding to evaluation in $\mathbb{C}$ of the word $\lambda_j$, by letterwise substitution, at $\alpha^{(j)} = (\alpha^{(j)}_1, \ldots, \alpha^{(j)}_{n_j})$ in $\mathbb{C}^{n_j}$. Finally, for $\alpha = (\alpha^{(1)}, \alpha^{(2)}, \ldots, \alpha^{(k)})$ in $\mathbb{C}^{n_1} \times \ldots \times \mathbb{C}^{n_k}$ define

$$\lambda(\alpha) = \lambda_1(\alpha^{(1)}) \lambda_2(\alpha^{(2)}) \cdots \lambda_k(\alpha^{(k)}).$$

Thus we only evaluate the general path $\lambda$ if it is expressed in its uniquely factored form. If $\alpha$ lies in the open ball product $\mathbb{B}_{n_1}^0 \times \ldots \times \mathbb{B}_{n_k}^0$, then we may define the unit vector $\nu_\alpha = \omega_\alpha / \|\omega_\alpha\|_2$ in the Fock space $\mathcal{H}_\Lambda$, where $\omega_\alpha = \sum_{\lambda \in \Lambda} \lambda(\alpha) \xi_\lambda$. Indeed,

$$\|\omega_\alpha\|_2^2 = \sum_{\lambda \in \Lambda} |\lambda(\alpha)|^2 = \sum_{\lambda_1 \in \mathcal{F}_{n_1}^\Lambda} \ldots \sum_{\lambda_k \in \mathcal{F}_{n_k}^\Lambda} |\lambda_1(\alpha^{(1)})|^2 \ldots |\lambda_k(\alpha^{(k)})|^2 = \prod_{i=1}^k (1 - ||\alpha^{(i)}||_2^2)^{-1}.$$

Suppose first that the commutation relations given by $\theta = \{\theta_{i,j} : 1 \leq i < j \leq k\}$ are the commuting relations arising when each $\theta_{i,j}$ is the identity permutation of $d^{-1}(\delta_i)d^{-1}(\delta_j)$. In particular, for each
generating edge $e = e^{(i)}_j$ with degree $\delta_i$ we have

$$e\lambda = e\lambda_1\lambda_2\cdots\lambda_k = \lambda_1\cdots\lambda_{i-1}(e\lambda_i)\lambda_{i+1}\cdots\lambda_k$$

and so $(e\lambda)(\alpha) = \alpha^{(i)}_j(\lambda(\alpha))$. We may now deduce that $L_e^*\omega_\alpha = \alpha^{(i)}_j\omega_\alpha$. Indeed, for all $\lambda \in \Lambda$,

$$\langle L_e^*\omega_\alpha, \xi_\lambda \rangle = \langle \omega_\alpha, (e\lambda)(\xi_\lambda) \rangle = \langle \omega_\alpha, \alpha^{(i)}_j(\lambda(\xi_\lambda)) \rangle = \langle \alpha^{(i)}_j\omega_\alpha, \xi_\lambda \rangle.$$

Thus, with $N = n_1 + \ldots + n_k$, we have shown that each $N$-tuple in the product $B_{n_1}^0 \times \ldots \times B_{n_k}^0$ (of open unit balls) is a joint eigenvalue for the $N$-tuple $\{L_{e^{(1)}}^*, \ldots, L_{e^{(k)}}^*\}$ with eigenvector $\omega_\alpha$, and that $\{\omega_\alpha\}^\perp$ is therefore a codimension one subspace in $\text{Lat}\, \Lambda$. Here, as we have already noted in (3.1), $L_{\omega,\theta}$ is naturally identifiable with the spatial tensor product $L_{\omega_n} \otimes \ldots \otimes L_{\omega_n}$.

Suppose now that $\theta = \{\theta_{i,j} : 1 \leq i < j \leq k\}$ is a general family of permutations. For $1 \leq i \leq k$ let $z_{i,1}, \ldots, z_{i,n_i}$ be the coordinate variables for $\mathbb{C}^{n_i}$ so that there is a natural bijective correspondence $e^{(i)}_k \rightarrow z_{i,k}$ between edges and coordinate variables. We define $V_\theta \subseteq \mathbb{C}^{n_1} \times \ldots \times \mathbb{C}^{n_k}$ to be the complex algebraic variety determined by the equation set

$$\{z_{i,p}z_{j,q} - \hat{\theta}_{i,j}(z_{i,p}z_{j,q}) : 1 \leq p \leq n_i, 1 \leq q \leq n_j, 1 \leq i < j \leq k\}$$

where $\hat{\theta}_{i,j}$ is the permutation induced by $\theta_{i,j}$ and the bijective correspondence.

We now obtain the following identification of the eigenvalues for the adjoint algebra of $L_{\omega,\theta}$ and the Gelfand space of the norm closed algebra $A_{\omega,\theta}$. We write $B^0_{n_i}$ for the product of open unit balls $B_{n_1}^0 \times \ldots \times B_{n_k}^0$.

