Since January 2020 Elsevier has created a COVID-19 resource centre with free information in English and Mandarin on the novel coronavirus COVID-19. The COVID-19 resource centre is hosted on Elsevier Connect, the company’s public news and information website.

Elsevier hereby grants permission to make all its COVID-19-related research that is available on the COVID-19 resource centre - including this research content - immediately available in PubMed Central and other publicly funded repositories, such as the WHO COVID database with rights for unrestricted research re-use and analyses in any form or by any means with acknowledgement of the original source. These permissions are granted for free by Elsevier for as long as the COVID-19 resource centre remains active.
Geriatric risk factors for serious COVID-19 outcomes among older adults with cancer: a cohort study from the COVID-19 and Cancer Consortium

Arielle Elkrief, Cassandra Hennessy, Nicole M Kuderer, Samuel M Rubinstein, Elizabeth Wulff-Burchfield, Rachel P Rosovsky, Karen Vega-Luna, Michael A Thompson, Orestis A Panagiotou, Aakash Desai, Donna R Rivera, Ali Raza Khaki, Lisa Tachiki, Ryan C Lynch, Catherine Stratton, Rawad Elias, Gerald Batist, Anup Kasi, Dimpy P Shah, Ziad Bakouny, Angelo Cabal, Jessica Clement, Jennifer Crowell, Becky Dixon, Christopher R Friese, Stacy L Fry, Punita Grover, Shuchi Gulati, Shilpa Gupta, Clara Hwang, Hina Khan, Soo Jung Kim, Elizabeth J Klein, Chris Labaki, Rana R McKay, Amanda Nizam, Nathan A Pennell, Andrew L Schmidt, Armin Shahrokni, Justin A Shaya, Tanya M Wildes*, on behalf of the COVID-19 and Cancer Consortium

Summary

Background Older age is associated with poorer outcomes of SARS-CoV-2 infection, although the heterogeneity of ageing results in some older adults being at greater risk than others. The objective of this study was to quantify the association of a novel geriatric risk index, comprising age, modified Charlson comorbidity index, and Eastern Cooperative Oncology Group performance status, with COVID-19 severity and 30-day mortality among older adults with cancer.

Methods In this cohort study, we enrolled patients aged 60 years and older with a current or previous cancer diagnosis (excluding those with non-invasive cancers and premalignant or non-malignant conditions) and a current or previous laboratory-confirmed COVID-19 diagnosis who reported to the COVID-19 and Cancer Consortium (CCC19) multinational, multicentre, registry between March 17, 2020, and June 6, 2021. Patients were also excluded for unknown age, missing data resulting in unknown geriatric risk measure, inadequate data quality, or incomplete follow-up resulting in unknown COVID-19 severity. The exposure of interest was the CCC19 geriatric risk index. The primary outcome was COVID-19 severity and the secondary outcome was 30-day all-cause mortality; both were assessed in the full dataset. Adjusted odds ratios (ORs) and 95% CIs were estimated from ordinal and binary logistic regression models.

Findings 5671 patients with cancer and COVID-19 were included in the analysis. Median follow-up time was 56 days (IQR 22–120), and median age was 72 years (IQR 66–79). The CCC19 geriatric risk index identified 2365 (41·7%) patients as standard risk, 2217 (39·1% (IQR 22–120), and median age was 72 years (IQR 66–79). The CCC19 geriatric risk index identified 2365 (41·7%) patients as standard risk, 2217 (39·1%) patients as intermediate risk, and 1089 (19·2%) as high risk. 36 (0·6%) patients were excluded due to non-calculable geriatric risk index. Compared with standard-risk patients, high-risk patients had significantly higher COVID-19 severity (adjusted OR 7·24; 95% CI 6·20–8·45). 920 (16·2%) of 5671 patients died within 30 days of a COVID-19 diagnosis, including 161 (6·8%) of 2365 standard-risk patients, 409 (18·5%) of 2217 intermediate-risk patients, and 350 (32·1%) of 1089 high-risk patients. High-risk patients had higher adjusted odds of 30-day mortality (adjusted OR 10·7; 95% CI 8·54–13·5) than standard-risk patients.

Interpretation The CCC19 geriatric risk index was strongly associated with COVID-19 severity and 30-day mortality. Our CCC19 geriatric risk index, based on readily available clinical factors, might provide clinicians with an easy-to-use risk stratification method to identify older adults most at risk for severe COVID-19 as well as mortality.

