Measurement of b-hadron masses

LHCb Collaboration; Anderson, J; Bernet, R; Büchler-Germann, A; Bursche, A; Chiapolini, N; De Cian, M; Serra, N; Steinkamp, O; Straumann, D; Vollhardt, A; van Tilburg, J; Elsasser, C

Abstract: Measurements of b-hadron masses are performed with the exclusive decay modes $B^+ \rightarrow J/\psi K^+$, $B_0 \rightarrow J/\psi K^0$, $B_0^* \rightarrow J/\psi \phi$, $B_0^* \rightarrow J/\psi \Lambda_b$ using an integrated luminosity of $35 \pm 1 \text{ pb}^{-1}$ collected in pp collisions at a centre-of-mass energy of $7 \text{ TeV}$ by the LHCb experiment. The momentum scale is calibrated with $J/\psi \rightarrow \mu^+ \mu^-$ decays and verified to be known to a relative precision of $2 \times 10^{-4}$ using other two-body decays. The results are more precise than previous measurements, particularly in the case of the $B_0^*$ and $\Lambda_b$ masses.

Measurement of $b$-hadron masses

The LHCb Collaboration

Abstract

Measurements of $b$-hadron masses are performed with the exclusive decay modes $B^+ \rightarrow J/\psi K^+$, $B^0 \rightarrow J/\psi K^{*0}$, $B^0 \rightarrow J/\psi K_S^0$, $B^0_s \rightarrow J/\psi \phi$ and $\Lambda^0_b \rightarrow J/\psi \Lambda$ using an integrated luminosity of 35 pb$^{-1}$ collected in $pp$ collisions at a centre-of-mass energy of 7 TeV by the LHCb experiment. The momentum scale is calibrated with $J/\psi \rightarrow \mu^+ \mu^-$ decays and verified to be known to a relative precision of $2 \times 10^{-4}$ using other two-body decays. The results are more precise than previous measurements, particularly in the case of the $B^0_s$ and $\Lambda^0_b$ masses.

1 Introduction

Within the Standard Model of particle physics, mesons and baryons are colourless objects composed of quarks and gluons. These systems are bound through the strong interaction, described by quantum chromodynamics (QCD). A basic property of hadrons that can be compared to theoretical predictions is their masses. The most recent theoretical predictions based on lattice QCD calculations can be found in Refs. [1, 2]. The current experimental knowledge of the $b$-hadron masses as summarized in Ref. [3] is dominated by results from the CDF collaboration [4]. In this Letter precision measurements of the masses of the $B^+$, $B^0$, $B^0_s$ and $\Lambda_b$ are presented as well as the mass splittings with respect to the $B^+$. The results are based on a data sample of proton-proton collisions at $\sqrt{s} = 7$ TeV at the Large Hadron Collider collected by the LHCb experiment, corresponding to an integrated luminosity of 35 pb$^{-1}$.

The LHCb detector [5] is a forward spectrometer providing charged particle reconstruction in the pseudorapidity range $2 < \eta < 5$. The most important elements for the analysis presented here are precision tracking and excellent particle identification. The tracking system consists of a silicon strip vertex detector (VELO) surrounding the $pp$ interaction region, a large area silicon strip detector located upstream of a dipole magnet with a bending power of about 4 Tm, and a combination of silicon strip detectors and straw drift-tubes placed downstream. The combined tracking system has a momentum resolution $\delta p/p$ that varies from 0.4% at 5 GeV/c to 0.6% at 100 GeV/c. Pion, kaon and proton separation is provided by two ring imaging Cherenkov (RICH) detectors whilst muons are identified by a muon system consisting of alternating layers of iron and multi-wire proportional chambers.

The data used for this analysis were collected in 2010. The trigger system consists of two levels. The first stage is implemented in hardware and uses information from the calorimeters and the muon system. The second stage is implemented in software and runs on an event filter farm. Dedicated trigger lines collect events containing $J/\psi$ mesons. For this analysis all events are used regardless of which trigger line fired.

