Abstract
We study certain functions arising in the context of the calculation of correlation functions of the XXZ spin chain and of integrable field theories related to various scaling limits of the underlying six-vertex model. We show that several of these functions that are related to linear integral equations can be obtained by acting with (deformed) difference operators on a master function $\Phi_1$. The latter is defined in terms of a functional equation and of its asymptotic behavior. Concentrating on the so-called temperature case, we show that these conditions uniquely determine the high-temperature series expansions of the master function. This provides an efficient calculation scheme for the high-temperature expansions of the derived functions as well.

1. Introduction

In [4, 6, 7, 10], an algebraic structure of the correlation functions of the XXZ model (or of the underlying six-vertex model) called factorization was identified in a rather general setting. It was shown that the correlation functions consist of an algebraic part and of a physical part. The algebraic part is determined by a set of operators $t^*, b, c, b^*, c^*$ which act on a space $W^{(\alpha)}$ of quasi-local operators. They do not depend on the physical parameters such as temperature, magnetic field, etc. The operators $b, c$ (annihilation operators) and $b^*, c^*$ (creation operators) are two pairs of Fermi operators satisfying characteristic anti-commutation relations. The creation operator $t^*$ is 'bosonic' and commutes with all Fermi operators. With the help of the creation operators, one can construct a ‘fermionic basis’ of the space of quasi-local operators. In contrast to the algebraic part, the physical part depends on the physical parameters and is represented by two transcendental functions $\rho$ and $\omega$.

The proof of the factorization in [10] covers the rather general case of a six-vertex model which is finite in the vertical, so-called Matsubara direction and carries arbitrary inhomogeneity parameters on the horizontal lines. The proof is based on the properties of the fermionic and bosonic operators. It also relies on a generalization of the density matrix (denoted as $Z^*$ in
Abelian integrals of the second kind. The transcendental functions $\rho$ in particular, taking the scaling limits $\rho$ on a lattice with cylindrical topology and with creation operators inserted. This involves, in function of correlation functions of the XXZ model, which is realized as a six-vertex model\(\text{2}\)). Such a 'normalization condition' for their $q$-deformed Abelian integrals of the second kind.

In\[2\], we suggested an alternative description of the function $\omega$ by means of the solutions of certain linear and nonlinear integral equations. We also proved the equivalence of this description and the one suggested in \[10\]. In \[3\], we discussed some properties of those integral equations in the case of finite temperature. The normalization condition for $\omega$ turned out to be a consequence of the integral equations for the auxiliary functions $a$ and $G$ introduced in \[2, 8, 15, 16\]. An important point in \[3\] was to introduce the 'dressed charge' $\sigma$ which, like the function $G$, fulfills a linear integral equation. Using Baxter's TQ-relation, it appeared to be possible to find a solution to this equation in 'explicit form' in terms of the ratio $\Phi$ of eigenvalues of two $Q$-operators with different twist parameters.

In our recent works \[1, 5\], we studied the scaling limit toward CFT on a cylinder. We conjectured that the creation operators $t^*, b^*, c^*$ have well-defined scaling limits $\tau^*, \beta^*, \rho^*$. We could identify the states generated by their action on the vacuum with the Virasoro module of the CFT descendant states up to level 6. This identification was achieved by considering the three-point CFT correlators on the cylinder with a descendant field $P^d(1 - \eta)\phi_d(0)$ at the origin and two asymptotic 'edge'-fields $\phi_\kappa(\infty)$ and $\phi_{-\kappa}(-\infty)$ at $\pm\infty$ or their descendants, where the primary field $\phi_\kappa$ has the conformal dimension $\Delta_\kappa = v^2\alpha(\alpha - 2)/(4(1 - \nu))$. On the other hand, we took the scaling limit of the determinant formula derived in \[10\] for the generating function of correlation functions of the XXZ model, which is realized as a six-vertex model on a lattice with cylindrical topology and with creation operators inserted. This involves, in particular, taking the scaling limits $\rho^{\kappa}$ and $\omega^{\kappa}$ of $\rho$ and $\omega$. Comparing the coefficients of the asymptotic expansions at a large spectral parameter, we could perform the above identification. Unfortunately, this was possible only in a weak sense, i.e. modulo integrals of motion.

Let us further comment on the latter point, because it is of particular importance for the motivation of this paper. First, we considered the six-vertex model at a finite disorder parameter $\alpha$ and magnetic field $\kappa$ which also plays the role of a twist or flux parameter. In fact, in order to determine the correlation functions on the lattice in such a way that they have appropriate scaling limits, we also needed to introduce some kind of 'lattice screening operators' that change the spin by some number $s$. Then we came to a picture in which the twist parameter on the 'left' edge of the cylinder is $\kappa$ and on the 'right' edge $\kappa' = \kappa + 2s(1 - \nu)/\nu$, where $\nu$ is related to the deformation parameter $q = e^{i\pi s}$.

We argued that $\kappa'$ becomes an independent variable in the scaling limit. Thus, expectation values of quasi-local operators turn into three-point functions of two independent primary fields at $\pm\infty$ and a descendant field at 0 as was pointed out above. When $\kappa' = \kappa$, it follows that $\rho = \rho^{\kappa} = 1$, and the integrals of motion do not contribute. In this case, we managed to develop (see \[1, 5\]) a technique for the calculation of the coefficients in the asymptotic expansion of the function $\omega^{\kappa}$ based on Wiener–Hopf factorization.

The problem is how to extend this to the general case $\kappa' \neq \kappa$ and $\rho \neq 1$. It seems that we have to develop a new technique here. This work is the first attempt in this direction. We consider the temperature case, where the high-temperature expansion is a powerful tool to generate explicit results.

We shall take up some ideas of \[3\], where we studied the properties of linear integral equations, like the one for the dressed charge $\sigma$, using the above mentioned function $\Phi$ in...
the temperature case. The idea elaborated below is to introduce a generalized function \( \Phi \) of two arguments in such a way that it satisfies a functional relation which involves the original function \( \Phi_1 \) of one argument. Inserting the high-temperature expansions of the two functions, we see that the expansion coefficients of the new function are recursively determined by those of the old function. This provides an efficient scheme to calculate them on a computer.

We also consider the calculation schemes for the coefficients in the high-temperature expansions of the resolvent \( R \), the function \( G \), its dual \( \overline{G} \) and the function of our main interest \( \omega \). We find that they are all connected to our new function \( \Phi_1 \) in a simple way:

\[
R(\xi, \xi') = -\frac{1}{2\pi i} \Delta \Delta_1 \Phi(\xi, \xi'), \quad \frac{1}{4} \omega(\xi, \xi') = H_\xi H_{\xi'} \Phi(\xi, \xi'),
\]

\[
G(\xi, \xi') = \Delta H_\xi \Phi(\xi, \xi'), \quad \overline{G}(\xi, \xi') = -\frac{1}{2\pi i} H_\xi \Delta_1 \Phi(\xi, \xi'),
\]

where \( \Delta \) and \( H \) are certain difference operators defined in (2.10) and (2.31). These formulae are valid in general, in particular, in the temperature case and in the scaling limit. This is the main result of this paper. The function \( \Phi(\xi, \xi') \) has simpler analytic properties than the resolvent or the \( \omega \)-function and together with the function \( \rho \) contains the whole information that we need for the correlation functions. In this paper, we show how to calculate the high-temperature expansion of \( \Phi(\xi, \xi') \). For now this seems to be easier as compared to the problem of calculating the asymptotic expansions in the scaling limit. We do not need to use the Wiener–Hopf technique here. Still, we plan to obtain the asymptotic expansion of the \( \Phi \)-function in the scaling limit in our future work. Although our primary aim is CFTs, this may turn out to be useful in conjunction with the recent progress in the understanding of the massive integrable sine-Gordon theory \([11–14]\) as well.

The paper is organized as follows. In section 2, we recall some definitions from \([2, 3, 5]\) and introduce those objects that we need for further consideration. We also discuss the basic thermodynamic functions and the integral equations they fulfill. In section 3, we define the function \( \Phi(\xi) \) of one spectral parameter and recall how the ‘dressed charge’ \( \sigma \) can be expressed in terms of this function. We derive an equation for the coefficients of the high-temperature expansion of \( \Phi(\xi) \) which can be solved by iteration. In section 4, we generalize this method to solve the linear equation for the resolvent \( R(\xi, \xi') \). To this end, we introduce a function \( \Phi(\xi, \xi') \) which is a generalization of \( \Phi(\xi) \). We constitute lemma 4.1 on the representation of the resolvent in terms of the function \( \Phi(\xi, \xi') \) and obtain its high-temperature expansion. In section 5, we formulate lemma 5.1 comprising the above formulae representing the functions \( G, \overline{G} \) and \( \omega \) by the action of difference operators on \( \Phi(\xi, \xi') \). We also argue that these formulae are valid in general and not only in the temperature case. In the appendices, we prove lemmas 4.1 and 5.1 and show several lowest order coefficients of the high-temperature expansions of the above functions.

2. Basic objects and equations

2.1. Correlation functions and the functional \( Z^{s, \delta} \)

This work is about the properties of special functions arising in the context of the calculation of correlation functions of the XXZ chain and of conformal field theories. Before defining these functions we would like to briefly sketch the context. For more details, the reader is referred to \([5, 7, 10]\).

A correlation function is an expectation value of a local operator \( \mathcal{O} \), typically calculated as a thermal average by means of the statistical operator of, say, the canonical ensemble. Having in mind the scaling limits toward conformal and massive field theories, it is natural and useful
to generalize both the notion of a local operator and the notion of the statistical operator. Instead of local operators, so-called quasi-local operators with tail were introduced in [6, 7]. In these articles, the XXZ chain, a model of locally interacting spins, was considered on an infinite lattice. On such a lattice, the action of $S(k) = \frac{1}{2} \sum_{j=-\infty}^{\infty} \sigma_j^k$, where $\sigma^z$ is a Pauli matrix, makes sense. A quasi-local operator is an operator of the form $q^{2S(0)}O$, local, where $O$ is local.