Introduction

The COVID-19 pandemic, caused by SARS-CoV-2, has disproportionately affected older adults. Mortality and complication rates from the disease have been reported as higher among older adults than younger adults.1 Individuals with cancer who develop COVID-19 are at risk for more severe outcomes than those without cancer.2 Among those with cancer, age also increases the risk of adverse outcomes of infection.3 Because aging is heterogeneous, subgroups of older adults with cancer will probably be at greater risk than others for developing adverse outcomes of COVID-19, and identification of individuals at the highest risk is important in their clinical care. Studies in the general geriatric population have shown that the presence of comorbidities and frailty increase the risk of death and other complications of COVID-19, as do the presence of comorbidities and poor performance status in those with cancer.4,4
Research in context

Evidence before this study

We searched PubMed for studies published from inception up to Oct 28, 2021, using the key terms “COVID-19” in combination with “cancer”, “frailty”, and “comorbidities”. Systematic reviews showed the increased risk of adverse outcomes of COVID-19 among people of older age, with cancer, comorbidities, and who were frail. Studies identifying older adults at greatest risk for adverse outcomes and mortality after SARS-CoV-2 infection are scarce.

Added value of this study

Among patients aged 60 years or older reported to the COVID-19 and Cancer Consortium, patients categorised as high risk—using a novel geriatric risk index comprising age, performance status, and comorbidities—had significantly higher COVID-19 severity, including hospitalisation, need for intensive care and mechanical ventilation, and death, within 30 days due to any cause than patients categorised as standard risk or intermediate risk.

Implications of all the available evidence

Patients with cancer identified as high risk are at higher risk for severe complications due to COVID-19 than patients categorised as standard risk or intermediate risk, highlighting the need for continued protective strategies for this vulnerable population.

Despite this heightened risk of mortality, there is insufficient understanding of which subpopulations are at high risk for adverse outcomes of COVID-19.1 The Cancer and Aging Research Group and the International Society of Geriatric Oncology released statements on older people with cancer, but noted that these statements were based on clinical consensus, not robust evidence.8,9 As a result, there is an urgent need to determine the effect of COVID-19 in older adults with cancer and identify those most vulnerable for adverse outcomes. The primary objective of this study was to determine whether a measure of geriatric risk—combining age, comorbidities, and performance status—could capture risk of severe clinical outcomes among older patients with cancer and COVID-19. We also sought to describe the presentation, complications, and effect of COVID-19 on subsequent cancer care among older adults with cancer.

Methods

Study design and participants

This was a cohort study of patients reported to the COVID-19 and Cancer Consortium (CCC19) registry.10,11 The CCC19 registry is accruing deidentified data, from contributing institutions (appendix pp 1–5), on patients aged 18 years or older with a current or past history of haematological malignancy or invasive solid tumour who have either a laboratory-confirmed SARS-CoV-2 infection or a presumptive diagnosis of COVID-19. Contributing institutions in the consortium independently identify patients and report data through the online REDCap data collection survey instruments developed by CCC19, described in detail previously.12 The mechanism of data collection survey instruments developed by CCC19, patients and report data through the online REDCap data collection survey instruments developed by CCC19, described in detail previously.12 The mechanism of data collection can be retrospective (after the acute course of COVID-19) or concurrent, at the discretion of the contributing institutions (appendix pp 1–5), on patients and report data through the online REDCap data collection survey instruments developed by CCC19, described in detail previously.12 The mechanism of data collection can be retrospective (after the acute course of COVID-19) or concurrent, at the discretion of the contributing institutions (appendix pp 1–5).13 Patients considered to have atypical presentations reported one or more atypical symptoms only: fatigue, altered mental status, abdominal discomfort, conjunctivitis, and all other symptoms not previously categorised as typical.

Procedures

Presentation of SARS-CoV-2 infection was categorised as typical, atypical, or none of the listed symptoms.11 Patients considered to have typical presentations reported one or more typical symptoms, as classified by the US Centers for Disease Control and Prevention: fever (subjective, >100·4°F, or >38°C), cough, dyspnoea, myalgia, arthralgia, headache, anorexia, ageusia, sore throat, rhinorrhea, nausea, vomiting, diarrhoea, and abdominal pain.11 Patients considered to have atypical presentations reported one or more atypical symptoms only: fatigue, altered mental state, abdominal discomfort, conjunctivitis, and all other symptoms not previously categorised as typical.
COVID-19 severity at presentation was categorised as follows: mild if no hospitalisation indicated, moderate if hospitalisation indicated, and severe if intensive care unit (ICU) admission indicated. Presentation of infection was categorised on the basis of the level of care medically indicated for COVID-19 as reported in the registry, rather than only on the level of care administered, to more accurately reflect the true severity of disease than categorisation on the basis of patient preference or institutional policies in the setting of resource limitation.

