Glucocorticoids suppress inflammation via the upregulation of negative regulator IRAK-M

Masanori Miyata1,*, Ji-Yun Lee1,*, Seiko Susuki-Miyata1, Wenzhuo Y. Wang1,2, Haidong Xu1, Hirofumi Kai3, Koichi S. Kobayashi4, Richard A. Flavell5 & Jian-Dong Li1

Glucocorticoids are among the most commonly used anti-inflammatory agents. Despite the enormous efforts in elucidating the glucocorticoid-mediated anti-inflammatory actions, how glucocorticoids tightly control overactive inflammatory response is not fully understood. Here we show that glucocorticoids suppress bacteria-induced inflammation by enhancing IRAK-M, a central negative regulator of Toll-like receptor signalling. The ability of glucocorticoids to suppress pulmonary inflammation induced by non-typeable Haemophilus influenzae is significantly attenuated in IRAK-M-deficient mice. Glucocorticoids improve the survival rate after a lethal non-typeable Haemophilus influenzae infection in wild-type mice, but not in IRAK-M-deficient mice. Moreover, we show that glucocorticoids and non-typeable Haemophilus influenzae synergistically upregulate IRAK-M expression via mutually and synergistically enhancing p65 and glucocorticoid receptor binding to the IRAK-M promoter. Together, our studies unveil a mechanism by which glucocorticoids tightly control the inflammatory response and host defense via the induction of IRAK-M and may lead to further development of anti-inflammatory therapeutic strategies.
Gluocorticoids (GCs) are the most widely used and most effective treatment to control inflammatory diseases1-3. GCs are known to exert their anti-inflammatory effects by binding to glucocorticoid receptors (GRs), leading to the suppression of proinflammatory regulators such as nuclear factor-κB (NF-κB) or activator protein 1 (AP-1) (refs 4,5). Several mechanisms of action of GR have been reported in the past6. First, GR binds to p65 and AP-1 to prevent downstream transcription (tethering). Second, GR binds to the glucocorticoid response element (GRE) to initiate the transcription of anti-inflammatory genes (transactivation). Third, negative GRE has been shown to suppress proinflammatory cytokines (transrepression)7,8.

The innate immune and inflammatory response is activated by pattern recognition receptors, including Toll-like receptors (TLRs), on recognition of pathogen-associated molecular patterns9. Pattern recognition receptors activate a number of downstream molecules such as tumour necrosis factor (TNF) receptor-associated factor 6 (TRAF6), NF-κB essential modulator, inhibitor of NF-κB (IκB) kinase β (IκKβ) and NF-κB to produce proinflammatory cytokines9. Myeloid differentiation factor 88 (MyD88) is a critical downstream adaptor molecule of all TLRs, known as IRAK3) is one of the most critical negative feedback regulators of the TLR/IL-1R family signalling via the inhibition of IRAK-M (also known as IRAK) expression at both mRNA and protein levels in lung tissue of mice, as assessed by performing qPCR and immunostaining analyses (Fig. 1h-j). To further determine which cells express IRAK-M in the lung of mice treated with NTHi and DEX, we next performed immunofluorescence double staining using anti-IRAK-M with anti-E-cadherin or anti-F4/80 antibodies, the marker of epithelial cells and macrophages, respectively. As shown in Fig. 1k, NTHi and DEX markedly induced the expression of IRAK-M in both epithelial cells and macrophages. Of note, IRAK-M-specific staining was completely abolished by an IRAK-M-specific blocking peptide (Fig. 1k).

Results

GCs synergistically enhance NTHi-induced IRAK-M expression. We sought to determine if GCs regulate the expression of IRAK-M induced by NTHi. Because airway epithelial cells are the front line of defense through initiating inflammatory response, we first examined the effect of GCs on NTHi-induced expression in human respiratory epithelial cells BEAS-2B and A549. DEX synergistically enhanced the NTHi-induced IRAK-M expression at the mRNA level in BEAS-2B and A549 in a dose- and time-dependent manner (Fig. 1a,b and Supplementary Fig. 1a,b). Immunoblot analysis revealed that DEX also synergistically enhanced NTHi-induced IRAK-M expression at the protein level (Fig. 1c,d). Moreover, DEX-mediated synergistic enhancement of NTHi-induced IRAK-M expression is also confirmed in primary normal human bronchial epithelial cells (Fig. 1e). We also examined the effect of GCs on IRAK-M expression in macrophages due to their important role in innate immune responses against bacteria23,24. As shown in Fig. 1f, the induction of IRAK-M by NTHi and DEX was also observed in primary human monocyte-derived macrophages. Under the same experimental condition, NTHi-induced IL-6 expression was suppressed by DEX (Supplementary Fig. 2). Consistent with these results, DEX also synergistically enhanced the NTHi-induced IRAK-M expression in primary alveolar macrophages of mice (Fig. 1g). Moreover, DEX also synergistically enhanced the NTHi-induced IRAK-M expression at both mRNA and protein levels in lung tissue of mice, as assessed by performing qPCR and immunostaining analyses (Fig. 1h-j). To further determine which cells express IRAK-M in the lung of mice treated with NTHi and DEX, we next performed immunofluorescence double staining using anti-IRAK-M with anti-E-cadherin or anti-F4/80 antibodies, the marker of epithelial cells and macrophages, respectively. As shown in Fig. 1k, NTHi and DEX markedly induced the expression of IRAK-M in both epithelial cells and macrophages. Of note, IRAK-M-specific staining was completely abolished by an IRAK-M-specific blocking peptide (Fig. 1k).