**Theorem 4.1.** (i) Each invariant subspace of $L_{\omega,\theta}$ of codimension one has the form $\{\omega_\alpha\}^\perp$ for some $\alpha$ in $B^0_{n_i} \cap V_\theta$.

(ii) The character space $\mathcal{M}(A_{\omega,\theta})$ is biholomorphically isomorphic to $B^0_{n} \cap V_\theta$ under the map $\varphi$ given by

$$\varphi(\rho) = (\rho(L_{e^{(1)}_i}), \ldots, \rho(L_{e^{(k)}_n})), \quad \text{for} \quad \rho \in \mathcal{M}(A_{\omega,\theta}).$$

**Proof.** To see (ii) first let $\rho \in \mathcal{M}(A_{\omega,\theta})$. Since $\rho$ is a multiplicative linear functional it is completely contractive. Thus, since the row operator $R_i = [L_{e^{(1)}_i}, L_{e^{(2)}_i}, \ldots, L_{e^{(n_i)}_i}]$ satisfies $R_i R_i^* \leq I$ it follows that the scalar row matrix $[\rho(L_{e^{(1)}_i}), \rho(L_{e^{(2)}_i}), \ldots, \rho(L_{e^{(n_i)}_i})]$ is a contraction, and hence that $\alpha^{(i)} = (\rho(L_{e^{(1)}_i}), \ldots, \rho(L_{e^{(n_i)}_i}))$ is the point in $B^0_{n_i}$ which derives in this way from $\rho$. We have thus shown
that the map \( \varphi \) maps \( \mathcal{M}(\mathbb{A}_{n,\theta}) \) into the product ball \( \mathbb{B}_{n} \). In view of the relations \( e_p^{(i)} e_q^{(j)} = (\theta_{i,j}(e_p^{(i)} e_q^{(j)}))^\text{op} \), we have \( e_p^{(i)} e_q^{(j)} = e_s^{(j)} e_r^{(i)} \) for some \( r, s \) depending on \( p, q \), thus

\[
\alpha_p^{(i)} \alpha_q^{(j)} = \rho(L_{e_p^{(i)}} L_{e_q^{(j)}}) = \rho(L_{e_p^{(i)}} L_{e_q^{(j)}}) = \rho(L_{e_p^{(i)}} L_{e_q^{(j)}}) = \rho(L_{e_p^{(i)}} L_{e_q^{(j)}}) = \rho(L_{e_p^{(i)}} L_{e_q^{(j)}}) = \alpha_s^{(j)} \alpha_r^{(i)}
\]

and so in particular the polynomial

\[
z_{i,p} z_{j,q} - \hat{\vartheta}_{i,j}(z_{i,p} z_{j,q}) = z_{i,p} z_{j,q} - z_{j,s} z_{i,r}
\]

vanishes on \( \alpha \). This is true for all appropriate \( p, q, i, j \) and so \( \alpha \in \mathbb{B}_{n} \cap V_\theta \).

On the other hand suppose that \( \alpha \in V_\theta \). Then it follows that for \( e = e_j^{(i)} \) we have \( (e\lambda)(\alpha) = \alpha_j^{(i)} \lambda(\alpha) \), and indeed, for any (unfactored) path \( \lambda \) in the edges of the \( k \)-graph the substitutional evaluation of \( \lambda \) at \( \alpha \) coincides with the evaluation of the factored form of \( \lambda \) at \( \alpha \), which we denote \( \lambda(\alpha) \). If, in addition, \( \alpha \in \mathbb{B}^0_{n} \cap V_\theta \) then our earlier calculation shows that the vector \( \omega_\alpha \) is an eigenvector for the joint eigenvalue \( \alpha \) for the \( N \)-tuple \( (L_{e_1^{(1)}}, \ldots, L_{e_{nk}^{(k)}}) \). It follows readily that the unit vector \( \nu_\pi \) defines a vector functional

\[
\rho(A) = \langle A \nu_\pi, \nu_\pi \rangle
\]

which defines a character \( \rho \) in \( \mathcal{M}(\mathbb{A}_{n,\theta}) \) with \( \varphi(\rho) = \alpha \). Since \( \mathcal{M}(\mathbb{A}_{n,\theta}) \) is a compact Hausdorff space, and since we have shown that the range of \( \varphi \) contains \( \mathbb{B}^0_{n} \cap V_\theta \) and is contained in \( \mathbb{B}^0_{n} \cap V_\theta \), it follows that the range of \( \varphi \) is precisely \( \mathbb{B}^0_{n} \cap V_\theta \). From this, part (ii) of the theorem now follows.