To define geriatric risk level, we a priori adapted the simplified International Myeloma Working Group (IMWG) frailty score, developed in non-COVID-19 patients, adding an intermediate group (appendix p 6). The CCC19 registry uses data generally available from electronic health records and was not specifically designed to examine frailty or the population of older adults. As such, no comprehensive geriatric assessment data or specific data encompassing most extant approaches to operationalising frailty (ie, Clinical Frailty Scale) are collected. Of the available registry variables that can be associated with ageing, performance status and comorbidities were the most complete and a priori expected to be prognostic, on the basis of existing literature. However, rather than simply examining each variable, we sought to aggregate these ageing-associated variables into a single index to provide a clinically useful measure. Adapting the IMWG measure into the CCC19 variables into a single index to provide a clinically useful variable, we sought to aggregate these ageing-associated expected to be prognostic, on the basis of existing comorbidities were the most complete and a priori associated with ageing, performance status and complications.

Data are n/N (%). Cells with less than five patients were masked (ie, <5) to minimise the risk of re-identification as per data. Age-adjusted[26] and Eastern Cooperative Oncology Group (ECOG)[27] performance status as follows: age (≥75 years, 0 points; 76–80 years, 1 point; >80 years, 2 points); CCI (zero, 0 points; one or two, 1 point; more than two, 2 points); and ECOG performance status (zero, 0 points; 1 point, 1 point; 2 points, 2 points; 3 points, 3 points).
### Type of malignancy

|        | Solid tumour | Haematological neoplasm | Other |
|--------|--------------|-------------------------|-------|
| Remission or no evidence of disease | 1194 (50.5%) | 1844 (83.2%) | 405 (17.1%) |
| Active and responding | 271 (11.5%) | 237 (10.7%) | 208 (19.1%) |
| Active and stable | 445 (18.8%) | 405 (18.3%) | 350 (15.8%) |
| Active and progressing | 251 (10.6%) | 350 (15.8%) | 161 (14.8%) |
| Unknown | 201 (8.5%) | 190 (8.6%) | 106 (9.7%) |
| Missing data | 3 (0.1%) | 2 (0.1%) | 0 |

### Race and ethnicity

|                  | Non-Hispanic White | Non-Hispanic Black | Hispanic | Other |
|------------------|--------------------|--------------------|----------|-------|
| Age ≥80          | 27 (1.1%)          | 518 (23.4%)        | 751 (68.9%) |
| Smoking status   | Ever               | Never              | Missing data or unknown |
| Obese            | 883 (37.3%)        | 1482 (62.7%)       | 43 (1.8%) |
| Has dementia     | Yes                | No                | Missing data or unknown |
| Type of malignancy | Solid tumour | Haematological neoplasm | Other |
| Cancer status    | Remission or no evidence of disease | Active and responding | Active and stable |
|                 | Active and progressing | Unknown | Missing data |
| Timing of anti-cancer therapy | Never or after COVID-19 diagnosis | <2 weeks before COVID-19 diagnosis | 2–4 weeks before COVID-19 diagnosis |
|                  | 2–4 months before COVID-19 diagnosis | >3 months before COVID-19 diagnosis | Missing data or unknown |

### Covariates

Covariates were defined a priori and were sex, race and ethnicity, smoking status, obesity, dementia, malignancy type (solid cancer or haematological neoplasm), cancer status (remission or no evidence of disease vs active or measurable disease, with active or measurable disease defined as responding to therapy, stable, or progressing), anti-cancer therapy within 3 months before COVID-19 diagnosis (any systemic therapy, radiotherapy, and excluding surgery), country of patient residence (USA or outside USA), and month of COVID-19 diagnosis (January to April, 2020; May to August, 2020; September to December, 2020; January to April, 2021; and May to June, 2021).

### Outcomes

The primary outcome was a six-level ordinal scale of COVID-19 severity based on a patient’s most severe reported disease status: none of the following complications; hospitalisation; hospitalisation with oxygen requirement; ICU admission; requirement for mechanical ventilation; and death due to any cause. This scale was similar to the five-level ordinal variable used in previous CCC19 analyses, but with the additional level of hospitalisation with oxygen requirement, to account for older adults with greater severity than those hospitalised without oxygen requirement, but not requiring ICU admission. These outcomes were assessed over the patient’s total follow-up period. The secondary outcome was death from any cause within 30 days of COVID-19 diagnosis. Primary and secondary outcomes were assessed in the full dataset.