Figure 1 | DEX synergistically enhances the NTHi-induced IRAK-M expression in vitro and in vivo. (a) IRAK-M mRNA expression in human bronchial epithelial BEAS-2B cells treated with DEX (0.01, 0.1, 1, 10, 100 or 1,000 nM) for 1 h, followed by the stimulation of NTHi for 5 h. (b) IRAK-M mRNA expression in human lung epithelial A549 cells stimulated with DEX (100 nM) for 1 h, followed by NTHi for indicated time. (c) A549 cells were treated with DEX (100 nM) for 1 h, followed by NTHI for 12 h. IRAK-M protein was detected by anti-IRAK-M antibody. (d) IRAK-M protein expression was quantified from three independent experiments. (e) IRAK-M mRNA expression in primary NHBE cells treated with DEX (10, 100 or 1,000 nM) for 1 h and subjected to NTHI stimulation for 5 h. (f) Human peripheral blood CD14+ monocytes were differentiated to macrophages by culturing them with granulocyte-macrophage colony-stimulating factor for 7 days. IRAK-M mRNA was determined after the macrophages were treated with DEX (100 nM) for 1 h, followed by stimulation of NTHI for 5 h. (g) Mice were stimulated with DEX (1 mg kg-1, intraperitoneally) for 2 h and intratracheally inoculated with NTHi (1 × 106 cfu) for 24 h. The mRNA expression in alveolar macrophages was assessed by qPCR. (h) The IRAK-M mRNA expression in lung was assessed by qPCR. (i) Immunostaining of mouse lung with control IgG or anti-IRAK-M antibody by LSAB (Labelled Streptavidin Biotin) staining system (Scale bar, 50 μm; magnification, × 400). (j) Treatment-blind observers scored the IRAK-M expression from the histology results. (k) The lung sections were stained by using indicated antibodies. The arrows and arrowheads indicate the epithelial cells and macrophages merged with IRAK-M expression, respectively. (Scale bar, 50 μm; magnification, × 400. Data in a,b,d-h, n = 3; j, n = 6) are mean ± s.d. *P < 0.05; t-test.
Taken together, our data suggest that DEX synergistically enhances NTHi-induced IRAK-M expression at both mRNA and protein levels in vitro and in vivo.

**IRAK-M negatively regulates the NTHi-induced inflammation.**

To determine the role of the induction of IRAK-M expression in the NTHi-induced inflammatory responses, we established stable BEAS-2B cells expressing IRAK-M (IRAK-M-stable cells; Fig. 2a). As shown in Fig. 2b, the NTHi-induced expression of TNF-α, IL-1β, IL-6, CXCL10 and CCL5 was significantly inhibited in IRAK-M-stable cells as compared with mock cells. Next we sought to confirm the role of endogenous IRAK-M expression in...
NTHi-induced expression of proinflammatory mediators by depleting IRAK-M using short interfering RNA (siRNA). Immunoblot analysis using two different anti-IRAK-M antibodies revealed that the siRNA depletion of IRAK-M specifically reduced IRAK-M expression (Fig. 2c). IRAK-M depletion markedly enhanced NTHi-induced expression of TNF-α, IL-1β, IL-6, CXCL10 and CCL5 (Fig. 2d). Moreover, the ability of DEX to suppress these proinflammatory mediators was also significantly attenuated in IRAK-M-depleted cells (Fig. 2e). These data thus provide direct evidence for the role of the induction of IRAK-M expression in the presence of DEX.