To see (i), suppose now that \( \nu \) is a unit vector such that \( \{ \nu \}^\perp \) is invariant for \( \Sigma_{n,\theta} \), and hence that \( \nu \) is a joint eigenvector for the \( [n] \)-tuple \( (L_{e_1^{(1)}}, \ldots, L_{e_{nk}^{(k)}}) \) with corresponding eigenvalue \( \beta = (\beta^{(1)}, \ldots, \beta^{(k)}) \). Since the column operators \( R_{i} \), \( 1 \leq i \leq k \), are contractions it follows that \( \beta^{(i)} \in \mathbb{B}_{n} \). Since \( \nu \) is a joint eigenvector it follows that the map \( L_\alpha \mapsto \langle L_\alpha \nu, \nu \rangle \) extends to a multiplicative linear functional on \( \mathbb{A}_{n,\theta} \) and so from the calculation above \( \overline{\beta} \), and hence \( \beta \), lies in \( \mathbb{B}_{n} \cap V_\theta \).

Suppose now that \( \nu = \sum_{\lambda \in \Lambda} b_\lambda \xi_\lambda \). Then

\[
b_\lambda = \langle \nu, \xi_\lambda \rangle = \langle L_\lambda^* \nu, \xi_\lambda \rangle = \lambda(\beta) \langle \nu, \xi_\lambda \rangle = \lambda(\beta) b_\lambda,
\]

where, as before, \( \lambda(\beta) \) represents the factored form substitution of the word \( \lambda \) in \( \Lambda \). Our earlier calculation of the norm of \( \nu_\alpha \) applies here and the finiteness of \( \sum |\lambda(\beta)|^2 \) implies that \( \beta \in \mathbb{B}^0_{n} \cap V_\theta \).  

\( \blacksquare \)
Remark 4.2. As an illustration of the theorem let \( n = (n_1, n_2) \) and let \( z_1, \ldots, z_{n_1} \) and \( w_1, \ldots, w_{n_2} \) be coordinate variables for \( \mathbb{C}^{n_1} \) and \( \mathbb{C}^{n_2} \). If \( \theta \) is a simple cyclic permutation of all the \( n_1n_2 \) pairs \( \{z_iw_j\} \) then \( V_\theta \) is the variety \( V_\theta = \{(z, w) : z_1 = \ldots = z_{n_1}, w_1 = \ldots = w_{n_2}\} \) and so \( B_n \cap V_\theta \) is the direct product of two discs with radii \( n_1^{-1/2}, n_2^{-1/2} \). This is the minimal such subset of \( B_n \) associated with a permutation and it is not hard to see that many other permutations, including products of cycles, also lead to this minimal case. In general it can be shown that the Gelfand space \( B_n \cap V_\theta \) does not determine the operator algebra \( A_n, \theta \) up to isometric isomorphism.

5. Reflexivity

Recall that a (wot-closed) operator algebra \( \mathfrak{A} \) is reflexive if \( \mathfrak{A} = \text{Alg Lat } \mathfrak{A} \). On the other hand, a measure of the distance to an operator algebra \( \mathfrak{A} \) is given by \( \beta_\mathfrak{A}(X) = \sup_{L \in \text{Lat } \mathfrak{A}} ||P_L XP_L|| \), where \( P_L \) is the projection onto the subspace \( L \). Clearly \( \beta_\mathfrak{A}(X) \leq \text{dist}(X, \mathfrak{A}) \) and \( \mathfrak{A} \) is said to be hyper-reflexive if there is a constant \( C \) such that \( \text{dist}(X, \mathfrak{A}) \leq C \beta_\mathfrak{A}(X) \) for all \( X \). We begin by identifying a new class of hyper-reflexive algebras.

As a generalization of terminology from [17, 18], we define the ‘double pure cycle property’ for a higher rank graph. Firstly, a pure cycle is one composed of edges of the same degree (a monochromatic cycle), and, secondly, \( \Lambda \) has the double pure cycle property if for every \( v \in \Lambda^0 \) there is a path \( \lambda \in \Lambda \) with \( s(\lambda) = v \) and \( r(\lambda) = w \) such that \( w \) lies on a double pure cycle in the sense that there is a pair of distinct pure cycles \( \lambda_i = w_\lambda \lambda_i w, i = 1, 2 \), of the same colour, neither of which may be written as a product of cycles.

Lemma 5.1. If \( \Lambda \) satisfies the double pure cycle property then \( \mathfrak{L}_\Lambda \) contains a pair of isometries with mutually orthogonal ranges.

Proof. We may construct isometries \( U, V \in \mathfrak{L}_\Lambda \) with \( U^*V = 0 \) in a direct manner as follows. Let \( \lambda_1 \neq \lambda_2 \) be a double pure cycle with \( s(\lambda_i) = r(\lambda_i) = v \) for some \( v \in \Lambda^0 \). We may assume that for all \( w \in \Lambda^0 \) there is a \( \lambda_w \in \Lambda \) such that \( s(\lambda_w) = w \) and \( r(\lambda_w) = v \). Since the general case follows easily from this special case. By hypothesis and from the factorization property, for \( k \geq 1 \) the paths \( \lambda_k^1 \lambda_k^2 \) are cycles over \( v \) and the partial isometries \( L_{\lambda_k^1 \lambda_k^2} \), \( k \geq 1 \), have mutually orthogonal ranges with initial projection \( L_v \). Let \( w \mapsto \{k^w_a, k^w_b\} \) be a one-to-two map from
Λ^0 to the positive integers \( \mathbb{N} \). As the desired isometries we may define

\[ U = \sum_{w \in \Lambda^0} L_{\lambda_1}^{k_w} L_{\lambda_2} L_{\lambda} \] \quad and \quad \[ V = \sum_{w \in \Lambda^0} L_{\lambda_1}^{k_w} L_{\lambda_2} L_{\lambda} w, \]

the sums converging sot when \( \Lambda^0 \) is infinite.

\[ \square \]

**Theorem 5.2.** If \( \Lambda^t \) satisfies the double pure cycle property then \( \mathfrak{L}_\Lambda \) is hyper-reflexive with distance constant at most 3.