Expectation values of local operators (of spin zero) can be defined by means of a functional

$$Z^{s,\epsilon}[q^{2S(0)}O] = \frac{\text{Tr}_S \text{Tr}_M \{ Y_M^{(s)} \text{Tr}_S q^{2S(\infty)} b_{-\infty,0}^{s} \cdots b_{-1,0}^{s} \} \{ q^{2S(0)}O \} }{\text{Tr}_S \text{Tr}_M \{ Y_M^{(s)} \text{Tr}_S q^{2S(\infty)} b_{-\infty,0}^{s} \cdots b_{-1,0}^{s} \} }$$

(2.1)

generalizing the canonical ensemble average of statistical mechanics. The ‘lattice screening operators’ $b_{-\infty,j}^{s}$, which are the coefficients in the expansion of the singular part of $b^s(\zeta)$ at $\zeta^2 = 0$, increase the spin of $O$ by $s$. This is compensated by the operator $Y_M^{(s)}$ at the boundary which carries the spin $-s$ and ensures that the ice rule of the six-vertex model is satisfied.

As was discussed in [5], functional (2.1) does not depend on the concrete choice of $Y_M^{(s)}$. The spin is needed as an additional parameter, necessary to exhaust the full space of descendants in the conformal limit.

The ‘thermodynamic properties’ of the average are determined by the monodromy matrix $T_{S,M}$ and the operator $q^{2S(\infty)}$. Mathematically, the monodromy matrix is defined by evaluating the universal $R$-matrix of $U_q(sl_2)$ on the tensor product of two evaluation representations $\delta_S$ and $\delta_M$. Both of them realize the space of states of a spin chain. With $\delta_S$ we associate an infinite chain and with $\delta_M$ a finite chain of length $N$,

$$T_{S,M} = \prod_{j=-\infty}^{\infty} T_{j,M}, \quad T_{j,M} \equiv T_{j,M}(1), \quad T_{j,M}(\zeta) = \prod_{m=1}^{\zeta_0} L_{j,m}(\zeta/\zeta_m).$$

Here the $\zeta_j \in \mathbb{C}$ are inhomogeneity parameters, and $L$ is the standard $L$-operator of the six-vertex model,

$$L_{j,m}(\zeta) = q^{-1/2} \zeta_j \sigma_m^z - \zeta \left(q^{-1} \sigma_m^z + \sigma_m^z \right).$$

Different physical realizations of the spin chain (e.g. finite temperature or finite length) can be realized by appropriate choices of the parameters $\xi_j$ and $\kappa$ [2]. These parameters are also at our disposal for realizing scaling limits toward CFT [5] or massive integrable quantum field theories [12–14].

For the direction of infinite extension of the lattice, one can change the boundary conditions and, instead of taking the traces on the right-hand side of (2.1), insert two one-dimensional projectors $|\zeta\rangle \langle \zeta|$ and $|\zeta + \alpha - s, s\rangle \langle \zeta + \alpha - s, s|$ at the boundary. Then

$$Z^{s,\epsilon}[q^{2S(0)}O] \rightarrow \frac{\langle \kappa + \alpha - s, s| T_{j,M} q^{2S(\infty)} b_{-\infty,0}^{s} \cdots b_{-1,0}^{s} (q^{2S(0)}O)|\kappa \rangle}{\langle \kappa + \alpha - s, s| T_{S,M} q^{2S(\infty)} b_{-\infty,0}^{s} \cdots b_{-1,0}^{s} (q^{2S(0)}O)|\kappa \rangle},$$

(2.2)

where $|\kappa\rangle$ is the eigenvector of the transfer matrix $T_M(\zeta, \kappa) = T_{j,M}(q^{2S(0)})$ with the maximal eigenvalue $T(\zeta, \kappa)$ in the spin-zero sector, and the eigenvector $|\kappa + \alpha - s, s\rangle$ corresponds to the maximal eigenvalue $T(\zeta, \kappa + \alpha - s, s)$ of the transfer matrix $T_M(\zeta, \kappa + \alpha - s)$ in the sector with spin $s$. In [5], we argued that the combination

$$\kappa' = \kappa + \alpha + 2 \frac{1-v}{v} s$$

(2.3)

becomes an independent parameter in the CFT scaling limit.

3 For the case $s < 0$, one can replace the operators $b_{-\infty,j}^{s}$ by $c_{-\infty,j}^{s}$ as in [14].

4 For $s \neq 0$, depending on the choice of the inhomogeneities, the eigenvalues may be generally degenerate. This is, however, irrelevant for our discussion below.
2.2. Functions $\rho$, $\omega$ and basic thermodynamic functions

In [7], the ‘fermionic basis’ described in the introduction was constructed. The creation operators $t^*$, $b^*$ and $c^*$ generate the space of quasi-local operators by acting on the pure tail $q^{2aS(0)}$ which plays the role of the Fock vacuum for these operators. Note that the creation operators are very special. Their most important property is their compatibility with the above-defined functional $Z^{\alpha,\beta}$ revealing itself in the following formulae proved in [10]:

$$
Z^{\alpha,\beta}[t^*(\xi)(X)] = 2\rho(\xi|\kappa + \alpha, s)Z^{\alpha,\beta}[X],
$$

$$
Z^{\alpha,\beta}[b^*(\xi)(X)] = \frac{1}{2\pi i} \oint_G \omega(\xi, \zeta|\kappa, \alpha, s)Z^{\alpha,\beta}[c(\xi)(X)] \frac{d\xi^2}{\xi^2},
$$

$$
Z^{\alpha,\beta}[c^*(\xi)(X)] = -\frac{1}{2\pi i} \oint_G \omega(\xi, \zeta|\kappa, \alpha, s)Z^{\alpha,\beta}[b(\xi)(X)] \frac{d\xi^2}{\xi^2}.
$$

(2.4)

Here the contour $\Gamma$ encircles all the singularities of the integrand except $\xi^2 = \zeta^2$. The functions $\rho$ and $\omega$ appearing in this theorem are in the center of interest of this work. We shall provide a precise definition below. They are fundamental for the description of all static correlation functions of the XXZ chain and its various scaling limits, since Wick’s theorem combined with (2.4) implies the determinant formula

$$
Z^{\alpha,\beta}[t^*(\xi^0_1)\cdots t^*(\xi^0_r)\cdot b^*(\xi^s_1)\cdots b^*(\xi^s_r)\cdot c^*(\xi^-_1)\cdots c^*(\xi^-_r)(q^{2aS(0)})]
$$

$$
= \prod_{i=1}^{\rho} 2\rho(\xi^0_i|\kappa + \alpha, s) \times \det(\omega(\xi^+_j|\zeta^-_j|\kappa, \alpha, s))_{j,i=1,\ldots,r}.
$$

(2.5)

From this formula, one can obtain any correlation function by Taylor expanding both sides and comparing coefficients, because the operators appearing on the left-hand side generate a basis of the space of quasi-local operators as was proved in [4].

The function $\rho$ in (2.4) is the ratio of two eigenvalues of the transfer matrix

$$
\rho(\xi|\kappa + \alpha, s) = \frac{T(\xi, \kappa + \alpha - s, s)}{T(\xi, \kappa)}.
$$

(2.6)

In the following, we shall replace it with

$$
\rho(\xi|\kappa, \kappa') = \frac{T(\xi, \kappa')}{T(\xi, \kappa)}
$$

(2.7)

and treat $\kappa'$ as a real parameter independent of $\alpha$ (which reappears below in the definition of $\omega$). As was explained in section 4 of [5], this replacement is possible and necessary in the CFT scaling limit.

For the function $\omega$, the following representation was originally obtained5 in [2] and then used in [5],

$$
\frac{1}{4} \omega(\xi, \zeta|\kappa, \kappa'; \alpha) = (f_{\text{left}} \star f_{\text{right}} + f_{\text{left}} \star R \star f_{\text{right}})(\xi, \zeta') + \omega_0(\xi, \zeta|\alpha).
$$

(2.8)

In the CFT scaling limit, the function $\omega(\xi, \zeta|\kappa, \kappa'; \alpha)$ is identical to $\omega(\xi, \zeta'|\kappa, \alpha, s)$ in (2.4) if (2.3) is fulfilled [5].