Simulation samples used are based on the PYTHIA 6.4 generator [6] configured with the parameters detailed in Ref. [7]. QED final state radiative corrections are included using the PHOTOS package [8]. The EVTGEN [9] and GEANT4 [10] packages are used to generate hadron decays and simulate interactions in the detector, respectively.

The alignment of the tracking system, as well as the calibration of the momentum scale based on the $J/\psi \rightarrow \mu^+\mu^-$ mass peak, were carried out in seven time periods corresponding to different running conditions. The procedure takes into account the effects of QED radiative corrections which are important in the $J/\psi \rightarrow \mu^+\mu^-$ decay. Figure 1 shows that the reconstructed $J/\psi$ mass after alignment and calibration is stable in time to better than 0.02% throughout the data-taking period. The validity of the momentum calibration has been checked using samples of $K_S^0 \rightarrow \pi^+\pi^-$, $D^0 \rightarrow K^-\pi^+$, $D^0 \rightarrow K^+\pi^-$, $\psi(2S) \rightarrow \mu^+\mu^-$, $\Upsilon(1S) \rightarrow \mu^+\mu^-$ and $\Upsilon(2S) \rightarrow \mu^+\mu^-$ decays. In each case the mass distribution is modelled taking into account the effect of radiative corrections, resolution and background, and the mean mass value extracted. To allow comparison between the
Figure 1: Reconstructed $J/\psi \rightarrow \mu^+\mu^-$ fitted mass as a function of run number after the momentum calibration procedure discussed in the text. The vertical dashed lines indicate the boundaries of the seven calibration periods. A fit of a constant function (horizontal line) has a $\chi^2$ probability of 6%. The shaded area corresponds to the assigned uncertainty on the momentum scale of 0.02\%.

Figure 2: Momentum scale bias $\alpha$, extracted from the reconstructed mass of various two-body decays after the momentum calibration procedure described in the text. By construction one expects $\alpha = 0$ for the $J/\psi \rightarrow \mu^+\mu^-$ calibration mode. The black error bars represent the statistical uncertainty whilst the (yellow) shaded areas include contributions to the systematic error from the fitting procedure, the effect of QED radiative corrections and the uncertainty quoted by the PDG [3] on the mass of the decaying meson. The (red) dashed lines correspond to the assigned uncertainty on the momentum scale of 0.02\%.

decay modes, the deviation of the measured mass from the expected value [3] is converted into an estimate of the momentum scale bias, referred to as $\alpha$. This is defined such that the measured mass is equal to the expected value if all particle momenta are multiplied by $1 - \alpha$. Figure 2 shows the resulting values of $\alpha$. The deviation for the considered modes is $\pm 0.02\%$, which is taken as the systematic uncertainty on the momentum scale.
2 Event selection

A common strategy, aiming at high signal purity, is adopted for the reconstruction and selection of $B^+ \rightarrow J/\psi K^+$, $B^0 \rightarrow J/\psi K^{*0}$, $B^0 \rightarrow J/\psi K_S^0$, $B_s^0 \rightarrow J/\psi \phi$ and $\Lambda^0 \rightarrow J/\psi \Lambda$ candidates (the inclusion of charge-conjugated modes is implied throughout). In general, only tracks traversing the whole spectrometer are used; however, since $K_S^0$ and $\Lambda$ particles may decay outside of the VELO, pairs of tracks without VELO hits are also used to build $K_S^0$ and $\Lambda$ candidates. The $\chi^2$ per number of degrees of freedom ($\chi^2$/ndf) of the track fit is required to be smaller than four. The Kullback-Leibler (KL) distance $d = \sum (\log p - \log q)$ is applied on the particle associated with each track. To eliminate background, a requirement of $p_{T} > 1$ GeV/c is applied on the particle associated with the $J/\psi$ candidate. For final states including a $V^0$ ($K_S^0$ or $\Lambda$), an additional requirement of $L/\sigma_L > 5$ is made, where $L$ is the distance between the $b$-hadron and the $V^0$ decay vertex, and $\sigma_L$ is the uncertainty on this quantity.