**Proof.** As \( \mathfrak{R}_\Lambda \) is unitarily equivalent to \( \mathfrak{L}'_{\Lambda} = \mathfrak{L}'_{\Lambda} \), the previous lemma shows that \( \mathfrak{L}'_{\Lambda} \) contains a pair of isometries with mutually orthogonal ranges. Thus the result follows as a direct application of Bercovici’s hyper-reflexivity Theorem [4]. \[ \square \]

As an immediate consequence we obtain the following.

**Corollary 5.3.** Let \( \underline{n} = (n_1, \ldots, n_k) \in \mathbb{N}^k \) and suppose that \( n_j \geq 2 \) for some \( j \). Then \( \mathfrak{L}_{\underline{n},\theta} \) is hyper-reflexive for all choices of \( \theta \).

Note that the single vertex algebras \( \mathfrak{L}_\Lambda \) which do not satisfy the hypothesis of Corollary 5.3 are each unitarily equivalent to \( \mathbb{C} \) or \( H^\infty(\mathbb{T}^k) \cong (H^\infty)^{\otimes k} \) for some \( k \geq 1 \), and these algebras are known to be reflexive [33]. (We note that the problem of hyper-reflexivity for \( H^\infty(\mathbb{T}^k) \), \( k \geq 2 \), appears to remain unresolved at present.) Reflexivity of these algebras is well-known, but for the interested reader we mention that this fact may be deduced from the first part of the proof of Theorem 5.5. Thus, as hyper-reflexivity subsumes reflexivity, it follows now that every single vertex algebra \( \mathfrak{L}_\Lambda \) is reflexive. We use this in the proof below.

We shall prove reflexivity for \( \mathfrak{L}_\Lambda \) up to a mild graph constraint. We shall say \( v \in \Lambda^0 \) is a radiating vertex when \( \lambda \in \Lambda^1 \) with \( r(\lambda) = v \) implies that \( s(\lambda) = v \). Such a vertex is multiplicity one if there is at most one loop edge at \( v \) of each colour. Further we say that a radiating vertex \( v \in \Lambda^0 \) is relational if there are loop edges \( \mu \neq \mu' \) at \( v \) and paths \( \lambda, \lambda' \in \Lambda \) with \( s(\lambda) = v = s(\lambda') \) that immediately leave \( v \) such that \( \lambda \mu = \lambda' \mu' \).

**Theorem 5.4.** Let \( \Lambda \) be a higher rank graph with no multiplicity one relational radiating vertices. Then \( \mathfrak{L}_\Lambda \) is reflexive.

**Proof.** Let \( A \in \text{Alg Lat} \mathfrak{L}_\Lambda \). We shall show that if \( x \in d^{-1}(0) \) and \( A = AL_x \) then \( A \in \mathfrak{L}_\Lambda \). Since every operator \( B \) on \( \mathcal{H}_\Lambda \) is the weak operator topology limit of the sums \( \sum_{i \geq 1} BL_{x_i} \), where \( x_1, x_2, \ldots \) is an enumeration of \( d^{-1}(0) \), the proof will be complete.

Given \( \mu \in \Lambda \) with \( r(\mu) = x \) we have

\[ A\xi_\mu = \sum_{s(\lambda)=x} \alpha_\lambda^\mu \xi_\lambda \mu \]
for some choice of scalars $\alpha_\lambda^\mu$. This follows since the subspace $\mathcal{M}$ spanned by \{\{\xi_\lambda^\mu : \lambda \in \Lambda\} belongs to $\text{Lat} \mathcal{L}_\Lambda$. Note that $A\xi_\mu = 0$ if $r(\mu) \neq x$. We shall show that for all paths $\mu, \nu$ with $r(\mu) = x = r(\nu)$ we have $\alpha_\lambda^\mu = \alpha_\lambda^\nu$ for all paths $\lambda$ with $s(\lambda) = x$. If this is the case then for all $\lambda' \in \Lambda$ with $r(\lambda') = s(\mu)$

$$R_{\lambda'} A\xi_\mu = \sum_\lambda \alpha_\lambda^\mu \xi_\lambda \lambda' = \sum_\lambda \alpha_\lambda^\mu \xi_\lambda \lambda' = A\xi_\lambda \lambda' = A R_{\lambda'} \xi_\mu,$$

and $R_{\lambda'} A\xi_\mu = 0 = A R_{\lambda'} \xi_\mu$ when $r(\lambda') \neq s(\mu)$. Hence $A \in \mathcal{A}_\Lambda'$ and so $A \in \mathcal{L}_\Lambda$, as desired.