Predefined exploratory outcomes included symptoms and severity of COVID-19 at presentation, as well as one, 1 point; two or more, 2 points). ECOG performance status was determined by the health-care professionals abstracting from the patient’s chart, and they were instructed to enter the ECOG performance status at the time closest to COVID-19 diagnosis, or to note that no ECOG performance status was recorded within 3 months before COVID-19 diagnosis if applicable. Based on the sum of these data patients were categorised as standard risk (0 or 1 point), intermediate risk (2 or 3 points), or high risk (4–6 points). To maximise use of the available data, all patients had a geriatric risk point total calculated; patients with unknown ECOG performance status were initially categorised separately on the basis of the available age and comorbidity data and denoted as belonging to at least that category, recognising that their level of geriatric risk might be underestimated. For simplicity of clinical application and given similarity to the next lowest groups, these at least categories were consolidated (eg, at least standard risk was consolidated with standard risk). We analysed the non-consoliated measure in a sensitivity analysis. Variables used to define the CCC19 geriatric risk measure are summarised in the appendix (p 6).
as receipt of anti-COVID-19 treatments (including remdesivir, hydroxychloroquine, and corticosteroids), major clinical complications (including cardiovascular, pulmonary, and gastrointestinal complications and acute kidney injury), and COVID-19 effect on subsequent cancer care (ie, therapy modifications).

Statistical analysis
All analysis approaches were specified in a statistical analysis plan before the initiation of the analysis. Standard descriptive statistics were used to summarise baseline demographic and clinical characteristics, symptoms and severity of COVID-19 at presentation, rates of anti-COVID-19 treatments, outcomes, clinical complications, and anti-cancer therapy modifications among geriatric risk subgroups. Intersections of COVID-19 symptoms were summarised overall and among patients aged 80 years or older. Multiple imputation (ten iterations; missingness rates were <5%) using additive regression, bootstrapping, and predictive mean matching was used to impute missing and unknown data, except unknown ECOG performance status. Imputation was done on the full dataset before exclusions.

Unadjusted and adjusted odds ratios (ORs) quantifying the association of geriatric risk with COVID-19 severity were estimated from ordinal logistic regression models and 30-day mortality from binary logistic regression models. Models for COVID-19 severity included an offset for (log) follow-up time because severity was assessed models. Models for COVID-19 severity included an offset and 30-day mortality from binary logistic regression were estimated from ordinal logistic regression models dataset before exclusions.

Results
In total, 5671 patients were included in the final analysis, with only 36 (0·6% of 5671) patients excluded from the cohort because of non-calculateable geriatric risk index due to both missing or unknown performance scores and comorbidities (figure 1). The median age was 72 years (IQR 66–79); 1296 (22·9%) patients were 80 years or older. Median follow-up time was 56 days (IQR 22–120). 4659 (82·2%) patients had a solid tumour diagnosis. Regarding cancer status, 2730 (48·1%) patients had cancer in remission or no evidence of disease, and 2439 (43·0%) had active malignancy; the remainder had unknown or missing cancer status. When categorised using the CCC19 geriatric risk measure, 2365 (41·7%) patients were standard risk, 2217 (39·1%) were intermediate risk, and 1089 (19·2%) were high risk (table 1; appendix p 7). Smoking and dementia were substantially more common in high-risk patients than standard-risk patients (table 2); no other substantial differences were

Table 2: Demographic and clinical characteristics at COVID-19 diagnosis of older adults with cancer, stratified by geriatric risk index

| Country of residence | Standard risk (n=2365) | Intermediate risk (n=2217) | High risk (n=1089) |
|----------------------|------------------------|--------------------------|-------------------|
| USA                  | 2266 (95·8%)           | 2132 (96·2%)             | 1005 (92·3%)      |
| Outside USA          | 99 (4·2%)              | 85 (3·8%)                | 84 (7·7%)         |
| Month of COVID-19 diagnosis |
| January–April, 2020  | 558 (23·6%)            | 571 (25·8%)              | 377 (34·6%)       |
| May–August, 2020     | 980 (41·4%)            | 886 (40·0%)              | 403 (37·0%)       |
| September–December, 2020 | 493 (20·8%)         | 401 (18·3%)              | 154 (14·1%)       |
| January–April, 2021  | 320 (13·5%)            | 338 (15·2%)              | 142 (13%)         |
| May–June, 2021       | 10 (0·4%)              | 14 (0·6%)                | 9 (0·8%)          |
| Missing data or unknown | 4 (0·2%)           | 7 (0·3%)                 | 4 (0·4%)          |