The definition of the functions entering into (2.8) is slightly involved. But they either derive from the elementary function

$$
\psi(\xi, \alpha) = \xi^\alpha \frac{\xi^2 + 1}{2(\xi^2 - 1)}
$$

(2.9)

5 In [2], we used a slightly different notation. In particular, up to some multiplier, the first two terms in the parentheses on the right-hand side of (2.8) were denoted by $\Psi$. 5
or from the functions appearing in the $TQ$-relation. For their definition, we shall also need the two difference operators

$$\Delta \Delta \zeta f(\zeta) = f(\zeta q) - f(\zeta q^{-1}), \quad \delta^{-1} f(\zeta) = f(\zeta q) - \rho(\zeta | \kappa, \kappa') f(\zeta).$$

Then

$$f_{\text{left}}(\zeta, \zeta', \alpha) = \frac{1}{2\pi i} \delta^{-1} \psi(\zeta / \zeta', \alpha), \quad f_{\text{right}}(\zeta, \zeta', \alpha) = \delta^{-1} \psi(\zeta / \zeta', \alpha)$$

and

$$\omega_0(\zeta, \zeta' | \alpha) = \delta^{-1} \Delta^{-1}_{\zeta} \Delta^{-1}_{\zeta'} \psi(\zeta / \zeta', \alpha),$$

where $\Delta^{-1}_{\zeta} \psi$ is defined as a principal-value integral

$$\Delta^{-1}_{\zeta} \psi(\zeta, \alpha) = -PV \int_{0}^{\infty} \frac{d\eta}{2\pi i} \frac{\psi(\eta, \alpha)}{2^\nu (1 + (\eta/\zeta) \tau)}, \quad \zeta^2 > 0, \quad -\frac{1}{\nu < \Re \alpha < 0.}$$

The function $R$ is the resolvent of a linear integral operator. For its definition, we introduce the kernels

$$K_{\alpha}(\zeta) = \frac{1}{2\pi i} \Delta \Delta \zeta \psi(\zeta, \alpha), \quad K(\zeta) = K_0(\zeta).$$

Then $R$ is defined by the integral equation

$$R - R \ast K_\alpha = K_\alpha.$$ 

Here and in (2.8) we used the notation

$$(f \ast g)(\zeta, \zeta') = \int_{\gamma} dm(\eta) f(\zeta, \eta) g(\eta, \zeta')$$

for the convolution. The ‘measure’ $dm$ is given as

$$dm(\eta) = \frac{d\eta}{\eta^2 \rho(\eta | \kappa, \kappa')(1 + a(\eta, \kappa))},$$

and the contour $\gamma$ is described below.

The auxiliary function $a(\zeta, \kappa)$ is defined by

$$a(\zeta, \kappa) = \frac{d(\zeta) Q(q\zeta, \kappa)}{a(\zeta) Q(q^{-1} \zeta, \kappa)},$$

where $Q(\zeta, \kappa)$ is the eigenvalue of the $Q$-operator (for the definition of the $Q$-operator, see section 3 of [5]). It satisfies Baxter’s $TQ$-equation

$$T(\zeta, \kappa) Q(\zeta, \kappa) = d(\zeta) Q(q\zeta, \kappa) + a(\zeta) Q(q^{-1} \zeta, \kappa),$$

where $q = \exp(\pi \nu i)$ and

$$a(\zeta) = \prod_{j=1}^{N} (1 - q \xi^2_j / \xi^2_j), \quad d(\zeta) = \prod_{j=1}^{N} (1 - q^{-1} \xi^2_j / \xi^2_j).$$

For our convenience, we assume $N$ to be even. The function $\xi Q(\zeta, \kappa)$ is a polynomial and, hence, is determined by its zeros $\xi_j$ (the Bethe roots) satisfying the Bethe ansatz equation

$$a(\zeta_j, \kappa) = -1, \quad j = 1, \ldots, N/2.$$ 

Instead of (2.17), one can use a nonlinear integral equation to characterize the auxiliary function $a$ [15, 16]. Its precise form depends on the position of the inhomogeneity parameters [2]. The nonlinear integral equation is particularly useful for numerical calculations, the calculation of the large-$N$ asymptotics and performing the limit $N \to \infty$ in the temperature case

$$\xi_{2j-1} = \exp(\pi \nu i / 2 - \beta / N), \quad \xi_{2j} = \exp(-\pi \nu i / 2 + \beta / N), \quad j = 1, \ldots, N/2.$$
In [5], we considered the conformal limit. In this paper, we deal with the temperature case with the inverse temperature \( \beta = T^{-1} \). Then, after taking the limit \( N \to \infty \), the nonlinear equation for the auxiliary function becomes

\[
\log(a(\zeta, \kappa)) = -2i\pi \nu \kappa - i\sin(\pi \nu)\beta e(\zeta) - \int_{\mathcal{V}} \frac{d\xi^2}{\xi^2} K(\zeta/\xi) \log(1 + a(\xi, \kappa)) \tag{2.21}
\]

with the ‘bare energy’ \( e(\zeta) = e(\exp \lambda) = \coth(\lambda) - \coth(\lambda + \pi \nu i) \). The contour \( \mathcal{V} \) in the complex \( \xi^2 \) plane encompasses the essential singularity at \( \xi^2 = 1 \), but the poles of the kernel at \( \xi = \zeta^{q\pm 1} \) are outside. In terms of the variable \( \mu = \log \xi \), it is depicted in [2] with the opposite integration direction. In the following, we assume \( \kappa \) and \( \nu \) to be real. This corresponds to the unphysical case of a purely imaginary magnetic field, but is convenient for our purpose of studying the function \( \omega \) by means of the high-temperature expansion.

\[2.3\) Functions \( G \) and \( \overline{G} \)

Originally the correlation functions in the temperature case for \( \alpha = 0 \) were represented by means of a function \( G \) introduced in [8, 9]. The generalization to \( \alpha \neq 0 \) was achieved in [2]. Using the above notation, we can define a generalized \( G \)-function and its ‘dual’ \( \overline{G} \) through the linear integral equations

\[
G(\zeta, \zeta' | \kappa, \kappa'; \alpha) = f_{\text{right}} + K_{\alpha} \ast G, \tag{2.22}
\]

\[
\overline{G}(\zeta, \zeta' | \kappa, \kappa'; \alpha) = f_{\text{left}} + \overline{G} \ast K_{\alpha}. \tag{2.23}
\]

A formal solution utilizing the resolvent is

\[
G(\zeta, \zeta' | \kappa, \kappa'; \alpha) = (f_{\text{right}} + R \ast f_{\text{right}})(\zeta, \zeta'), \tag{2.24}
\]

\[
\overline{G}(\zeta, \zeta' | \kappa, \kappa'; \alpha) = (f_{\text{left}} + f_{\text{left}} \ast R)(\zeta, \zeta'). \tag{2.25}
\]

Up to some factor, we reproduce the functions \( G \) and \( \overline{G} \) from [2] for \( \kappa' = \alpha + \kappa \). In the general case, \( \Psi \) is equal to the terms in the parentheses on the right-hand side of (2.8).

The important ‘normalization condition’ for the function \( \omega \), originally suggested in [10], includes the asymptotics for the large spectral parameter

\[
\lim_{\zeta \to \infty} \zeta^{-\alpha} \omega(\zeta, \zeta' | \kappa, \kappa + \alpha; \alpha) = 0. \tag{2.26}
\]

In [3], we showed this directly from the definition of the previous section using the properties of the linear integral equation (2.22). The key identity in our proof was

\[
\lim_{\zeta' \to \zeta} 2(\zeta/\zeta')^{-\alpha} G(\zeta, \zeta') = q^{-\alpha} - \rho(\zeta') - \int_{\mathcal{V}} \frac{d\eta}{2\pi i} G(\eta, \zeta') \Delta_{\alpha}(\eta/\zeta')^{-\alpha} = 0, \tag{2.27}
\]

valid for \( \kappa' = \kappa + \alpha \) in the measure.

\[2.4\) Functions \( \sigma \) and \( \Phi \)

In order to prove (2.27), we introduced a generalized ‘dressed charge’ \( \sigma \) and a function \( \Phi \) in [3]. Here we will use slightly modified and generalized definitions of these functions adapted to the notation in [5]. Namely, we define a function \( \sigma \) which satisfies the following linear integral equation:

\[
\sigma(\zeta | \kappa, \kappa'; \alpha) = \Delta_{\xi} \zeta^{-\alpha} + \int_{\mathcal{V}} d\eta \Delta(\eta | \zeta, \zeta' | \kappa, \kappa'; \alpha) K_{\alpha}(\eta/\zeta). \tag{2.28}
\]
The so-called dressed function trick implies that
\[ \int_{\gamma} d\eta \, G(\eta, \zeta|\kappa, \kappa'; \alpha) \Delta_{\eta}^{-\alpha} = \int_{\gamma} d\eta \, \sigma(\eta|\kappa, \kappa'; \alpha) \right(\eta, \zeta'). \]

Then (2.27) is reduced to an identity for \( \sigma \) with \( \kappa' = \kappa + \alpha \) which can be proved with the help of the properties of the function\( \Phi(\zeta|\kappa, \kappa') = \frac{Q(\zeta, \kappa)}{Q(\zeta, \kappa')}. \)

(2.29)

The key observation here is that two TQ-equations (2.18) with the twist parameters \( \kappa \) or \( \kappa' \), respectively, can be combined into the following relation for \( \Phi \):
\[ \frac{1}{\rho(\eta|\kappa, \kappa') (1 + a(\eta, \kappa))} = -\frac{\Phi(\eta|\kappa, \kappa')}{\Delta_{\eta} \Phi(\eta|\kappa, \kappa')} + \frac{\Phi(q \eta|\kappa, \kappa')}{\Delta_{\eta} \Phi(\eta|\kappa, \kappa')} . \]

(2.30)

Introducing an operator
\[ H_{\eta} = \frac{1}{1 + \bar{a}(\eta, \kappa)} \, d_{\eta}^{+} + \frac{1}{1 + a(\eta, \kappa)} \, d_{\eta}^{-} - \rho(\eta|\kappa, \kappa'), \]

(2.31)

where \( d_{\eta}^{\pm} f(\eta) = f(q^{\pm1} \eta) \) and \( \bar{a}(\eta, \kappa) = 1/a(\eta, \kappa) \), we can rewrite this more compactly as
\[ H_{\eta} \Phi(\eta|\kappa, \kappa') = 0 . \]

(2.32)

This is the operator \( H \) which we mentioned already in the introduction and which will be useful for the characterization of our main function \( \omega \) as well.

For \( \kappa' = \kappa + \alpha \), the solution of the integral equation (2.28) for \( \sigma \) can be expressed in terms of the function \( \Phi \),
\[ \sigma(\zeta) = \Delta_{\eta} \Phi(\zeta)/\Phi_{0}, \]

(2.33)

with some known normalization constant \( \Phi_{0} \) [3]. This was shown in [3] for the inhomogeneous model with finite \( N \). Here we shall repeat the argument for the temperature case.