We consider two cases. Suppose first that there is a path $\nu$ with $\nu = xyx$ and $y \neq x (x, y \in d^{-1}(0))$. Then the range $\mathcal{N}'$ of $R_x + R_y$ is spanned by the set of vectors \{\{\xi_{\lambda x} + \xi_{\lambda y} : s(\lambda) = x\} and the vectors in this set are pairwise orthogonal. Since $\mathcal{N}' \in \text{Lat} \mathcal{L}_\Lambda$ it follows that

$$A(\xi_x + \xi_\nu) = A(R_x + R_\nu)\xi_x = \sum_{s(\lambda) = x} \gamma_\lambda (\xi_{\lambda x} + \xi_{\lambda y})$$

for some choice of scalars $\gamma_\lambda$. But $A\xi_x$ and $A\xi_\nu$ are given in terms of the coefficients $\alpha_\lambda^\nu$, $\alpha_\lambda^\nu$ respectively and so $\alpha_\lambda^\nu = \gamma_\lambda = \alpha_\lambda^\nu$ since $s(\nu) \neq x$. Precisely the same argument holds if we replace $x$ by a path $\mu$ with $\mu = x\mu x$, and so we obtain $\alpha_\lambda^\mu = \alpha_\lambda^x = \alpha_\lambda^x$ for all $\lambda$ for such a path at $x$.

It follows that $\alpha_\lambda^\mu = \alpha_\lambda^x$ for all $\lambda$ and for all paths $\mu'$ which terminate at $x$, as desired.

If there is no such path $\nu = x\nu y$ with $y \neq x$ then we are in the second case in which $\mu = x\mu x$ whenever $r(\mu) = x$. Plainly this entails that there is a single vertex induced sub-$k$-graph $\Gamma$ of $\Lambda$ such that $L_{\lambda_1} \mathcal{L}_\Lambda |_{L_{\lambda_1} \mathcal{H}_\Lambda}$ is unitarily equivalent to $\mathcal{L}_\Gamma$. By the previous discussion $\mathcal{L}_\Gamma$ is reflexive, and so we do at least have $\alpha_\lambda^\mu = \alpha_\lambda^x$, for all $\lambda = x\lambda x$, when $\lambda = x\lambda (= x\lambda x)$. We shall now show that this equality also holds for paths $\lambda'$ with $\lambda' = y\lambda' x$, $y \neq x$, and this will complete the proof.

If the loop edges at $x$ include a double pure loop then we may argue as above and use the Bercovici Theorem to deduce this equality for all $\lambda'$. Further, the equality trivially holds when there are no loops at $x$. Thus we may reduce to the case that $x$ is a multiplicity one vertex.

Suppose first that $\lambda'$ is not of the form $\lambda_1 h$ with $h \in \Gamma$ and with $d(h) \neq 0$. Consider the restriction operator $A_{\lambda'} = L_{\lambda'}^* A |_{H_{\Gamma'}}$. We show that $A_{\lambda'}$ lies in $\mathcal{L}_\Gamma$. To this end let $\mathcal{M} \in \text{Lat} \mathcal{L}_\Gamma$ and define $\tilde{\mathcal{M}} = \bigvee_{s(\lambda) = x} L_{\lambda} \mathcal{M}$ in $\text{Lat} \mathcal{L}_\Gamma$. Then

$$A_{\lambda'} \mathcal{M} = L_{\lambda'}^* A \mathcal{M} \subseteq L_{\lambda'}^* \tilde{\mathcal{M}}.$$
with $h \in \Gamma$. Thus
\[ L_{\lambda'} \widetilde{M} \subseteq \bigvee_{h=xhx} L_h M \subseteq M.\]
Since we have shown that $A_{\lambda'}$ belongs to $\text{Alg Lat} \mathfrak{L}_\Gamma$, it follows that $A_{\lambda'}$ is in $L_{\Gamma}$ and hence that there exist scalars $\alpha_h$ such that $A_{\lambda'} \sim \sum_{h=xhx} \alpha_h L_h$.

Thus if $\mu$ is a path in $\Gamma$ then
\[ \sum_{h \in \Gamma} \alpha_h \xi_{\lambda'h\mu} = L_{\lambda'} (A_{\lambda'} \xi_\mu) = L_{\lambda'} L_{\lambda'}^* A_{\lambda'} = L_{\lambda'} L_{\lambda'}^* \left( \sum_{s(\lambda)=x} \alpha_{\lambda}\xi_{\lambda\mu} \right) = \sum_{h \in \Gamma} \alpha_{\lambda'h} \xi_{\lambda'h\mu}.\]

Therefore, $\alpha_{\lambda'h} = \alpha_h$ for all $h, \mu \in \Gamma$ and $\alpha_{\lambda'h} = \alpha_{\lambda'h}$ for all $\mu, \nu \in \Gamma$. As we are in the second case it follows that $\alpha_{\lambda} = \alpha_{\lambda'}$ for all $\mu, \nu$ with $r(\mu) = x = r(\nu)$ and $\lambda$ with $s(\lambda) = x$, as desired. \[ \square \]

The following proof of reflexivity for the free semigroup algebras $L_n$ is considerably more elementary than other proofs in the literature \[3, 7\] and gives a more direct generalization of Sarason’s approach for $L_1 = H^\infty$ \[33\]. We include it for interest’s sake.