Data are n (%) or median (IQR). The missing data or unknown category indicates either missingness due to non-response to optional survey questions or a response of unknown; an unknown category was provided for all survey questions. *For patients older than 89 years, age was truncated to 90 years. Truncation was done in concordance with the Health Insurance Portability and Accountability Act of 1996 and to reduce the risk of re-identifiability. †Patient reported to be obese or to have a body-mass index ≥30 kg/m². ‡Percentages could sum to >100% because categories are not mutually exclusive. Within 3 months before COVID-19 diagnosis.
The primary objective of our study was to examine COVID-19 severity across the different risk groups. High-risk patients had higher COVID-19 severity as indicated by a greater burden of hospitalisation with and without supplemental oxygen, ICU admission, mechanical ventilation, and death (figure 2) than standard-risk patients (table 1). 920 (16·2%) of 5671 patients died within 30 days of a COVID-19 diagnosis, including 161 (6·8%) of 2365 standard-risk patients, 409 (18·5%) of 2216 intermediate-risk patients, and 288 (13·0%) of 2210 intermediate-risk patients and 350 (32·1%) of 1089 high-risk patients (table 1). After adjustment for other factors associated with COVID-19 severity and 30-day mortality, there was a strong significant association between the high CCC19 geriatric risk index and higher COVID-19 severity and higher odds of 30-day mortality compared to standard-risk patients (adjusted OR for COVID-19 severity: 7·24, 95% CI 6·20–8·45; adjusted OR for 30-day mortality: 10·7, 95% CI 8·54–13·5; figure 3). In a sensitivity analysis, we examined the subgroups of patients who were initially categorised by available data into at least a member of the associated group (eg, at least intermediate risk if they met criteria for intermediate risk by age and modified CCI but had unknown ECOG performance scores). The estimated ORs for the primary outcome among these subgroups were similar to that among those with complete geriatric risk measure data, supporting the consolidation of these adjacent categories for clinical use (appendix p 9).

Among our secondary objectives was to examine COVID-19 presentation. Few patients presented with only atypical symptoms (table 1). Cough, fever, fatigue or malaise, and dyspnoea were the most common symptoms (figure 2A). Notably, altered mental state was more common among patients aged 80 years and older compared to younger patients (figure 2B). Severity of COVID-19 at presentation varied across geriatric risk groups, with only 193 (8·2%) of 2360 standard-risk patients presenting with severe disease, compared with 288 (13·0%) of 2210 intermediate-risk patients and 177 (16·3%) of 1084 high-risk patients. Most patients did not receive any specific treatment for COVID-19, and treatments were similar across geriatric risk groups (table 1).

Complications from COVID-19 were common, with the most common being pulmonary complications. High-risk patients had more complications reported than intermediate and standard risk groups (table 1). Of the patients for whom cancer therapy status was known and who were on active anti-cancer therapy within 3 months before COVID diagnosis, approximately half had subsequent modification of their therapy (table 1). The most common cancer therapy modification for those with available data was delay in cancer therapy, and this was similar across all risk groups (table 1).

Discussion
In this large study of 5671 older adults with COVID-19 and cancer, we found that the CCC19 geriatric risk index was associated with poorer outcomes, including clinical complications, hospitalisation, and mortality. A higher CCC19 geriatric risk index was significantly associated with higher COVID-19 severity and 30-day all-cause mortality after adjustment of major prognostic confounding factors and explained the greatest amount of variation in these outcomes compared with all other
Figure 4: Presenting symptoms of COVID-19 among older adults with cancer

UpSet plot indicating intersection between symptoms in older adults with cancer in a matrix layout. The bar graph in the lower left corner depicts symptom-level distribution across each category (typical or atypical). Each row in the dot graph represents a symptom classification; solid dots represent each symptom part of the intersecting sets. The centre bar graph depicts the number of symptoms in each intersection.
risk factors. Our results suggest that the CCC19 geriatric risk index, using a combination of previously studied poor prognostic factors for COVID-19 mortality,14,19,20 can effectively risk stratify this vulnerable patient population.

Our study examines the relationship between our novel geriatric risk index and adverse outcomes from COVID-19 among older adults with cancer, as well as the frequency of atypical presentations in this population. With this geriatric risk index, we identified that individuals categorised as high risk had a 10 times greater odds of death within 30 days than standard-risk patients. Although data on frailty specifically are not available in this dataset, frailty is a commonly used perspective to capture age-associated vulnerability. In a meta-analysis of studies of frailty and COVID-19, of 23 944 patients with COVID-19 in the general population, frailty was present in 51% of patients and was strongly associated with higher mortality than non-frail patients, with a pooled OR of 2.48 (95% CI 1.78–3.46), regardless of frailty tool used or geographical location.1 However, operationalising frailty requires specific data, such as comprehensive geriatric assessment or objective measures that are rarely available in routine clinical practice. Thus, the applicability of frailty in real-world clinical care is limited. The CCC19 geriatric risk index, in contrast, uses information readily available from routine oncology care (age, comorbidities, and ECOG performance status) to identify a group with an extremely high risk for severe outcomes of COVID-19, lending credence to our approach of combining known risk factors into a single geriatric risk index.