**GCs suppress inflammation and improve survival via IRAK-M.**

To determine if DEX suppresses NTHi-induced inflammatory response via the induction of IRAK-M expression, we compared the inhibitory effect of DEX on NTHi-induced innate inflammatory response in WT (Irak-m+/+) with IRAK-M-deficient (Irak-m−/−) mice. We observed that DEX markedly suppressed the NTHi-induced mRNA expression of key proinflammatory mediators including TNF-α, IL-1β, IL-6, MIP2, CXCL5/LIX, CXCL10 and CCL5, at the mRNA level, in Irak-m+/+ but not in Irak-m−/− mice (Fig. 3a). Enzyme-linked immunosorbent assay analysis confirmed that DEX failed to markedly suppress the NTHi-induced expression of these proinflammatory mediators at the protein level in the bronchoalveolar lavage (BAL) fluid of Irak-m−/− mice as compared with Irak-m+/+ mice (Fig. 3b). Consistent with these results, similar results were also observed in mouse alveolar macrophages (Fig. 3c). Moreover, histopathological analysis of the lung of NTHi-infected mice showed that DEX inhibited NTHi-induced leucocyte infiltration in the peribronchial and interstitial area and also inhibited alveolar wall injury by the inflammatory process in Irak-m+/+ but not in Irak-m−/− mice (Fig. 4a,b). Similarly, DEX also suppressed NTHi-induced leucocytes infiltration in BAL fluid of Irak-m+/+ but not of Irak-m−/− mice (Fig. 4c). Because an innate inflammatory response initiated by pulmonary epithelial cells is critical for bacterial clearance, we further evaluated the effects of DEX on bacterial clearance in the lungs of Irak-m−/− mice compared with Irak-m+/+ mice. DEX treatment increased the colony-formation unit (c.f.u.) of NTHi in the lung of Irak-m−/− mice (Fig. 4d). Consistent with the result of bacterial clearance, DEX also inhibited the NTHi-induced expression of mouse β-defensin 4, an orthologue of human BD2, in Irak-m−/− mice, but not in Irak-m−/− mice (Fig. 4e). Because overactive inflammatory responses contribute significantly to the increased morbidity and mortality in patients with NTHi infections25,26, we next evaluated the contribution of IRAK-M in mortality induced by NTHi by infecting mice with a lethal dose of NTHi (5 × 10⁸ c.f.u.) and monitoring survival rate for 7 days. As shown in Fig. 4f, we observed ~50% mortality in Irak-m+/+ mice 7 days after infection. We found no statistically significant difference in

---

**Figure 2 | IRAK-M suppresses the NTHi-induced proinflammatory mediator expression.** (a) The proteins from BEAS-2B cells stably overexpressing IRAK-M and its control pcDNA3.1 (Mock) cells were detected by immunoblot with indicated antibodies. (b) The mRNA expression was detected by qPCR after the stable cells were treated with DEX (100 nM) and NTHi. (c) BEAS-2B cells were transfected with siRNA control or IRAK-M for 72h. IRAK-M protein expression was detected by immunoblot with anti-IRAK-M antibodies (SC, Santa Cruz Biotechnology sc-100389; PS, ProSci #2355). (d) siRNA-transfected BEAS-2B cells were infected with NTHi followed by qPCR. (e) The mRNA level was calculated by following: (NTHi-induced mRNA without DEX)/(NTHi-induced mRNA without DEX). Data in b,d,e, n = 3) are mean ± s.d. *P < 0.05; t-test.
**Figure 3** | DEX suppresses the NTHi-induced proinflammatory mediator expression in *Irak-m*+/+ but not in *Irak-m*−/− mice. WT and IRAK-M-deficient mice were inoculated with DEX (1 mg kg−1, intraperitoneally) for 2 h, followed by intratracheal inoculation with NTHi (1 × 107 c.f.u. per lung) for 24 h. (a) The mRNA expression in the mouse lung tissue was analysed by qPCR. (b) The protein level of proinflammatory mediators in BAL fluid was determined by enzyme-linked immunosorbent assay. (c) The mRNA expression in alveolar macrophages was analysed by qPCR. Data in a, c, n = 3; b, n = 9 are mean ± s.d. *P<0.05, NS, non-significant; t-test.

**IKKβ and GR mediate synergistic induction of IRAK-M.** Having shown that GCs suppress NTHi-induced inflammatory response via the induction of IRAK-M, the mechanism underlying the regulation of IRAK-M expression still remains unknown. Because NTHi is recognized by TLR2 (refs 27–29), we sought to first evaluate the generalizability of our findings by determining if DEX also enhances the induction of IRAK-M expression by TLR-dependent and -independent inflammatory stimuli. GCs enhanced upregulation of IRAK-M by TNFα, IL-1β and Pam3CSK4 in lung epithelial cells (Fig. 5a). Because all of these stimuli that induce IRAK-M, including NTHi, are known to induce inflammatory response via IKKβ27–29, we thus examined if DEX synergistically enhances upregulation of IRAK-M induced by activating IKKβ signalling through the overexpression of a constitutively active form of IKKβ (IKKβ CA). DEX indeed synergistically enhanced the induction of IRAK-M by the direct activation of IKKβ signalling (Fig. 5b). We further determined if IKKβ mediates the synergistic upregulation of IRAK-M by DEX and NTHi. Inhibition of IKKβ using specific inhibitor significantly suppressed the synergistic upregulation of IRAK-M expression at both mRNA and protein levels by DEX and NTHi (Fig. 5c,d), suggesting the requirement of IKKβ signalling in mediating the synergistic induction of IRAK-M. Because GR is crucial for GC-mediated biological effects5,6, we next assessed the role of GR using RU486 (mifepristone), a GR antagonist. RU486 significantly inhibited the synergistic upregulation of IRAK-M expression at both mRNA and protein levels by DEX and NTHi (Fig. 5e,f and Supplementary Fig. 3a). Moreover, GR depletion using siRNA also markedly inhibited the synergistic upregulation of IRAK-M by DEX and NTHi (Fig. 5g and Supplementary Fig. 3b), indicating that GR mediates synergistic induction of IRAK-M.
GR is known to regulate gene expression by influencing transcription or mRNA stability. Interestingly, the mRNA stability of IRAK-M remained largely unchanged by NTHi or DEX (Supplementary Fig. 4). Consistent with this result, actinomycin D, a transcriptional inhibitor, abrogated the synergistic induction of IRAK-M protein expression induced by DEX and NTHi (Fig. 5h). These data suggest that DEX and NTHi are unable to induce IRAK-M expression in the absence of the ongoing transcription.