Each $b$-hadron candidate is associated with the reconstructed $pp$ primary interaction vertex with respect to which it has the smallest impact parameter significance, and this significance is required to be less than five. As there is a large combinatorial background due to particles originating directly from the $pp$ primary vertex, only $b$-hadron candidates with a reconstructed decay time greater than 0.3 ps are considered for subsequent analysis. A decay chain fit [12] is performed for each candidate, which constrains the reconstructed $J/\psi$ mass and, if applicable, the reconstructed $K_S^0$ or $\Lambda$ mass to their nominal values [3]. The $\chi^2$/ndf of the fit is required to be smaller than five. The mass of the $b$-hadron candidate is obtained from this fit and its estimated uncertainty is required to be smaller than 20 MeV/c$^2$. 

毎の$b$-hadron キャンデイトは、そのノイズが最も小さい発生粒子のインパクトパラメーターの重要性をもとに再構成されるppの主相互作用ビンチから関連付けられ、その重要性が五未満であることが要求されます。存在する大きなコンビネーションバックグラウンドは、ppの主相互作用ビンチから直接発生する粒子によって発生するため、$b$-hadron キャンデイトの再構成の崩れ時間が0.3 ps以上である場合に考慮されます。各キャンドイドに対して、再構成された$J/\psi$の質量に制限をかけ、$K_S^0$や$\Lambda$の質量が他们的名義値に一致する場合に、$\chi^2$/ndfのフィットは五未満であることが要求されます。フィットから$b$-hadron キャンデイトの質量はこのフィットから得られると、その推定誤差は五未満であることが必要です。
Table 1: Signal yields, mass values and mass resolutions obtained from the fits shown in Fig. 3 together with the values corrected for the effect of QED radiative corrections as described in the text. The quoted uncertainties are statistical.

| Decay mode | Yield       | Fitted mass [MeV/c²] | Corrected mass [MeV/c²] | Resolution [MeV/c²] |
|------------|-------------|----------------------|-------------------------|---------------------|
| B⁺ → J/ψK⁺ | 11151 ± 115 | 5279.24 ± 0.11       | 5279.38 ± 0.11          | 10.5 ± 0.1         |
| B⁰ → J/ψK*⁰ | 3308 ± 65   | 5279.47 ± 0.17       | 5279.58 ± 0.17          | 7.7 ± 0.2          |
| B⁰ → J/ψK³       | 1184 ± 38   | 5279.58 ± 0.29       | 5279.58 ± 0.29          | 8.6 ± 0.3          |
| Bˢ → J/ψφ      | 816 ± 30    | 5366.90 ± 0.28       | 5366.90 ± 0.28          | 7.0 ± 0.3          |
| Λ⁰ → J/ψΛ      | 279 ± 19    | 5619.19 ± 0.70       | 5619.19 ± 0.70          | 9.0 ± 0.6          |

3 Results

The b-hadron masses are determined by performing unbinned maximum likelihood fits to the invariant mass distributions, in which the signal and background components are described by a Gaussian and an exponential function, respectively. Alternative models for both the signal and background components are considered as part of the systematic studies. Figure 3 shows the invariant mass distributions and fits for the five modes considered in this study. The signal yields, mass values and resolutions resulting from the fits are given in Table 1.

The presence of biases due to neglecting QED radiative corrections in the mass fits is studied using a simulation based on Photos [8]. The fitted masses quoted in Table 1 for the B⁺ → J/ψK⁺ and B⁰ → J/ψK*⁰ are found to be underestimated by 0.14 ± 0.01 MeV/c² and 0.11 ± 0.01 MeV/c², respectively, when radiative corrections are ignored; they are therefore corrected for these biases, and the uncertainty is propagated as a systematic effect. The bias for the Bˢ → J/ψφ mode is negligible due to the restricted phase space for the kaons from the φ decay. There is no bias for the B⁰ → J/ψK³ and Λ⁰ → J/ψΛ modes since the J/ψ, K³ and Λ masses are constrained in the vertex fits.