Given the adverse COVID-19 outcomes observed in this high-risk population, our study reinforces the need to focus efforts on SARS-CoV-2 infection prevention strategies among older adults with cancer, including vaccination.25–27 Given concerns about vaccine efficacy among older adults and those with cancer, vaccination is only one part of a broader mitigation strategy for this extremely vulnerable population, which must also include public health measures: social distancing, mask wearing, and aggressive vaccination of household contacts. Unfortunately, these public health measures have their own serious adverse consequences, as older adults with or without cancer are at risk of poor outcomes from social isolation, loneliness, physical deconditioning, and loss of autonomy, which all increase the risk of depression and anxiety.25–26

Clinicians should remain cognisant of atypical presentations of COVID-19. Nearly one in ten patients aged 80 years and older in our cohort presented with only atypical symptoms. The recognition that older adults might present with fewer and atypical symptoms of infection predates the pandemic; in a study of the presentation of community-acquired pneumonia in older adults, 639 (20·5%) of 3124 patients older than 65 years presented with atypical symptoms, and 175 (4·8%) of 3630 presented with altered mental state.27 In our study, altered mental state was the sixth most common symptom present at diagnosis. Of note, our study probably underestimated the prevalence of delirium, because it is under-recognised and under-reported in clinical practice. In a study that used a standardised method for identifying acute confusion as a proxy for delirium in patients with COVID-19, the prevalence of delirium was 34·6% (45 of 130 patients) in the subgroup of frail older adults.28

The high prevalence of complications in the high-risk group in our study is noteworthy and might inform simple changes in care to prevent complications. For instance, one in three (35·4%) high-risk older adults in our cohort developed acute kidney injury (compared with 23·7% in the intermediate-risk group and only 11·4% in the standard-risk group). Although renal function naturally declines with age, the acute illness presents a number of potential threats to renal function, including haemodynamic and nephrotoxic medications. Adopting a nephroprotective mindset for these patients, such as avoiding nephrotoxic medications and contrast for computed tomography imaging if possible, could be a simple step to reduce this complication.29

Despite being a large multicentre study examining a comprehensive cohort of older adults with cancer and COVID-19, our study has several limitations that are inherent to its retrospective registry nature. First, the CCC19 registry was designed to report COVID-19 outcomes with time intervals rather than with precise timing of COVID-19 diagnosis and cancer-related outcomes, to meet Health Insurance Portability and Accountability Act (HIPPA) and general data protection regulation requirements. Second, COVID-19-specific death is underspecified, as this variable was included several months after the inception of the registry and would lead to high rates of missingness if included in our study, and this is an important limitation. Given the diverse mechanisms of pathophysiology resulting from SARS-CoV-2, accurate attributable cause of death is a limitation common to most COVID-19 studies. Patients aged 89 years or older were masked per HIPAA de-identification requirements, such that we cannot examine subpopulations of patients aged 90 years or older; notably, 272 (5%) of the patients in our analysis fall into this category. Moreover, as with any registry-based study, there might be selection bias toward hospitalised patients.30 Similarly, although adjusted analyses were done, observational studies are subject to selection bias and unmeasured confounding. Additionally, we used a simplified geriatric risk measure adapted from a measure validated in myeloma patients.44 This measure does not fully approximate the existing approaches to operationalising frailty, such as the phenotypic frailty approach, which requires assessment of grip strength or gait speed36 and which are rarely obtained in routine practice and are not included in the CCC19 registry. Another key limitation is that the IMWG score was validated in patients with haematologic malignancies, and...
our cohort was primarily a cohort of patients with solid tumours; however, the proportion of patients with solid tumours versus haematologic malignancies in each risk group was similar, lending face validity to its application in this study. Another limitation is possible misclassification of ECOG in older adults when compared with geriatric assessment, as performance scores have been shown repeatedly to underestimate the level of vulnerability in older adults, as even individuals with good performance scores might have impairments in functional status and other important domains.13,14 Consequently, the CCC19 geriatric risk index might not identify at-risk patients who have ageing-associated vulnerabilities other than impaired performance scores or comorbidities. Lastly, the CCC19 geriatric risk index will require external validation. Despite these limitations, our large study generates important data and sets the foundation for further investigation in this large vulnerable population.

Future research questions include the extent to which vaccines will reduce incidence and severity of COVID-19 in this vulnerable population who might not mount as robust an immune response to vaccination; these studies are ongoing, with encouraging initial results with regard to older adults with cancer.14 Older adults with cancer should be prioritised for vaccination roll-out.10 It is unknown how modifications of anti-cancer therapy affect cancer control, and whether functional decline due to COVID-19 affects subsequent ability to tolerate cancer therapy in a group who might already have been at high risk for toxicity of therapy.