We sought to further elucidate the molecular mechanism underlying the synergistic induction of IRAK-M by DEX and NTHi. DEX is known to exert its transcriptional activity via the induction of the ligand-dependent dimerization of GR and the subsequent binding of the dimerized GR to GRE in the gene regulatory region of the driven genes. We thus first determined if the ligand-induced binding of GR dimer to the GRE in the promoter region of IRAK-M is involved in the synergistic induction of IRAK-M transcription by using a non-steroidal GR-monomer-favouring compound, compound A (CpdA). Unlike DEX, CpdA exhibits no effect on GRE-driven gene transcription. We found that CpdA failed to enhance NTHi-induced expression of IRAK-M (Fig. 5i). In contrast, it still significantly inhibited the NTHi-induced NF-κB activity (Fig. 5j). These data thus suggest that the binding of dimerized GR to GRE is required for the synergistic induction of IRAK-M transcription by DEX and NTHi.
GR and p65 synergistically bind to IRAK-M promoter. We next sought to define the cis-acting DNA elements critical for the synergistic induction of IRAK-M. We constructed a series of deletion mutants in the upstream region of IRAK-M promoter, inserted them to a pGL3 basic vector and measured their luciferase activity. As shown in Fig. 6a, the key cis-acting elements critical for mediating the synergistic induction of IRAK-M transcription resided within the promoter region from −500 to +71
Figure 6 | DEX and NTHi synergistically induce IRAK-M transcription via inducing the binding of p65 and GR to IRAK-M promoter. (a-c) Relative luciferase activity (RLA) was measured after the transfection of IRAK-M promoter in pGL3 basic vector and treated with DEX (100 nM) and NTHi in BEAS-2B cells (a,b). (c) MEF cells were transfected with IRAK-M-luc (−500 bp), followed by DEX (1 μM) and NTHi stimulation. (d) Immunoblot shows IRAK-M protein expression in BEAS-2B cells transfected with siRNA p65. (e,f) ChiP assay in BEAS-2B cells treated with DEX and NTHi for 1 h. IRAK-M promoter regions from −38 to +39 bp for GRE, from −231 to −99 bp for xB site were amplified by qPCR. (g) Re-ChIP assay (detailed in Methods). PCR products were detected in agarose gel. (h, i) ChiP assay in BEAS-2B cells treated with IKKβ inhibitor (1 μM), RU486 (1 μM), DEX (100 nM) and NTHi. Data (a–c, n = 3; e, f, n = 2) are mean ± s.d. *P < 0.05; t-test.

base pair (bp). Further in silico sequence analysis revealed the existence of three putative NF-κB-binding sites (xB site) and one GRE in the IRAK-M promoter region from −300 to +71 bp (Supplementary Fig. 5). Interestingly, mutation of this GRE and these three xB sites markedly inhibited the synergistic activation of IRAK-M promoter by DEX and NTHi (Fig. 6b), thereby further demonstrating the requirement of NF-κB and GR. Since p65 is a key subunit of NF-κB [3] and IRAK-M transcription via synergistically inducing the binding of p65 and GR to IRAK-M promoter. We observed no synergistic induction of IRAK-M in p65-deficient mouse embryonic fibroblasts (MEFs) treated with NTHi and DEX as compared with WT MEFs, and the reconstitution of p65-deficient MEFs with WT p65 plasmid restored their responsiveness to NTHi and DEX (Fig. 6c). Consistent with these results, p65 knockdown by siRNA inhibited the synergistic induction of IRAK-M expression at the protein level in BEAS-2B cells (Fig. 6d and Supplementary Fig. 6a) and DEX also synergistically enhanced IRAK-M expression induced by expressing WT p65 in BEAS-2B cells (Supplementary Fig. 6b). Taken together, our data suggest that both p65 and GR are required for mediating the synergistic induction of IRAK-M transcription by DEX and NTHi.