**Theorem 5.5.** $L_n$ is reflexive.

**Proof.** Let $A \in \text{Alg Lat} \mathfrak{L}_n$. For $\alpha = (\alpha_1, \ldots, \alpha_n)$ in $\mathbb{B}_n$ we may define eigenvectors for $L_n^*$ by $\nu_\alpha = \sum_{w \in \mathbb{F}_n^+} w(\alpha) \xi_w$. Then $\{\nu_\alpha\}^\perp$ is invariant for $L_n$ and so $A^* v_\alpha = \overline{\lambda}_\alpha v_\alpha$ for some scalar $\lambda_\alpha$ in $\mathbb{C}$.

Let $A_{\xi_x} = \sum_w a_w \xi_w$. Then
\[ \lambda_\alpha \langle \xi_x, v_\alpha \rangle = \langle A_{\xi_x}, v_\alpha \rangle = \sum_w a_w \langle \xi_w, v_\alpha \rangle = \sum_w a_w \langle \xi_x, L_w^* v_\alpha \rangle = \sum_w a_w w(\alpha) \langle \xi_x, v_\alpha \rangle,\]
and so $\lambda_\alpha = \sum_w a_w w(\alpha)$.

Note that for each $v \in \mathbb{F}_n^+$ the subspace $M_v$ spanned by $\{\xi_{wv} : w \in \mathbb{F}_n^+\}$ belongs to $\text{Lat} \mathfrak{L}_n$ and so for some scalars $b_{wv}^v$, $w \in \mathbb{F}_n^+$,
\[ A_{\xi_v} = \sum_w b_{wv}^v \xi_{wv}.\]
We show that $b_w = a_w$ for all $w$. This will complete the proof since we obtain for any choice of $v$

$$R_vA\xi_x = \sum_w a_w \xi_{wv} = \sum_w b_w^v \xi_{wv} = A\xi_v = AR_v\xi_x.$$  

As $A \in \text{Alg Lat } \mathfrak{L}_n$ was arbitrary, it follows that $R_vAL_w = AL_wR_v = AR_vL_w$ and hence $R_vA\xi_w = R_vAL_w\xi_x = AR_v\xi_w$ for all $w$. Thus $R_vA = AR_v$ for all $v$, and so $A$ belongs to $\mathfrak{R}_n' = \mathfrak{L}_n$.

Observe that

$$\langle A\xi_v, v_\alpha \rangle = \sum_w b_w^v \langle L_wv\xi_x, v_\alpha \rangle = \sum_w b_w^v w(\alpha) v(\alpha) \langle \xi_x, v_\alpha \rangle.$$  

Further,

$$\langle A\xi_v, v_\alpha \rangle = \langle \xi_v, A^*v_\alpha \rangle = \lambda\alpha v(\alpha) \langle \xi_x, v_\alpha \rangle,$$

and hence

$$\lambda_\alpha = \sum_w b_w^v w(\alpha).$$

Now

$$\sum_w b_w^v w(\alpha) = \sum_w a_w w(\alpha)$$

for all $||\alpha||_2 < 1$. (Observe that in the case of $H^\infty$ or $H^\infty(\mathbb{T}^k)$ this fact finishes the proof.)

In particular, we have $a_x = b_x^w$ for all choices of $v$. Thus, by replacing $A$ with $A - a_xI$ we may assume that $a_x = b_x^w = 0$ for all $v$. Suppose now that $k \geq 1$ is minimal such that $a_w = 0 = b_w^v$ for all $|w| < k$ (where $|w| = \delta(w)$ is word length) and all $v$. We claim that $L_w^*A$ belongs to $\text{Alg Lat } \mathfrak{L}_n$ for all $|w'| = k$. If this holds then observe

$$L_w^*A\xi_x = L_w^* \sum_w a_w \xi_w = \sum_u a_{w'u} \xi_u$$

and hence by the above argument $a_{w'} = b_{w'}^v$ for all $v$. Thus we finish the proof by verifying the claim.