4 Systematic studies and checks

To evaluate the systematic error, the complete analysis is repeated (including the track fit and the momentum scale calibration when needed), varying within their uncertainties the parameters to which the mass determination is sensitive. The observed changes in the central values of the fitted masses relative to the nominal results are then assigned as systematic uncertainties.

The dominant source of uncertainty is the limited knowledge of the momentum scale. The mass fits are repeated with the momentum scale varied by ±0.02%. After the calibration procedure a ±0.07% variation of the momentum scale remains as a function of the particle pseudorapidity η. To first order the effect of this averages out in the mass
determination. The residual impact of this variation is evaluated by parameterizing the
momentum scale as a function of $\eta$ and repeating the analysis. The amount of material
traversed in the tracking system by a particle is known to 10% accuracy [13]; the mag-
nitude of the energy loss correction in the reconstruction is therefore varied by 10%. To
ensure the detector alignment is well understood a further test is carried out: the horizon-
tal and vertical slopes of the tracks close to the interaction region, which are determined by measurements in the VELO, are changed by $1 \times 10^{-3}$, corresponding to the precision with which the length scale along the beam axis is known [14]. Other uncertainties arise from the fit modelling: a double Gaussian function (with common mean) for the signal resolution and/or a flat background component are used instead of the nominal Gaussian and exponential functions. The effect of possible reflections due to particle mis-identification is small and can be neglected. Finally, a systematic uncertainty related to the evaluation of the effect of the radiative corrections is assigned. Tables 2 and 3 summarize the systematic uncertainties assigned on the measured masses and mass differences.

The stability of the measured $b$-hadron masses is studied by dividing the data samples according to the polarity of the spectrometer magnet, final state flavour (for modes where the final state is flavour specific), as well as whether the $K_S^0$ and $\Lambda$ daughter particles have VELO hits. As a cross-check the analysis is repeated ignoring the hits from the tracking station before the magnet. This leads to an average shift in measured masses compatible with statistical fluctuations. In addition, for the $B^+$ and $B^0$ modes where the event samples are sizable, the measurements are repeated in bins of the $b$-hadron kinematic variables. None of these checks reveals a systematic bias.

## 5 Conclusions

The $b$-hadron masses are measured using data collected in 2010 at a centre-of-mass energy of $\sqrt{s} = 7$ TeV. The results are

$$
M(B^+ \rightarrow J/\psi K^+) = 5279.38 \pm 0.11 \text{ (stat)} \pm 0.33 \text{ (syst)} \text{ MeV}/c^2 , \\
M(B^0 \rightarrow J/\psi K^{*0}) = 5279.58 \pm 0.15 \text{ (stat)} \pm 0.28 \text{ (syst)} \text{ MeV}/c^2 , \\
M(B^0_s \rightarrow J/\psi \phi) = 5366.90 \pm 0.28 \text{ (stat)} \pm 0.23 \text{ (syst)} \text{ MeV}/c^2 , \\
M(\Lambda^0_b \rightarrow J/\psi \Lambda) = 5619.19 \pm 0.70 \text{ (stat)} \pm 0.30 \text{ (syst)} \text{ MeV}/c^2 ,
$$

where the $B^0$ result is obtained as a weighted average of $M(B^0 \rightarrow J/\psi K^{*0}) = 5279.58 \pm 0.17 \pm 0.27 \text{ MeV}/c^2$ and $M(B^0 \rightarrow J/\psi K_S^0) = 5279.58 \pm 0.29 \pm 0.33 \text{ MeV}/c^2$ assuming all systematic uncertainties to be correlated, except those related to the mass model. The dominant systematic uncertainty is related to the knowledge of the average momentum scale of the tracking system. It largely cancels in the mass differences. We obtain