We next determined if DEX synergizes with NTHi to induce IRAK-M transcription via synergistically inducing the binding of p65 and GR to IRAK-M promoter region (−300 bp to +71 bp) containing three xB sites and GRE. Quantitative analyses using chromatin immunoprecipitation (ChiP) assays revealed that DEX and NTHi synergistically enhanced the binding of both p65 and GR to IRAK-M promoter (Fig. 6e,f). In addition, Re-ChIP assay revealed that DEX and NTHi induced the interaction of p65 with GR in the context of chromatin (Fig. 6g). Moreover, the synergistic induction of the binding of p65 and GR to IRAK-M-
promoter induced by NTHi and DEX was significantly inhibited by RU486 and IKKβ inhibitor, respectively (Fig. 6h,i). Together these data suggest that DEX synergizes with NTHi to induce the binding of both GR and p65 to IRAK-M promoter, which, in turn, leads to the induction of IRAK-M transcription in a synergistic manner (Fig. 7).

Discussion

On infection, an innate inflammatory response can be activated through a TLR. The adaptor proteins IRAK1 and IRAK4 (IRAK1/4) and MyD88 mediate all TLR signalling, except TLR3, in triggering inflammation. It has been demonstrated that MyD88 and IRAK1/4 are critical in activating an inflammatory response in mice, as well as in humans. Since GCs have a potent anti-inflammatory effect for multiple usages in a clinical setting, we hypothesized that GCs could target central bottleneck proteins such as MyD88 or IRAK1/4 to tightly regulate inflammatory responses. Here we show that GCs synergistically enhance bacteria-induced IRAK-M, a critical negative regulator of IRAK1/4, in vitro and in vivo. We found that NTHi and GCs cooperatively induced recruitment of p65 and GR to the IRAK-M promoter. In addition, the inhibitory effect of DEX on NTHi-induced inflammatory response is significantly attenuated in mice lacking IRAK-M. Thus, we propose that IRAK-M is a novel functional target of GCs for suppression of bacteria-induced inflammation.

In the present study, we provided experimental evidence for a novel anti-inflammatory mechanisms by which GCs suppress inflammation via the cooperative upregulation of IRAK-M by the GR and NF-κB. This finding may be of particular significance as it contradicts a widespread assumption that GCs exert their anti-inflammatory effects principally by antagonizing NF-κB activity. If extended to other models of inflammatory diseases, our study may have significant translational implications for design of novel anti-inflammatory agents. Previous studies have predominantly focused on understanding the GC-mediated anti-inflammatory actions through the inhibition of positive regulators such as NF-κB and AP-1. Although it has been shown that GCs suppress inflammation by targeting more distal regulators such as IkBα or MKP-1 (refs 37–39), the role of GCs in regulating more proximal and central regulators of inflammation, such as the key bottleneck proteins MyD88 and IRAK1/4, remains unknown. Recently, systematic approaches revealed that MyD88 is a non-redundant core element. Owing to GCs’ prominence among anti-inflammatory agents, it is logical that GCs may target MyD88-IRAK1/4 to tightly control inflammation. Thus, our study provides novel insight into the tight regulation of MyD88 and IRAK1/4 via modulating the endogenous inhibitor IRAK-M by GCs.

GR has been shown to suppress inflammatory responses via the inhibition of p65-induced transcription. A recent genome-wide study revealed that GR and p65 mutually enhance their binding to a specific promoter. The regulation of p65- and GR-associated transcription is likely gene specific. Despite previous studies showing that the expression of IRAK-M is induced by inflammatory stimuli in macrophages and osteoblasts, the precise molecular mechanism of IRAK-M regulation at the transcriptional level remains to be understood. We demonstrated that the co-treatment of cells with both NTHi and GCs leads to the synergistic binding of p65 and GR to the IRAK-M promoter. Interestingly, NTHI- and GR-induced binding of p65 to the IRAK-M promoter is inhibited by the GR antagonist, RU486 (Fig. 6h). Consistently, previous studies, our data suggest that both p65 and GR synergize with each other to bind to the IRAK-M promoter. These data suggest a novel regulatory mechanism for IRAK-M promoter activity. Future studies investigating how the p65-GR complex activates IRAK-M transcription may lead to a better understanding of the elaborate interplay between bacteria and GCs.