Let $M$ belong to Lat $\mathfrak{L}_n$. Without loss of generality assume $M$ is cyclic. Then an orthonormal basis for $M$ is given by $\{L_w\eta : w \in \mathbb{F}_n^+\}$ where $\eta$ is some unit vector. (This is follows from part of the Beurling Theorem for $\mathfrak{L}_n$ [7, 28].) As $A\mathcal{M} \subseteq \mathcal{M}$ we have $A\eta = \sum_w c_w L_w\eta$ for some scalars $c_w$. By our assumption on the scalars $a_w, b_w^v$, a ‘graded
The Fock space’ type argument can be used to show that $c_w = 0$ for all $|w| < k$. Thus
\[
L_{w'}^*A\eta = \sum_{|w| \geq k} c_w L_{w'}^* L_w \eta = \sum_u c_{w'u} L_u \eta \in \mathcal{M}.
\]
More generally, for arbitrary $u$ we have $AL_u \eta = \sum_{|w| \geq k+|u|} c_w L_w \eta$ and similarly $L_{w'}^* A \mathcal{M} = \mathcal{M}$. Thus $L_{w'}^* A \mathcal{M} \subseteq \mathcal{M}$ for all $|w'| = k$ and all cyclic subspaces $\mathcal{M} \in \operatorname{Lat} \mathcal{L}_n$ and it follows that $L_{w'}^* A$ belongs to $\operatorname{Alg Lat} \mathcal{L}_n$, as claimed. \hfill \blacksquare

6. Semisimplicity

We say that an edge $\lambda \in \Lambda^1$ ‘lies on a cycle’ when there is a cycle $\mu \in \Lambda$, $s(\mu) = r(\mu)$, that includes $\lambda$ in at least one of its factorizations as a product of edges. Let $\text{NC}(\Lambda)$ be the edges in $\Lambda^1$ that do not lie on a cycle. We show that the Jacobson radical of $\mathcal{L}_{\Lambda}$, $\text{rad}(\mathcal{L}_{\Lambda})$, is determined by the operators $L_\lambda$, $\lambda \in \text{NC}(\Lambda)$, and in the finite vertex case we obtain a complete description of $\text{rad}(\mathcal{L}_{\Lambda})$. Recall that $\text{rad}(\mathcal{L}_{\Lambda})$ is the largest quasinilpotent ideal of $\mathcal{L}_{\Lambda}$ and that $\mathcal{L}_{\Lambda}$ is semisimple if and only if $\text{rad}(\mathcal{L}_{\Lambda})$ is the zero ideal.

We begin with a combinatorial lemma that shows extremal paths, in the sense of the distance measure, have special factorization properties. Given $\lambda, \mu \in \Lambda$ with $d(\lambda) = (m_1, \ldots, m_k)$ and $d(\mu) = (n_1, \ldots, n_k)$ we write $\lambda \geq \mu$ when the corresponding lexicographic ordering on these $k$-tuples is satisfied in $\mathbb{N}^k$.

**Lemma 6.1.** Let $\Gamma$ be a nonempty subset of $\Lambda$ such that $\delta(\lambda_1) = \delta(\lambda_2)$ for all $\lambda_1, \lambda_2 \in \Gamma$ and let $\gamma \in \Gamma$ satisfy $\gamma \geq \lambda$ for all $\lambda \in \Gamma$. If $\gamma^r = \lambda_1 \cdots \lambda_r$ for some $r \geq 1$ and $\lambda_i \in \Gamma$ then $\gamma = \lambda_i$ for $1 \leq i \leq r$.

**Proof.** Suppose $\gamma^r = \lambda_1 \cdots \lambda_r$ with $\gamma, \lambda_i \in \Gamma$ for $1 \leq i \leq r$ and put $d(\gamma) = (n_1, \ldots, n_k)$ and $d(\lambda_i) = (n_1^{(i)}, \ldots, n_k^{(i)})$. Then $r n_j = \sum_{i=1}^r n_j^{(i)}$ for $1 \leq j \leq k$ and since $\gamma \geq \lambda_1$ we have $n_1 \geq n_1^{(1)}$ for all $i$. This gives (with $j = 1$) $n_1 = n_1^{(1)}$ for all $i$. As $\gamma \geq \lambda_i$, this forces $n_2 \geq n_2^{(i)}$ for all $i$ and again (with $j = 2$) $n_2 = n_2^{(i)}$ for all $i$. Hence we may proceed inductively to obtain $n_j = n_j^{(i)}$ for all $1 \leq i \leq r$ and $1 \leq j \leq k$. Thus we have $\gamma^r = \lambda_1 \cdots \lambda_r$ with $d(\gamma) = d(\lambda_i)$ for all $i$, and the result follows from the factorization property. \hfill \blacksquare

**Theorem 6.2.** $\mathcal{L}_{\Lambda}$ is semisimple if and only if every edge in $\Lambda$ lies on a cycle. If $\Lambda$ has finitely many vertices, $|\Lambda^0| = n < \infty$, then $\text{rad}(\mathcal{L}_{\Lambda})$ is nilpotent of degree at most $n$ and is equal to the wot-closed two-sided ideal generated by $\{L_\lambda : \lambda \in \text{NC}(\Lambda)\}$.\hfill \blacksquare
Proof. Suppose first that every edge in $\Lambda$ lies on a cycle. Let $A \in \mathfrak{L}_\Lambda$ be non-zero. Then $A\xi_\lambda = R_\lambda A\xi_{r(\lambda)}$ for all $\lambda$ and so there is some $v \in \Lambda^0$ such that $A\xi_v = \sum_{s(\lambda)=v} a_\lambda \xi_\lambda \neq 0$. Let $\Gamma$ be the set of $\lambda \in \Lambda$ such that $a_\lambda \neq 0$ and $\delta(\lambda)$ is minimal with this property. Let $\gamma$ be a maximal element in $\Gamma$ with respect to the lexicographic ordering discussed above.