Patients with high-risk geriatric profiles present with more severe initial presentations and are at greater risk for death and other adverse sequelae of COVID-19 than those with standard-risk profiles. Our CCC19 geriatric risk index, based on readily available clinical factors, might provide clinicians with an easy-to-use risk stratification method to identify older adults most at risk for severe COVID-19 as well as mortality.

Contributors
AE, JLW, NMK, OAP, and TMW conceived and designed the study and reviewed and edited the manuscript. AE, JLW, and TMW did the formal analysis and methodology, and wrote the original draft. BF and CHe designed the study, did the formal analysis, visualisation, and methodology, wrote the original draft, and reviewed and edited the manuscript. SM did project administration and coordination and reviewed and edited the manuscript. KV-L did the data analysis (for treatment change) and reviewed and edited the manuscript. SMR, EW-B, RPR, MAT, AD, DRR, ARK, LT, RCL, CS, RE, GB, AK, and DPS designed the study and reviewed and edited the manuscript. ZB, AC, ICL, JCR, BD, CRF, SLF, PGR, PCro, Gsoul, SGoup, CHW, HK, SJK, EJK, CL, RRM, AN, NAP, MP, ALS, AS, JAS, CTS, SW, NW, and TMW-D contributed substantial patient cases to the CCC19 and were responsible for reading and editing the manuscript. BF, CHe, and JLW accessed and verified the data. BF, CHe, and JLW had full access to data in the study. All authors had final responsibility for the decision to submit for publication.

Declaration of interests
The following authors declare competing interests not related to the current work: ZB reports grants from Genentech/imCORE, non-financial support from Bristol Myers Squibb, and personal fees from UpToDate. AE reports salary support from the Canadian Institute of Health Research, the Detweiler Travelling Fellowship (Royal College of Physicians and Surgeons of Canada), and the Henry R Shihata Fellowship (Cedar’s Cancer Foundation). CRF reports grants from Merck Foundation, NCCN/Pfizer, and National Cancer Institute, and other support from National Cancer Institute and the Patient-Centered Outcomes Research Institute. PGrí reports personal fees and non-financial support from AstraZeneca, personal fees from Astellas Pharma, personal fees from Bayer, grants and personal fees from Bristol Myers Squibb, grants and non-financial support from Clovis Oncology, personal fees from Dynaia Health, grants and personal fees from EMD Serono, personal fees from Elsevier, personal fees from Foundation Medicine, personal fees from Genentech/Roche, personal fees from Genzyme, grants and personal fees from GlaxSmithKline, personal fees from Guardant Health, grants and personal fees from Immunomedics/Gilead, personal fees from Infinity Pharmaceuticals, personal fees from Janssen, grants and personal fees from Merck, grants and personal fees from Mirati Therapeutics, grants and personal fees from Pfizer, grants and personal fees from QED Therapeutics, personal fees from Regeneron Pharmaceuticals, personal fees from Seattle Genetics, personal fees from 4D Pharma, personal fees from UroGen, grants from Bavarian Nordic, and grants from Debiopharm. SGoup reports grants and personal fees from Bristol Myers Squibb, personal fees from Merck, Janssen, Seattle Genetics, EMD Serono, and Pfizer, and grants from Astellas and BMS. CHw reports grants from Merck, Bayer, and AstraZeneca, and personal fees from Tempus and EMD Serono, and other support from Johnson and Johnson. AK reports other support from TESARO, Fibrogen, Geistlich Pharma, Astellas Pharma, Rafael Pharmaceuticals, and Novocure. ARK reports other support from Merck and Sanofi, personal fees from Onclive, grants from ASCO Conquer Cancer Foundation, and grants from Bladder Cancer Advocacy Network. HK reports position as an advisory board of Sanofi Genzyme, NSCLC Northeast. NMR reports personal fees from BMS, Janssen, Seattle Genetics, Celldex, Sandoz, Invitae, Beyond Spring, Spectrum GI Therapeutics, and Total Health, and grants from ASCO Conquer Cancer Foundation, and grants from Bladder Cancer Advocacy Network. EL reports position as an advisory board of Janssen. ZB reports grants and other support from National Institutes of Health (NIH) and Agency for Healthcare Research and Quality, and personal fees from National Cancer Institute and the Patient-Centered Outcomes Research Institute. NAP reports personal fees from AstraZeneca, Merck, Pfizer, Eli Lilly, Genentech, BMS, Amgen, Inivata, G1 Therapeutics, and Total Health, and grants from Amgen, Jazz Therapeutics, GI Therapeutics, and Samsung. CL reports grants from imCore/Genentech. RRM reports serving on advisory board or as a consultant for AstraZeneca, Aveo, Bayer, BMS, Cars, Dendreon, Exelixis, Janssen, Merck, Myovant, Novartis, Pfizer, Sanofi, Sorrento Therapeutics, and Tempus. RRM received institutional research funding from Pfizer, Bayer, Tempus. SM reports personal fees from National Geographic. OAP reports grants from National Institutes of Health (NIH) and Agency for Healthcare Research and Quality, and personal fees from Foundation Medicine. NAP reports personal fees from AstraZeneca, Merck, Pfizer, Eli Lilly, Genentech, BMS, Amgen, Inivata, G1 Therapeutics, and Total Health, and grants from Amgen, Jazz Therapeutics, and Total Health. AE reports grants from Pfizer, personal fees from AstraZeneca, and personal fees from BMS, Janssen, Dova, and Inari. MAT reports personal fees from VIA Oncology, GSK, and Adaptive Advisory Board, other support from Syapse, UpToDate, Takeda, Celgene, Doximity, AbbVie, BMS, CRAB CTC, Denovo, Hoosier Research Network, Lilly, LynxBio, Strata Oncology, and TG Therapeutics. JLW reports personal fees from Roche, Westat, Flatiron Health, Melas Tech, and IBM Watson Health, other support from HemOnc and Janssen, and grants from AACR. TMW reports personal fees from Carevue, and personal fees from Sanofi, and Seattle Genetics. TMW-D reports grants from BMS, Merck, Janssen, and GSK/Tesaro, personal fees from Excure, Shattuck Labs, Merck, Caris Life Science, and SITC; and other support from High Enroll. EW-B reports grants from Pfizer Global Medical Grants, personal fees from Astellas, Avere Oncology Bristol Myers Squibb, Exelixis, and Janssen, and other support from Immunomedics and Nektar. The following authors declare competing interests during the conduct of the study: SM reports grants and other support from National Cancer Institute and from the International Association for the Study of Lung Cancer. DPS reports grants from American Cancer Society and Hope Foundation for Cancer Research and from NIH. LT reports grants from NIH. JLW reports grants from NIH. All other authors declare no competing interests.