Initially, IRAK-M expression was predominantly characterized in monocytes/macrophages. Recently, it has been shown that during respiratory infections, IRAK-M is expressed and induced, not only in alveolar macrophages, but also in respiratory epithelial cells. In the present study, we found that GCs synergize with NTHi to induce IRAK-M expression in both respiratory epithelial cells and alveolar macrophages in vitro and in vivo. Importantly, GCs are unable to suppress the NTHi-induced upregulation of proinflammatory mediators in IRAK-M-depleted lung epithelial cells as well as IRAK-M-deficient alveolar macrophages. Our findings are in line with previous studies demonstrating the expression of IRAK-M in non-myeloid cells including epithelial cells. Thus, it is likely that IRAK-M expressed in both respiratory epithelial cells and macrophages are involved in mediating the ability of GCs to suppress inflammation induced by the respiratory bacterial pathogen, NTHi. It should be noted that our study did not exclude the involvement of other cell types. Future studies using conditional knockout mice with tissue-/cell type-specific deletion of IRAK-M may help determine the contribution of cell-specific induction of IRAK-M expression.

IRAK-M has been shown to act as a critical negative regulator for inflammatory responses. In line with previous findings in pneumonia models, we observed elevated inflammatory responses in the lung of IRAK-M-deficient mice compared with WT mice. We found that GCs suppressed the NTHi-induced inflammation and significantly improved the survival rate in WT mice but not in IRAK-M-deficient mice (Fig. 4f). Interestingly, no statistically significant difference in survival rate was found between DEX-untreated WT and IRAK-M-deficient mice although IRAK-M-deficient mice show a trend of better survival.
survival. Our finding is consistent with a recent study showing a reduced lethality in IRAK-M-deficient mice after infection with S. pneumoniae via the airway. Given that the markers of inflammation are indeed elevated in IRAK-M-deficient mice, it is unclear why IRAK-M-deficient mice did not show an increased mortality. Although the current study does not provide a clear explanation for this apparent anomaly, our preliminary finding on the negative role of IRAK-M in bacteria-induced mucus production may provide possible explanations for this difference. Recently, there is an increasing evidence suggesting that the host has the ability to reduce the tissue damage caused directly by both pathogens and immunopathology through the enhancement of tolerance mechanisms, thus improving host survival. IRAK-M may act as a negative regulator for NTHI-induced host tolerance. Indeed, our preliminary studies revealed that IRAK-M is also a negative regulator for bacteria-induced mucus production, an important mucosal defense mechanism for protecting the host from inflammation- and pathogen-induced tissue damage. Thus, IRAK-M-deficiency results in, not only overactive inflammation, but also increased mucus, which may appear counteractive. This disparity may explain why IRAK-M-deficient mice did not show an increased mortality. Future studies using mice deficient in mucus production may help to further address this question.

In conclusion, our studies unveil a novel mechanism by which GCs suppress bacteria-induced innate immune and inflammatory responses by upregulating IRAK-M. Our study provides new insights into the previously unidentified role of GCs in suppressing inflammation by targeting the central bottleneck proteins MyD88 and IRAK1/4. It may also lead to the development of new therapeutic strategies to control overactive inflammation.

Methods

Reagents and antibodies. DEX, Mifepristone (RU486) and Actinomycin D were purchased from Sigma-Aldrich. Compound A was purchased from Enzo Life Sciences. IKK2 inhibitor IV was purchased from EMD Millipore. Antibodies: GR (sc-8992), p65 (sc-8008, sc-372, sc-109), IRAK-M (sc-100389), a-Tubulin (sc-69986), β-actin (sc-4325), F4/80 (sc-26642), E-cadherin (sc-3120), Donkey anti-rabbit IgG-FITC (sc-2090) and bovine anti-rabbit IgG-TR (sc-2765) were purchased from Santa Cruz Biotechnology, IRAK-M (#2355) from ProSci, anti-rabbit HRP-linked antibody (#7074) and anti-mouse HRP-linked antibody (#7076) were from Cell Signaling. siRNAs; GR (cat# L00424-00-005), ON-TARGET plus Human NR3C1 (2908)-SMARTpool, p65 (cat# L003533-00-005), ON-TARGET plus Human RELA (5975)- SMARTpool and the control siRNA (cat# D-001810-10-05) were from Thermo Scientific Dharmacon, IRAK-M (IRAK3 (ID 11213) cat# SR307690) and control siRNA (cat# SR30004) were from OriGene.

Mice and animal experiments. Inbred C57BL/6 J mice were used as WT controls. For investigation of the NTHI-induced inflammation in mice, anaesthetized mice were intratracheally inoculated with NTHI at a concentration of 1 × 10^7 to 5 × 10^8 c.f.u. per mouse and saline was inoculated as control. The inoculated mice were then killed after NTHI inoculation. For PMN analysis, BAL fluid was collected by cannulating the trachea with sterilized PBS in mice followed by staining with Diff-Quik staining system (modified Giemsa staining). For isolation of macrophages, we collected BAL fluid with 3 ml sterilized PBS. After centrifuge the BAL fluid, macrophages were purified by percoll gradient separation (Amersham Pharmacia Inc.). For inhibition study, mice were pretreated with DEX (1 mg kg⁻¹) intraperitoneally 2 h before NTHI inoculation. All animal experiments were approved by the Institutional Animal Care and Use Committee (IACUC) at Georgia State University.