By assumption there is a path $\mu$ such that $\mu\gamma$ is a cycle and so the paths $(\mu\gamma)^k$, $k \geq 1$, are also cycles. Further, $\mu\gamma$ is maximal in the set $\mu\Gamma$. Hence, by the minimality of $\delta(\gamma)$ and an application of the previous lemma to $\mu\gamma \in \mu\Gamma$ for each $k \geq 1$, from a consideration of Fourier expansions we have

$$ (L_{\mu}A)^k \xi_v = a_\gamma^k \xi_{(\mu\gamma)^k} + \sum_{\lambda' \neq (\mu\gamma)^k} b_\lambda \xi_{\lambda'}. $$

Hence for $k \geq 1$ this yields

$$ \| (L_{\mu}A)^k \|^{1/k} \geq \left| \langle (L_{\mu}A)^k \xi_v, \xi_{(\mu\gamma)^k} \rangle \right|^{1/k} = |a_\gamma| > 0. $$

Thus $L_{\mu}A$ has positive spectral radius and is not quasinilpotent. Since $0 \neq A \in \mathfrak{L}_\Lambda$ was arbitrary it follows that $\text{rad}(\mathfrak{L}_\Lambda) = \{0\}$ and $\mathfrak{L}_\Lambda$ is semisimple.

Conversely, suppose that $\lambda \in \text{NC}(\Lambda) \neq \emptyset$. Since $\lambda$ does not lie on a cycle there are no paths $\mu_1, \mu_2 \in \Lambda$ such that both $\mu_1$ and $\mu_2$ contain $\lambda$ as an edge and $\mu_1 \mu_2$ belongs to $\Lambda$. Hence, a consideration of Fourier expansions shows that $(A L_\lambda)^2 = 0$ for all $A \in \mathfrak{L}_\Lambda$. Thus $L_\lambda$ belongs to $\text{rad}(\mathfrak{L}_\Lambda)$ and $\mathfrak{L}_\Lambda$ has non-zero radical.

It remains to verify the structure of $\text{rad}(\mathfrak{L}_\Lambda)$ in the finite vertex case. Let $\mathcal{J}$ be the wot-closed two-sided ideal in $\mathfrak{L}_\Lambda$ generated by $\{L_\lambda : \lambda \in \text{NC}(\Lambda)\}$. Suppose first that $A$ belongs to $\text{rad}(\mathfrak{L}_\Lambda)$ with expansion $A \sim \sum_\lambda a_\lambda L_\lambda$. We claim that a coefficient $a_\lambda$ is non-zero only if $\lambda$ includes an edge $\lambda' \in \text{NC}(\Lambda)$. Since the Cesaro sums for $A$ would then belong to $\mathcal{J}$, and they converge in the strong operator topology to $A$, this would show that $A$ belongs to $\mathcal{J}$. Suppose by way of contradiction that there is a path $\lambda$ with $a_\lambda \neq 0$ which includes no edges from $\text{NC}(\Lambda)$ and, as above, assume $\lambda$ is maximal in the lexicographic ordering amongst the paths of minimal length with this property. Then $\lambda$ belongs to a transitive component of $\Lambda$. So we may choose $\mu \in \Lambda$ such that $\mu\lambda$ is a cycle in $\Lambda$ and hence $(\mu\lambda)^k$ belongs to $\Lambda$ for $k \geq 1$. Then by assumption $(\mu\lambda)^k$ is a path of minimal length and satisfies the maximality condition amongst the paths in the expansion of $(L_{\mu}A)^k$ that have non-zero coefficients. Hence an application of the lemma shows the coefficient of $L_{(\mu\lambda)^k}$ in this expansion is $(a_\lambda)^k$. Thus we may argue as above to obtain that $L_{\mu}A$ has positive spectral radius and hence is not quasinilpotent. This contradiction verifies the claim and
shows that $\mathcal{J}$ contains $\text{rad}(\mathcal{L}_\Lambda)$. Notice that this inclusion does not rely on finitely many vertices.

For the converse inclusion note that, in the case that $|\Lambda^0| = n < \infty$, if $\mu_1, \ldots, \mu_n$ are paths in $\Lambda$, each of which has a factorization that includes at least one edge from $\text{NC}(\Lambda)$, then the product $\mu_n \cdots \mu_1$ cannot belong to $\Lambda$. It follows that $\mathcal{J}^n = \{0\}$ in this case because any operator $X$ of the form $X = A_1 \cdots A_n$ with each $A_i \in \mathcal{J}$ can have no non-zero Fourier coefficients. Thus, $\mathcal{J}$ is contained in $\text{rad}(\mathcal{L}_\Lambda)$ and the result follows. ■