For the proof we need to know the location of the singularities of the involved functions. If \( N \) is finite, the function \( \Phi(\zeta) \) has poles at the Bethe roots corresponding to the zeros of the denominator \( Q(\zeta, \kappa) \). It follows from our definition of the \( Q \)-operator described in section 3 of [5] that
\[ Q(\zeta, \kappa) = \zeta^{-x} \Lambda(\zeta, \kappa), \]

(2.34)

where \( \Lambda(\zeta, \kappa) \) is a rational function in \( \zeta^{2} \). As explained above, we consider the sector \( s = 0 \) here. Thus,
\[ \Phi(\zeta|\kappa, \kappa')/\Phi_{0} = \zeta^{-x+4} \phi(\lambda|\kappa, \kappa'), \]

(2.35)

where \( \lambda = \log \zeta \) by definition and where \( \phi(\lambda|\kappa, \kappa') \) has constant asymptotics for \( \text{Re} \lambda \to \pm\infty \).

It is well known that in the temperature case all Bethe roots ‘condense’ to the point \( \zeta = 1 \) which becomes an essential singularity of \( \Phi(\zeta|\kappa, \kappa') \). We conclude that \( \phi(\lambda|\kappa, \kappa') \) has an expansion of the form
\[ \phi(\lambda|\kappa, \kappa') = 1 + \sum_{j \geq 0} c_{j} \text{cth}^{(j)}(\lambda), \]

(2.36)

where \( \text{cth}^{(j)}(\lambda) : = (\partial/\partial \lambda)^{j} \text{cth}(\lambda) \) and where the dependence on the inverse temperature \( \beta \) is in the coefficients \( c_{j} \) which also depend on \( q, \kappa, \kappa' \). Note that all partial sums in (2.36) are still meromorphic in the original variable \( \zeta^{2} \). The coefficients \( c_{j} \) have the high-temperature expansions
\[ c_{j} = \sum_{k > j} \beta^{k} c_{k,j} \]

(2.37)
with respect to \( \beta \). The most convenient way to calculate the coefficients \( c_{k|j} \) is to consider the functional equation

\[
\frac{\Phi(q \xi | \kappa, \kappa')}{{\Phi(q^{-1} \xi | \kappa, \kappa')}} = \frac{a(\xi, \kappa')}{a(\xi, \kappa)},
\]

where the high-temperature expansion on the right-hand side follows directly from the integral equation (2.21). In appendix C, we will explain how to calculate the lowest coefficients explicitly.

For \( \kappa' = \kappa + \alpha \), we have \( \Phi(\eta | \kappa, \kappa + \alpha)/\Phi_0 = \eta^{-\alpha} \phi(\eta | \kappa, \kappa + \alpha) \), and the factor \( \eta^{-\alpha} \) cancels the corresponding factor under the integral in (2.28) stemming from the kernel \( K_\alpha(\eta/\xi) \). Then, if we substitute (2.30) into the integral and take into account that both the function \( \sigma(\xi) \) and the second term on the right-hand side of (2.30) do not have singularities inside the contour, we conclude that this second term does not contribute to the integral. Hence, it can be dropped and the integral can be calculated by deforming the contour as was explained in [3].

3. Solving the generalized dressed charge equation by means of the high-temperature expansion

We now generalize the above ideas step by step. We will show that all the linear integral equations considered above, such as equation (2.28) for the function \( \sigma \), equations (2.22) and (2.23) for the \( G \)-functions or equation (2.15) for the resolvent, can be solved in terms of a single function of one or two spectral parameters with essential singularities if one of the spectral parameters equals 1 and a certain behavior at 0 and \( \infty \), as in the above example of the function \( \sigma(\xi) \) at \( \kappa' = \kappa + \alpha \). We shall see in the next section that one such function \( \Phi(\xi, \xi'; \alpha) \) with essential singularities at \( \xi = \xi' = 1 \) will be all we need. The full information about the solutions of the above-mentioned linear integral equations is contained in this single function.

Before we proceed to the general case, let us describe how our method works for equation (2.28) with the independent parameters \( \kappa, \kappa' \) and \( \alpha \). We have seen above that \( \sigma \) given by (2.33) with \( \Phi(\xi | \kappa, \kappa') \) defined by (2.29) solves equation (2.28) only if \( \kappa' = \kappa + \alpha \). The problem with the general case is that the behavior at \( \xi = 0, \infty \) does not match the corresponding behavior of the kernel \( K_\alpha \) in the integral of (2.28). Hence, we need a generalized function \( \Phi(\xi|\kappa,\kappa';\alpha) \).

In order for a formula similar to (2.33) to work, we first of all need a relation similar to (2.30):

\[
\frac{1}{\rho(\eta | \kappa, \kappa')(1 + a(\eta, \kappa))} = -\frac{\Phi(\eta | \kappa, \kappa'; \alpha)}{a(\eta, \kappa')} + r(\eta | \kappa, \kappa'; \alpha),
\]

where the remainder function \( r \) is not defined yet. The only property of this function is that it does not have singularities inside the contour \( \gamma \). We will call such functions ‘regular’. We also need a generalization of the asymptotic property and expansion (2.35), (2.36),

\[
\Phi(\xi | \kappa, \kappa'; \alpha) = \xi^{-\alpha} \phi(\lambda | \kappa, \kappa'; \alpha), \quad \lambda = \log \xi,
\]

with

\[
\phi(\lambda | \kappa, \kappa'; \alpha) = 1 + \sum_{j \geq 0} c_j^\prime \operatorname{cth}^{(j)}(\lambda),
\]

where the coefficients \( c_j^\prime \) now depend on \( q, \kappa, \kappa', \alpha \) and on the inverse temperature \( \beta \). The high-temperature expansion is of the same form as (2.37),

\[
c_j^\prime = \sum_{k \geq j} \beta^k c_{k|j}. \tag{3.4}
\]
Relations \((2.30)\) and \((3.1)\) can be combined into
\[
\frac{\Phi(\eta | \kappa', \gamma)}{\Delta_\eta \Phi(\eta | \kappa', \gamma')} = \frac{\Phi(\eta | \kappa, \gamma; \alpha)}{\Delta_\eta \Phi(\eta | \kappa, \gamma; \alpha)} = \tilde{\tau}(\eta | \kappa, \gamma'; \alpha)
\] (3.5) with a regular remainder \(\tilde{\tau}\). Our first claim is that this equation has a unique solution in terms of expansion \((3.3)\). Our second claim is that, due to similar arguments as at the end of the previous section, the solution to equation \((2.28)\) can be expressed as
\[
\sigma(\xi | \kappa, \gamma; \alpha) = \Delta_\xi \Phi(\xi | \kappa, \gamma; \alpha).
\] (3.6)

We can interpret \((3.5)\) as a cancelation condition for the singular part at \(\lambda = 0\) of the functions on the left-hand side. Inserting \((2.35)\) and \((3.2)\), we find that the following expression is regular (which we denote by ‘\(=\) reg’):
\[
\phi(\lambda | \kappa, \gamma') (q^{-\alpha} \phi(\lambda + \pi \nu | \kappa, \gamma'; \alpha) - q^{\alpha} \phi(\lambda - \pi \nu | \kappa, \gamma'; \alpha)) - \phi(\lambda | \kappa, \gamma; \alpha)(q^{-\kappa' + \alpha} \phi(\lambda + \pi \nu | \kappa, \gamma') - q^{\kappa' - \alpha} \phi(\lambda - \pi \nu | \kappa, \gamma')) = \text{reg.}
\] (3.7)

We substitute expansions \((2.36)\) and \((3.3)\) here and use the elementary formula
\[
\text{cth}(\lambda') \text{cth}(\lambda') = 1 + \text{cth}(\lambda) \text{ct}(\lambda' - \lambda) - \text{ct}(\lambda') \text{ct}(\lambda' - \lambda)
\]
to extract the singular part with respect to \(\lambda\) for both terms on the left-hand side of \((3.7)\). Comparing the coefficients in front of the corresponding terms \(\text{ct}(\lambda')\), we obtain the following equation for \(c_j, c_j'\):
\[
(q^a - q^{-a}) c_j - (q^{\gamma - \alpha} - q^{-\gamma + \alpha}) c_j' = \sum_{j' : j' \geq 0} c_j c_{j'}' \left( (-1)^j \left( \sum_{k = 0}^{k' - 1} c_k c_{k' - j} \right) \right) \left( (-1)^j \left( \sum_{k = 0}^{k' - 1} c_k c_{k' - j} \right) \right)
\] (3.8)
where
\[
\gamma_j(\alpha) := (q^a + (-1)^j q^{-a}) \text{ct}(\lambda') \text{ct}(\lambda')
\] (3.9)
and where the binomial coefficients are defined in such a way that \(\binom{a}{b} = 0\) for \(a < b\). If \(\kappa' = \kappa + \alpha\), the unique solution is \(c_j = c_j\), since both sides of \((3.8)\) vanish identically.

Further inserting the high-temperature expansions \((2.37)\) and \((3.4)\), we obtain
\[
(q^a - q^{-a}) c_{\ell j} - (q^{\gamma - \alpha} - q^{-\gamma + \alpha}) c_{\ell j}' = \left( \sum_{k' = 0}^{k' - 1} \sum_{k = 0}^{k' - 1} c_{\ell k} c_{\ell k'} c_{\ell k - j}ight) \times \left[ (-1)^j \left( \sum_{k' = 0}^{k - 1} c_{\ell k} c_{\ell k'} c_{\ell k - j} \right) \right] \gamma_{j' + j - j'}(\kappa' - \kappa)
\] (3.10)
for \(0 \leq j \leq k - 1\).