Histology and immunostaining. For histological analysis, formalin-fixed paraffin-embedded lung tissues were sectioned (4 μm) and then stained with haematoxylin and eosin to visualize inflammatory responses and pathological changes in the lung. The stained sections were then imaged and recorded under light systems (AxioVert 40 CFL, Axiocam MRc, and AxioVision LE Image system, Carl Zeiss). The detection of IRAK-M protein was performed using rabbit anti-IRAK-M (ProSci, 2 μg ml⁻¹) for Immunohistochemistry, 10 μg ml⁻¹ for Immunofluorescence and Donkey anti-rabbit-FITC (Santa Cruz Biotechnology, 5 μg ml⁻¹) in the paraffin section of mouse lung tissue. Blocking IRAK-M peptide (ProSci, cat# 2355 P, 25 μg ml⁻¹) was used for the negative control experiments. Epithelial cells and macrophages were recognized by antibodies of anti-E-cadherin (Santa Cruz Biotechnology, 10 μg ml⁻¹) and anti-Ly6/80 (Santa Cruz Biotechnology, 10 μg ml⁻¹), respectively and followed by bovine anti-goat TR (Santa Cruz Biotechnology, 8 μg ml⁻¹) incubation. Immuno localization in haematoxylin and eosin staining (Grade; 0 to 3) and IRAK-M protein expression intensity score in immunostaining (Grade; 0 to 4) were validated in a blinded fashion.

Bacterial culture. NTHI strain 12 (also known as R2095) used in this study was a clinically isolated strain that was kindly provided by H. Faden (Children's Hospital of Buffalo, State University of New York, Buffalo, NY). NTHI were grown on chocolate agar plate at 37 °C in an atmosphere of 5% CO₂ overnight and inoculated in brain heart infusion broth supplemented with 3.5 μg ml⁻¹ NAD and haemoglobin (BD Biosciences). After overnight incubation, bacteria were subcultured into fresh brain heart infusion and the log phase NTHI, monitored by measurement of optical density (OD600) value, was washed and suspended in DMEM for in vitro experiments and in isotonic saline for in vivo animal experiments.

Cell culture. All media described below were supplemented with 10% fetal bovine serum (Sigma-Aldrich). Human airway epithelial A549 cells were maintained in F-12 K media (Gibco), BEAS-2B cells in RPMI 1640 media (Gibco). BEAS-2B cells stably expressing human IRAK-M were obtained by plasmid transfection following generation selection (300 μg ml⁻¹). Human primary bronchial epithelial (Lonza) cells were maintained in BEGM (bronchial epithelial growth media) supplemented with BEGM SingleQuots. Human peripheral blood CD14 + monocytes (Lonza) were cultured in RPMI 1640 media (Gibco) containing 1 mM pyruvate and GM-CSF (50 ng ml⁻¹) and re-suspended (50 ng ml⁻¹) in DMEM for 2 h before incubation with 10 μg ml⁻¹ MIF. CD14 + monocytes were obtained from E18 embryos and maintained in DMEM (Corning Cellgro). p65⁻/⁻ / MEFs reconstituted with p65 WT were cultured in DMEM (Corning Cellgro) containing pyruconium (1.5 μg ml⁻¹). All cells were cultured in a humidified atmosphere of 5% CO₂ at 37 °C.

Real-time quantitative RT-PCR analysis. Total RNA was isolated with TRIzol reagent (Invitrogen, Carlsbad, CA) following the manufacture's protocol. The reverse transcription reaction was performed by using 1 μg of RNA in 25 μl of reaction buffer of TaqMan reverse transcription reagents (Applied Biosystems) and run under the following protocol: 25 °C for 10 min, 42 °C for 1 h and 95 °C for 5 min (refs 29,58–60). PCR was performed by using Fast SYBR Green Master Mix (Life Technologies). In brief, the reactions were performed in triplicate containing 2 x Universal Master Mix, 1 μl of template cDNA, 400 nM primers in a final volume of 12.5 μl and they were analysed in a 96-well optical reaction plate (Applied Biosystems). Reactions were amplified under the following protocol: 95 °C for 20 s followed by 40 cycle of 95 °C for 3 s and 60 °C for 30 s and quantified by using StepOnePlus Real-Time PCR System and the manufacturer’s corresponding software (StepOnePlus Software v2.3; Applied Biosystems). The relative quantities of mRNAs were obtained by using the comparative Ct method and were normalized using human cyclophilin or mouse glyceraldehyde-3-phosphate dehydrogenase as an endogenous control. The primers are described in Supplementary Table 1.