$$
M(B^0 \rightarrow J/\psi K^{*0}) - M(B^+ \rightarrow J/\psi K^+) = 0.20 \pm 0.17 \text{ (stat)} \pm 0.11 \text{ (syst)} \text{ MeV}/c^2 , \\
M(B^0_s \rightarrow J/\psi \phi) - M(B^+ \rightarrow J/\psi K^+) = 87.52 \pm 0.30 \text{ (stat)} \pm 0.12 \text{ (syst)} \text{ MeV}/c^2 , \\
M(\Lambda^0_b \rightarrow J/\psi \Lambda) - M(B^+ \rightarrow J/\psi K^+) = 339.81 \pm 0.71 \text{ (stat)} \pm 0.09 \text{ (syst)} \text{ MeV}/c^2 ,
$$

where the $B^0$ result is a combination of $M(B^0 \rightarrow J/\psi K^{*0}) - M(B^+ \rightarrow J/\psi K^+) = 0.20 \pm 0.20 \pm 0.12 \text{ MeV}/c^2$ and $M(B^0 \rightarrow J/\psi K_S^0) - M(B^+ \rightarrow J/\psi K^+) = 0.20 \pm 0.31 \pm 0.10 \text{ MeV}/c^2$ under the same hypothesis as above.

As shown in Table 4, our measurements are in agreement with previous measurements [3, 4]. Besides the difference between the $B^+$ and $B^0$ masses they are the most accurate to date, with significantly improved precision over previous measurements in the case of the $B^0_s$ and $\Lambda^0_b$ masses.
Table 2: Systematic uncertainties (in MeV/c^2) on the mass measurements.

Table 4: LHCb measurements, compared to both the best previous measurements and the results of a global fit to available $b$-hadron mass data [3]. The quoted errors include statistical and systematic uncertainties. All values are in MeV/c^2.

| Quantity                  | LHCb measurement | Best previous measurement | PDG fit |
|---------------------------|------------------|---------------------------|---------|
| $M(B^+)$                  | 5279.38 ± 0.35   | 5279.10 ± 0.55 [4]        | 5279.17 ± 0.29 |
| $M(B^0)$                  | 5279.58 ± 0.32   | 5279.63 ± 0.62 [4]        | 5279.50 ± 0.30 |
| $M(B^0_s)$                | 5366.90 ± 0.36   | 5366.01 ± 0.80 [4]        | 5366.3 ± 0.6  |
| $M(\Lambda_b^0)$         | 5619.19 ± 0.76   | 5619.7 ± 1.7 [4]          | –       |
| $M(B^0) - M(B^+)$         | 0.20 ± 0.20      | 0.33 ± 0.06 [15]          | 0.33 ± 0.06 |
| $M(B^0_s) - M(B^+)$       | 87.52 ± 0.32     | –                         | –       |
| $M(\Lambda_b^0) - M(B^+)$| 339.81 ± 0.72    | –                         | –       |

Acknowledgements

We would like to thank our colleague Adlène Hicheur who made, as a member of our collaboration, significant contributions to the tracking alignment algorithms and provided the first realistic version of the magnetic field map. He is currently unable to continue his work, and we hope that this situation will be resolved soon. We express our gratitude to our colleagues in the CERN accelerator departments for the excellent performance of the LHC. We thank the technical and administrative staff at CERN and at the LHCb institutes, and acknowledge support from the National Agencies: CAPES, CNPq, FAPERJ and FINEP (Brazil); CERN; NSFC (China); CNRS/IN2P3 (France); BMBF, DFG, HGF and MPG (Germany); SFI (Ireland); INFN (Italy); FOM and NWO (The Netherlands); SCSR (Poland); ANCS (Romania); MinES of Russia and Rosatom (Russia); MICINN, XuntaGal and GENCAT (Spain); SNSF and SER (Switzerland); NAS Ukraine (Ukraine); STFC (United Kingdom); NSF (USA). We also acknowledge the support received from the ERC under FP7 and the Region Auvergne.