If the coefficients \(c_j\) are known up to a certain order \(k\) of the high-temperature expansion \((2.37)\), we can obtain the \(c_j'\) from the above relation \((3.10)\) up to the same order, because all coefficients on the right-hand side are of lower order. Thus, one can iteratively solve equation \((3.10)\) with respect to the coefficients \(c_j'\), once the \(c_j\) are known. The solution obtained in this way is obviously unique. In appendix \(D\), we show the lowest order coefficients explicitly.

**Remark.** Instead of relation \((3.5)\), we could consider, for example,
\[
\frac{\Phi(\eta | \kappa, \gamma'; \alpha)}{\Delta_\eta \Phi(\eta | \kappa, \gamma'; \alpha)} - \frac{\Phi(\eta | \kappa, \gamma'; -\alpha)}{\Delta_\eta \Phi(\eta | \kappa, \gamma'; -\alpha)} = \text{reg.}
\] (3.11)
Then, repeating the above arguments, we come to the following compatibility condition:

\[(q^\alpha - q^{-\alpha})(c_j' + \overline{c}_j') = - \sum_{j, j' \geq 0} (-1)^j c_j' \overline{c}_{j'}' \left( -(-1)^j \left( \frac{j}{j'} - \left( \frac{j'}{j} \right) \right) \right) y_{j' + j - \alpha}(\alpha), \]  

(3.12)

where the coefficients \(\overline{c}_j'\) appear in

\[\phi(\lambda|\kappa, \kappa'; -\alpha) = 1 + \sum_{j \geq 0} \overline{c}_j' \coth(j, \kappa|\lambda), \]  

(3.13)

and have the high-temperature expansion

\[\overline{c}_j' = \sum_{k > j} b_k \overline{c}_k', \]  

(3.14)

4. Resolvent and master function

We shall show in this section that the arguments applied above in order to obtain a solution \(\sigma\) of the dressed charge equation (2.28) in terms of a function \(\Phi\), which has a simple high-temperature expansion, can be generalized to the linear integral equation (2.15) for the resolvent \(R\). To this end we introduce another function \(\Phi(\zeta, \zeta'|\kappa, \kappa'; \alpha)\) now depending on two spectral parameters \(\zeta, \zeta'\). As we shall see, this function contains the whole information which is necessary for the description of all functions defined by means of linear integral equations that appeared before. For this reason, it may be called a ‘master function’.

Generalizing the ideas of the previous section, we define it as follows:

\[\Phi(\zeta, \zeta'|\kappa, \kappa'; \alpha) = \Phi'(\zeta, \zeta'|\kappa, \kappa'; \alpha) + \Delta_\zeta^{-1} \psi(\alpha), \]  

(4.1)

\[\Phi'(\zeta, \zeta'|\kappa, \kappa'; \alpha) = \frac{1}{2} (\zeta / \zeta')^\alpha \phi(\lambda, \lambda'|\kappa, \kappa'; \alpha), \quad \lambda = \log(\zeta), \quad \lambda' = \log(\zeta'), \]  

(4.2)

where

\[\phi(\lambda, \lambda'|\kappa, \kappa'; \alpha) = \sum_{j, j' \geq 0} c_{j, j'} \coth(j, \kappa|\lambda) \coth(j', \kappa'|\lambda') \]  

(4.3)

and where \(\Delta_\zeta^{-1} \psi(\zeta, \alpha)\) was defined in (2.13). We complete the definition by demanding that \(\Phi(\zeta, \zeta'|\kappa, \kappa'; \alpha)\) satisfies an equation similar to (3.1),

\[\frac{1}{\rho(\eta|\kappa, \kappa')(1 + a(\eta, \kappa))} = - \frac{\Phi'(\eta, \zeta'|\kappa, \kappa'; \alpha)}{\Delta_\eta \Phi(\eta, \zeta'|\kappa, \kappa'; \alpha)} + r(\eta, \zeta'|\kappa, \kappa'; \alpha) \]  

(4.4)

\[= - \frac{\Phi'(\zeta, \eta|\kappa, \kappa'; \alpha)}{\Delta_\eta \Phi(\zeta, \eta|\kappa, \kappa'; \alpha)} + r'(\zeta, \eta|\kappa, \kappa'; \alpha), \]  

(4.5)

where the remainders \(r, r'\) are regular functions of \(\eta\).

We shall see below that (4.2) and (4.4), (4.5) determine the coefficients \(c_{j, j'}\) in the high-temperature expansion (4.3). The relation of our master function with the resolvent is explained in the following.

**Lemma 4.1.** The resolvent \(R\) defined by the linear integral equation (2.15) can be represented as

\[R(\zeta, \zeta'|\kappa, \kappa'; \alpha) = - \frac{1}{2\pi i} \Delta_\zeta \Delta_\zeta^{-1} \Phi(\zeta, \zeta'|\kappa, \kappa'; \alpha). \]  

(4.6)

A proof of this lemma is provided in appendix A.
The function \( \Phi \) of one spectral parameter introduced in the previous section is recovered in the limits of large \( \zeta, \zeta' \),

\[
\lim_{\zeta \to \infty} \zeta^{-\alpha} R(\zeta, \zeta'|k, k'; \alpha) = -\frac{1}{4\pi i} \sigma(\zeta'|k, k'; \alpha) = -\frac{1}{4\pi i} \Delta_\zeta \Phi(\zeta'|k, k'; \alpha),
\]

\[
\lim_{\zeta' \to \infty} \zeta'^{-\alpha} R(\zeta, \zeta'|k, k'; \alpha) = -\frac{1}{4\pi i} \sigma(\zeta|k, k'; -\alpha) = -\frac{1}{4\pi i} \Delta_\zeta \Phi(\zeta|k, k'; -\alpha),
\]

or

\[
\lim_{\zeta \to \infty} \zeta^{-\alpha} \Phi(\zeta, \zeta'|k, k'; \alpha) = \frac{\Phi(\zeta'|k, k'; \alpha)}{2(q^\alpha - q^{-\alpha})},
\]

\[
\lim_{\zeta' \to \infty} \zeta'^{-\alpha} \Phi(\zeta, \zeta'|k, k'; \alpha) = \frac{\Phi(\zeta|k, k'; -\alpha)}{2(q^{-\alpha} - q^\alpha)}.
\]

Let us now come back to our claim that the high-temperature expansion (4.3) is determined by (4.4), (4.5) and by the asymptotic condition (4.2). Combining (4.4), (4.5) with (3.1), we obtain

\[
\frac{\Phi(\eta|k, k'; -\alpha)}{\Delta_\eta \Phi(\eta|k, k'; -\alpha)} - \frac{\Phi(\eta, \zeta'|k, k'; \alpha)}{\Delta_\eta \Phi(\eta, \zeta'|k, k'; \alpha)} = \tilde{\gamma}(\eta, \eta|k, k'; \alpha),
\]

\[
\frac{\Phi(\eta|k, k'; \alpha)}{\Delta_\eta \Phi(\eta|k, k'; \alpha)} - \frac{\Phi(\zeta, \eta|k, k'; \alpha)}{\Delta_\eta \Phi(\zeta, \eta|k, k'; \alpha)} = \tilde{\gamma}'(\zeta, \eta|k, k'; \alpha),
\]

where the remainders \( \tilde{\gamma}, \tilde{\gamma}' \) are also regular with respect to the variable \( \eta \).

First of all we shall see that (4.9) and (4.10) are equivalent to each other. We substitute (4.1) into (4.10) and obtain the regularity condition

\[
\phi(\mu|k, k'; \alpha)(q^{-\alpha} \phi(\lambda, \mu + \pi v)i|k, k'; \alpha) = q^\alpha \phi(\mu - \pi v|i|k, k'; \alpha) - \text{c.th.}(\lambda - \mu))
\]

\[
-\phi(\lambda, \mu|k, k'; \alpha)(q^{-\alpha} \phi(\mu + \pi v|i|k, k'; \alpha) - q^\alpha \phi(\mu - \pi v|i|k, k'; \alpha)) = \text{reg},
\]

where \( \mu = \log(\eta) \) and where the variable \( \zeta \) corresponding to \( \lambda = \log(\zeta) \) must be outside the integration contour \( \gamma \).

If we repeat the procedure described in the previous section, namely, if we substitute expansions (3.3), (3.3) into (4.11) and into the equation obtained from (4.11) by replacing \( \alpha \to -\alpha \) and then take the singular part, we obtain two equations for the expansion coefficients \( c_{j,l} \),

\[
\sum_{j' \geq 0} c_{j',l} U_{j,l} = \left( \frac{j + l}{l} \right) c_{j+l},
\]

\[
\sum_{j' \geq 0} \tilde{U}_{j,l} (-1)^{j+l} c_{j',l} = -(-1)^{j+l} \left( \frac{j + l}{l} \right) \tilde{c}_{j+l},
\]

where

\[
U_{j,l} = (q^\alpha - q^{-\alpha}) \delta_{j,l} + \sum_{j' \geq 0} c_{j'} \gamma_{j,l'},
\]

\[
\tilde{U}_{j,l} = (q^\alpha - q^{-\alpha}) \delta_{j,l} - \sum_{j' \geq 0} (-1)^j \tilde{c}_{j'} \gamma_{j',lj}
\]

and

\[
\gamma_{j,l'} = \left( -(-1)^j \left( \frac{j}{j'} \right) - (-1)^j \left( \frac{j}{j'} \right) \right) \gamma_{j+l',l}(-\alpha)
\]

with \( \gamma_j \) defined in (3.9).
The compatibility condition for equations (4.12) and (4.13) is
\[ \sum_{j \geq 0} (-1)^{j} \binom{j + j}{j} \tilde{c}_{j+j} U_{j,j} = - \sum_{j \geq 0} \tilde{U}_{j,j} (-1)^{j} \binom{j + l}{l} \tilde{c}_{j+l}. \]
Substituting (4.14) and (4.15) here, using the identity
\[ (-1)^{j} \binom{j + l}{l} y_{j,l} - j y_{j+1,l} y_{j,l} = (-1)^{j} \binom{j + l}{l} \tilde{y}_{j+1,l} y_{j,l}, \]
where
\[ \tilde{y}_{j,l} = \binom{j}{l} - (-1)^{j} \binom{j}{l} y_{j+1,l}, \]
and doing some algebra, we come back to our previous compatibility condition (3.12).