Plasmids and transfections. The expression plasmid of a constitutively active form of IkBα (IKKβ-CA, S73A,S116E) was a gift from Dr Anjana Rao (Addgene plasmid # 11105) (ref. 61). The expression plasmid of p65 was cloned and the insert was transferred to pcDNA3.1 vector (Life Technologies) with BamHI and HindIII sites after we amplified the insert with primers shown in Supplementary Table 2. The luciferase reporter construct of NF-κB (BAC) P1223-IRAK3 was a template, which was a gift from Drs William Hahn and David Root (Addgene plasmid # 23627) (ref. 63). The insert was then transferred to pcDNA3.1 vector (Life Technologies) with XhoI and BamHI site after we amplified the insert with primers shown in Supplementary Table 2. For cloning of IRAK-M promoter, we used BAC clone RP11-937C6 (BACpac Resources Center, Children’s Hospital Oakland Research Institute) as a template. PCR was performed using primers shown in Supplementary Table 2. PCR products were transferred into pGL3 basic vector (Promega) with MluI and XhoI site. The sequences were verified at least from three cloning attempts. The WT and NF-κB mutants of IRAK-M promoter were constructed by using the QuikChange II site-directed mutagenesis kit (Agilent Technologies) with primers shown in Supplementary Table 2.

Western blot analysis. Western blots were performed using whole-cell extracts in protein lysis buffer (20 mM Tris-HCl (pH 7.4), 50 mM NaCl, 50 mM Na₂PO₄,
Chromatin immunoprecipitation. ChIP assay was performed with minor modifications of the previous study.34 The cells were crosslinked by incubation with 1% formaldehyde at room temperature for 10 min, followed by incubation with 0.125 M glycine for 5 min. Cells were washed twice with ice-cold PBS and lysed with cell lysis buffer (50 mM HEPES (pH 7.4), 1 mM EDTA, 85 mM KCl, 10% glycerol, 0.5% NP-40, supplemented with protease inhibitor cocktail). Nuclei was collected by centrifugation at 850 g for 5 min and suspended in Nuclei lysis buffer (50 mM Tris-HCl (pH 8.0), 2 mM EDTA, 150 mM NaCl, 5% glycerol, 1% Triton-X-100, 0.1% SDS, supplemented with protease inhibitor cocktail). The chromatin was sheared by sonication (Branson digital sonicator) to an average size 500 bp and precleared with Protein G PLUS-Agarose (Dynamabeads Protein G) for 2 h. The precleared chromatin was incubated with 5 μg of primary antibodies overnight at 4°C, followed by incubation with Protein G PLUS-Agarose or Dynabeads protein G for 2 h. The immunoprecipitates were washed twice with ChIP wash buffer II (20 mM Tris-HCl (pH 8.0), 500 mM NaCl, 1% Triton-X-100, 0.1% SDS, 2 mM EDTA), one time with ChIP wash buffer III (20 mM Tris-HCl (pH 8.0), 150 mM NaCl, 500 mM LiCl, 0.1% NP40, 1% deoxycholate, 1 mM EDTA) and two times with TE buffer (10 mM Tris-HCl (pH 8.0), 1 mM EDTA). The precipitated chromatin complexes were eluted in elution buffer (1% SDS, 0.1 M NaHCO3) at room temperature for 5 min and suspended with vortex every 5 min. After reverse crosslink at 65°C for 3 h, protein digestion with Proteinase K (Thermo Scientific) at 55°C for 3 h, DNA was isolated using MinElute PCR purification kit (Qiagen) with 30 μl elution with PureUltra DNAase/RNase-Free Distilled Water (Life Technologies). PCR was performed with primers shown in Supplementary Table 2.

Re-ChIP. Re-ChIP assay was performed as described previously.24 In brief, crosslinking was performed using 2 mM dithiothreitol (Thermo Scientific) for 45 min followed by 1% formaldehyde for 10 min at room temperature. After the first IP, immune complexes were eluted in Re-ChIP elution buffer (10 mM Tris-HCl (pH 8.0), 2 mM EDTA, 2% SDS, 15 mM DTT) including protease inhibitor cocktail at room temperature for 30 min. The elution was diluted 20 times with ChIP dilution buffer (16.7 mM Tris-HCl (pH 8.0), 167 mM NaCl, 1.2 mM EDTA, 1.1% Triton-X) supplemented with protease inhibitor cocktail, 100 μg/ml bovine serum albumin, 100 μg/ml salmon sperm DNA, followed by second IP. The second IP samples were washed, eluted and purified as described above ChIP procedure. PCR was performed with 1 μl purified DNA by using Primestar Max DNA polymerase (Takara) with primers IRAK-M – 300 bp forward and IRAK-M 0 bp reverse shown in Supplementary Table 2.

Statistical analysis. Data are shown as mean ± s.d. Statistical analysis was assessed by t-test. P < 0.05 was considered statistically significant.