Data sharing
The statistical analysis plan and data dictionary used for this study are included in the appendix. The full CCC19 data dictionary and the code to create all derived variables is publicly available at https://github.com/covidcancer/ccc19-data-dictionary. The deidentified patient data with site identifiers removed and geographical region of patient residence masked to a level no smaller than USA census
divisions will be made publicly available for any purpose beginning from 6 months and ending a minimum of 36 months after publication of this Article through the CCC19 website. Individual deidentified patient data with site identifiers removed and geographical region of patient residence masked to a level no smaller than USA census divisions will be made available to researchers who provide a methodologically sound proposal, whose proposed use of the data has been approved by an independent review committee identified for this purpose. Proposals can be submitted beginning 6 months and up to 36 months after publication of this Article through the following REDCap form: https://redcap.unc.edu/CCC19-data-request. To gain access, approved data requestors will need to sign a data access agreement.

Acknowledgments

We thank all members of the CCC19 steering committee: Toni Choueiri, Petros Grivas, Gilberto Lopes, Corrie Painter, Solange Peters, Brian Rini, Dimpy Shah, Mike Thompson, Dimitrios Farmakiotis, Narjust Duma, and Jeremy Warner for their invaluable guidance of the CCC19 consortium. We also thank Gary Lyman for important contributions to the study design. The CCC19 Research Coordinating Center (ChHe, SM, BF, JLW, and KLV) is supported by the NIH National Cancer Institute (NCI) Cancer Center Support Grants P30 CA068485. AE is supported by the Canadian Institute of Health Research, the Dettwiler Traveling Fellowship, and the Henry R Bishlata Fellowship. AS was supported in part by the Beartizt and Samuel Seaver Foundation, the Memorial Sloan Kettering Cancer Center Support Grant P30 CA008748. CRF was supported by T32 CA 236621 and part by the Beatriz and Samuel Seaver Foundation, the Memorial Sloan Kettering Canadian Institute of Health Research, the Detweiler Traveling Cancer Center Support Grants P30 CA068485. AE is supported by the study design. The CCC19 Research Coordinating Center (ChHe, SM, BF, JLW, and KLV) is supported by the NIH National Cancer Institute (NCI) Cancer Center Support Grants P30 CA008748. AE is supported by the Canadian Institute of Health Research, the Dettwiler Traveling Fellowship, and the Henry R Bishlata Fellowship. AS was supported in part by the Beartizt and Samuel Seaver Foundation, the Memorial Sloan Kettering Cancer Center Support Grant P30 CA008748. CRF was supported by T32 CA 236621 and P30 CA 046592. OAP was supported by P01 AG027296 and R01 AG531307. PGri was supported by P30CA05704–04. REDCap is developed and supported by Vanderbilt Institute for Clinical and Translational Research grant support (UL1TR000445 from NCATS/NIH).