Hence, either of the two equations (4.12) or (4.13) can be used to determine the coefficients \( c_{j,j} \). Their high-temperature expansion is of the form
\[ c_{j,j} = \sum_{k \geq j+1} \beta^{k} \epsilon_{k,j,j}. \]
Substituting this together with (3.4), (4.14) into equation (4.12), we obtain
\[ (q^{\alpha} - q^{-\alpha}) \epsilon_{k,j,j} = \binom{j + l}{l} \tilde{c}_{k,j,j} - \sum_{k' \geq j+1} \sum_{k'' \geq j+1} \sum_{l' = 0}^{k''} c_{k',j,j} \tilde{c}_{k''-k',j,l'} y_{j+l',j,j}. \]
Again, like in equation (3.10), the coefficients \( c_{k,j,j} \) are completely determined by the previous coefficients \( c_{k',j,j} \) with \( k' < k \). Again we obtain an iterative calculation scheme which is very efficient and allows us to quickly calculate high-order terms in the high-temperature expansion (4.19).

5. Representation of \( G, \tilde{G} \) and \( \omega \) in terms of the master function

Since we have formulae (2.24), (2.25) and (2.8) which relate the functions \( G, \tilde{G} \) and \( \omega \), respectively, to the resolvent \( R \) given by (4.6), it is merely a technical problem to express these three functions in terms of \( \Phi(\zeta, \zeta' | \kappa, \kappa'; \alpha) \). An important point here is that it turns out to be possible to get rid of all integrations.

**Lemma 5.1.** The functions \( G, \tilde{G} \) and \( \omega \) are expressed in terms of the function \( \Phi \) as follows:
\[ G(\zeta, \zeta' | \kappa, \kappa'; \alpha) = \Delta_{\beta} H_{\gamma} \Phi(\zeta, \zeta' | \kappa, \kappa'; \alpha), \]
\[ \tilde{G}(\zeta, \zeta' | \kappa, \kappa'; \alpha) = - \frac{1}{2\pi i} H_{\gamma} \Delta_{\beta} \Phi(\zeta, \zeta' | \kappa, \kappa'; \alpha), \]
\[ \frac{1}{4} \omega(\zeta, \zeta' | \kappa, \kappa'; \alpha) = H_{\gamma} H_{\beta} \Phi(\zeta, \zeta' | \kappa, \kappa'; \alpha), \]
where the operators \( \Delta_{\beta} \) and \( H_{\gamma} \) are defined in (2.10) and (2.31), respectively.

The proof of this lemma is deferred to appendix B.

The master function \( \Phi \) has the symmetry
\[ \Phi(\zeta, \zeta' | \kappa, \kappa'; \alpha) = \Phi(\zeta', \zeta | \kappa, \kappa', -\alpha) \]
which follows from (4.1), (4.9) and (4.10). Due to our lemmas 4.1, 5.1, this symmetry carries over to \( R, \omega, G \) and \( \tilde{G} \),
\[ R(\zeta, \zeta' | \kappa, \kappa', \alpha) = R(\zeta', \zeta | \kappa, \kappa', -\alpha), \]
\[ \omega(\zeta, \zeta' | \kappa, \kappa', \alpha) = \omega(\zeta', \zeta | \kappa, \kappa', -\alpha), \]
\[ \tilde{G}(\zeta, \zeta' | \kappa, \kappa', \alpha) = - \frac{1}{2\pi i} G(\zeta', \zeta | \kappa, \kappa', -\alpha). \]
A few comments are in order here. First, expression (5.3) for our main function $\omega$ is rather appealing as compared to the original expression (2.8). We could get rid of all unpleasant integrations that make the analysis hard. Second, we derived our formulae in the temperature case. Yet, (4.6), (5.1)–(5.3) are valid in the general inhomogeneous case for finite $N$. This means that we can use our formulae for the future analysis of the CFT scaling limit.

As we pointed out above, our master function $\Phi_1$ of two spectral parameters encodes the complete information about various functions appearing in the description of the physical part of the correlation functions of the XXZ chain. This function $\Phi_1$ can be characterized by either of relations (4.4), (4.5), (4.9) or (4.10) which ensure the cancelation of singularities inside the integration contour $\gamma$. These relations make sense in the general case as well, when the lattice is finite in the Matsubara direction. In that case, they mean that the residues at all poles corresponding to the Bethe roots must vanish. In the temperature case, we could use the high-temperature expansion (4.3) and determine the coefficients $c_{j,f}$. This procedure can be efficiently implemented on a computer. We hope that it will be possible in the future to find a generalization of this procedure to the CFT scaling limit, where relations such as (4.4), (4.5) or (4.9), (4.10) may turn into a Riemann–Hilbert problem.

We also believe that it would be interesting to understand the deeper meaning of the operator $H$ defined in (2.31).

Appendix A. Proof of lemma 4.1

The statement of the lemma can be verified rather directly. First we write (2.15) in the following way:

$$R(\zeta, \zeta') = K_\alpha(\zeta/\zeta') + (K_\alpha * R)(\zeta, \zeta'), \quad (A.1)$$

where we omit the other arguments of the resolvent for simplicity. We will also omit such arguments in all other functions during this proof.

Let us substitute the right-hand side of (4.6) into the right-hand side of (A.1) and use (4.4). Then

$$K_\alpha(\zeta/\zeta') + \int_\gamma \frac{d\eta}{\eta^2} K_\alpha(\zeta, \eta) \frac{R(\eta, \zeta')}{\rho(\eta)(1 + a(\eta))}$$

$$= K_\alpha(\zeta/\zeta') - \int_\gamma \frac{d\eta}{\eta^2} K_\alpha(\zeta, \eta) \left(-\frac{\Phi'(\eta, \tau)}{\Delta \Phi(\eta, \tau)} + r(\eta, \tau)\right) \frac{1}{2\pi i} \Delta \Phi(\eta, \zeta')$$

$$= K_\alpha(\zeta/\zeta') + \int_\gamma \frac{d\eta}{\eta^2} K_\alpha(\zeta, \eta) \left(-\frac{\Phi'(\eta, \tau)}{\Delta \Phi(\eta, \tau)} - r(\eta, \tau)\right)$$

$$\times \frac{1}{2\pi i} \Delta \Phi(\eta, q \zeta') - \Phi(\eta, q^{-1} \zeta')$$

$$= K_\alpha(\zeta/\zeta') + \int_\gamma \frac{d\eta}{\eta^2} K_\alpha(\zeta, \eta) \left(-\frac{\Phi'(\eta, q \zeta')}{\Delta \Phi(\eta, q \zeta')} - r(\eta, q \zeta')\right) \frac{1}{2\pi i} \Delta \Phi(\eta, q \zeta')$$

$$- \left(\frac{\Phi'(\eta, q^{-1} \zeta')}{\Delta \Phi(\eta, q^{-1} \zeta')} - r(\eta, q^{-1} \zeta')\right) \frac{1}{2\pi i} \Delta \Phi(\eta, q^{-1} \zeta').$$
where we used the arbitrariness of the parameter $\tau$ and choose either $\tau = q\zeta'$ or $\tau = q^{-1}\zeta'$.

We further rewrite the last line as

$$K_\omega(\zeta/\zeta') + \int_{\gamma} \frac{d\eta^2}{\eta^2} K_\omega(\zeta, \eta) \frac{1}{2\pi i} \Delta_\gamma(\Phi'(\eta, \zeta') - r(\eta, \zeta')\Delta_\gamma\Phi(\eta, \zeta'))$$

$$= K_\omega(\zeta/\zeta') + \frac{1}{2\pi i} \int_{\gamma} \frac{d\eta^2}{\eta^2} K_\omega(\zeta, \eta) \Delta_\gamma\Phi'(\eta, \zeta')$$

$$= K_\omega(\zeta/\zeta') - \frac{1}{2\pi i} \Delta_\gamma \Delta_\gamma\Phi'(\zeta, \zeta') = \frac{1}{2\pi i} \Delta_\gamma\psi(\zeta/\zeta', \alpha) - \frac{1}{2\pi i} \Delta_\gamma \Delta_\gamma\Phi'(\zeta, \zeta')$$

$$= -\Delta_\gamma \Delta_\gamma\left(\frac{1}{2\pi i} \Phi'(\zeta, \zeta') + \frac{1}{2\pi i} \Delta_\gamma^{-1}\psi(\zeta/\zeta', \alpha)\right) = -\frac{1}{2\pi i} \Delta_\gamma \Delta_\gamma\Phi(\zeta, \zeta'),$$

where we deformed the contour in such a way that it does not contain the essential singularity $\eta = 1$, but the two poles coming from the kernel $K_\omega(\zeta, \eta)$ instead. One also has to verify that the contribution of the boundary terms is equal to 0. This can be done in a similar way as was explained in [3].

**Appendix B. Proof of lemma 5.1**

(i) Let us start with (5.1). In accordance with formula (2.24), we have (again we keep only spectral parameters in arguments and omit all other arguments)

$$G(\zeta, \zeta') = f_{\text{left}}(\zeta, \zeta') + (R \ast f_{\text{left}})(\zeta, \zeta').$$

$$f_{\text{right}}(\zeta, \zeta') = \psi(q^{-1}\zeta/\zeta') - \rho(\zeta')\psi(\zeta/\zeta').$$

Hence, the integral on the right-hand side is

$$(R \ast f_{\text{right}})(\zeta, \zeta') = \int_{\gamma} \frac{d\eta^2}{\eta^2} \frac{R(\zeta, \eta)}{\rho(\eta)(1 + a(\eta))} f_{\text{right}}(\eta, \zeta') = I_1 - \rho(\zeta')I_2,$$

where both the spectral parameters $\zeta$ and $\zeta'$ are inside the integration contour $\gamma$ and

$$I_1 = \int_{\gamma} \frac{d\eta^2}{\eta^2} \frac{R(\zeta, \eta)}{\rho(\eta)(1 + a(\eta))} \psi(q^{-1}\eta/\zeta'), \quad I_2 = \int_{\gamma} \frac{d\eta^2}{\eta^2} \frac{R(\zeta, \eta)}{\rho(\eta)(1 + a(\eta))} \psi(\eta/\zeta').$$

We treat the integral $I_1$ in a similar way as in the proof of lemma 4.1.

$$I_1 = -\int_{\gamma} \frac{d\eta^2}{\eta^2} \frac{1}{2\pi i} \Delta_\gamma \Delta_\gamma\Phi(\zeta, \eta) \left(-\frac{\Phi'(\tau, \eta)}{\Delta_\gamma\Phi(\tau, \eta)} + r'(\tau, \eta)\right)\psi(q^{-1}\eta/\zeta')$$

$$= -\int_{\gamma} \frac{d\eta^2}{\eta^2} \frac{1}{2\pi i} \left(\Delta_\gamma\Phi(\eta, \zeta) - \Delta_\gamma\Phi(q\zeta, \eta)\right) \psi(q^{-1}\eta/\zeta')$$

$$\times \left(-\frac{\Phi'(\tau, \eta)}{\Delta_\gamma\Phi(\tau, \eta)} + r'(\tau, \eta)\right)\psi(q^{-1}\eta/\zeta')$$

$$= -\int_{\gamma} \frac{d\eta^2}{\eta^2} \frac{1}{2\pi i} \left(\Delta_\gamma\Phi(\zeta, \eta) - \Delta_\gamma\Phi(q\zeta, \eta)\right) \psi(q^{-1}\eta/\zeta')$$

$$\times \left(-\frac{\Phi'(q\zeta, \eta)}{\Delta_\gamma\Phi(q\zeta, \eta)} + r'(q\zeta, \eta)\right)\psi(q^{-1}\eta/\zeta')$$

We conclude that

$$I_1 = \int_{\gamma} \frac{d\eta^2}{\eta^2} \frac{1}{2\pi i} \left(\Phi'(q\zeta, \eta) - \Phi'(q^{-1}\zeta, \eta)\right)\psi(q^{-1}\eta/\zeta') = \Delta_\gamma \Phi'(\zeta, q\zeta').$$
Finally we prove (5.3) which is the main result of this paper. The function $\psi(\eta/\zeta')$:

$$I_2 = -2\pi i \frac{R(\zeta', \zeta')}{\rho(\zeta')(1 + a(\zeta'))} + \int_{\gamma'} \frac{d\eta^2}{\eta^2} \frac{R(\zeta, \eta)}{\rho(\eta)(1 + a(\eta))} \psi(\eta/\zeta'),$$

where the contour $\gamma'$ does not contain the point $\zeta'$. The corresponding integral can be calculated in the same manner as $I_1$. The result is

$$I_2 = -2\pi i \frac{R(\zeta', \zeta')}{\rho(\zeta')(1 + a(\zeta'))} + \Delta_\zeta \Phi' (\zeta, \zeta').$$

Altogether

$$G(\zeta, \zeta') = \psi(q^{-1} \zeta/\zeta') - \rho(\zeta')\psi(\zeta/\zeta') + I_1 - \rho(\xi)I_2$$

$$= \psi(q^{-1} \zeta/\zeta') - \rho(\zeta')\psi(\zeta/\zeta') + \Delta_\zeta \Phi' (\zeta, q\zeta')$$

$$+ 2\pi i \frac{R(\zeta, \zeta')}{1 + a(\zeta')} - \rho(\zeta')\Delta_\zeta \Phi' (\zeta, \zeta')$$

$$= \Delta_\zeta \Phi (\zeta, q\zeta') - \rho(\zeta')\Delta_\zeta \Phi (\zeta, \zeta') - \frac{1}{1 + a(\zeta')} \Delta_\zeta \Delta_\zeta \Phi (\zeta, \zeta')$$

$$= \Delta_\zeta \left( \delta_\zeta - \frac{1}{1 + a(\zeta')} \Delta_\zeta \right) \Phi (\zeta, \zeta') = \Delta_\zeta H_\zeta \Phi (\zeta, \zeta').$$

(ii) The proof of formula (5.2) proceeds similarly to the above proof of (5.1). We end up with

$$\mathcal{G}(\zeta, \zeta') = -\frac{1}{2\pi i} \left( \delta_\zeta - \frac{1}{1 + a(\zeta')} \Delta_\zeta \right) \Delta_\zeta \Phi (\zeta, \zeta') = -\frac{1}{2\pi i} H_\zeta \Delta_\zeta \Phi (\zeta, \zeta').$$

(iii) Finally we prove (5.3) which is the main result of this paper. The function $\omega$ is given by (2.8)

$$\frac{1}{2} \omega (\zeta, \zeta') = (\mathcal{G} \ast f_{\text{right}})(\zeta, \zeta') + \delta_\zeta \delta_\zeta \Delta_\zeta^{-1} \psi(\zeta/\zeta'). \tag{B.1}$$

After inserting (5.2), the first term on the right-hand side takes the form

$$- \int_{\gamma'} \frac{d\eta^2}{\eta^2} \frac{1}{2\pi i} \frac{1}{\rho(\eta)(1 + a(\eta))} H_\zeta \Delta_\eta \Phi (\zeta, \eta) f_{\text{right}} (\eta, \zeta')$$

$$= - \frac{1}{1 + a(\zeta')} \int_{\gamma'} \frac{d\eta^2}{\eta^2} \Delta_\eta \Phi (\zeta, \eta) f_{\text{right}} (\eta, \zeta') - \frac{1}{1 + a(\zeta')} \rho(\zeta) f_1^{(0)}$$

$$+ \frac{\rho(\zeta')}{1 + a(\zeta')} f_2^{(0)} - \frac{\rho(\zeta')}{1 + a(\zeta')} f_2^{(0)}, \tag{B.2}$$

where

$$I_1^{(0)} = \frac{1}{2\pi i} \int_{\gamma'} \frac{d\eta^2}{\eta^2} \frac{1}{\rho(\eta)(1 + a(\eta))} \Delta_\eta \Phi (q^{-1} \zeta, \eta) \psi (q^{-1} \eta/\zeta'),$$

$$I_2^{(0)} = \frac{1}{2\pi i} \int_{\gamma'} \frac{d\eta^2}{\eta^2} \frac{1}{\rho(\eta)(1 + a(\eta))} \Delta_\eta \Phi (q^{-1} \zeta, \eta) \psi (q^{-1} \eta/\zeta'),$$

$$I_1^{(0)} = \frac{1}{2\pi i} \int_{\gamma'} \frac{d\eta^2}{\eta^2} \frac{1}{\rho(\eta)(1 + a(\eta))} \Delta_\eta \Phi (\zeta, \eta) \psi (q^{-1} \eta/\zeta'),$$

$$I_2^{(0)} = \frac{1}{2\pi i} \int_{\gamma'} \frac{d\eta^2}{\eta^2} \frac{1}{\rho(\eta)(1 + a(\eta))} \Delta_\eta \Phi (\zeta, \eta) \psi (q^{-1} \eta/\zeta').$$
In order to calculate all these integrals, we proceed in a similar way as before

\[ I_1^{(\pm)} = \frac{1}{2\pi i} \int_{\gamma} \frac{\partial}{\partial \eta} \left( -\frac{\Phi'(q^{\pm 1} \xi, \eta)}{\Delta_\eta \Phi(q^{\pm 1} \xi, \eta)} + r(q^{\pm 1} \xi, \eta) \right) \Delta_\eta \Phi(q^{\pm 1} \xi, \eta) \psi(q^{-1} \eta/\zeta') \]

\[ = -\frac{1}{2\pi i} \int_{\gamma} \frac{\partial}{\partial \eta} \Phi'(q^{\pm 1} \xi, \eta) \psi(q^{-1} \eta/\zeta') = -\Phi'(q^{\pm 1} \xi, q \zeta'). \] (B.3)

\[ I_2^{(\pm)} = \frac{1}{2\pi i} \int_{\gamma} \frac{\partial}{\partial \eta} \left( -\frac{\Phi'(q^{\pm 1} \xi, \eta)}{\Delta_\eta \Phi(q^{\pm 1} \xi, \eta)} + r(q^{\pm 1} \xi, \eta) \right) \Delta_\eta \Phi(q^{\pm 1} \xi, \eta) \psi(\eta/\zeta') \]

\[ = \frac{1}{2\pi i} \int_{\gamma} \frac{\partial}{\partial \eta} \left( -\Phi'(q^{\pm 1} \xi, \eta) + r(q^{\pm 1} \xi, \eta) \Delta_\eta \Phi(q^{\pm 1} \xi, \eta) \right) \psi(\eta/\zeta'). \]

Since \( \zeta' \) is inside the contour, one can see that the first term inside the bracket does not contribute, and we have

\[ I_2^{(\pm)} = \frac{1}{2\pi i} \int_{\gamma} \frac{\partial}{\partial \eta} r(q^{\pm 1} \xi, \eta) \Delta_\eta \Phi(q^{\pm 1} \xi, \eta) \psi(\eta/\zeta') \]

\[ = -r(q^{\pm 1} \xi, \zeta') \Delta_\xi \Phi(q^{\pm 1} \xi, \zeta') = -\Phi'(q^{\pm 1} \xi, \zeta') - \frac{\Delta_{\xi'} \Phi(q^{\pm 1} \xi, \zeta')}{\rho(\zeta')(1 + a(\zeta))}. \] (B.4)

Furthermore,

\[ I_1^{(0)} = \frac{1}{2\pi i} \int_{\gamma} \frac{\partial}{\partial \eta} \left( -\frac{\Phi(\xi, \eta)}{\Delta_\eta \Phi(\xi, \eta)} + r(\xi, \eta) \right) \Delta_\eta \Phi(\xi, \eta) \psi(q^{-1} \eta/\zeta') \]

\[ = -\Phi'(\xi, q \zeta') - r(\xi, \zeta') \psi(q^{-1} \xi/\zeta') \]

\[ = -\Phi'(\xi, q \zeta') - \frac{1}{\rho(\xi)(1 + a(\xi))} \psi(q^{-1} \xi/\zeta'). \] (B.5)

since the term with \( \lim_{\xi' \to \zeta} \) vanishes. Finally

\[ I_2^{(0)} = \frac{1}{2\pi i} \int_{\gamma} \frac{\partial}{\partial \eta} \left( -\frac{\Phi(\xi, \eta)}{\Delta_\eta \Phi(\xi, \eta)} + r(\xi, \eta) \right) \Delta_\eta \Phi(\xi, \eta) \psi(\eta/\zeta') \]

\[ = -r(\xi, \zeta') \Delta_\xi \Phi(\xi, \zeta') - r(\xi, \zeta) \psi(\xi/\zeta') \]

\[ = -\Phi'(\xi, \zeta') - \frac{\Delta_{\xi'} \Phi(\xi, \zeta')}{\rho(\zeta')(1 + a(\zeta))} - \frac{1}{\rho(\xi)(1 + a(\xi))} \psi(\xi/\zeta'). \] (B.6)

If we now substitute (B.3)–(B.6) into expression (B.2), combine with the last term on the right-hand side of (B.1) and do some algebra, we come to the final result (5.3).

Appendix C. Coefficients in the high-temperature expansion of the function \( \phi(\lambda) \kappa, \kappa' \)

As we mentioned in section 2.4, we can compute the coefficients \( c_j \) of expansion (2.36) by solving the functional equation (2.38) and by using the corresponding high-temperature expansion (2.37). Unfortunately, the resulting formulae for the coefficients \( c_{kj} \) are not simple, not even at lower orders. There is a better object though, for which the coefficients of the high-temperature expansion are much simpler and from which the coefficients \( c_{kj} \) can be obtained.

It might seem that the function \( A \) considered in section 2.4 is a candidate to be such a simple function. Unfortunately, \( A \) is not well defined in the temperature case when the limit
order to define it, we first introduce a function \( N \to \infty \) into the equation
\[
\Phi(\xi | \kappa', \kappa) = \xi^{-x_{\alpha}} \tilde{\Phi}(\xi | \kappa, \kappa'), \quad \lambda = \log \xi.
\]

Due to (2.36), the function \( \tilde{\Phi} \) has an expansion of the form
\[
\tilde{\Phi}(\xi | \kappa, \kappa') = 1 + \sum_{j \geq 0} c_j \tilde{\Phi}^{(j)}(\lambda), \quad c_j = \sum_{k > j} \beta^k \tilde{c}_{kj}.
\]

It can be obtained from expansion (2.36) by taking into account that \( \Phi_0 = (\tilde{\Phi}(\infty | \kappa, \kappa') + \tilde{\Phi}(-\infty | \kappa, \kappa'))/2 \). There is a unique solution \( A(\lambda, \kappa) \) of the functional equation
\[
A(\lambda, \kappa) = \frac{\Phi(\xi | \kappa, \kappa')}{\Phi(\xi | \kappa', \kappa)} = \frac{\tilde{A}(\lambda, \kappa)}{A(\lambda, \kappa)}
\]
in form of a high-temperature series
\[
\tilde{A}(\lambda, \kappa) = \exp \left\{ \sum_{j \geq 0} a_j \coth^{(j)}(\lambda) \right\}, \quad a_j = \sum_{k > j} \beta^k a_{kj},
\]
with the coefficients \( a_{kj} \) which depend only on \( \kappa \). These coefficients are comparatively simple.

Here are the first few of them,
\[
a_{1|0} = -(q - q^{-1})/v, \quad v := q^{2\kappa} + 1,
\]
\[
a_{2|0} = -(q^2 - q^{-2})(v - 1)(v - 2)/v^3,
\]
\[
a_{2|1} = -(q - q^{-1})^2(v - 1)/(2v^2),
\]
\[
a_{3|0} = -(q - q^{-1})(v - 1)(v - 2)((q^2 + q^{-2})(v^2 - 6v + 6) + 4v^2 - 12v + 12)/(3v^5),
\]
\[
a_{3|1} = -(q - q^{-1})(q^2 - q^{-2})(v - 1)(v - 2)/(2v^4),
\]
\[
a_{3|2} = -(q - q^{-1})^3(v - 1)/(2v^3),
\]
\[
a_{4|0} = -(q^2 - q^{-2})(v - 1)(v - 2)((q^2 + q^{-2})(v^4 - 18v^3 + 78v^2 - 120v + 60)
+ 8v^4 - 9v^3 + 24v^2 - 30v + 15))/(3v^7),
\]
\[
a_{4|1} = -(q - q^{-1})^2(v - 1)(q^2 - q^{-2})(11v^4 - 138v^3 + 498v^2 - 720v + 60)
+ 2(19v^4 - 186v^3 + 546v^2 - 720v + 360))/(36v^6),
\]
\[
a_{4|2} = -(q - q^{-1})^3(v - 1)(v^2 - 6v + 6)/(144v^4).
\]

The explicit coefficients \( c_{kj} \) can now be obtained following the above prescription in the opposite direction.

**Appendix D. High-temperature expansion of the function \( \Phi(\xi | \kappa', \kappa; \alpha) \)**

Following the above scheme, one can obtain the coefficients \( c_{j} \) up to any order in \( \beta \). In this sense, we shall imply now that all these coefficients are already known. The next step is to calculate the coefficients \( c'_{kj} \) from (3.3) which determine the function \( \Phi(\xi | \kappa, \kappa'; \alpha) \) given by (3.2). To this end we can simply solve equation (3.8) with respect to the \( c'_{kj} \). Here are the first coefficients obtained this way,
\[
c'_{1|0}/\chi = c_{1|0}, \quad \chi := \frac{q^{\alpha} - q^{-\alpha}}{q^{\alpha - x_{\alpha}} - q^{\alpha + x_{\alpha}}},
\]
\[
c'_{2|0}/\chi = c_{2|0} + \frac{(q + q^{-1})(q^{(x_{\alpha} + a)/2} - q^{-(x_{\alpha} + a)/2})(q^{(x_{\alpha} - a)/2} - q^{-(x_{\alpha} - a)/2})}{(q - q^{-1})(q^{x_{\alpha} - x_{\alpha}} - q^{x_{\alpha} + x_{\alpha}})} c_{1|0}.
\]
Appendix E. High-temperature coefficients for $\Phi(\zeta, \zeta'|\kappa, \kappa'; \alpha)$

Here we show some coefficients $c_{j,\bar{f}}, c_{k|\bar{f}}$ that determine the function $\Phi(\zeta, \zeta'|\kappa, \kappa'; \alpha)$ via expansions (4.3) and (4.19). Let us start with two useful observations:

**Remark E.1.** Analyzing equations (4.12) and (4.13), we observe the following:

\[
    c_{j,0} = \frac{\alpha}{q^a - q^{-a}}, \quad c_{0,j} = \frac{c_j}{q^a - q^{-a}}. \tag{E.1}
\]

This can also be deduced from the limiting relations (4.8). As in the remark above, these two relations hold to all orders in the high-temperature expansions.

**Remark E.2.** Equations (4.12) and (4.13) have the symmetry

\[
    c_j \leftrightarrow -(-1)^j c_j', \quad c_{j,f} \leftrightarrow (-1)^{j+f} c_{f,j}. \tag{E.2}
\]

It is easy to check that equation (3.12) is also explicitly symmetric under transformation (E.2).

Due to remark E.1, it is easy to obtain the high-temperature expansions for $c_{j,0}$ and $c_{0,j}$. We will not show the corresponding coefficients $c_{k|0,j}$ and $c_{k|0,j}$ here. The other coefficients can be obtained solving equation (4.20) order by order. Here are several examples:

\[
    c_{3|1,1} = \frac{2}{q^a - q^{-a}} c_{3|2,2},
\]

\[
    c_{4|1,1} = \frac{2}{q^a - q^{-a}} c_{4|2,2} + \frac{2(1 + q^{-1)}(q^a + q^{-a})(q^a - q^{-a})}{(q - q^{-1})(q^a - q^{-a})^2} c_{1|0} c_{3|2} = \frac{(q + q^{-1})(q^a + q^{-a})}{(q - q^{-1})(q^a - q^{-a})^2} (c_{3|1,1})^2,
\]

\[
    c_{4|1,2} = c_{4|2,1} = \frac{3}{q^a - q^{-a}} c_{4|3,3}.
\]

All the coefficients $c_{k|j}$ can be obtained following the previous appendix. With the help of a computer, one can efficiently obtain the higher coefficients $c_{k|j}$ and $c_{k|j,f}$ as well by means of the above scheme.
